| Oil.—The eight, carpelled fruit of this plant yields by distillation with water an essential OIL somewhat resembling that of aniseed for which it is used in England.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0il.<br><b>34</b>                  |
| The authors of the <i>Pharmacographia</i> remark that "the volatile oil amounts to four or five per cent. Its composition is that of the oils of fennel or anise." It remained fluid at a temperature below 8°C, but soon solidified when a crystal of anethol was brought in contact with the oil. "The crystallized mass began to melt again at i6° C.; the oils of anise and Star Anise possess no striking optical differences, both deviating very little to the left." Eykman ( <i>Phar. Jour. &amp; Trans., XL, 1048</i> ) gives a comparative analysis of the oils of Anise, Fennel, the true Star Anise of China and the Sacred Star Anise of Japan. The differences between the true Star Anise and that of Japan may be here briefl v indicated. The former consists (according to Eykman) chiefly of solid and liquid anethol; its melting point "s QPC; specific gravity 0*978; molecular rotation O° to 0*4°; action of alcoholic hydrochloric acid—colourless; chloral reagent—colourless, then beautifully red; ammoniacal silver solution—after 24 hours no reduction. The latter consists of much of a turpentine, boiling at 173°to 176° C, liquid anethol boiling at 232° to 233° C.; melting point—not solid when cooled to 20° C.; specific gravity 1 "006, molecular rotation—8*6°; action of alcoholic hydrochloric acid—colourless, afterwards blue; chloral reagent—colourless, afterwards dirty brown-yellow; ammoniacal silver solution—reduction in a few hours. In the volatile oil of the leaves Eykman discovered eugenol, shikimen and shikimol— the second a terpine and the last identical with safrol. |                                    |
| The seeds also contain a large quantity of a FIXED OIL. I. religiosum was found by Eykman to contain as much as 30 per cent, of fixed oil. By experiments on dogs he discovered that neither the essential nor the fatty oil represent or contain the poisonous principle. He succeeded, however, isolating a poisonous principle as a crystallizable substance. This he named <i>Sikimine</i> . This analysis has been carried still further by Eykman and the Japanese plant found to contain proto-catechuic acid, shikiminic acid, and shikimipicrin, the last mentioned being the actual poisonous principle. It forms large transparent crystals, freely soluble in water and may be represented by the formula $C_7H_{10}O_3$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                    |
| Medicine.—While the <i>Star Anise</i> has long been employed in China<br>and Japan, but has in India only come into use in modern times. It is<br>chiefly employed in Europe to flavour spirits, the greatest consumption<br>being in Germany, France, and Italy. It is not used as a medicine in<br>Europe, but in India is regarded as stomachic and carminative. It is<br>viewed as of great service in flatulent and spasmodic affections of the<br>intestinal canal. Ainslie remarks that in his time (1826) Europeans in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 35<br>Flavouring<br>Spirits.<br>36 |
| India were not familiar with the drug, but the <i>Vytians</i> consider the FRUITS powerfully stomachic and carminative, and the Muhammadans occasion-<br>ally prepare from them a very fragrant volatile oil.<br>Dr. Dymock mentions that a consignment of a kind of <i>Star Anise</i><br>reached Bombay which was found unsaleable, and chiefly because the fruits<br>were almost devoid of scent. He formed the opinion that they were the<br>produce of I. Griffithii, and apparently because of the fact of their consist-<br>ing of 13 instead of 8 carpels. In a correspondence on this subject Dr.<br>Dymock informed the writer that the consignment in question was first<br>offered for sale at Calcutta, but not finding a purchaser there, was sent on<br>to Bombay. A subsequent enquiry, alluded to under the generic note<br>above, throws considerable doubt, however, on the possibility of the 13-car-<br>pelled consignment in question having been the fruits of I. Griffithii.<br>The <i>Flora of British India</i> does not mention the number of carpels                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                    |

|                          | A genus of succulent herbs, rarely shrubs, comprising in all some $150$ <sup>5</sup> P®iff <sup>es*</sup> chiefly distributed throughout the mountains of Tropical Asia and Africa. They become rare in Temperate Europe, North America, and South Africa, though in India some of the most prevalent species are those met with on the Temper-<br>ate Himálaya, the under vegetation of the mixed forests of the Western divi-<br>sion often consisting almost exclusively of a rampant annual growth of one <i>or</i><br>perhaps two or three species of Balsam. Indeed, India alone possesses 123 of the<br>known species, and of these the vast maiority occur on the Western Ghats the<br>mountains extending from Bombay and Madras to Ceylon. Some of thesespecies<br>are distributed throughout the area indicated, but Madras possesses 40, Bombay<br>35» and Ceylon 211; while the lower mountains of Bengal, the Central Provinces,<br>the North West Provinces and the Panjab each have only one or at most two<br>species and these are common also to all the other provinces of India. In Assam<br>(chiefly on the Khasia Hills) there are 23 species and 9 in Burma. The Burn<br>mess species may be described as the most implical Indian members of the<br>Equation of the last being also found in the Khasia Hills. Many of the<br>Western Himilayan species extend from Kumaion to Kashmir, a few only going<br>eastward to Sikkim. These Western forms are also by far the most prevalent,<br>and, as already remarked, miles of country during the monsoons (June to Sep-<br>tember) are literally covered with one or two species. This is peculiarly the<br>case near Simla where I. <b>amphorata</b> a magenta coloured one, dispute pos-<br>session with the yellow-flowered I. <b>scabrida. It</b> is significant also that with<br>the exception of I. Balsamina all the West Himalaya species belong to the<br>section with linear capsules, and most of them possess in addition edible seeds. |

| FIBRE.<br>52                   | Habitat,— A small perennial grass inhabiting the plains and hills of<br>Bengal, the North-West Provinces, the Panjab and Sind, in moist, stiff<br>pasture ground It is particularly common over Bengal, and ascends the<br>Himalaya to altitudes of 7,500 feet. When in flower about April and<br>May, the fields, roadsides, and railway embankments become white with<br>its silky heads. It is, in fact, a very characteristic grass of the neighbour-<br>hood of Calcutta, the <i>maidan</i> being chiefly carpetted with it.<br>Fibre.—Used for the same purpose as that obtained from the <i>Munja</i><br>(Saccharum ciliare, <i>Anders.</i> ), namely, to prepare the sacrificial thread of<br>the Hindus; and the leaves are employed for thatching ( <i>Atkinson's Hima-<br/>layan Districts</i> ). Roxburgh says that the Telingas make use of it in |
|                                | their marriage ceremonies. He adds that it is much used in Bengal for<br>thatch, and Mason remarks that this is the case in Burma also. Thwaite<br>states that in Ceylon this grass is viewed as making excellent thatch.<br>I. 52                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

(G. Wait.) **INDIA-RUBBER.** Incense; Caoutchouc. FODDER. Fodder.—Not of much use as a fodder, because cattle refuse it except when quite young, or when no other forage can be obtained. M£. Duthie 53 writes: " In Australia it is called ' blady-grass/ and the young succulent foliage which springs up after the occurrence of a fire is much relished by stock. I have observed the same effect resulting from periodical fires on certain parts of the Himálaya where this grass is plentiful.' Implements and Machinery, &C, Woods used for. See Agricultural Implements, Vol. I., 145. 54 >ncense, an odoriferous preparation burned at religious ceremonies. Frankincense (= pure incense) may be regarded as the chief and more expensive ingredient (see Boswellia, Vol /., pp. 511 to 514), the following being the materials of incense used by the poor or employed as adulterants with Olibantfm :-(1) Boswellia serrata, Roxb. Gugul or Salhi gum, the Indian Olibanum. (2) Cupressus torulosa, Don. (3) Juniperus communis, *Linn*. The smoke of the green roots was considered by the ancients to be most acceptable to the infernal gods. (4) J. macropoda, Boiss (? J. excelsa, Rieb.). (5) J« recurva, Ham. (6) Jurinea macrophylla, *Benth*. The roots of this herbaceous plant are largely collected in Kumáon and Garhwal under the name of Dhúp, and either exported to the plains or made into a resinous preparation which in that condition is exported, (7) Morina Coulteriana, *Royle*. (8) Pinus longifolia, Roxb. Known in Oudh as Dhúp. (9) Saussurea Lappa, Clarke. The sacred Costus root largely exported from Kashmir and used in the preparation of perfumery, medicine, and expensive forms of incense. (zo) Taxus baccata, *Linn*. Though mentioned by writers on this subject as ingredients in incense, it is not known to what extent the coniferous plants in the above list are used in the incense burned at Hindu temples. After Olibanum, Nos. 1, 6, and 9 are the most important and in that order relatively. ndian Fig or Prickly Pear, see Opuntia, Vol. V. ndian Red, see Pigments, Vol. V. ndiatl Shot, see Canna indica, Vol. II., p. 102. INDIA-RUBBER, CAOUTCHOUC or GUM ELASTIC. GOMME ELASTIQUE, CAOUTCHOUC, Fr.; KAUTSCHUK, Germ. \$ VERDERHARS, Dutch; COMMA ELASTIC, //. & Port.; GOMA ELASTIC, Sp., • GUMMI, Da. & Sw. ; CHIRIT MURAI, Malay.; SIANG-PI, Chin. **DESCRIP-**TION. 55 **Caoutchouc or India-rubber** is the inspissated milk or sap obtained from at least six genera of plants which belong- to three widely different Natural Orders, vie., Landolphia and Willoughbeia, to APOCY-NACEJE ; Castilloa and Ficus, to URTICACEJE (sub-order ARTOCARPEJE); and Hevea and Manihot, to EUPHORBIACEJE In the plant tissue Caoutchouc is found to circulate within certain anastomosing vessels which are distributed throughout the middle or more rarely the inner layer of bark. A far larger number of plants possess a milky sap (and even a caoutchoucvielding sap) than those generally viewed as the sources of India-rubber. The term Caoutchouc is sometimes used synonymously with that of Indiarubber, but it is more correctly the pure hydrocarbon isolated from the

DESCRIP-TION. Chemical and Physical Peculiarities of

other materials with which it forms the impure rubber of commerce. Under the microscope the milk appears as a kind of emulsion with minute globules, the caoutchouc granules suspended in it. These range from **20^000** to **¥050**. Of an incn in diameter. Caoutchouc is highly elastic, lighter than water, has neither taste nor smell, is fusible at about 120°C (248° Fh.) and inflammable at higher temperatures. According to Faraday it consists of 87-2 parts of carbon and 12 8 of hydrogen. The sample he examined came from India, and was thus probably obtained from Ficus elastica. It is interesting to add, therefore, that Faraday makes no mention of having detected ammonia in the rubber he examined.

When the bark of plants containing this substance is cut, the milk exudes, and in time hardens on exposure to the air. This agglutination may be hastened by adding salt water or alum to the milk, but the former increases one of the defects of rubber, vis., its hygroscopic property, and thus injures it commercially. It would seem that the chemist has still to perform a service to the planter and extractor of rubber that is likely to prove of the greatest importance, *viz.*, to analyse the fresh milk of each and all the rubber-yielding plants. The methods of coagulation in practice are very much the hereditary arts of savages, instead of being based, as they should, be, on scientific principles. It does not follow that the acid process, though applicable to one milk, is at all suited to another; in fact, systems of extraction have been brought about by experience blindfoldly instead of based on demonstrated science, hence the full amount of rubber contained in the milk is not, as a rule, removed. It is commonly stated that the best rubber is obtained by boiling the milk, but delay in agglutination is reported to be injurious, since destructive oxidation takes place. Where the climate of the rubber forests is detrimental to human life, the collectors frequently add alum to the fresh milk, as a temporary measure, and  $ence \pounds$ the complete separation of the rubber with greater deliberation on reaching their homes at some distance from the forests. It is believed by most writers that the milk is kept in its fluid state within the plant tissue through the agency of ammonia—a theory in part supported by the facts that the fresh milk has often an ammoniacal odour, and that a little ammonia \* added to the milk has been observed to facilitate its retention in the liquid state. On coagulation, the milk changes colour, assuming a more or less reddish tint, and forming a plastic leathery substance. A thin piece is seen under the microscope to contain irregular rounded pores which partially communicate with each other and dilate under the influence of fluids.

Chemically India-rubber may be said to approximately consist of two substances—an elastic material, on which its merit depends, and a viscid, resinous, readily oxidisable principle, to which it owes its depreciation. The greater the amount of resin present in a sample of rubber, the less is its value, but it is remarkable that the amount of this oxidisable substance seems to be more consequent on a tardy precipitation of the caoutchouc from the milk, than on individual or even specific differences in the plants from which it is obtained. The property of the elastic substance also varies, and in a marked degree, between that obtained from one genus of plants and another, for every gradation exists between the non-elastic hydrocarbon known as Gutta-percha and the finer qualities of Gum Elastic, such as the Para and Ceara rubbers which contain the smallest known amount of resinous matter. The African and Guatemala rubbers possess the highest percentage, and are consequently the least valuable.

Caoutchouc is quite insoluble in water, alcohol, and acids. It is, how-

Caoutchouc or Gum-elastic. (G. Wait.) INDIA-RUBBER.

ever, oxidised by strong nitric and charred by strong sulphuric acid. SOLVENTS for Ether, benzone, rock-oil, and sulphide of carbon penetrate it rapidly, causing CAOUTCHOUC it to swell up and ultimately assume an apparent though not actual con-"The liquid thus formed is not, however, a complete dition of solution. solution, but a mixture formed by the interposition of the dissolved portion between the pores of the insoluble substance, which is considerably swelled up, and has thus become easy to disintegrate. By employing a sufficient quantity of these solvents, renewed from time to time, without agitation, so as not to break the tumefied portion, the caoutchouc may be completely separated into two parts, *viz.*, a substance perfectly soluble, ductile, and adhering strongly to the surface of bodies to which it is applied; and another substance, elastic, tenacious, and sparingly soluble. The proportions of these two principles vary with the quantity of the caoutchouc and the na'ure of the solvent employed. Anhydrous ether extracts from the amber-coloured caoutchouc 66 per cent, of white soluble matter; oil of turpentine separates from common caoutchouc 49 per cent, of soluble matter having a yellow colour. The best solvent for caoutchouc is a mixture of 6 to 8 pts. of absolute alcohol and 100 pts. of sulphide of car-•\* Caoutchouc yields by dry distillation an empyreumatic oil called bon." OIL OF CAOUTCHOUC or CAOUTCHOUCIN, which forms an excellent solvent for caoutchouc and other resins. It is a mixture of a considerable num-ber of hydrocarbons. Ordinary impure caoutchouc likewise yields small quantities of carbon anhydride, carbonic oxide, water and ammonia " (Watts' Chemistry).

Continued boiling in fixed oils also causes the separation of the caoutchouc particles thus seemingly to dissolve the rubber. Of this nature doubtless is the action of *garjan* oil, the property of which, as a solvent for caoutchouc, the writer has already alluded to under Dipterocarpus turbinatus *(Vol. III., 165),* Mr. Laidlay in 1839 reported that when frag-ments of rubber are dropped into *garjan* oil (especially if the oil be heated or boiled) the rubber swells and dissolves. Since the date on which this republication was made of Mr. Laid lay's discovery, the writer has come across another passage which would seem to refer to the solvent property across another passage which would seem to refer to the solvent property of garjan oil, and he has also performed certain preliminary experiments to test the accuracy of the reports regarding *garjan* oil as a solvent. Mr. **Strettell, in his** Narrative or my Journey in Search of Fiws e last tea in Burma Proper, states (p. 184) that a Mr. Henri who was employed by the King to work the serpentine mines bethought him of a method of repairing the gutta-percha tubing that had got out of order. Observing water-proof baskets used by the people for baling water he enquired as to the material used in rendering these waterproof. He found it to be the India-rubber of Ficus elastica. Further on, Mr. Strettell, commenting on Mr. Henri's discovery, remarks: " I had endeavoured to find out the process adopted by Mr. Henri to utilize caoutchouc in the form of a cement for repairing the gutta-percha tubing of his pumps, but no reliable information could be obtained. One account was that he boiled ten *ticknls* of caoutchouc with two-and-a-half *tickals* of *hunnin* oil, but this is impossible." The writer's elemcYitary experiments, suggested on reading Mr. Laid lay's report, have satisfied him that far from being impossible it is probable that the above re-port was correct, and he strongly suspects that the Burmans use more extensively than we have any positive knowledge of, a solution of caoutchouc dissolved in In or Kanyin oils. Procuring in the Simla bazar a bottle of the substance sold as garjan oil, the writer performed Mr. Laidlay's experiments, but was more successful in dissolving gutta-percha than India-rubber. It was thought, however, desirable to obtain from Burma well authenticated samples of the various forms of wood oil; accordingly Mr. J. W.

22 A

INDIA-RUBBER.

DESCRIP-TION. Industrial Uses of Gutta-Percha.

Oliver, Conservator of Forests, Upper Burma, was addressed on this subject, and that officer very obligingly furnished samples. Messrs. **Stade**, fitToussaint kindly collected these samples at Mr. Oliver's request, but unfortunately the jar containing *In* oil got broken on its way to Simla, so that the experiments could be tried only with the various forms of *Kanytp*<sup>A</sup> oils. These oils after prolonged boiling all acted as solvents both of India, rubber and Gutta-percha, and it was observed that the pure oils decantea from the resin possessed this property to a less extent than when used in the impure form—resin and oil mixed.

Thinking that perhaps a solution of rubber in *Kanyin* oil might be **used** in the water-proofing of Burmese umbrellas, the writer also invited Oliver to investigate that subject, remarking that it was customary to i ead of umbrella water-proofing as accomplished by a decoction preparea from the fruits of a Diospyros. Mr. H. Jackson, Deputy Conservator of Forests, Prome, furnished the report and samples which this enquiry elicited. Two bottles were received, one containing a strongly adhesive balsamic substance, said to have been prepared from the fresh fruits oi Diospyros burmanica, and the other a varnish made from earth-oil, rosin, wax\* and vegetable oil. There is thus no India-rubber used in the Burmese umbrella water-proofing, and the process and manipulation pursued by the Burmese appears to differ from that followed by the Chinese mainly in that the latter people use the fruits of Diospyros pyrrhocarpa (Conf. with Vol. III., 154). Whether or not the above facts regarding the solvent property of the Dipterocarpus oils on caoutchouc may prove of industrial value, they are of interest in amplifying what has been said under Dipterocarpus and Diospyros. It may, therefore, be added that the writer observed that hot garjan oi<sup>1</sup> painted on cloth previously dyed with cutcW, and mordanted with alum, dried in a few hours. This latter fact may be of considerable utility, since (as remarked under Dipterocarpus) the chief drawback to the utilisation oi gar jan oil has hitherto consisted in the difficulty of drying the oil. A cloth painted with cold or hot gar jan oil took some months to dry and when dry became stiff, so that on being folded it cracked and gave out the resinous principle of the oil. The cutch-dyed cloth, on the other hand, dried in a few hours and never became stiff nor parted with its resin. It was, however, not completely water-proof, and the gar jan oil seemed to soften when water was left on the cloth for some hours.

The reader should consult the article Gutta-percha {Vol. III., 101*iog*). A comparison of the list of plants there given, as yielding that substance with those that afford rubber, will reveal the fact that the majority of the former belong to the Natural Order SAPOTACE; E, while the latter are mainly obtained from members of the URTICACE^K and EUPHORBIACE/E. The APOCYNACEJE and ASCLEPIADACE^ appear sometimes to yield guttas, at other limes rubbers. The exact nature of the hydrocarbons obtained from these families, however, must remain undetermined until they have been subjected to a careful chemical examination. The allotment given in this work of certain species as yielding gutta and of others rubber, may there-fore have to be adjusted hereafter. Mr. W. T. Thiselton Dyer read *a*. paper on this subject before the Linnean Society [Proceedings, June 1882, p. 35] in which he discussed the Apocynaceous India-rubber plants of the Malaya and of Tropical Africa. He pointed to the interesting fact that these all belong to the TRIBE CARISSEJE. Mr. J. Q. Baker, in an article which appeared in the *Gardener's Chronicle (1886)*, dealt with the sources of the India-rubber of commerce. "Part of the supply," he wrote, " comes from South America (shipped principally from Para and Carthagena), part of it from Sierra Leone, Mozambique, and Madagascar, and the remainder from tropical Asia." .Besides the two genera of APOCYNACEJE (Landol-

The facts in the above tabulated statement, and the arguments used by Mr. Baker regarding the present immense trade and future possible décU,(e in supply, should cultivation be not resorted to, have been urged by rn^nTwritersand have proved the keynote to the extensive experiments inducted in India and other tropical countries. An attempt will be made, in the subsequent pages, to discuss very briefly the nature of these experiments, but in concluding the present introductory remarks it may safely be said that the Assam plantations of Ficus elastica represent the most rational efforts that have been made, though high expectations are also entertained of the Tenasserim Hevea (Para) plantations. So long ago as 1880 Dr. King, while reporting the successful introduction of the climbing Landolphia rubber plants into the Botanic Gardens, Calcutta, remarked : **INDIA-RUBBER.** 

**DESCRIP-**TION.

CAOUT-

CHOUC PLANTS. Indigenous Caoutchouc-vielding Plants.

w But I fear, even if it were to turn out to be suited to the climate of Calcutta, Landolphia would prove rather an unmanageable crop ; for it is described to be an enormous creeper, climbing to the tops of the highest trees. With regard to all these exotic rubbers, it must be remembered that' with the exception of Ceara' they are either very large trees or climbers; ana although it may pay well to collect rubber from them in their native forests, where they have grown to maturity without cost to ths collector, it is quite a different matter when their planting and protection have to be paid for, and their coming to maturity has to be awaited for years. opinion has since been only too truly confirmed, so far as the interest ot European planters (who are at most but temporary residents in the tropics: are concerned, though perhaps the plantations undertaken by Government may ultimately prove of considerable value to the country. \*

#### PLANTS WHICH YIELD CAOUTCHOUC.

It is perhaps unnecessary to deal exhaustively with this subject, since during what may be called the various spasmodic India-rubber fevers, that have periodically engrossed the attention of planters, the cry has been raised needlessly, as it would now seem, for more and still more Caoutchoucvielding plants. The natural result has followed, namely, small fortunes made by adventurers and powerful advertisements obtained for would-be public benefactors at the expense of the earnest workers in tropical fields» who now suffer in their present apathy the consequences of undue haste. It is probable that much time and money were spent on experiments with worthless milky shrubs, or climbers, that necessitated a more expensive system of cultivation than the value of the produce obtained. The public were thereby compelled to consider as caoutchouc-yielding a far larger number of plants than there was any occasion for, and the merits of the commercial-rubber trees were thereby largely neglected. Even with the true caoutchouc-yielding plants legitimate experiments in testing the suitability of soils, climates, and methods of treatment were subordinated to hallucinations of immediate fortunes which were to now from saplings" of a few years' growth. Indeed, few subjects of commercial importance have been dealt with in the same spirit of precipitation as the India-rubber enquiry. But this is perhaps accounted for by the practically unprecedented growth of the European manufactures to meet which an almost inexhaustible supply of raw material existed and could be remuneratively furnish\* ed by the indigenous forests of tropical America.

The caoutchouc-yielding plants that alone need be discussed here may be dealt with very briefly in alphabetical order, under two sections-(A) Indigenous. (B) Introduced.

(A). INDIGENOUS CAOUTCHOUC-YIELDING PLANTS. (For B. see page 364.)

| Habitat. <sup>A</sup> A large evergreen tree, a native of the forests of the Western<br>Gháts : cultivated for its fruit throughout the hotter parts of India.<br>Caoutchouc.—A writer in the <i>Indian Agriculturist</i> discusses the pro-<br>perties of this rubber. He says it is elastic, leathery, water-resisting, &c.<br>frach green fruit, he remarks, yields about two ounces of milk from which a<br>drachm and a half of caoutchouc may be obtained. Many years ago                                                                              |                                |
| (1837) Dr. Heifer experimented with this rubber in Assam. He wrote,<br>"The milky juice emanating in moderate quantity from every part of the<br>tree, but most copiously from the immature fruits, has till now not been<br>transformed by me in a perfectly solid state. Pouring the milky juice<br>fresh from the tree in earthen moulds as is done in America, did not                                                                                                                                                                                   |                                |
| answer the purpose; the moulds exposed to a slow fire, instead of drying<br>the substance, rendered it more fluid, and so it continued for weeks."<br>Dr. Heifer's process for obtaining the Caoutchouc, he thus describes:—<br>"The milky juice brought in a flat basin is mixed with an equal quantity<br>of water, and then agitated for two hours with sticks, by which a good                                                                                                                                                                           |                                |
| deal of carbonic acid is evolved. In about an hour the caoutchouc sub-<br>stance begins to separate from the water and extractive matter and co-<br>agulates; in one hour more the separation is perfectly effected, the caout-<br>chouc gets a milk-white appearance and a tolerable consistency, but it<br>does not dry perfectly." Dr. Heifer also describes a further process:<br>"The juice, after having been agitated about one hour as above mention-                                                                                                |                                |
| ed, I added to the fluid, acetic acid, which had the property of separating<br>the thinner parts of the juice at once by coagulating it. I put it then on<br>a moderate fire in a tin vessel, till the aqueous parts were evaporated and<br>obtained the caoutchouc substance more elastic, but perfect dryness re-<br>mained a desideratum."                                                                                                                                                                                                                |                                |
| 3. Carissa (several species); <i>Diet. Econ. Prod., II.,</i> 765/ApocYNACR.ffi.<br>These milk-giving shrubs are said to afford caoutchouc, and if of suffi-<br>ciently good quality and in such abundance as to make its collection remu-<br>nerative, these plants should prove of great value to India, since they exist<br>in great abundance though hitherto viewed as worthless. Mr. T. Christy<br>is reported to have sold the seeds of an African species at six pence each,<br>but nothing more has been heard of these reputed caoutchouc plants. A | 59                             |
| climber spoken of as Carissa macrophylla (see Report, Botanic Gardens,<br>Nilghiri Hills, 1883-84, p. g) was experimentally cultivated as a possible<br>source of rubber, but with no result. It is probable the plant in question<br>was Carissa suavissima, a lofty climber of the Deccan Peninsula. The<br>rubber of an African species was collected by Sir J. Kirk (Livingstone<br>Expedition), and much correspondence ensued for some years after, the                                                                                                |                                |

Ficus elastica—the Assam Rubber. (G. Watt) INDIA-RUBBER.

Gazetteers -.—Mysore and Coorg, /., 70; ///., 25; Madras Man. Admin /., 360: Official Correspondence in Revenue and Agricultural Department (Forests) on Ficus elastica and also introduced rubber plants from 1869 to present date.

**Habitat.**—A large evergreen tree, usually epiphytic in its young stage, but finally or originally rooting in the ground and sending down aerial roots from its branches. It is found in the damp forests at the base of the Sikkim Himalaya and eastward to Assam, Chittagong, and Burma.

Fuller particulars regarding the natural and acclimatised habitat of this tree will be found in the details given in a further paragraph regarding its CULTIVATION as a source of rubber; see also under Ficus, **Vol. III.**, **350** 

**Caoutchouc**—The rubber of Indian commerce, originally derived from the regions inhabited by savage tribes on the frontier of Assam and Chittagong, is produced from this tree. It is now extensively cultivated and is perhaps the only rubber plant in India which can be said to give indications of a future greatly extended commercial importance.

# HISTORY OF THE CAOUTCHOUC OF FICUS ELASTICA.

The earliest writer on this subject was the late Dr. Roxburgh, whose attention was directed to the rubber on a vessel containing honey sent to him from Sylhet. He described the plant that yielded the Sylhet elastic water-proofing gum in the 5th Volume of the Asiatick Researches, but his remarks in his subsequent *Flora Indica* contain the main facts, and as being of historic interest these may be here quoted : "Towards the close of 1810, Mr. Matthew Richard Smith of Sylhet sent me a vessel, there called a Turong, filled with honey in the very state in which it had been brought from the fundua or Juntipoor Mountains north of Sylhet. The vessel was a common or rather coarse basket in the shape of a four-cornered, widemouthed bottle, made of split rattans, several species of whic'i grow in abundance among the above-mentioned mountains, and contained about two gallons. Mr. Smith observed that the inside of the vessel was smeared over with the juice of a tree which grows on the mountains. I was therefore more anxious to examine the nature of this l'ning than the quality of the honey. The *Turong* was, therefore, emptied and washed out, when to my gratification I found it very perfectly lined with a thin coat of caoutchouc." Several more recent writers assert that the Natives of Assam have for ages been acquainted with the properties of gum-elastic, using it to water-proof theirbaskets and to burn as candles. Mr. Smith was thus the actual European discoverer of Assam caoutchouc, since he thought it necessary to draw Dr. Roxburgh's attention to the same, and thought it necessary to draw Dr. Roxburgh's attention to the same, and he was also the agent through whom Dr. Roxburgh was enabled to prosecute the enquiry that finally led to its determination. Interest in India was thus awakened in caoutchouc, and the writings of subsequent investigators for several years were replete with reports on the subject. The resources of Assam were at once drawn upon, and a system of reck-less ^extermination of all accessible trees took place without any real pro-gress towards establishing a commercial industry. With the decline of the Assam supply interest died out as suddenly as it had been awakened, but it may serve a useful purpose to review the early literature of Indian but it may serve a useful purpose to review the early literature of Indian caoutchouc prior to the revival which was consequent on the introduction of the American rubber plants into Asia.

In the Transactions of the Agri.-Horticultural Society of India {Vol. VI., 29) mention is made of a sample of Sylhet rubber sent to Sir D. Brewster by Mr. Q. Swinton, which, after being in Edinburgh for eleven years, was found to possess its elasticity and to be superior to the South

not the smallest doubt of this becoming" an extensive article of Indian commerce, if managed with moderate prudence."

In their annual report for the year 1839, the Agri .-Horticultural Society stated that the caoutchouc from Ficus elastica is liable to decomposition In the same year a Committee of the Society of Arts reported on Captain Jenkins' and Lieutenant Vetch's samples of Assam rubber, pronouncing the former superior to the latter. In the Proceedings of 1843 it <sup>1s</sup> complained that few of the samples of Assam rubber examined by the Society have been carefully enough prepared to resist the damp and heat of the Calcutta climate.

In 1852, Dr. Falconer, commenting on a decline in the Assam traffic in Caoutchouc, and in answer to certain questions as to the best modes and position of tapping the trees, threw out the suggestion that the decomposition Assam Caoutchouc was liable to was probably due to the mixing "f the milk obtained from the roots with that from the stem. He contended that the milk being obtained from the descending sap of the plant which had been elaborated in the leaves was probably in its more perfect state high up the stem than in the lower portions, and hence he urged that tapping should be made on the branches instead of on the roots and lower part of the stem. He recommended that this theory should be investigated by keeping the milk from the various psrts of the plant distinct until it was seen which of these imparted to the mixture the soft and adhesive property complained of by the manufacturers. Careful preparation and above all the avoidance of mixing *other* milky saps with that of the true rubber plant would effect great improvements, but it must be here added that Dr. Falconer's suggested explanation is at variance with the accepted physiological conception of the character and movement of the laticiferous fluid. It is quite distinct from the elaborated descending sap of the plant, and its motion is /n reality from the older to the newer structures or upwards instead of downwards. The caoutchouc grafiules contained within it are useless excretary materials which when once formed are probably never again chemically altered, so that but for the other ingredients of the milk it would be quite immaterial from what part of the stem or root it was drawn. The question, however, as to the part which could be tapped with least injury to the plant would have to be answered in favour of Dr. Falconer's recommendations.

In a most instructive report, from the pen of Mr. G. Mann, Conservator of Forests, Assam (Progress Report of Forest Administration in Bengal for the year 1868-69 5 reprinted Jour. Agri.-Hort. Sac, India (New Series<sup>^</sup>, Selections, 70-81), many facts are given regarding the destructive methods of tapping pursued in Durrang and other districts of Assam. In 1865, "<sup>ne</sup> privilege of tapping in the Government Forests between the Bor Nuddy and the Moora Dhunseeree Nuddy was sold for R 1,012 to Kyabs in the Mungledye Bazar. These contractors purchased from the people who worked the forests 2,500 maunds of rubber, " but had not," Mr. Mann remarks, "the slightest control over the tapping" of the trees] and encouraged the latter as much as in their power to obtain the largest possible quantity during the short time they held the monopoly of buying it, consistent with their interests without any regard, however, for future supplies, which was of most disastrous consequence, in so far as it induced the men who tapped and collected the rubber to indulge in the most outrageous wholesale destruction of these valuable trees, by either telling them with axe, or, if this was too troublesome, to collect firewood and burn them down, so as to render the operation of tapping more convenient than it would have been had the trees were counted, in all direcASSAM RUBBER.

Indigenous Caoutchouc-yielding Plants.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| HISTORY.  | tions, lying on the ground with cuts across their trunks and roots from 6 to 18 inches long, 3 inches broad, and a foot to 18 inches apart, with smaller cuts on the upper branches, by which all that they could yield was extracted immediately after they were felled, with utter disregard tor tuture wants." A less immediately destructive system was pursued in other parts of the province, which, nevertheless, in time resulted in the trees losing their power of yielding the milk. Messrs. Martin, Ritchle « 00. of Tezpore, for example, got the exclusive right of tapping over a certain tract of forests for fiften years from 1852 and free of payment, but on condition that tapping should only be made between the 1st of November and the 30th April, and that yearly they should plant 200 caoutchoucyielding trees. The trees, however, embraced by this concession' got exhausted, and one year before the tern fixed Messrs. Martin, Ritchle. of C. discontinued tapping them, because, as Mr. Mann remarks, pubber could not now be drawn from them at a remunerative price. Continuous tapping for six months year after year, Mr. Mann affirms, will kill the trees, and accordingly he urged either that tapping of forests more frequently than once every three years. Martin, Ritchle. of the every three years. Mr. Mann concludes his remarks on the exhaustion of the Assam rubber supply by saying that "unless the time of collecting is much more limited and some plantations are started to provide for iuture supplies, there will he no more rubber procurable from these forests a few years here, and their yield of caoutchouc. "Assuming that a tree reaches its full size at fifty years without tapping, and would after that yield every the year which yield was per maund, whilst it fetches R15 ac mand, and should realise the present price of good rubber, <i>viz.</i> R35 per maund, it would have a net profit of R20 per tree every threy years which is a portic of R5 at leash per tree such more than the tope in adus of rubber tradus at this per maund, and shoul |
|           | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

#### Ficus elastica—the Assam Rubber. (G. Watt) INDIA-RUBBER.

soon rose to R5 for the best or thickest procured from the roots, and 84 for the next best procured from the lower part of the stem, and £3 for the worst supposed to come from the upper branches of the tree and to have been mixed with the juice of other species of Figs and water." The italics nave been given here to contrast this opinion with that given above in Dr. Falconer's suggested explanation of the inferiority of Assam rubber; Dr. Falconer held that it would be found that the most inferior rubber would likely be found to be that drawn from the roots and lower part of the stem.

Since the year 1869 (the date of Mr. Mann's report which has been so frequently placed under quotation above), the Government have started caoutchouc plantations of Ficus elastica in Assam. But it seems likely that, had the similar recommendation made by Dr. Royle in 1839 been acted ^pon, India would have now possessed a flourishing caoutchouc industry. Mr. Mann tells us that the total revenue derived by Government from Assam rubber between the years 1861 and 1870 amounted to <sup>R8</sup>3»733» the total for the last year (1869-70) having been 823,940. That small sum, thtrefore, practically (or only a portion of it) was the purchase money for a right to exterminate or ruin the Ficus elastica trees within British Indian territory And so completely had this been accomplished that we read of contractors abandoning rubber collection before the expiration of the terms of their concessions.

Mr. Charles Brown low in 1869 \Jour. Agri.-Hort. Soc, New Series,  $??rr * > 3^{)}$  started on a journey up the valley of the Jatinga in Cachar, with the object of studying among other things the India-rubber of that neighbourhood. His account is most instructive, but want of space prohibits more than a mere mention of one or two of the points he Drings out. The tree, germinating on other trees as an epiphyte, sends down immense aerial roots and from the top of these (often at a great height above the ground) produces its horizontal branches and dome of boughs and  $\mathbf{R}^{\mathsf{ves}_{1}} \wedge e^{\mathsf{r} \circ o t \, \mathsf{s} \, t_1 \, i \, \mathsf{at a r e}} \, ^{\mathsf{tare ta}} PP^{\mathsf{e} \wedge \mathsf{w}} \, ^{\mathsf{anc} \ast}$  to which allusion has been made above, are these aerial roots which at first sight look like unbranched stems. Speaking of this great tree Mr. Brownlow says : --- '' Among forest trees and in regard to dimensions, this is 'facile princeps,' and there is no other, not even the Banyan, that approaches it in dimensions and grandeur. Again, •• It will be observed that every portion below the head of the foster tree is strictly root and incapable of throwing out a branch, and as the head <sup>15</sup> u<sup>arefv less than 60 to 1()0 feet</sup> high, it is no easy matter to procure throw out smaller and subsidiary rootlets of all thicknesses down to that of twine. If any of these be cut they die below, but from above grow again downwards. . . It is only necessary to see the tree to appreciate the fearful risk encountered by the gum gatherers, who by no means confine their operations to the base, but climb up as high as the roots extend and higher along the horizontal branches, chopping with their dhaus at intervals of every few inches, the cuts answering as well for their foothold as for the sap to exude from. . . Were the base of the tree alone tapped the yield would be very insignificant, especially in trees that have been frequently tapped before. And as the trees occur very sparsely, and long distances have to be gone over to meet them, it becomes an object to get as much off at each cutting as possible. The tree must be twice climbed, once to cut it and a second time after the gum has dried (which takes a day or two) to gather it. This is done by pulling off the tear which gathers below the wound, which brings away with it all the gum that has exuded, and these tears have only to be moulded together to agglutinate into a ball. The quantity that can thus be collected at one cutting does not exceed 4 to 5

Indigenous Caoutchouc-yielding Plants.

HISTORY. seers (8 to ioft) Of course, no mercy is shown to the trees, all of which (at least those that 1 saw) suffer severely; many, I was assured, are killed outright. The damage they sustain is apparent in the large cankers, and buttresses rotted off, owing to the bark bring unable to heal over the frequent wounds they have received all round. The foliage is wanting in luxuriance, and dried branches and roots lying about testify to the injury in health that the tree has sustained. . . At present the trees are having a long respite which will no doubt do them good, but it is only-owing to a clause in the conditions of Government which provides that the monopolist shall, at his own cost, plant a certain number of trees yearly . . Practice will soon show how the gum should be gathered ; probably the best plan would be by scoring the bark on one side (not chopping it and leaving the other half "of the bark to carry on the circulation". Of course, the only season in which the gathering is practicable is the dry months; during the rains the tears would be washed away before they had time to solidify. The rubber trade of Cachar amounts to about 2,000 maunds per month during the dry months (November to April). The price at which the gatherers sell averages from R20 to R25 per maund." Mr. Mann states that in Assam in 1868 there were sold in Mungledye Bazár 2,500 maunds, in Tezpore about the same quantity, and in Chydooar 1,500 maunds. For the year in question there was sold in Assam and Cachar close on 9,000 maunds, but of course a large proportion of that amount was drawn from trees beyond the Assam frontier.

It will thus be observed that from 1810 to 1839 <sup>1</sup><sup>A</sup> e keenest possible interest was taken in the subject of Assam rubber. From the latter date the defects of the substance were spoken of as damaging its further development as an article of European consumption, and various theories were advanced as to the cause of this. It seems only natural since the earlier reports speak highly of Assam rubber and recommend as necessary a peculiar method of collection, a method adapted to the then known way of utilising rubber, that the defects subsequently complained of were due to adulteration or selfish and exhaustive extraction that sacrificed quality to bulk. About this time also the alarm of extermination was established and down to 1869 various reports and regulations of Government appeared which aimed at checking the danger anticipated. The Journals of the Agri.-Horticultural Society of India which, for twenty years became the enlightened medium of disseminating information regarding Assam rubber, were from 1839 practically silent on the subject, until a new interest, and perhaps, though this could not have been foreseen, an unfortunate one, was awakened in 1872-73 by the expectations of immediate fortunes to be made from the superior rubber-yielding trees of tropical America and the figantic climbers of Africa. Some of these introduced plants have taken indly, however, to certain districts of India, and may yet come to be a source of wealth in their new homes; but they have by no means fulfilled the high expectations once entertained. Indeed, it may confidently be stated that even from the present date it will take some time before the money spent on their introduction will be recouped to the planter or to Government Greater success may, in fact, be looked for from the efforts put forth by the Assam Government to regulate and resuscitate the forests of Ficus elastica.

|   | the forests, no satisfactory result can be expected. If this is not practic-<br>able, then we must for future improvements entirely rely on the caoutchouc<br>plantations to be established.<br>"Under all circumstances plantations of the Ficus elastica should be<br>commenced at once in Assam on a large scale. The tree strikes readily<br>from cuttings; its cultivation therefore is easier than that of most other                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                  |
|   | trees. In one of his first reports on the subject Mr. Mann suggests that<br>lines be cleared through the forest, and that cuttings, as large as possible,<br>be planted at convenient distances on either side of these lines. Very<br>likely this would be a good plan to begin with, and as the carriage of big<br>cuttings over long distances would be expensive, nursery beds should be<br>prepared and enclosed for the growth of such cuttings from small slips. If<br>suitable soil **nd localities are selected, and if these plantations are at                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |

HISTORY.

Indigenous Caoutchouc-yielding Plants.

once placed under efficient supervision, there ought to be no difficulty in this undertaking, and operations should in my opinion be commenced as soon as possible on a large scale, and in accordance with a wellconsidered plan."

Mr. Mann's report for 1884 gives the result of the experiments in the cultivation of Ficus elastica in Assam; the following passages from that report may be given here :—

"The past history of rubber plantations in Assam, and, for the matter of that, in India, dates from the year 1872, when Mr. James Collins was charged by Her Majesty's Secretary of State for India to prepare a report on the caoutchouc or If<sup>TM</sup> rubber of Commerce, the plants yielding it, their geographical distribution, and the possibility of their cultivation and acclimatisation in India. The only rubber-tree indigenous in India (Ficus elastica) is noticed on pages 19 to 21, 32 to 39, and 48 to 54 of that report.

"This report was largely circulated by Government in this country, and the <sup>at</sup>J<sup>e</sup>•" tion of Local Governments was directed to the necessity of protecting the trees wnich yielded this valuable commodity, because it had become quite evident that the caout-chouc-trees were being recklessly destroyed in all parts of the world, and particularly so in Assam, which is, so to speak, the only province in India where caoutchouc-trees grow, and the experimental cultivation of the indigenous rubber-tree (FICUS elastica) was accordingly ordered in May 1873 by His Honour the Lieutenant-Governof ot Bengal. But by the time these orders reached the Commissioner of Assam the season was so much advanced that but little could be done that summer, because there was only one small iorest plantation with a resident forest officer in existence at that time, and this was at the Kulsi river, which is not as favourable a locality as the Charduar in the Darrang district. In the latter district forest work had not been started, and, consequently, the first commencement in the present Chardua< rubber plantation was not made until the next cold season. A detailed account of these first attempts at planting rubber will be found in paragraphs 80 to 114 of the Assam Forest Report for 1873-74.

"A particular impetus was given to this work by the complications and difficulties that had arisen at about the same time in the proper management of and cuntrol over the India-rubber trade in this province, brought on by competing speculators, which had necessitated an order from the Supreme Government that the operations of the Forest Department should be limited to conservancy and reproduction of the rubbertrees in certain well-defined areas, and to the collection and manipulation of the pro" duce in such limited areas through their own agency.

"This order of the Government of India was repeated in 1876, and has been acted up to until now: all work in the way of rubber plantations is based on it, and, what is more, the experience gained in the twelve years that have elapsed since the issue of that order has made it clear that the effectual protection of selected areas, *with naturally grown rubber-trees on them*, is next to impossible, on account of the localities where these trees grow being, generally speaking, very inaccessible, and the unequal way in which these trees are scattered about in the forests, as it would mean the protection of enormous areas to ensure anything like the present export of rubber irom Assam, and this in turn would mean the employment of very large establishments to watch over the forests, because rubber is so very portable, and its removal not necessailly confined to roads or tracks, rivers, and so forth, as is the case with timber, and the rubber trade. This simply reduces the whole question of permanently keeping up the export of this valuable product from India to making plantations of the tree that yields it.

" In April 1874 the Government of India called for a special progress report on the caoutchouc plantations in Assam, which was furnished and subsequently printed and circulated with the Governmentol India, Department of Revenue, Agriculture, and Commerce (Forests) letter No. 22, dated the 31st August 1875. The efforts made up to that time in the way of planting caoutchouc-trees in Assam, and all information regarding the yield of caoutchouc-trees then available, have been fully stated in that report.

"The Charduar plantation has, as was maintained from the commencement, proved in every respect the best locality in Assam where the rubber-tree has been planted; the land, it is true, is not high, and so we must, no doabt, have some area planted on J!KL<sup>e</sup>!if<sup>roul</sup> **1**<sup>o</sup> 
#### Ficus'elastica—Cultivation in Assam. (G. Watt.) INDIA-RUBBER.

as the Chief Commissioner has sanctioned an extension of 200 acres. The present area under cultivation is fully stocked, containing 12,511 trees; they have been planted at 25 feet apart in the lines, which latter are 100 feet apart; this is double the number of trees that was planted on an acre at the commencement. The oldest trees are about 30 to 40 feet in height, and a few from 45 to 50 feet, but this cannot be put **down as the average growth of Ficus elastica** in ten years, since half this time, and longeir, these plantations were entirely experimental and everything had to be learned, as, for instance the first trees were ull mined from suttings, which mode of mode of mode wor has antirely been given up, since the trees raised from seed have proved much hardier and faster growing, and as to the planting of rubber seedIngs high up in the forks of other trees, this also has almost entirely been given up, because such trees in most instances did not make more than a tew leaves in the year, and "it would, as a matter of course, be out of the question to plant rubber-trees where they would take a century to become large enough for tapping, when such trees can be grown in a different way in one-fourth this time. " On the other hand, it has been found that trees planted on small mounds of earth,

" On the other hand, it has been found that trees planted on small mounds of earth, 3 to 4 feet in height, grow very much better than if they are planted on ordinary level ground, and this plan has therefore also been adopted, although it adds considerably to the cost of making these plantations, but the faster growth of the trees amply compensates for the higher expenditure.

"The method of planting adopted from the beginning has been to dear lines from e?st, to west^ through the forest for the young trees a hundred feet apart; the width or the lines is 40 feet, so that a broad strip of forest 60 teet wide is left standing between these lines, to ensure the utmost amount of moisture in the atmosphere for the young rubber-trees. At first, the lines were only cleared 20 teet broad, but it was found after a few years that these closed up very soon, ar.d thus retarded the growth of the young trees by shutting out the requisite amount of light. However, the widening of the lines also brought about the faster growth of the scrub in them, besides that of the rubber-trees, and more money, time, and attention has in consequence to be spent, especially in the rainy season, on those plantations, than had at first been anticipated; but the greatest and most costly difficulty that had to be overcome was the effectual protection of the rubber-trees against deer, which during the first few years constantly bit off the young plants, and, where they were not entirely ruined by this, they were so much injured and retarded in growth that a considerable increase in the expenditure on these plantations had to be incurred or?fencing- to prevent it. But for the future this expenditure will not be necessary, since it has been found that saplings 10 feet and more in height can b^ transplanted without difficulty and with pertect success, and if such saplings are tied firmly to stakes the deer can do little or no damage to them.

"The efforts made to inter plant with timber trees besides the rubber, so as to obtain a yield ot timber in addition to that of caoutchouc, have up to the present met with but partial success in the Charduar plantation, but there is no reason to doubt that this will soon improve, as the officer in charge gains more experience; in the rubber plantation at the Kulsi in the Kamrup district, this work has been most successful.

<sup>•1</sup> The total area of the Charduar caoutchouc plantation is now 892 acres, and has cost 1\*64,351, or R72 per acre; this is abnormally high, since much of the work dur ing the first five years had to be done twice over, and sometimes of tener, because the planting of caoutchouc trees was new. and everything had to be learned and found out by experiments, which naturally took some time. But matters have changed in this respect; we know now what we are about, and the officer in charge of this work, Mr. T. J. Campbell, has estimated the cost of the extension which is at present being carried out at R29 per acre, to which another R6 for subsequent cultivation and clearing should be added, bringing the cost, including everything, up to R35 per acre.

"Besides the experimental nature of the work, to which the cost of R72 per acre of this plantation must to a great extent be attributed, we have also prepared extensive nurseries, covering an area of about 23 acres, and containing some 184,000 plants of different sizes, which is sufficient to extend the plantation by 200 acres per annum for the next fifteen years, or a square mile per annum for the next five years, if desired and these nurseries have been so planted that, il for special reasons it is considered advisable not to extend the plantation at any particular time, the trees can be kept almost stationary for fifteen to twenty years, without becoming less suited for transplanting, a particular advantage enjoyed by **Ficus elastica** in common with other semi-epiphytes, as compared with ordinary trees

# Indigenous Caoutchouc-yielding Plants.

HISTORY.

"Thus far I have given an account of the Charduar rubber plantation as an experimental undertaking only, and shown that it has been a perfect success as far as the S'ing of the trees is concerned; but it remains to be considered what the financial  $r \wedge Jr$ of the undertaking are likely to be, since, as I have always held, and do now noia, the financial success of forest management is the only sound basis on which it can \*\*\* permanently established and maintained. To make an even approximately COTV, estimate of the probable revenue that may be expected from these plantations, nestimate of the probable revenue that may be expected from these plantations,  $th_{i}$  estimate of the probable revenue that may be expected from these plantations,  $th_{i}$  first and foremost necessary to know what a rubber-tree will yield, and on this pour our information is most imperfect. The statements made by rubber collectors and the exhausted state of the naturally grown rubber-frees has prevented us until last year from making experiments; the result of last y^st/" interesting as it is, and much as it has increased our knowledge of the yield ot can chouc from **Ficus elastica**, still leaves us in considerable doubt on the subject, as not chouc from **Ficus elastica**, still leaves us in considerable doubt on the subject, as not been stated in paragraph 118 of that report. However, so much is certain, that if ull-grown rubber-tree of about fifty years old will yield at the very lowest^ se end rubber, if very carefully tapped, and this quantity may be expected about sixteen O "1^ which will be an equally safe estimate for calculating the yield of a rubber-tree, i be quite on the safe side, I will only calculate ten trees per acre, which "would fitude to the barrang district and sold, and deducting the expenditure be incurred on collecting it, would give us a net profit of R54 per maund, or R 1,000 per acre in fifty years, and if the rubber-trees have a longer life, the yield may be reckoned for their remaining years of life at the same if not at a higher rate. J " An acre of first-class timber trees would cost about double as much to plant ana

An acre of first-class timber trees would cost about double as much to plant ana maintain; at the rate of sixty trees per acre and taking the value of the trees at Kio each (the present royalty charged), this would give us R600 only, as compared with Ri,080 from rubber, and most of the first-class timber trees will require one hundrea years to reach maturity, or double the time of a rubber-tree; this means, in other "<sup>of</sup> J especially if the compound interest on the capital used is taken into consideration, thas an acre planted with rubber-trees will give about four times as much revenue as a acre planted with first-class timber trees. --r^iiv

acre planted with first-class timber trees. "It may be and in fact has been argued that rubber might be produced a "Incx of factors of the produced a "Incx of factors of the produced a The produce attribute with the produced 
have positively no authentic information to make comparison; but I am very  $P^{o}J$ , ful whether any of them will yield more than **Ficus elastica**, and. certainly, the **diameter** ence, if any, could not be so much as to make the cultivation of the latter unadvisable.

" Of the two exotic rubber-trees which have been tried in Assam,  $vtz_{.9}$  Heven brasiliensis, the Para rubber, and Manihot Glaziovii\* the Ceara rubber, the former has failed completely, as the climate of Assam is altogether too cold for it, iand although the latter tree grows remarkably fast during the first year or two, and seem to thrive very well, its appearance is not at all such as to make me hope that it will do as well as our indigenous trees, much less that it will do better. Nothing positive can be said on this score until experiments with both have been made under carcell super be said on this score until experiments with both have been made under carc«il super-vision by a competent and responsible officer.

Under the circumstances as sketched above, and considering that Assam is the only province in India in which rubber grows to a considerable extent naturally, I  $_{\mu}^{am}$  of opinion that it is a duty of the State to have rubber plantations in this province.

The Government of India supported Mr. Mann's opinion as to its being the duty of the State to organise rubber plantations. Accordingly directions were given in May 1884, that for five years from that date the Assam plantations should be increased by 200 acres a year. Part of that extension, it was recommended, should be situated on higher ground than 1. 63

Ficus elastica—Cultivation in Assam. (G. Watt.) **INDIA-RUBBER.** 

hitherto planted, at Charduar. At the same time, it was added, endeavours should be made to induce private persons to plant India-rubber trees on their estates, seedlings being supplied to them for this purpose at cost price. It was also suggested "that the experimental plantation of Ficus elastica as an epiphyte might with advantage be undertaken by the Forest Department on a somewhat larger scale than has been done up to date. Naturally, rubber generally reproduces itself in this way; and although the growth of the seedlings thus raised is slow at first, the trees are likely to grow to much larger dimensions ultimately. This method of reproduction is, moreover, inexpensive, as the seedlings do not require any attention after they have once been deposited in the upper forks of trees:" The Government of India also desired that in order to test the financial results of the cultivation of this rubber fifty mature trees should be experimentally tapped, year by year. Acting up to these suggestions, the subsequent reports give the results. The area under Ficus elastica was steadily increased and the tapping of the trees proceeded with, showing an inexplicable irregularity year by year, in the amount obtained from each tree. The trees experimentally tapped were numbered from i to 50, and the record of each tree kept, as also the average of all the fifty trees year by year. In 1882-83, the average yield was 4 seers 4 chataks; in 1883-84, 1 seer 1 chatak; in 1884-85, 2 seers 5 chataks; but in this year six new trees (51 to 56) were tapped and gave 12 seers 10 chataks; in 1885-86, 3 seers 4 chataks; but Nos. 51 and 52 were also tapped giving 5 seers 13 chataks; and in 1886-87, 1 seer; but Nos. 55 and 56 were also tapped giving 3 seers 3 chataks. Commenting on these results the Conservator in his annual report says : " The above figures show that the average quantity of rubber yielded by one tree has been less than in any previous year, it being 1 chatak less than in 1883-84. The value in money depends of course on the market, and on t»' ! account is higher than it was in 1883-84. A close examination and comparison of the detailed statement (appendix X.) with those of former years shows that the fluctuations in the yield of one and the same tree, in different years, is often very considerable, and remains up to the present inexplicable, since the officers, under whose personal supervision these experiments were made, have up to date not been able to find out any reasons for, or causes of, these very material fluctuations. It is quite evident that we have as yet much to discover to be able to make an even approximately correct estimate of the yield of rubber trees. As pointed out by Mr. Jellicoe, the difference in yield has been sometimes very remarkable, as, for instance, tree No. 50 gave in 1884-85, 4 seers; in 1885-86, 5 seers 4- chataks, when suddenly in 1886-87, its yield came down to 6 chataks only, and there are other trees, as, for example, Nos. 12, 17, 18, 20, 21, 42, and 49 that show equally remarkable differences in yield between last year and this, which Mr. Jellicoe has not been able to account for in any way. The Conservator feels sure these are not ordinary fluctuations in the yield of rubber trees, and that a much closer watching of this tapping will *l*& necessary in future. The slight but general falling off in the yield of these trees is probably natural, and the figures seem to show that this difference is not due so much to the differences in the seasons as to that in the individual trees. The falling off in the average yield per tree of the six, Nos. 51 to 56, has even been more marked than of the other fifty trees." The Conservator is careful to explain that all the tappings were made on the stem, and that no roots or branches were touched. The tappings commenced about four feet from the ground and were never less than two feet apart. This careful and (considerate system is pointed to as the reason why much less was obtained than is currently reported by native dealers as  $^{2}3^{A}$

the yield. In the report for 1883-84, for example, it is stated," Regarding^ the possible yield of a rubber-tree, instances are veil known in this district" where a large tree has been tapped for the third time, and yielded between 2 and T maunds. Subsequent tappings gave from 4 to 10 seers, but these have not been carried over a sufficiently large number of years to lead to exact conclusions. Of course, this yield was obtained from a mode of tapping very different to what is departmentally adopted : roots, branches, and trunk, receiving as many incisions as they wore capable of bearing."

It is difficult, and perhaps unwise, while compiling from books and reports, to attempt to offer practical suggestions, but it would seem. Ssince the yield of rubber fluctuated and even declined, on the trees which were subjected to the moderate tapping pursued in the Government reserves and plantations, that we have by no means learned the maximum yield commensurate with financial success. The formation of caoutchouc is what may be called a by-product in vegetable economy, though, of course, the milk contains other substances of importance to life. Severe tapping may set up what for the moment could be called an abnormal or diseased condition. But it would seem desirable to ascertain the effect of a much more severe system than that hitherto followed and to tap year by year the maximum amount short of reckless injury to the growing woody structure or complete destruction of the tree. It would, from past experience, be scarcely safe to affirm that the fluctuations or even the decline established the conviction of an injury done to the trees, but rather that whether tapped or not the formation of milk is not constant. A large amount of milk remained in the structures not tapped which might have been removed without doing any greater harm than was done by the tapping of the lower part of the stem. The current of the lacticiferous fluid being upwards rather tjian downwaids it cannot be held that the few cuts made on the stem drained the milk from the whole tree. If these ideas be correct in a year of less formation a smaller quantity would be obtained from a uniform degree of tapping, whether that degree was injuring the tree or not. If we possessed data by which an opinion could be formed as to the maximum yield, until death supervened, it would be possible to fix the degree of  $Ht^{ping}$  the way  $df^{ping}$  the supervened, it would be possible to fix the degree of  $Ht^{ping}$  the true  $f^{ping}$  the supervened  $f^{ping}$  to the true  $f^{ping}$  tothetrue  $f^{ping}$  to the tr

#### Ficus elastica—in Bengal, Burma, &c. (G. Watt.) INDIA-RUBBER.

BURMA RUBBER. II. BENGAL.—The following note on the caoutchouc of the Chittagong Hill Tracts has been contributed by the Deputy Conservator of Forests: '• The table herewith furnished gives the quantity of rubber brought by the hill tribes to Demagiri, the frontier police ^ost, and sold there to traders:-

| Year.                                                                                                                 | Maunds.                                                                | Seers.                                     | Chataks.                          |
|-----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------------------|-----------------------------------|
| 1879-80<br>1880-81<br>1881-83<br>1882-83<br>1883-84<br>1883-84<br>1884-85<br>1885-86<br>1885-86<br>1886-87<br>1887-88 | <b>964</b><br>906<br>222<br>183<br>125<br>39<br>14<br>66<br><b>174</b> | 7<br>19<br>4<br>17<br>29<br>20<br>22<br>21 | <sup>#</sup> *8<br>14<br>"4<br>"8 |

"The above figures show a rapid decline from 1880-81 to 1885-86 of the amount brought in, due probably to excessive and wasteful tapping in previous years. The rubber comes from the Lushai hills north and northeast of Demagiri. This is a thickly wooded and thinly peopled tract, so that it is difficult to conceive the complete destruction of all the rubber trees. but the tendency is certainly in that direction. The Ficus elastica has been introdued into the Sitaphahar reserves and promises well. Price per maund at Demagiri R40. It is thence exported to Calcutta."

III. MADRAS.—The Conservator of Forests, Southern Circle, reports that Ficus elastica has been introduced into Malabar from Assam, and several thousand trees have been raised. "There is also a good stock of healthy young plants coming on and a well supplied nursery besides. The experiment has been successful, proving that the tree can b" grown in Malabar.'

IV. BOMBAY.—The Conservator of Forests, Southern Circle, thinks this fig would grow well in some parts of Bombay : it thrives in gardens at Belgaum.

**V. BURMA.—Mr. Strettell** (*Narrative of my Journey in Search of Ficus* elastica in Burma Proper, pages 9 to 12) quotes a report by Mr. Hough regarding the Prome plantations of the India-rubber tree. The plants came from Bhamo in 1872; twenty-three plants in all, of which six were sent to Rangoon for the Division. No further information is available as to the success or otherwise of this experimental cultivation in Lower Burma of Ficus The following communication has been obtained, however, from elastica. in the Mogaung district of Upper Burma. The collection of the rubber was till lately in the hands of a monopolist who paid Government R 1,00,000 a year, but the collection is now open to all. About 100,716 viss of rubber appear to have been collected last year. A very fair quantity is also collected in the Upper Chindwin district. There is another Ficus in the Mogaung district which the natives say gives just as good rubber as the Ficus elastica. This appears to be the Ficus laccifera. There are no Indiarubber plantations of any importance in Burma. Foreign rubber-yielding trees have been grown in gardens in the Mergui district with fair success the Hevea,  $Parn_t$  and Castilloa have succeeded best. Parameria glandulifera grows in the Mergui and Tovoy districts, but the cost of collecting the rubber is too great ever to make the growing of it a paying speculation. There is another rubber creeper in these two districts called the *Talaing* Sok, but this also is too costly to collect."

BURMA

RUBBER.

Indigenous Caoutchouc-yielding Plants.

The following passages appeared in *The Times* (1888) regarding Burmese Rubber :--- Mr. Warry, of the British Consular service in China, who is at present stationed as political officer at Bhamo, has made a report to the Chief Commissioner on the India-rubber trade of the Mogaung District. Rubber was first exported from Upper Burma in 1870; and until 1873 <sup>th</sup> trade was free to all. Since the latter year, however, the forests have been worked under the monopoly system, five Chinese firms being the joint concessionaires, two supplying the money, and three superintending the work. The price ranged from R60,000 to R00,000 per annum, but in the present year the sale of the right produced a lakh of rupees. The f<\*ests occupy an extensive Kachin district north of Mogaung and stretching east across the Chinese border. The Kachins are exceedingly jealous of interference with their trees, and although at first they made the r<sup>m</sup>S<sup>take</sup> of overbleeding them, they are more careful now, and though the trees seen by Mr. Warry were covered with innumerable small incisions even up to the tiny topmost branches, they were obviously not drained to the extent 01 half their power.\* Mogaung is the head-quarters of the trade; four-fifths 01 the yearly supply is brought in there by Kachins in the employ of Chinese, the remaining fifth is purchased in the districts by Chinese agents of the lessees. The practice is for the Chinese manager in Mogaung to make liberal advances to the Kachins to defray expenses during the collecting season; when the rubber is brought in, the refund is made by selling the rubber to the manager at half the market price. Formerly the Kachins were cheated in the weighing, and they retaliated by passing off Indiarubber balls the insides of which were mostly stones and dirt. The travelling Chinese agents who also collect rubber merely travel from place to place buying such quantities as the Kachins offer, but as the latter have no standard weights they are usually cheated to the extent of about 70 per cent. The profit on this difference of weight more than pays the expenses 01 the agents. In most cases rubber is the subject of certain transit charges through the Kachin districts, the Tsawbas, or local chieftains, levying a certain tax—perhaps two or three balls out of a hundred. So long as these charges do not amount to 10 per cent, there is no complaint; they sometimes exceed this and then the Chinese protest usually with success. An ex-chief of Mogaung who is now a fugitive was of great service in arranging disputes of this nature, and now a regular expenditure in presents to the chiefs is necessary in order to keep the amount of the tran-sit dues at a reasonable level. Whatever the toll, the Chinese manager and Kachin owner bear the loss in equal shares, but the latter is amply compensated by being housed and fed at the expense of the Chinese during his stay in Mogaung. Last year a new district was opened, and a Chinese capitalist employed 400 Chinese and Shan labourers to work the forests in the neighbourhood of the amber mines. The local Kachins objected to the inroad and insisted on their right to the forest. A compromise was reached, 200 of the labourers being sent back at once, the remainder collecting rubber under Kachin supervision, to whom 10 perjcent. was to be paid, and 200 Kachins paid at the current rate took the places of the 20b dismissed coolies.'

YIELD. 08

EFFECTS OF CULTIVATION WITH REFERENCE TO YIELD.

In the remarks below regarding the yield of rubber from the introduced trees, Mr. Lawson, Government Botanist, Madras (supported by other writers), says that he cannot believe the yielding powers of the Cearas could have decreased on account of their having been transplanted from Brazil to Southern India. "At any rate,\*\* he remarks, "I can give no scientific

,

• Con/, with the remarks at page 356.

I. 68

Ficus elastica—Effects of Cultivation. (G. Watt.) INDIA-RUBBER.

reason for believing that such is the case." A few jottings may be here given which have a bearing on this subject. Dr. Heifer in experimenting YIELD. with the wild caoutchouc-yielding plants of Assam found that Ficus reli-giosa produced a different kind of rubber, and in varying proportions according to position and nature of soil. On elevated ground it yielded a very coarse substance without value : growing close to water it afforded a reddish fluid which remained unaltered for several days (Trans. Agri.-Hort. Soc. Inala, Vol. V., 40). So also Mr. G. Mann (Report on the Caoutchouc Tree in the Darrang District, Assam) says : " As the distance from the hills increases, and the atmosphere in which the tree grows, gets drier, the quantity of rubber to be obtained from a tree decreases; and whilst it is stated by the men who fetch it from the hills, that one tree is able to produce from 2 to f maunds, the men who gather it from the forests at the foot of the hills only get from 20 to 30 seers per tree, and if far away from the hills, only half that quantity is obtained, especially if the ground is gravelly or otherwise severely drained " (Journ. Agri.-Rort\* Soc. (New Series), /., 73). Again in the Proceedings of the A gri.-Horticultural Society of India (Vol. V., New Series, Hi) information is given regarding the yield of rubber from Ficus elastica in Furreedpore, the Collector being so encouraged by the result as to have commenced planting the tree on road-sides. In the Kew Report for 1875 this action, in the light thrown on it by the passage given above from Mr. Mann's report, is thus commented on :----'' It is found that although the Ficus elastica will grow with undiminished rapidity and luxuriance in situations remote from the hills, it fails to yield caoutchouc. Mr. Mann concludes that no greater mistake could be made than to start plantations of Ficus elastica in any part of Bengal. It appears, therefore, judging from this case, that conditions which may ensure the successful growth of caoutchouc-yielding trees may not be sufficient to determine their producing caoutchouc." Although this may be discouraging to planters who, daily looking upon their healthy plantations of Para and Ceara rubber trees, await the discovery of some successful mode of tapping them, it is feared the doubt implied by the above facts has to be reiterated. The defect complained of may be a permanent one, namely, that while the trees will grow freely enough, they may not form their milky sap in sufficient abundance or they may produce a sap containing ingredients that prove detrimental to the rubber extraction, or a sap so deficient in caoutchouc grains as to make cultivation in India unprofitable. Mr. Thomas T. P. Bruce Warren *{Planters\* Gazette*)haiS asked the question whether Para rubber trees, acclimatised in tropical countries, produce free ammonia in their milk. The only rubber milk, he says, which he has examined that contains a large amount of ammonia, is the Syphonia elastica grown in Para. As the soil contains comparatively little nitrogenous matter, he suggests an explanation of this nitrogenous sap in the diffused lightning that occurs within the basin of the Para river. If tropical countries, where the tree is acclimatised, do not have such a meteorological condition, he further suggests that nitrogenous manuring should be tried. In this connection area a remark in the *Kew Bulletin* (1888, p. 259) regarding the West Coast of Africa as a future field of rubber cultivation may be quoted :-" In a locality so favourable for the growth of India-rubber producing plants, it would be interesting to know whether any of the plants yielding good descriptions of rubber could be acclimatised successfully without invalidating the product.\*' In the French Bulletin of Agriculture (Dec. 1888) M. Naudin gives much useful information, but regarding Ficus elastica he remarks that although the tree thrives admirably for landscape and ornamental purposes at Algiers, it does not form its milk in such abundance as to make it a profitable source of rubber,

| In the account given below of the rubber of Ficus Vogelii a power,<br>ful <b>argument</b> is advanced <b>regarding the composition of the</b> milk<br>caoutchouc-yielding plants. The necessity for more chemical analys<br>has been urged (at page 340) and it need only be here added that a<br>important service would be rendered by the chemist furnishing an analy<br>of the fresh milk of each and every rubber-yielding tree. A <sup>com</sup> P <sup>a</sup> F <sup>r</sup> % <sup>n</sup><br>of these results with those obtained by the analysis of the same milks tr-<br>the acclimatised stock would save needless expenditure in forcing cultiva-<br>tion, if adverse departures were found, and the chemist would at the sa be<br>time afford the data on which a rational system of coagulation might be<br>framed. ( <i>Conf.</i> with the remarks regarding the variability of both Hermp,<br>Vol. II., 110, 118, and Flax, Vol. V, in their production of fibre, accu-<br>under different climatic conditions.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 9«. F. Vogelii, <i>Miq.</i><br>A West African tree, supposed to be the source of the <sup>sCM:an_e</sup><br>Abba rubber that is being experimentally introduced into commethe<br>from Badagry. A sample of this rubber was recently examined by-,<br>India-rubber, Gutta-percha and Telegraph Company at Silverton. "Int<br>report will be found in the Kew Bulletin for 1888, pages 253 -261. iffe-<br>report is of special interest to India, since the properties of the rubbers af-<br>rived from the genus Ficus will most probably be found to be more near y<br>allied to each other than to the rubbers of the other plants resorted to <sup>a</sup><br>sources of the commercial article. Interest may also be viewed as existing<br>in the fact that it seems probable plantations of this Fig will <sup>s0</sup> on VI,<br>started. In the report on the samples of Abba rubber it is stated trai<br>"The sap of a tree may contain a large quantity of caoutchouc, but the<br>same may be associated with other principles contained in the sanie or<br>o-her plant tis-ues, which completely modify its character." Ag&m the<br>author of the report remarks:—"I am not aware of any native India-<br>rubber with an acid re-action; even the juice or the Para-rubber tree,<br>Hevea brasiliensis, is distinctly alkaline when drawn, and exudes a strong<br>smell of ammonia. The rubber from this source is strongly acid. In roast-<br>ing the nuts of the Urucari palms, a large quantity of acetic acid is given<br>off, which probably, by neutralising the ammonia, brings about the coagu-<br>lation of the caoutchouc; the excess of acid from the roasting of the nuts may<br>help to explain the acid re-action of the Para rubber, but as the negrohead<br>variety is obtained from the same source, and is <i>not</i> smoked although it is |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Habitat.—An extensive climber found on the trees of the tidal forests of Martaban, Malacca, Singapore, and the Andaman Islands, but by mistake spoken of (in <i>the Kew Report</i> ) as abundant in Southern India. The above quoted official correspondence, from this mistake of habitat, resulted in many futile attempts to find the plant in India proper. It has been experimentally cultivated in Burma, but interest in the climber appeals to nave died out.<br>% Caoutchouc.—Rubber of excellent quality was said to have been ob-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                       |
| tained from this creeper.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                       |

| Habitat.—A troublesome climber, which, after Ficus elastia, is said to<br>yield the best India-rubber. It is found in Martaban and Tavoy; and is<br>common all over Pegu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                       |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | I                                     |

# Parameria and Urceola Rubbers (G. Watt.) INDIA-RUBBER.

1.75

Indigenous Caoutchouc-yielding Plants.

Caoutchouc. I. BURMA.—A sample of very superior rubber obtained CAOUTCHOUC from a plant which Dr. Thomson thought might be the above was 1458 Burma. cured from Rangoon by the Agri.-Horticultural Society of India "finantia" It was furnished by Captain E. H. Power, and the report on Karates 76 that it was free from that stickiness which characterises and deienv the India-rubber obtained from Assam. rilbber Dr. Mason (Burma and Its People, 523) describes a superior Echies derived from a creeper which the Rev. Mr. Parish thought might of -- have "With care in preparation, it would be equal to the best South A."I uprect In 1874 fresh and more pointed attention was directed to this s jHe by the publication of Mr. Q. W. Strettell's pamphlet on the creepeIT...g ^ tells us that his attention was first directed to the subject <sup>by</sup>. <sup>ob</sup>f<sup>e</sup>\_Ls of Kachyen girl dyeing thread an indigo blue by means of the leath ^ Strobilanthes flaccidifolius (the *rum*, indigo of Assam and Burma)  $w_{1}^{*}$  and  $w_{1}^{*}$  equal quantity of the leaves of Urceola esculenta. This fact has a c mil interest since the allied plant Wrightia tinctoria and several other giving plants, such as Marsdenia tinctoria and Gymnema ting<sup>en</sup> ${}^{2}J_{aveS}$  known to afford indigo. It is thus highly probable that the  ${}^{1}$   ${}^{4}$ of Urceola esculenta contain indigo, and that the combination Strobilanthes serves a direct tinctorial purpose and is not a.  $m_{as}^{ere}$  wijj junct. If this be so, it is probable that Urceola might afford  $m_{as}^{in}$  &  $2J_{0}$  the as rubber. But Mr. Strettell being then engaged on an enquiry "Lerty source of Burmese rubber, was naturally more interested in that points of the plant. He collected a sample of the rubber, submitted highly Messrs. Galbraith, Dalziel & 90., and obtained a report of a 1  $^{\circ}$  encouraging nature. "We consider the quality to be very \*aixs... ^ the present market value of about R200 per 100 viss." Stimulated by the prospect held out Mr. Strettell went into the question of water hlenv mately correct, and assuming the trees to be 30 feet apart, the folio details will enable us to form a fair idea of the probable financial r e u ^ Area'to be cultivated 400 acres. Trees at 30 feet by 30 feet, equal acre to 48, or 19,200 creepers in 400 acres. Minimum yield of caoutchouc per annum, estimated at one viss per creeper, enual 19,200 viss, or at R200 per 100 viss, 1\*38,400 per annum/ The cost of Starting this project will on trifling in the extreme. All that will be necessary ought not to exoeed, on an average of seven years, R4. per acre per annum. After the first year the creepers will have attained a sufficient height to require little. or no further ottention beyond of accurate first for the first year further attention, beyond, of course, protection from fire. Thus, at the of seven years, the cost on 400 acres would represent R 11,200; ^5<sup>+</sup> e<sup>ven</sup> this expenditure might be reduced if Shans or others were induced to s en their labour for the privilege of cultivating within the area free of ta m Awhile a still further reduction might be brought about by intermedia while a suil luriner reduction might be brought about by intermediated sowing, tapping each alternate creeper to death immediately it commenced to interfere with its neighbour. At the expiration of seven years the ex-penses will embrace tapping, pressing, and preparing the caoutchouc, which I estimate at 124 per cent, of the profits. According to these figures and the present market value of the India-rubber of this creeper, the net assets of this scheme may be approximated at R33,600 per annum. Mr. Strettell affirms that the milk of the creeper more readily coagu-

jates than that of Ficus elastics, "for I have known it," he says, "resolved into a coagulum floating in an aqueous solution within a few hours after collecting, and without exposure to the direct rays of the sun, or artificial heat of any kind. This consolidated mass should be collected at once, and all moisture expelled by means of graduated pressure." The season for tapping, Mr. Strettell recommends, is from the end of April: from October to March, he says, the circulation is slow and the milk scarce. Mr. Strettell's pamphlet concludes with the statement that Messrs. Galbraith, Dalziel & Co. report that the rubber he has furnished them with is superior to that from the India-rubber tree, being purer and better suited to their purposes.

This species of rubber-yielding plant is cultivated to some extent in Burma on accovit of its fruit which finds a market as a substitute for tamarinds: if to this fact it were found that the leaves also had a value, additional arguments might be advanced in favour of an experimental cultivation of this creeper to those used by Mr. Strettell. At all events no action seems to have taken place and the subject has once more lapsed into the oblivion into which it fell, after the appearance of the reports (quoted above) which were published nearly a quarter of a century before the date of Mr. Strettell's paper. This is the more to be regretted since Landolphia and other foreign climbers and trees have received every attention, and money has been spent in their acclimatisation which might more profitably have been used in dispelling the uncertainty that still exists regarding Urceola elastica. The force of this recommendation will be apparent when it is added that Mr. Strettell affirms that an annual budget provision is made to exterminate this most destructive and persistent climber from the teak forests. It is thus probable that a considerable amount of rubber, which might even be collected from the wild stock, is being wasted. Without, therefore, corroborating, in any way, Mr Strettell<sup>5</sup>s statement of yield or his estimates of profit (which of course the writer has no means of doing), it would seem highly desirable that this subject should once more receive the consideration it seems to deserve, so that the public may be saved from other spasmodic reports in the future by the publishing of results either in support or in refutation of Mr. StrettelPsarguments. If this be the sok of the Talaingspeaking people, a recent report states that like the rubber from Parameria it will not pay its extraction and preparation.

II. MADRAS.—The Conservator of Forests, Southern Circle, reports that this rubber plant "has been introduced by Mr. Morgan into Malabar from Burma. The growth is very slow, the largest plant, now four years old, is only 15 feet high and 1J inches in diameter at the base. It does not promise to be of much value as a rubber-producer."

## 13. Willughbeia edulis, Roxb.; Die. Econ. Prod., I., 273-277; APOCY-

Syn.—VV. MARTABANICA, Wall.

The rubber from this and one or two **allied** species is commercially designated MALAYA or BORNEO RUBBER.

Mann.—Lati-am, BENG.; Thit kyouk nway, BURM.

portectly drained and dry the rubber cakes are fit for the market, and exported generally in casks." Alum is sometimes used in place of the moon-plant, or the milk is freely washed in water and slowly pressed. This process of preparing by means of water was described by Mr. Cross, the milk after washing being left to dry in vats. Mr. Niellson in a report on Abba rubber of the West Coast of Africa, states that in his experience of Castilloa •rubber in British Honduras, one gallon of milk yielded 3ft of rubber.

## CULTIVATION OP CASTILLOA RUBBER IN INDIA.

I. BENGAL.—In his annual report of the Botanic Gardens for 1881-82 Dr. King wrote that of this rubber tree he had up to that date only eight plants, *but* added it was being propagated as fast as possible. Other reports followed, but apparently no material progress was made in the acclimatization of this rubber.

II. MADRAS.—In the report of the Botanic Gardens, Nilghiri hills, for 1881-82, Mr. Jamieson reported receipt of the first plants. Two healthy young Castilloas were then obtained from Ceylon, Mr. Jamieson remarking regarding them :—" The reason I value these plants so much is that I have had to wait for them so long, having been led to expect a supply of Castilloa plants so far back as 1878. Shortly after receipt of the plants I took off a few cuttings, which rooted in less than a month. Since then every available cutting has been successfully propagated, and our stock now consists of fourteen healthy plants, including the two from Ceylon. The cuttings require constant care and close personal supervision for the first few days, being liable to damp off by the slightest excess of moisture. It, however, seems a strong growing plant when once rooted. The only drawback we have had to contend with in growing the Castilloa under glass is to keep it free from the attacks of the red spider, which, if allowed to get hold of the plants, would considerably retard their growth. One of the Ceylon plants has been put out in the Barliyar gardens, where I hope it will thrive, as in these days of uncertain coffee crops, and low prices, planters are anxious to cultivate any plant that will return a small interest on their outlay. It is therefore of the utmost importance that every effort should be made to propagate this plant for distribution. I have no doubt many localities in Wynaad and on the slopes of the hills will be found to suit the Castilloa and where it will yield a profitable return to the cultivator."

The Conservator of Forests, Southern Circle, reports that the trees in Nilambúr " are far too young to produce any quantity of rubber." In a recent report (1888) by Mr. M. A. Law son, on the present condition of the introduced rubber trees of South India, the following passage occurs regarding- this species :—" With respect to the Castilloa, there are in the Barliyár Gardens some five or six trees of about twenty feet in height, and with stems of about two feet in circumference. These plants flowered and seeded for the first time last year, and the seed germinated freely. They look as healthy as possible, and grow with great rapidity. Besides these *Jfees* at Barliyár, there are a few in the Teak Plantations at Nilambúr, and Mr. Ferguson has several in his garden near Calicut. They are easily propagated from cuttings, and could be, by this means, increased indefinitely, but the same difficulty has been experienced in extracting rubber from them as has occurred in the case of the Cearas."

Habitat.—This and one or two allied trees occur in the forest ot ^ emit\_ and Northern Brazil and in the forest of Para from the mouths of w Amazons, south and west. The region thus indicated has a cuma^B the markable for its uniformity of temperature, the mean being 8» r. ana greatest heat 95° F. (Plantations should not therefore be made in a regi where the temperature at any time falls below 60° F.) The rainfall occur h principally in January to June, the maximum being in April, where the region as having a  $de_A p^{e_A}$ soil, large tracts being flooded in the wet season and in the/jry <sup>A</sup> c ls completely intersected with water-courses. The most productive 1 -nd arc at most only 80 to 100 feet high, the soil full of moisture, ncn » fertile, but the atmosphere very unhealthy. The tree grows rapidly, attaining some thirty feet in three  $\frac{v e a rs}{t}$  A readily propagated by cuttings. Mr. Cross recommends plantations to made in seasons of inundation or flood, the cuttings being forced into to mud for half their length, leaving enough above ground to save the from being actually submerged. Propagation by seed is not so successi **REGIONS MOST LIKELY TO PROVE SUITABLE FOR THE PARA RUBBBR** Suitable Regions. TREE. The following extract from Sir D. Brandts' review of  $W^{r_w} \stackrel{\circ}{\longrightarrow} ?$  and report gives the tracts of India which Sir D. Brandis  $antiaP. \stackrel{\circ}{\longrightarrow} m_{O}$  at which all subsequent experience (since 1873) has confirmed, as being  $h_{raz}$  suited to Para rubber. Having compared the extremes of  $5^{iimat}f_{raz}h_{raz}$ 85 also the means, on the west coast of India and in Burma, with that ot » he rer.iarks: «'We may, therefore, conclude that Kanara, Malabar, 1<sup>14</sup> vancorc, and the Burma coast, from Moulmcin southwards, offer the ae sired conditions as regards temperature, for the successful cultivation of the caoutchouc-yielding species of Hevea. I would specially draw the auth tion of forest officers in this respect to the moist, evergreen forests a foot of the Coorg Ghdts, and in Kdnara, as well as to the Attaran vaney, and similar localities in Tcnasserim." - ₁t., Collection of Rubber.—Mr. Cross gives a detailed account of we method pursued at Para, of which the following are the main facts. Collection. milk is drained into small earthen vessels attached to the trees by » adhesive clay. The contents of fifteen of these cups make one  $?^{h}?''rJ$  imperial pint. "Arriving at a tree, the collector takes the axe in his ngn hand, and, striking in an upward direction as high as he can reach, <sup>rna</sup>J\*<sup>c\*</sup>, <sup>a</sup> deep upward sloping cut across the trunk, which always goes througn 1 bark and penetrates an inch or more into the wood. The cut is an me in breadth." Frequently a small portion of bark breaks of! from <sup>tn</sup>£.<sup>u</sup>Pt<sup>fr</sup><sub>v</sub> side, and occasionally a thin splinter of wood is also raised. QuiCKiy stoppingdlown he takes a cup, and pasting on a small quantity \*\*Cr ^ Or the fat side, presses itot ehrun c deel enclath the cut By this time the milk, which is of a dazzling whiteness, is beginning to exude, so that if requisite he so smooths the clay that it may trickle direct into the<sup>cu</sup> p a distance of four or five inches, but at the same height, another cup, is luted on, and so the process is continued until a row of cups encircle the tree at a height of about six feet from the ground. Tree after tree is treated in like manner, until the tapping required for the day is finished. This work should be concluded by nine or ten o'clock in tJic morning, because the milk continues to exude slowly from the cuts for three hours or perhaps I. 86

86

#### Pant Rubber.

(G. Watt.) INDIA-RUBBER.

longer." . . The quantity of milk that flows from each cut vanes, but if it is large and has not been much tapped, the major ty of the cups will be more than half full, or occasionally a few may be filed to the brim. But if the tree is much gnarled from tapping, whether it growsj" the rich !ludge of the ^ o' or dry land, many of the cups will be found to contaironly about 1 tablespdbnful of mifk, and sometimes hardly that. On the following morning the operation is performed in the  $^{me}$  way, on  $\stackrel{b}{\succ}$  that the cuts or gashes beneath which the cups are placed are made from six to eight inches lower down the trunks than those off the previous das. Thus each day brings the cups gradually lower until the pound is reached. The collector then begins as\*high as he can reach, and descends as tefore, taking care, howeverfto makers cuts in separate places from those pre. viously made. If the yield of milk from a tree is great, ^ o j o ws of cups are put<sup>n</sup> at once, the one as high as can be reached, and the other at the surfaceof the ground, and in the course of working, the upper row descending daily six or e&ht inches, while the lower one ascends the same distance, both rows in a few days come together. When the produce of milk diminishes in long wrought trees, two or three cups arc put on various partsi of the trunk, wW the bark is thickest. Although many of the trees of this class are large, the quantity of milk obtained is surprisingly little. This state of things is not the result of overlapping, as some have suggested. . . The best m:lk-yielding tree I examined had the marks of twelve rows of cups which had already been put on this season. The rows were only six inches apart, and in each row there were six cups, so that the total number of wood cuts within the space of three months amounted to sevent>-uo. There are other methods occasionally pursued, but the cup process is the most general and gives the best result. Dr. Tr.men afds to the above account that the trees are tapped if they have a arcumference of 18 to 24 inches, and the rough process described is carried on for many >ears, until the constant and extensive injury to the young wood causes f^ deathfor some years previous to which event they almost cease to yield milk and are practically abandoned. A writer in the Tropical Agriculturist hxes Tine the aget)f 25 years as that at which tapping should commence, actual yield of a tree per annum and for each year of its life, does not ap-Pear to have been worked out by Mr. Cross, but assuming 7\* cuts to bca high average, and that each cut yields half a cup full (also from Mr. Cross's statements a very high average) about six imperial pints of milk would De obtained from a tree in good bearing condition. Mr. Cross is careful to Point out, that although the trees are large, the yield is surprisingly little, and it would thus seem probable that the Para rubber may be remunerative at present prices, when dealing with wild plants in their indigenous habitat, but might not be so if expensive cultivation and supervision were necessary.

#### CULTIVATION OF PARA RUBBER IN INDIA.

HISTORY OY INTRODUCTION INTO ASIA.-In a letter dated April 1878, Mr. W. T. Thiselton Dyer gives the history of the attempt to introduce Hevea fc?aziliensis into India and Ceylon. On the 4th of June 18731.the Director of Kew Gardens received from Mr. Markham some hundreds of seeds which had been collected by Mr. James Collins. Of these less than a dozen germinated, and six were in that year taken out by Dr. King to Calcutta. These did not succeed well in Calcutta, and it was accordingly arranged that Ceylon should be established as the depot for supplying young plants to the parts of India where Hevea cultivation was thought possible. On June 14th, 1876,70,000 seeds were received at Kew from Mr. Wickham (who was paid for them at the rate ol £10 per i.000); 4 per cent, germinated. Of these, 1,919 plants were sent to Ceylon in 38

CULTIVA-TION. Introduction. **87**

HEVEA

BRASI-LIENSIS.

PARA RUBBER. Introduced Caoutchouc-yielding Plants.

Wardian cases, in charge of a gardener, and 90 per cent, reached in excellent condition. On August 23rd, 50 plants were sent to Colonel Seaton in Burma, but arrived in bad condition. A further supply of 100 plants was taken out to Ceylon from Kew by Mr. J. F. Duthie. Similar consignments were also issued from Kew, a'mounting in all to upwards of 2,000 plants sent to Ceylon, and smaller numbers to Burma, Calcutta, Mauritius, and Singapore. Mr. Dyer adds in his review of these endeavours to secure the acclimatisation of Para rubber that the plant is now therefore to be regarded as definitely established in the East Indies. So again, in Novem; ber 1876, Mr. Cross arrived at Kew with about 1,000 plants brought direct from South America, but only about 3 per cent, of these plants survivea, so that it would appear Mr. Cross's share in introducing Para rubber was a very small one.

On the subject of Para rubber introduction Dr. Trimen wete'. "The cost of procuring the seeds of Para rubber, <sup>f</sup>reight, and otnet expenses appears to have been no less than £1,505-4-2, the ^ar ^an \***n** e cases alone costing £120, and the gardener and his passage £103. ) B) whole of this large expenditure was borne by the Indian Government. the case, it is Ceylon which ' from climatic causes chiefly<sup>f</sup> appears likely of benefit most largely from the successful action of the Government ve (Tropical Agriculturist, Vol. /., 399). This view appears to na India" been so far correct, for Dr. King, in his Annual Report of the £> rub-Gardens, Calcutta, for 1881-82, wrote that the cultivation of the rara ber plant had been abandoned in Bengal. most en-

But even in Ceylon, and after some eight or ten years of the the state in thus is thus is thus in the solution, the opinion was finally army ? Tropi-Para rubber would not pay the planter to grow it. The pages of the cal Agriculturist from 18S1—86 literally teem with contributions, en(Jit and reports on Para and Coara with a state of the state of and reports on Para and Ceara rubber, with only one or two passing that Para and Ceara rubbers would not pay, and in many parts of trie  $cou^n \wedge$ try the trees have since been hewn down, being viewed as worth<sup>less</sup> he1888-89 fresh interest was, however, awakened, in consequence of favo<sup>ura</sup> reports having been furnished on samples of Cevion where cont to core. devoted to Ficus elastica. The planter's verdict ultimately was, as reports having been furnished on samples of Ceylon rubber sent to  $\& u_{mgn}^{ope}$ Dr. Trimen in his annual report for that year urges the Ceylon Governm to take the matter in hand as a State enterprise. He had tapped a tree (eie ven years old having a stem circumference of 4 feet 2J inches), during three of the off the state of the state periods of dry weather, and oLtained ift 12J oz. of dry rubber at a^cost of 62 cents. Dr. Trimen comments on this result:—" As the rubber <sup>o b t</sup>?" ed is probably worth at present prices about 45. per fl>, there is clearly a. 1 dS j profit to be made here out of a Hevea plantation. I urged the formation of such upon Government so far back as 1882, but in the absence at that 1 m of any organised Forest Department nothing could be done. As a valuable forest product, Para rubber may be confidently reckoned upon as as the source of future revenue, and I strongly recommend that large j\* antaiions of it be formed in suitable places." n &

It may thus be inferred that as a State undertaking Para rubber would likely prove as remunerative as most other trees, and it is perhaps the dur of all Governments in tropical countries to assume the responsibil. ble providing for the world's future wants in rubber by organising suit a of forests, but it may be accepted as established that such forests are n. likely to be of interest to the planter who requires to turn over his cap<sup>1\*\*</sup> in as short a period as possible. In January 1888, the Government.04 India (in consequence of a despatch from the Secretary of State in whick I. 87 attention was drawn to the fact that the Royal Botanic Gardens, Ceylon,

### Para Cultivation in Burma.

(£. Watt) INDIA-RUBBER.

PARA RUBBER. possessed a plentiful supply of the seeds of Hevea brasiliensis), issued a circular letter to Local Governments calling for a short r&sumi of the success which had attended the cultivation of that tree. The following extracts from the replies bring our knowledge of the cultivation of the Hevea rubber tree down to the most recent data :-Bengal. I. BENGAL.—" It has been ascertained from the Superintendent of the Royal Botanic Gården, Calcutta, that nearly ten years ago a quantity of the seeds of this 88 tree (one of the species from which South American India-rubber is obtained) was sent to the garden from Kew. Some of these seeds germinated, but it was found that the resulting seedlings were extremely sensitive to cold, and that the low night temperature of the cold weather of Bengal proved fatal to them, even when planted in the most sheltered situations. Some of the seedlings were supplied to Tea Planters likely to give att minor to their culture, and some were sent to Mr. Mann, the Conservator of Forests in Assam. The results obtained by these gentlemen were, however, the same as those obtained by Dr. King, and it was on his recommendation that subsequent supplies of Hevea seeds were sent to Ceylon, instead of to India. The Superintendent thinks that Hevea will grow well in Provinces like Malabar or Lower Burma, where the climate is said to be moist and equable; but in Northern India, where there provesn cccss: a Splisoli, Dru Klung is of Pinion that its cultivation is not likely to <sup><7<sup>h</sup>fu<sup>C</sup>?<sup>11</sup>servatorof For</sup>ests, Bengal, who has also been consulted on the subject, reports that it does not appear that any experiments in the culture of the tree in question have ever been undertaken by the Forest Department in this Province." Burma. II. BURMA.—Colonel W. J. Seaton wrote of Tenasserim :-" Early experiments\*-Experiments on a small scale were commenced at Mergui 89 in 1877, with eight seedlings, the survivors of a small batch received from Dr. King, of the Botanical Gardens, Calcutta. They were successfully set out in the Forest Office compound at Mergui, and although on a low hill, a not very desirable site, yet their growth was for some time satisfactory. In 1879, a large number of Hevea plants, be-lieved to be well-rooted cuttings, were forwarded by Dr. Thwaites, of \*he Royal Botanical Gardens, Ceylon, and although in the charge of a subordinate who had been sent to Ceylon for special instructions, only 178 survived the voyage. These were set out in the plantation area selected, about if miles inland from Mergui, on somewhat low ground drained by the sources of the Boke Chaung, a small tidal creek. Only 64 of the healthiest plants survived the planting operation, and of these again casualties continued to take place yearly, owing chiefly to attacks of white-ants until the number was reduced to 50 in 1886, since when there have been no further casualties. The following were the sizes of ten of the largest trees of 1879 measured on 29th March 1888:-Girth in inches No. Height in feet. at 2 feet from REMARKS. ground. 29I Forked into two branches 4 feet from ground. 1 39 2 34\* 37 Clean bole of 9 feet. 3 40 38 **Bitto** 1**8** 4 5 6 **43**\* 4∞£ Forked at 3 feet from ground. 394 **3**3\* Clean bole of 8 feet. 27\*\_ 7 8 3i 18 Ditto 10 3<>£ ,, <u>3</u>0 Ditto 6 ,, <u>9</u> **3**<sup>1</sup> 27 Ditto 6 ,, 18\* Ditto 8 10 21\* ,,

Propagation with cuttings —In the rains of 1879, 24 cuttings from the young trees in the Forest Office compound were set out in the plantation, but the experi-ment proved unsuccessful. Subsequent attempts, made from time to time, met with no better success, the cuttings generally dying off during the second year.

The following year a large quantity of seed was procured from the to older trees, but not being sown immediately after collection, a great portion of it To older trees, but not being sown immediately after contention, a first state, bether failed to gorminate, and only 121 seedlings were missed. In the rains of 1886, bether results were obtained by the timely sowing of the seed obtained from the older been and by the part removal of the bask enclosing the seed. As many as 7,000 seedlings were raised, germination occupying three to four days. Experiments were continued in 1887, and 3,430 additional seedlings obtained. From Ceylon 54 seeds were rotative ed in October 1887, of which only 31 were fit to sow, but all tailed to germine to Stock on hai. at end of March 1888, The stock of trees and plauts in the plantation and purseries was as follows: Trees set out in 1879 Scedlings of 1884 to 1885, act out in the main plantation 20<sup>7</sup> × 10<sup>4</sup> In the nurseries, ready for transplanting and tof 1886 2,752 distribution. -430 1 of 1887 14.04 GRAND TOTAL General remarks.—The 50 older trees appear to be in perfect health, with evi-dence of such vigour as to\_pave no doubt that they are fully established and have ou rown all danger from attacks of white-ants. They yield an abundant supply at seed, some of which, it\_illowadJtoJall,=Qee^sienatian all ^^^^fa=Ufi\_trees. The fl paper of which, it\_illowadJtoJall,=Qee^sienatian all ^^^^fa=Ufi\_trees. The and fSjSITiiS means and August about the middle of the rainy season. It me be seen that the propagation of the Hereas benefitiened to be the rainy season. It me be seen that the propagation of the Heves, brasiliensis in this part of Burma is not Other Tildepindent of external assistance, and that its archivation has been suc-cassfully demonstrated. It now only remains to subject the larger brees to periode tapping to ascertain the yield in caoutchour, after which the question will have to be determined as to the precise area which it may be advisable to plant up at Mergui tudTolTssuitable localities with this valuable tree. In a communication, dated 28th January 1889, Ogional W. J. Seaton gave the following account of the method of tapping and the yield of Pattier Ostalized SY film from the Para-rubber trees of Tenasserim :----"The tapping experiment was first undertaken in July, under the impression that the flow of milk would be more abundant during pots were in the first instance affixed to the trees by means of well-scought potter's clay, and above them small pieces of the were also placed in such a position as to pro-tect them from the rain; but, as the clay yielded to the rain and fill to the ground tapping had to be undertaken at intervals between the more, the bankour puts being affixed by sharpening the upper end and forcing them into the bankour puts over a fillow of the target in the upper end and forcing them into the bankour puts be seen that the propagation of the Heyea brasiliensis in this part of Bur Tield. 00 tapping had to be undertaken at intervals between the showers, the hambot pro-being affixed by sharpening the upper and and forcing them into the bark in the man-ner followed by the *Thitsi*' collectors. In order to obtain the largest quantity of milk in the shortest time possible, numerous incisions were made on the frees. The incisions were made in an upward direction and converging as required. The quan-tity of milk collected was so small in the intervals between the showers that it was deemed necessary to limit the experiment finally to five of the largest trees on the west bank of the Bokchaungale, which flows through the observed. The milk was found bank of the Bokchaungale, which flows through the plastation. The mile was found to flow much more freely from these the plastation. The mile was found trees first experimented on. They have, however, a thicker bark, and it was uur served that the exudation of milk was^testnearthiegrouid^^ ore the bark was thickest while at a height of six or served. served that the exudation of milk was^testnearthiegrouid^^ere the bark was thickest, while at a height of six or seven accel it was almost mill. Groups to cardinated wat weather, it was found necessary to dry the milk over a fire and keep it subsequently in a warm place near the fire for about three weeks. The experiment was renewed between and and a6th November, when the rains had fully creased, at trees being operated on, eis., 5 to the west and 37 to the east of the Bolichaungale. The me-incision being small (less in fact than was the case in the rains), the several brees werk to do it sapping was the same as that followed previously; but the yield from each incision being small (less in fact than was the case in the rains), the several brees will to to the in atmost extend, and, by constantly collecting the milk before it had to the west and 9 or. from the 37 trees to the east of the Bolichaungale." It may here be remarked that while Para was early seen to be unsuited to Bengal, and accordingly the Botanic Gardens of Ceylon were **I. GO**

Hevea Cultivation in South India. (G. Watt.) INDIA-RUBBER-

selected as the best locality for forming a nursery, the Ceylon planters PARA RUBBER. took a far keener interest in Ceara. It has since transpired that Burma stands the best chance of becoming the successful Asiatic acclimatisation home of Para, not Ceylon, and, it may be pointed out that Sir D. Brand is at the very commencement of the interest in foreign rubbers suggested Tenasserim as a likely locality for the Heveas but made no mention of Cevlon. HI. MADRAS.—In 1881-82 Mr. Jamieson reported of the Botanic Gar-Madras. dens on the Nilghiri hills that he had received from Mr. J. Fergusson a 91 few cuttings of this rubber tree. From these he succeeded in raising one Plant. It was sent to Barliyar, and Mr. Jamieson adds, "this garden now contains plants of the three most valuable species of rubbers." Later on  $Mr_n$  M. A. Laws on reported :—"There are three young trees of this species in the Barlivar Gardens. They are about twenty feet in height, and have stems of about eighteen inches in diameter at the base. Like the Ceara and the Castilloa, they grow vigorously, and have flowered for the first time this spring, but so far I have been unable to extract rubber from them in any large quantity." In a special communication for this work the Conservator of Forests, Southern Circle, Madras, states : " There are only two young trees in the experimental garden at Manontoddy averaging 20 feet in height by 3J inches in diameter at 4 feet from the ground. Their growth is decidedly good, and the climate seems suited to them. There are numerous trees in Nilambur which have made excellent growth, but all are too young to be tapped." It will thus be seen that in Tenasserim the Para-rubber tree would appear to have found a congenial home; according to Colonel Seaton, the tree is quite acclimatised. India is thus independent of external assistance, and from Tenasserim, seed or even seedlings might be furnished to all other

from Tenasserim, seed or even seedlings might be furnished to all other parts of India, where its cultivation was thought likely to prove successful and desirable. It cannot be said, however, that all has been learned that is necessary, to place Para cultivation in India on a commercial basis. Cultivators constantly raise the questions put by Mr. Lawson in his remarks quoted below under Manihot Glaziovii, and it seems probable that acclimatisation in a new country may have lessened the volume of milk or even altered its property. The season and age at which the trees should be tapped and the method best suited to India, are points that future experience alone can solve.

#### INDIAN-GROWN PARA RUBBER.

Samples of Hevea rubber collected in Tenasserim were sent to the Secretary of State for favour of report, and the following replies were received from the Kew authorities in June 18S9:—

"I am desired by **Mr. Thiselton Dyer** to acknowledge the receipt of your letter of the 26th April last (R S. and C. 614), forwarding a copy of a letter received from the Government of India, with enclosures, reporting the results obtained from tapping- trees of **Hevea brasiliensis** near Mergui in Tenasserim.

2. T\*M><sup>o</sup>specimens of caoutchouc referred to were duly received by Parcels Post and they were subsequently submitted for valuation and report, through S. W. Sil-, ver, Esq., F.L.S., to the India-Rubber, Gutta-percha and Telegraph Works Company (Limited) at Silvertown.

3. I enclose herewith a description of the specimens, and a copy of the valuation and report received respecting them. On the whole this report is favourable. The small quantity of rubber available (in no case exceeding a few ounces in weight) rendered its manipulation somewhat difficult; but, bearing this fact in mind, the result, as shewn in the samples of prepared rubber sent in a separate cover, is very encouraging.

4. It will be noticed that the best quality, valued at 25. 3/t. per pound, i\* nearly 24A

# Landolphia-Rubber-yielding Spedes. (G. Watt.) INDIA-RUBBER.

(shipped from Mozambique): L. florida found on the coast near Dares-Salam and extending inland, and L. Petersiana growing near Tanga on the coast of the main land opposite Pemba.

Caoutchouc--The species of these African climbers have been here collectively discussed, since, for the purpose of rubber-yielding, their differences are very small, the more so in the light of their possible acclimatisation in India It may be here remarked that the world is indebted to the exertfons of Sir J. Kirk for the East African supply of rubber. But as the species of Landolphia cannot be said to have been established commercially in India, only a few jottings need be given, and chiefly the facts regarding the attempts at their acclimatisation in India. The methed of collection of West Coast rubber from L. florida is peculiar. The milk dries so quirfcly as to form a ridge on the wound which stops the further flow, so that it cannot be collected into vessels placed on the stem. The natives collect it by making long cuts on the bark with a knife, and as the milky juice gushes out, it is wiped off continuously with the fingers, and smeared on the arms, shoulders, and breast till a thick covering is formed. This is peeled off their bodies and cut into small squares which are then said to be boiled in water (Journ. Soc. Arts, Notes by C. G. Warn/ord Lock). The West African rubber, Mr. F. T. Valdez states, is collected in June, July, and August, but he describes a process different from the above. An incision is made on the tree, and a vessel placed under it, which, by means of a conductor, is filled, in about 24 hours. From this the caoutchouc is poured into moulds of various forms, which have been well smoked with massic or palm tree, from which the gum that gives the black colour, which they consider indispensible, is procured. "The natives of West Africa are said to make playing balls from the juice of L. florida." It is also reported that in tapping these Landolphias the rubber is spoiled if the cut be made too deep as the milk obtains an injurious gum.

Sir J. Kirk describes the process of collecting rubber as pursued on the East Coast of Africa from *matere-L*. Kirkii-thus:-" The operation of tapping is very simple : a slice of the rough bark is cut off the surface, also just enough of the tree bark, when the juice starts out in drops. These dry as they are taken from the wound with the finger, and applied to the surface of the ball of caoutchouc. There is no evaporation required by exposure in vessels." An improved process is thus described by Mr. F. Holmwood: \*'A quantity of milk is daubed upon the forearm and being peeled off forms a nucleus. This is applied to one after another of the fresh cuts, and being turned with a rotary motion, the exuding milk is wound off like silk from a cocoon. The affinity of this liquid for the coagulated rubber is so great that not only is every particle cleanly removed from the cuttings, but also a large quantity of semicoagulated milk is drawn away from beneath the uncut bark, and during the process a break in the thread rarely occurs." Lieutenant O'Neill found L...^florida not easily killed by the process of collection. He observed hundreds of plants so thickly scarred with cuts that nearly |rds of the bark must have been stripped from the tree. Mr. Holmwood speaks of the *mbunga* (L. florida) as yielding a milk that does not, like L. Kirkii, coagulate quickly. Accordingly, the Maknas who were collecting it, used sand to assist this process, and not for the purpose of adulteration as was originally thought. The milk of L. Petersiana is also gathered in a fluid state by tapping and coagulated by heat. The produce is inferior to that of L. Kirkii.

In the annual report of the Royal Botanic Gardens, Ceylon, for 1880-81, it is stated that "Sir J. Kirk thinks the Landolphias (especially L. ACCRA RUBBER.

94

**INDIA-RUBBER.** Introduced Caoutchouc-yielding Plants. ACCRA Kirkii), by far the most promising of the rubber plants for cultivation, RUBBER. their stems can be cut down at frequent intervals for the rubber, and  $h^{\otimes *^7}$ shoots readily spring up from the stools." The suggestion is made that shoots readily spring up from the stoops. The baggers is the rubber still in the stems might be removed by crushing them ana the stops of carbon. Owing <sup>10</sup> the the removing the rubber by means of bisulphide of carbon. Owing <sup>10</sup> favourable opinion a demand at once arose for the seeds, and Sir J. Kir in a paper read before the Linnean Society on the Landolphias, of the bas Coast of Africa said, that the natives, in obedience to this demand, nag collected the seeds promiscuously, so that he feared much disappointment would be felt by planters. Sir John values first and foremost L. Kir $\frac{1}{2}$ because it hardens very rapidly, next L. florida, because it yields a very fine rubber. The other forms, he states, are of little value. In  $\frac{1}{8}$  s. the Landolphias in the Ceylon Botanic Gardens flowered. It may I\* said 1 conclusion that Sir J. Kirk stated that in 1882 the value of the exports 01 African rubber amounted to £300,000. **CULTIVATION** CULTIVATION IN INDIA. Bengal. I. BENGAL.—Dr. King, in his report of the Royal Botanic Gardens, Cal. 95 cutta, for 1880-81, says that, thanks to the kind exertions of Dr. (now oiri John Kirk, seeds of this rubber climber have been received, and some them have germinated. In 1882-83, Dr. King reported that the Lanaoiphias appear to have found a congenial home in Lower Bengal. II. NORTH.WEST PROVINCES.—The Horticultural Society of Luckny N.W. **Provinces.** in 1883-84 reported receipt of a dozen plants of the African Landoip 96 from the Botanic Gardens, Calcutta. trom the Botanic Gardens, Calcutta. III. MADRAS.—In the report of the Botanic Gardens, Nilghin hillsi \*\* 1882-83, Mr. Jamieson writes :—'' Four of the six Landolphias \*<sup>inal</sup> y&en sented to the gardens by F. J. Fergusson, Esq., Calicut, have lately, wen planted at Barliyar. The plants are rather small and weak, but I<sup>trust</sup> if planted at Barliyar. The plants are rather small and weak, but I<sup>trust</sup> if gd care and attention to establish them.'' In the following year he repor-that all these plants were dead, but that this rubber had been <sup>succes</sup>Z<sup>trully</sup> that all these plants were dead, but that this rubber had been <sup>succes</sup>Z<sup>trully</sup> that all these plants were dead, but that a second species received <sup>Trom</sup> established at Nilambur, and that a second species received <sup>Trom</sup> dest Agri.-Horticultural Society, Madras, was doing well. The Madras ro bepartment in 1883 reporting on the results of Landolphia <sup>crMtV</sup>\*tion, stated that their plants were sickly. Further Colonel Oampbell <sup>tMalkin</sup> 1886 informed the Government of India that of Mr. Fergusson's PItor Madras. 97 1886 informed the Government of India that of Mr. Fergusson's PJ-nts of Landolphia at Calicut, only two remained alive, and that they entimed of Landolphia at Calicut, only two remained alive, and that they sniwed no growth or vigour. So far as is known, all the plants distributed by Mr. Fergusson in the Wynaad and elsewhere are dead. The twelve plant? planted by Mr. Morgan in the experimental garden at Madantod dy all died within 18 months, but the plant received from Ceylon Botanical Gardens and planted at Nilambúr in August 1882 has grown two feet nine inches and is now six feet six inches in height and is healthy and robust, In a sport to hand home the C report to hand, however, the Conservator of Forests, Southern Circle, 6n ^ it as his opinion that the climate of Madras is too cold for the Lanooip 17. # Ceara or Scrap-rubber. (G. Watt.) INDIA-RUBBER.

the year." The rainy season begins in November and continues to May and June. The temperature during the period of Mr. Cross's observations ranged from  $82^{\circ}$  to  $85^{\circ}$  F. The tract of country, he adds, nowhere seemed to be elevated more than 200 feet above the sea. The soil was in places a sort'of soft sandstone or gravel. In another locality somewhat further from the coast large boulders of grey granite occurred between which many good-sized rubber trees were growing.

Mr. "Cross recommends propagation by means of seed (sown in brown sand kept pretty moist); but he adds that cuttings will also take root as easily as willow. Dr. H. Tn'men of Ceylon commenting on for. Cross's recommendations says: "Experience of the plant in the Bo-tanic Garden here has proved the" general accuracy of the above remarks. There^can be no doubt of the hardiness of the species, its readiness of culture, and adaptability to circumstances. It grows equally readily from seed or from cuttings, and, though a native of a tropical sea-level, thrives well here in Ceylon up to at least an altitude of 3,000 feet, and on the most barren soils. It has succeeded equally in Calcutta and Madras, but the wet season appears to have killed it at Singapore." Dr. Trimen adds that it would not be wise to risk it in localities where the temperature is liable to fall below 60° F. In Ceylon, in 1884, there were stated to be 977 acres under this rubber, but about that time the opinion seems to have been formed by the planters that the undertaking was a financial failure. The plant either did not form enough caoutchouc, or the methods of tapping were so defective as to prove futile. The following passage expresses very nearly the universal opinion of planters : "As to rubber cultivation, my advice to those intending to plant Ceara rubber is 'don't/ To those who have a large area under Ceara rubber trees only, my advice is let them grow, but spend nothing on their cultivation such as on weeding. I have not yet found that it pays even the cost of tapping and curing of the rub-ber, and some of the trees in my charge are  $5^{-1}$  years old. We have the assurance that the trees give a plentiful supply of rubber when they are older, and I have no reason to doubt it. Meantime, I am not aware of its having proved a paying investment to anyone in Ceylon, by harvesting the rubber, therefore, I do not recommend its cultivation. It is my honest opinion, there are far too many acres under the product already, and as regards rubber, any one with land suitable for rubber, would do better to select some other product" {Tropical Agriculturist).

COLLECTION OF RUBBER.—The process described by Mr. Cross differs materially from that pursued with the Para-rubber tree. After carefully sweeping the ground around the base of the tree a few large leaves are placed on the ground. The outer surface of the bark is pared or sliced off to a height of four or five feet- "The milk then exudes and runs down in many tortuous courses, some of it ultimately falling on the ground. After several days the juice becomes dry and solid, and is then pulled off in strings and rolled up in balls or put in bags in loose masses. Only a .tJiin paring should be taken off, just deep enough to reach the milk vessels; but this is not always attended to. Nearly every tree has been cut through the bark, and a slice taken off the wood. Decay then proceeds rapidly, and many of the trunks are hollow." Mr. Cross incidentally mentions that ceara-rubber trees may be tapped on attaining "a diameter of four or five inches."

#### CULTIVATION OF CEARA RUBBER IN INDIA.

1. BENGAL.—Dr. King, in his annual report of the Botanic Gardens, Calcutta, for 188081, wrote that this plant was growing vigorously. It is the only introduced species that can be said to have taken kindly to

Collection. 99

CULTIVATION Bengal. IOO

CEARA RUBBER.

I. 100

Introduced Caoutchouc-vielding Plants.

MANIHOT RUBBER. Bengal, and its rapid and easy growth and adaptability to dry soils are points which strongly recommend it. In his previous report Dr. King wrote of his first attempts to cultivate this plant that when freely exposed to sun and rain, this Manihoot is a wonderfully hardy plant, capable of standing the roughest treatment, easily grown, and rapidly propagated. If its rubber turns out really good, the cultivation of this species will, no doubt, be taken up by tea-planters whose gardens are on the plains, and by indigo planters, as adjuncts to their other cultivation. In expectation of large demands for young plants and seeds\* I have made a Ceara  $f^{\wedge'}$ tation on a suitable piece of ground on the outskirts of the garden.'  $\langle \rangle^n$ 1881-82, Dr. King reported that the trees had begun to seed and that in consequence he was able to distribute a good many seedlings to planters and other in Assam, Chittagong, and elsewhere. In 1882-83, h\* reports progress in the propagation of this tree, but remarks that it is rather I? blown down or broken by the wind, especially during wet weather. From that date the annual reports of the Botanic Gardens of Calcutta make only passing allusions to the exotic rubber trees; but in a report °l\*, Chittagong it is said there are a number of trees on the road to Nazirnat "which were planted out many years ago by the road cess officials, ana these are now in a flourishing condition." As large numbers of these trees were distributed by Dr. King, they doubtless exist here and there all over Bengal. II. NORTH-WEST PROVINCES.—TWO plants of this rubber tree were N. W. received in 1880 by the Horticultural Society and planted out; in i882-»3> it was stated that while they grew they did not appear to thrive wet. Seeds received from Ceylon did not germinate. In 1886-87, the apove Provinces. IOZ plants appeared to be dying, but other plants put in the open and not watered were doing better and were 24 feet high, the superintendent of the gardens adding: "It may safely be assumed that the tree can Pr grown in this part of India, but whether profitably remains to be P<sup>r0</sup>J<sup>e</sup> In 1881-82, the Superintendent, Government Botanical Gardens, ^?r ranpore, reported: "That about 100 seedlings of this valuable <sup>ruDD</sup>] plant have been raised from the seed sent last year by Dr. Tein plant have been raised from the seed sent last year by Dr. Trimen *trom* Ceylon." In 1882-83, the Superintendent again wrote that eight of these plants kept under glass survived the winter, but all those planted in "jc open or kept in pots under the shade of trees were killed by frost, bome of those planted out were from 5 to 7 feet high at the close of the rains. They were carefully protected with straw, but they all died off during the cold season." He adds "No one, therefore, need attempt to cultivate this tree in the North-West India with any hope of success?" III. SIND.—In the report of the Government Farm and Economic uar-dens at Hyderabad for 1883, it is stated that up to date sout of the 100 seeas received had germinated. In 1885-86,1! was further reported that the largest plant we have is 7 feet high. It is subject to injury from frost During the hot season it grows freely." In 1887, the report states that Sind. 102 all the plants had been killed by frost. Uv un IV. BUKMA.—This rubber tree was introduced by Colonel Seaton wijo Burma. sent "an intelligent lad to Ceylon to receive instructions from Or. 103 Thwaites " on its cultivation. IVT-I<sup>V</sup>V¥<sup>ADRAS</sup>  $\stackrel{Mr}{-}$  Cross in 1881, after inspecting the Ceara trees 01

Nilambur, wrote: •• This region is without doubt admirably adapted tor the growth of the tree." He recommended that cultivation should be con-fined "to rather dry arid situations and poor soils." He tapped a young tree by the usual process of slicing off the bark: "The milk exuded freely, but next day on around the tree found that the Freeter portion but next day on  $*r*^{anhi}n^{a}$  on it was found that the greater portion »evaporated, showing the watery and immature state in which milk exists **I.** 104

Madras. 104

#### Ceara Rubber in South India.

# (G. Watt.) INDIA-RUBBER

CEARA

in young growing plants." In a recent report (June 1888) Mr. M. A. RUBBER. Laws on furnishes the following information regarding this rubber plant in South India at the present date 1-

" In the Government Gardens at Barliyar there are some fifty or sixty trees, the largest of them being about thirty feet in height, with stems having a circumference of three to four feet. They flower and fruit freely, and are spreading through the forest of the neighbouring ghat. Besides these, there, are some thousands on an estate at Kullar, situated about four miles below Barliyar, belonging to Messrs- Gordon, Woodroffe & Co. of Madras. There are also some thousands of trees on th Government Teak Plantations at Nilambur; and in addition to these, there are many spread about over the Malabar and Wynaad districts, notably some of the finest on Mr. Fergusson's grounds in the vicinity of Calicut. The tree grows very rapidlyi and, to all appearance, thrives well; but 1 have been wholly unable to extract rubber from it in anything like a paying quantity, and every one else hitherto has also failed. The following is a letter which I wrote a short time ago to Messrs. Gordon, Woodroffe & Co. on the subject, and which gives in full the difficulties I have to contend with:--\* In continuation of my former letters on the subject of extracting rubber from the *Ceara*, 1 am very sorry to state that I have little or no information of any value to give you.

I have written to Kew and Cevlon to know if they could help me; the authorities at the former place have promised to make inquiries on the subject, of their West Indian correspondents, but I have not as yet received news from them. Dr. Trime n of Ceylon is in the same straits as myself, and has failed in all his experiments to extract the rubber in paying quantities.

- The following are the chief points which I have paid special attention to:— (1) Do our trees in India really produce as much rubber as they do in their native country 2

(2) Are they as yet too young to yield rubber in large quantities?
(3) What is the best time of the year for tapping the trees?
(4) What is the best mode of tapping?
With respect to the first consideration, I cannot believe that the yielding properties of the Cearas should have decreased on account of their having been transplanted to the first construction to their maximum terms of the best in the state of from Brazil to Southern India; at any rate, I can give no scientific reason for believing that such is the case.

With respect to the second consideration, we have now trees that are over three feet in girth; and one would think that a tree of that size would be sufficiently old to show what its full yield would be.

The third point is the one to which I desire particularly to call your attention. have made myself a large number of experiments with the view of finding out what the best time of year for tapping the trees is likely to be. The trees, as you know, lose their leaves at the beginning of the year; and do not regain them till after the early rains have set in. During this period of the year, the sap is quiescent, and there is very little exudation of the milky juice, which contains the rubber.

The least want of success which I have gained in my experiments has been when 1 have tapped the trees just at that time when the new leaves are beginning to show themselves, and so on till they have become matured; that is, during the months of May and June; and I would suggest that you should try the experiment upon a large scale in your Ceara forest at Kullar during; the present season.

With reference to the fourth consideration, *vie.*, the best mode of tapping, I can only tell you how I have proceeded. I have cut out wedges with an axe, and made incisions of various sorts, with knives and chisels, and 1 have followed the process which \*KO& described by Mr. Cross as being the one adopted by the natives in Brazil. This latter process is conducted as follows:—

(1) Peel off the outer brown bark, when the smooth green inner bark will be exposed. In this latter bark make incisions with a very sharp knife, forming a series of V's. The latex, it is said, which springs from the several gashes, unites into one stream, and is deposited at the apex of the V, where it is collected in tins, stuck into the true of the true of the true of the later to the late into the tree at that point; but in all my experiments, I have never found the latex to flow in such quantities as to form anything like a stream.

(2) The other method which I have adopted was one which was suggested to me by Dr. Trimen. He took an ordinary wood-marking implement, and cut out deep channels in the bark, instead of making gashes; the latex, when the tree is under this treatment, is certainly given up in larger quantities/and the rubber is more easy 377

h

CEARA RUBBER.

#### History of the Discovery and

to collect, as the size of the groove is sufficient to allow the workman to scoop.  $^{\circ}$  ut the rubber with a stick. I would recommend your trying this form of  $^{extrac}$ ?  $f_{f_{1}}$  rubber on a larger scale than I have been able to do; you might also attempt rej.  $j_{r_{1}}$ of litate a greater exudation of the latex by beating the tree with a mallet, thoug» course not too violently, otherwise you might destroy the tree itself. out

I am very sorry not to be able to give you any more satisfactory information,

I hope that, in time, we may discover where it is that our want of success lies. up into I do not know if you are aware that the roots of the *Ceara* often swell up into tuberous-looking masses, resembling a yam; they are full of starch very like that of tapioca, both in taste and other properties; me unders n oonea, up into a transmitter of the tapioca plant, that they com.\*" poison, something perhaps might be made from these roots."

The Conservator of Forests, Southern Circle, Madras, has furnished W<sup>r</sup> this work, the following remarks regarding the South Indian Ceara rus ber trees: "The Ceara rubber grows both in Wynaad and in <sup>N I t a r</sup> \* <sup>o</sup> A u, a weed. The largest tree in the experimental garden at Manontoday of several hundred is about 30 feet high with a crown of foliage  $4^\circ * \&$ diameter and a trunk 45 inches in circumference at 4 feet from the fil This tree is only five years old. On being tapped, the trees yield very i « ^ rubber and the cost of collecting the milky sap is greater than the vain the rubber obtained from it. Commercially this tree is, therefore, a tau ure at any rate for the present"

therefore, to be the only difficulty that now exists. The trees " $ay^e J * A^a$ quite acclimatised, but either they are too young or do not yield making the same amount of milk as in Brazil. It is possible to be a similar the same amount of milk as in Brazil. It is possible that the defect  $\mathbf{m} \mathbf{k}$  is lie in imperfect modes of tapping, or perhaps from the tree  $\mathbf{b}^{ein} \wedge \mathbf{f}^{ro} \wedge \mathbf{f}_{or} \mathbf{m}$ . region where a peculiar condition of vegetation takes the place of milk-ing. Cultivation of acclimatised stock in parts of India, where in kiai  $\frac{accl}{n_0 w}$ ing. Cultivation of acclimatised stock in parts of India, where in <iai  $n_{oW}$  matisation would have been impossible, might correct the defect trive  $n_m$ retards the enterprise of Ceara and other foreign rubbers. Man**y**<sup>xa</sup> j j pies might be cited in support of the idea of improved or determuly in fileaccompanying successful cultivation in a new country, for <sup>exa</sup>i<sup>T1</sup>P ell' Sia<sup>\*</sup> haviour of Cannabis sativa (Hemp) in Europe, India, and <sup>Ce</sup>"tr We case or Linum usitatissimum (Flax), t in Europe and India. If it be "V  $j_s$  that trees of equal age in Brazil and the localities of India where Let  $h_e$  being cultivated yield different proportions of milk, the cultivated  $h_e$  of f tree should not be abandoned until it had been tried in every Oisig u India, where its cultivation was at all possible. If it be found that if available tract of country in India can Ceara be grown profitably\* then, but not till then, should the hope of ultimate success be abandoneo. seems probable, however, that greater experience in methods 01 treater, and modes of tapping, together with more precise information as to age and season at which the milk flows in greatest abundance, may result in the attainment of better results than have as yet been reported.

DISCOVERY ft UTILISATION, .105

#### HISTORY OF THE DISCOVERY AND UTILISATION OF INDIA-RUBBER. AJL,

The earliest known mention of India-rubber is the remark by Herr? in connection with Columbus' second voyage (nearly 500 years ago) of the inhabitants of Hayti playing a game with balls made from the gum 01 tree. These balls, J he remarks, though large, were lighter and bounae better than those of Castile. A more direct allusion to rubber  ${}^{\circ C_{A} u_{A'}}$ however, in Torquemada's De la Monarquia Indiana (published at ....a...

<sup>\* {</sup>Con/, with the remarks in Vol. II., pp. 104-105.)

<sup>+ (</sup>Conf. with flax culture, Vol. V.)

t {Con/, with the remark regarding playing balls made of rubber under p. 373-/ I. 105

# Utilisation of India-Rubber. (G. Watt) INDIA-RUBBER.

rid in 1615) where the tree is said to be known to the Mexican Indians as *(IlequahuitU* A white milky substance, Torquemada says, which was thick and gummy and found in great abundance is got from it\* This is collected in calabashes and afterwards softened in hot water or the juice is smeared over the body\* and rubbed off when sufficiently dry. He also remarks that an oil is extracted from the *ulli* or rubber by heat which possesses soft and lubricous properties, and is of special effect in removing tightness of the chest. It was also drunk by the Mexicans with cocoa to stop haemorrhage.

Torquemada mentions that the Spaniards at the time of his visit used the juice of the *ule* to waterproof their cloaks, and he adds that "it is of great effect in resisting water, but not so the sun, for the rays thereof melt it." Perhaps the earliest accurate description of the South American caoutchouc-yielding plants is that given by Condaminein 1735. He speaks of the natives moulding the fresh juice in various forms, producing bottles, boots, and bowls, which may be squeezed flat and yet recover their form when no longer under restraint. The Portuguese of Para learnt from the Omaquas to make syringes which had no need for a piston or sucker. They were hollow, pear-shaped, with a pipe at the mouth. When compressed and held under water they filled with the fluid on being freed from pressure, and squirted it through the pipe when again compressed. This use of the milk led to the Portuguese name *Pao di Xirringa, i.e., "Syringe Tree."* 

These faqts did not, however, attract attention in the Old World till nearly a century later. Priestley, for example, mentions caoutchouc in the preface to his work on Perspective (1770) as a valuable material for erasing pencil marks, which might be purchased from Mr. Hairne, Mathematical Instrument Maker, opposite the Royal Exchange, at a cubic piece of about half an inch for three shillings. Hence the name India-rubber. The slow progress made by caoutchouc in the early stages of is European history is the more remarkable when it is added that the need had long been felt for some water-proofing material and a patent was taken out ir 1627 for <sup>w</sup> a newe invencon for the making and pparing of ctaine stuffe and skynns to hould out wett and rayne." The first patent granted for the use of India-rubber water-proofing was held by Samuel Peal in 1791. In 1813, Mr. John Clark obtained a patent for making air-beds, the inner layer of which was made air-tight by being coated with a solution of caoutchouc dissolved in spirits of turpentine boiled in linseed oil. The dawn of the great India-rubber era may, however, be said to have broken with the first of Mr. Thomas Hancock's patents in 1820. Hancock has accordingly been spoken of as " the father of this important and wonderfully increasing branch of the arts." A useful service was also rendered by Mr. Hancock in the publication of his 'Personal Narrative of the Origin and Progress of the Caoutchouc or India-rubber Manufacture in England, London, 1857.' In 1823 Mr. Charles Mackintosh of Glasgow obtained a patent jjpr making two fabrics water-proof by uniting them with a solution of ruD&er called ' water-proof double textiles,' the material used in the preparation of the now famous Mackintosh over-coats. In India about this time also Sir W. O'Shaughnessy reported that he had made a waterproofing fabric of a double layer of cloth with rubber between which might be used for surgical purposes. One of the greatest advances, however, was the invention of Hancock's <sup>c</sup> masticator' which tears the rubber to pieces and afterwards consolidates it into a homogeneous mass from which all impurities may be washed out and the rubber pressed into blocks or

<sup>\* (</sup>Con/, with methed of collecting Landolphia rubber in Africa, p. 373.)

DISCOVERY & UTILIZA-TION. History of the Discovery and

sheets. Prior to this invention the crude rubber had to be prepared in a peculiar manner so as to allow of its being cut into sheets and strings. The passages quoted above, from the Agn-Horticultural Society's Journals, contain directions for collection, so as to adapt the rubber to the then only known way of utilising it. Hancock's masticator dispensed with that necessity. An important feature of Mackintosh's discoveries was the utilisation of naphtha as the solvent, and Hancock's masticator having purified the caoutchouc, thus facilitated its rapid solution in naphtha. The curious discovery that caoutchouc stretched and retained for some time while kept cold, loses its elasticity, led to the invention of the elastic web by which fine threads of rubber could be worked up in a braiding or other machine and have their resilience restored by a hot iron being passed over the fabric. But the full utilisation of 1 ndia-rubber was only realisecj, by  $\overline{W}_{r}$ . Walter Hancock's discovery of what is now known as Vulcanizing Walter Hancock's discovery of what is now known as Vulcanizing. was attained in connection with experiments conducted with the object oi divesting caoutchouc of its adhesiveness, thus allowing of water-prooning garments of single textiles having a surface coating of rubber instead oi Mackintosh's double textiles. A sample of rubber obtained from America smelt of sulphur, but though this fact was noted Hancock followed up ws own researches and produced inadhesive rubber by combining it with silicate of magnesia and other substances such as fuller's earth, whiting, ochre, asphalte, &c. Having ascertained that rubber could be subjected to a temperature (240° Fh.) sufficient to melt sulphur without destroying the rubber he plunged pieces of rubber into a sulphur without desitelying the rubber he plunged pieces of rubber into a sulphur bath and obtained thereby a hard horny material penetrated but not chemically,  $a^{\text{it}}_{\text{ered}}$  by sulphur. By raising the heat to  $270^{\circ}$  or  $280^{\circ}$  Fh<sub>o</sub> at the end ot an hour, he found the caoutchouc had taken up all the sulphur that it could retain, vie., about 2 to 3 per cent, by weight. On subjecting these pieces of caoutchouc in an inert medium to a temperature of  $^{2}75^{\circ}$  to 320° Fh.; a chemical reaction took place, the rubber losing all tederecive properties but retaining all the peculiarities to which it owes us high posi-tion in the arts. By causing the penetration with sulphur to be effected by means of his hot rollers and masticator, Mr. Hancock obtained a substance which could be dissolved and applied to textiles. Commenting on the importance of Vulcanization, Mr. James Collins writes:-" Stage as were the applications of caoutchouc in its natural or una<sup>ste</sup> forms, it seemed at one time as if it were likely to fall into disuse, or the its applications would have to be circumscribed from certain defects, manufacture had been carried on in two ways: first, by direct mecnanical treatment of the gum after simple cleansing; secondly, by the action of some volatile solvent, and the application of the solution to some <sup>ma</sup>J<sup>erla</sup> so that a film of caoutchouc was left on the surface. But it was touna that such caoutchouc became rigid and inflexible under the  $*^{n_A uenC_A} ues^{n_A}$ cold, while it softened and ; ecomposed in the sun and hot weather, tn' defect alone rendering many manufactured goods a total loss, and causing, it is said, the failure of several American firms. Contact with greas!\* or any kind of fatty or essential oil quickly dissolved it, and perspiration had the same effect though slower in its action. It was also very adhesive and sticky, so that any substance pressed against its surface was quickly joined and could not be separated. By continued use or tension it lost its elasticity, and, besides this, an unpleasant odour produced by its solution pervaded the goods. But at the most critical time the method of Vulcanization was discovered, which, while preserving and even heightening the Properties for which it was valued, added to its stability and divested it of the defects which were so many barriers to its present sue cess and future extensions. Caoutchouc so treated was found to have I. 105

# Utilisation of India-rubber. (G. Watt.) INDIA-RUBBER.

almost perfect elasticity at *all* temperatures below 239<sup>0</sup> Fh., and not to become adhesive below \*a heat of 212<sup>0</sup> Fh<sub>M</sub> while fresh cut edges did not unite as in the unchanged substance. Its resistance to solvents too was very marked; though not absolutely insoluble, and iis capability of being inadhesive and unaltered by cold, heat, water, or solvents, opened at once a new field of industry."

The honour of this discovery is claimed in Germany by Hindersdorf, and in America by Goodyear, and it is probable many persons were working on the same lines about the period of Hancock's discoveries. Two years later (1846) Mr. Alexander Parkes took out a patent that gave an ulterior mode of Vulcanizing. By the employment of a solution of chloride or hypochloride of sulphur in bisulphuret or sulphuret of carbon, coal, naphtha, or turpentine, he obtained the same change as described above in Hancock's process of Vulcanization. Speaking of this process Mr. Collins writes :—<sup>∞</sup> Caoutchouc in the dry state, if kneaded with a certain amount of dry chloride of sulphur, slowly underwent the same change, and whilst hot could be pressed into any desired shape. Caoutchouc, previous to being submitted to the "changing," could be combined with wool, flax, cotton, wood or cork dust, earths, oxides of metals and with other gums. By this process, however, only thin sheets could be subjected to this method, as in the case of thick sheets, the action on the outside would have proceeded too far before it had penetrated to the centre. After the articles were taken out of this baih, they were placed in a hot chamber and then washed in water or in a solution oi caustic potash, or soda.

Vulcanized rubber may be hardened by various processes until it can be cut like ivory and hence it became applicable to a numerous series of new purposes such as the manufacture of combs, backs of brushes, in fact it was rendered suited for all the industries in which bone, ivory, whalebone, tortoiseshell, &c, are required. It might even be coloured to any shade and built up in mosaics, made into railway buffers, used as pavements, or a thousand new applications for which the natural rubber was quite unsuited. It could be moulded or engraved, or have its surface only hardened by Parkes' process. Goloshes manufactured and then Vulcanized were found to be superior to those made by any other process. Various patents were also taken out for other methods of hardening caoutchouc, such as by means of iodine or of bromine or of both and with or without sulphur, the discoveries thus widening and extending the uses of India-rubber until it may be said that substance has become an indispensable necessity of modern commerce.

The above brief sketch, compiled from most modern writers but mainly from Collins<sup>1</sup> various papers (in the British Manufacturing Industries, in the *Encyclopaedia Britanica*, &c.) will suffice to give some idea of the properties of caoutchouc as now manipulated; and to show that its extensive modern application justifies the importance given to it in tropical agriculture and forestry. To complete this sketch, it need only be necessary to brieflyjreview the Indian trade statistics of the substance.

# INDIAN TRADE IN CAOUTCHOUC.

Mr. J. E.O'Conor, in his Review of the Trade of British India for 1874, gives a retrospective account from 1868-69. "The trade, he says, for i874-75> <sup>was</sup> somewhat less than in previous years and still less than in 1872-73\* the supply of the market of shipment being somewhat uncertain under the conditions in which the rubber is collected by jungle tribes." "The exports of Bengal are much larger than those from Burma All the caoutchouc brought down to Calcutta is produced in Assam." **Mr. O'Conor** then gives the figures of exports, the average for the five

INDIAN TRADE. **106** 

Indian Trade in Caoutchouc.

years ending 1872-73 being 12,003 cwt., valued at £63,217, but for 1873\*74 INDIAN TRADE. they were 16,837 cwt., valued at £117,775 and for 1874-75\* J5>.%3[cwu, valued at £108,645. Mi\O'Conor then remarks: "The trade is sharea by Bengal and Burma, but by the former in much the larger proportion<sub>c</sub> The exports from Bengal fell off during the year from 16,255 cwt. wonn £115,754 to 13,938 cwt. worth £96,492. The exports from Burma, on the other hand, increased from 582 cwt., worth £2,020 to 1,954 cwt. wori £12,104. The export trade from Burma only commenced KI \*PP\*~1 able quantity, in 1873-74. All or nearly all the caoutchouc exporter from that province is produced in Upper Burma." In the corresponder defined as  $P = \prod_{n=1}^{\infty} ds$ ence quoted at page 346 the exports from Calcutta were 514  $^{ma}$   $U_{t}$ in 1836. In 1880-81, Mr. O'Conor reported a decline in quantity, DU increase in value, and in the following year he remarked that the  $e^{x}P \circ T^{fs}$  were 10,699 cwt., valued at R 10,88,426. "The shipments, he there staie^ are entirely made from Calcutta and ports in Burma, and the  ${}^{coun}J^{r}_{T}$  ie  ${}^{t}_{test}$ which the article is exported are the United Kingdom and the Unit, States of America, small quantities being sent also to the Straits oeulements and Egypt. The shipments to the United States show a consider able increase compared with the previous year." In 1885-86 the exports are pointed out as continuing to decline; in the following year the trade nad slightly improved. In 1888-89 the IMPORTS FROM FOREIGN COUNTM\*S were 53 cwt. valued at R6,i47, and the EXPORTS of FOREIGN MERCHAN-DISE were 52 cwt., valued at R8,630. These imports came mainly trom Madagascar to Bombay and were exported to the United Kingdom ana France. These transactions show, therefore, a certain amount of the 11ew African trade in rubber falling into the re-export route, that much or the African and Madagascar produce has followed from time imroem rial Of the Rubber of Indian produce there were EXPORTED to \*\*\* COUNTRIES, in 1888-89, 8,673 cwt., valued at R9,67,348 : this went irum Bengal, 5,609 cwt, and from Burma, 3,064 cwt. As in former Vear? the Indian caoutchouc of 1888-89 went chiefly to the United Kmgaon, United States, and Egypt. o T olO

The coastwise transactions last year were 118 cwt., valued at  $\mathbb{R}^{*1*}$  rts IMPORETD and 2,842 cwt., valued at R3,58,ii3, EXPORTED. The impond were mainly from other Bengal ports (Chittagong) into Calcutta.1.ft set the exports were from Burma into Bengal (namely, 2,731 cwt.). An set transactions, of course, overlap each other and to a certain extent reappers in the FOREIGN EXPORTS. Thus the Bengal exports to foreign countries would doubtless comprise Assam, Chittagong, and Burma rubber, but the exact amounts of each kind cannot bs made out since the Bengal consumption is not known.

The trans-frontier trade is mainly into Assam and Chittagong, and the figures for this trade have already been given (see page 356). To wnat extent, if any, a transfrontier export trade may take place from \*\*"" to China and other countries beyond that frontier, is not known ; but we are told the contractors paid Government R 1,00,000 for the right to collect and purchase rubber while the declared value of the foreign and Joastwise exports from Burma were valued at R7,06,378.

It will thus be seen that the Indian trade in caoutchouc  $|P^{ran} \times$ suddenly into importance, and from 1872 fluctuated forward until <sup>1882</sup>"?3? when it reached its maximum in the value of Ri2,59,165, and from wn\*n date it may be said to have fluctuated downwards. The whole of this rubber since about 1875 has been drawn from the indigenous tree ana mostly beyond the British frontiers of Assam, Burma, and Chittagong, the cultivated and acclimatised trees not having as yet contributed to the **supply**.

# INDIGOFERA, Linn.; Gen. PL, U49+

A genus of herbs or shrubs pelonging prises some 250 or 300 species, an tributed be readily recognised as being the plobe, India having about 40. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate lea. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate leas. They may  $\wedge \ c^{h}$  lear laterally attached papilionaceous plants, with inoparipinnate leas. They may here a box in the transformation of the plants, ascending the digenous species that are spoken of as w. ely distance that there is a marked decrease in the number of forms and abundance ot individuals. This sketch of the distribution of the Indian species may be viewed as of considerable interest when jt is added that Bombay is the only region where a botanist has spoken of Indigofera tinctoria (the true Indigo) as having been seen in what appeared a wild condition. The older records of commercial indigo also point to the Western Presidency (or the basin of the Indus) as the region of supply and earliest manufacture.

The following enumeration of the species of Indigofera comprises only those regarding which economic facts have been published. About as many more are Known to the Natives and bear specific vernacular names in the regions where they occur.

Indigofera Anil, Linn.; Fl. Br. Ind^ IL<sub>9</sub> gg; LEGUMINOS-E.

1

Vern.— Vilaiiunil (European Indigo), HIND.; Shimaiya-viri, TAM.; Shiinanili, TEL.; Skimenili, KAN. (Foreign Indigo in TAM., TEL., and KAN.); Vishashodhani, SANS. The Sanskrit name is derived from shdd to clear and visha poison.

Habitat.—This species is admitted by botanists to be purely American. It was cultivated by the Spaniards in Mexico and by the Portuguese in Brazil as a source of indigo. It nowhere exists in a wild state in India, and was probably introduced during the period of Portuguese ascendancy in the Western and Southern Presidencies. It is nearly allied to I. argentea *var*. ccerulea as may be seen from the fact that Kurz reduces that form to this species.

Dye.--The dry leaf indigo of Madras is to some extent obtained from this species. The reports furnished by the Madras Government, in connection with this work, do not afford sufficiently detailed information to allow of an opinion being formed as to the relative degree of cultivation of this species and of I. tinctoria. Nor do they supply the means of enabling us to judge as to their relative value as sources of the dye, but it may be presumed that tinctoria is superior, from the fact that mention is made of that species displacing Anil. The reader is referred for further information to the account of INDIGO in the pages below.

# I. argentea, Linn., m. Br. Ind., II., g8; also var. ccerulea.

Often called WILD INDIGO.

Syn.—INDIGOFERA CCERULEA, Poxb.; I. RET us A, Grdh.; 1. BRACHVCARPA, Grah.f I. TINCTORIA, var. BRACHYCARPA, DC. Prod.; 1. TINCTORIA, Forsk., Egypt.

Vern.—Surmainil, HIND; Nil, MERWARA,- K&rwnili, TEL.; Kat~ave'ri (according to Ainslie), TAM.J Karu-nili, KAN.; Kdlaklitaka, SANS. The above names mean black indigo. 107

| Medicine.—Mr. Maclean writes that it is considered<br>poisons of all kinds. The ROOT boiled in milk is used as<br>a decoction of the STEM as a gargle in mercurial salivation<br>Fodder.—Sheep are fond of this plant, and it grows fre<br>est soils. It has been experimentally cultivated at the<br>Madras, with satisfactory results. The opinion has been<br>Manual and Guide to the Farm that it may possibly become<br>Manure?—It is extensively employed as a manure fo<br>South India.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | an antidote to<br>a purgative and<br>n.<br>eely on the poor-<br>Sydapet Farm,<br>expressed in the<br>e a valuable crop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | MEDICINE.<br>Root & Stem*<br>138<br>FODDER.<br>139<br>MANURE.<br>140    |

| posed to promote the growth of hair" ( <i>Surgeon-Major C. W. Calthrop,</i><br><i>M.D., Morar)*</i> "It is used as an external application in the form of<br>paint over the abdomen in cases of tympanites and retention of urine. In<br>the form of paint or ointment it is largely used in sores and diseases of<br><b>cattle</b> " ( <i>Civil Surgeon J. H. Thornton, B.A., M.B., Monghyr).</i> "Indi-<br>go is used by natives as a cooling application to burns and sores of horses"<br>( <i>Assistant Surgeon Bhagwan Dass, Civil Hospital, Rawalpindi, Panjdb).</i><br>"An infusio*n of the ROOT is given as an antidote in cases of poisoning<br>by arsenic" ( <i>Surgeon W. F. Thomas, Madras Army, 33rd Regiment,</i><br><i>M. N. /., Man galore).</i> "Used as a medicine as well as a dye " ( <i>Surgeon-<br/>Major J. E. T. Aitchison, CI.E.</i> )<br><b>INDIGO.</b><br>HISTORY.<br>The chief source of the Indigo of Commerce is the Indigofera distin-<br>guished as tinctoria. The origin of that species is involved in the greatest<br>obscurity. Early botanists recorded having found it wild in India, Africa,<br>and Arabia; but it is now admitted that the form they referred to was<br>Indigofera cerulea—a plant by some writers viewed as the original wild<br>condition from which was derived through cultivation the modern indigo-<br>yielding stock. By others these plants are regarded as distinct. There<br>are in all some 300 species of Indigofera, distributed throughout the tropical<br>regions of the globe, with Africa as their head-quarters. India possesses<br>some 40 species, but with reference to Indigofera tinctoria there is no<br>authentic record of its haying been found far removed from human in-<br>fluence, still less of its having been observed in what could be viewed as an<br>indigenous habitat. It may perhaps be desirable to review here the chief<br>botanical opinions on this point. Bent ley and Trimen, following the view<br>once generally maintained, say, it is a native of the west coast of Africa,<br>where it is also extensively cultivated. But De Candolle's Indigofera<br>inctorial <i>var.</i> macrocarpa (upon which that opinion probably depended) is<br>now regarded as I. cccru | The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | (G. Watt.)                                                                                                                                                                                                                                                                                                                                                                              | INDIGOFERA                                           |

| The chief source of the Indigo of Commerce is the Indigofera distinguished as tinctoria. The origin of that species is involved in the greatest obscurity. Early botanists recorded having found it wild in India, Africa, and Arabia; but it is now admitted that the form they referred to was Indigofera ccerulea—a plant by some writers viewed as the original wild condition from which was derived through cultivation the modern indigovielding stock. By others these plants are regarded as distinct. There are in all some 300 species of Indigofera, distributed throughout the tropical regions of the globe, with Africa as their head-quarters. India possesses some 40 species, but with reference to Indigofera tinctoria there is no authentic record of its having been found far removed from human influence, still less of its having been observed in what could be viewed as an indigenous habitat. It may perhaps be desirable to review here the chief botanical opinions on this point. Bent ley and Trimen, following the view once generally maintained, say, it is a native of the west coast of Africa, where it is also extensively cultivated. But De Candolle's Indigofera tinctorial <i>var</i> . macrocarpa (upon which that opinion probably depended) is now regarded as I. ccerulea. Boissier ( <i>Flora Orient.</i> ) describes nine species of Indigofera as met with in Central Asia, Arabia, and Egypt; but he makes only an accidental allusion to Indigofera tinctoria as met with under cultivation. In the recent enumeration of the plants of China by                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | •                                                                                                                                                                                                                                                                                                                                                                                       |                                                      |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | The chief source of the Indigo of Commerce is the guished as tinctoria. The origin of that species is involve obscurity. Early botanists recorded having found it wild and Arabia; but it is now admitted that the form they Indigofera ccerulea—a plant by some writers viewed as condition from which was derived through cultivation the yielding stock. By others these plants are regarded a are in all some 300 species of Indigofera, distributed throur regions of the globe, with Africa as their head-quarters some 40 species, but with reference to Indigofera tinc authentic record of its having been found far removed fluence, still less of its having been observed in what coul indigenous habitat. It may perhaps be desirable to rev botanical opinions on this point. Bent ley and Trimen, the once generally maintained, say, it is a native of the west where it is also extensively cultivated. But De Canot tinctorial <i>var</i> . macrocarpa (upon which that opinion probanow regarded as I. ccerulea. The Indigo Plant of Commerce.

likely that their so-called "apparently wild" plant was one of the forms of L coerulea—these botanists thus making the same mistake that De Candolle did regarding Western Africa. Kurz speaks of I. tinctoria as frequently cultivated on the alluvium of the Irrawadi in Burma; but he incorrectly <sup>re. fe 5 s</sup> I. ccerulea, *Roxb.*, to be a synonym of I. Anil. The plant he deals with, he says, occurs all over Burma from Ava to Martaban and Tenassenm. And significantly he adds that he could not find \*ny sufficient grounds for separating specifically the two forms. Kurz was far too accurate a botanist to make such a statement without sufficient reasons, and it may safely be concluded that I. tinctoria and I. ccerulea are very easily confused one with the other, and that the popular Indian writers, who speak of the Indigo plant being wild in India, allude to I. ccerulea and not to either I. tinctoria or I. Anil.

There is thus no botanical evidence that Indigofera tinctoria is indigent.<sup>011</sup>?. i?, I<sup>m</sup><sup>dia</sup>; DeOandolle, however, lays stress on the fact, that it is the *Nth* of Sanskrit authors, from which circumstance he concludes that it must be of Asiatic origin. On the other hand, it may with equal force be urged that had it been a native plant of India, like the truly indigenous Indigoferas, it would have had its specific names in most of the languages and dialects of this country, more especially among the aboriginal races. The singular uniformity with which the word Nild is associated both with the plant and the dye argues a common origin in a centre from which the knowledge of so valuable a product was diffused-its name passing from tongue to tongue with the gift of a few seeds. According to Mitchison and other travellers, Isatis tinctoria—the woad—is the source of the Indigo prepared in Upper Asia, a region where Indigofera t does not apparently exist. The Sanskrit people may have accordingly therefore just possible that their *Mila*, of the earlier epochs, <sup>mav</sup>, **Fve**<sub>f</sub> the the woad which with the ancient Britons was used, like the **\***<sup>1</sup>\*\*\*\*</sup>, j<sub>t as</sub> American Indians, to dye the skin and hair. Complex and di<sup>FMed</sup> the the A the art of dyeing with Indigo is.it is more intimately sssociatea with early human race than any other dye or pigment. But in \*ndianonger the most striking features of the use of a blue dye is the large n `•fl of plants which are not only known to afford such a dye, b ut "hich are icit". day are regularly so employed in place of the modern commercia<sup>1</sup>.\* And it may be added that every source of blue dye (chemically "J" has its special and peculiar names in the regions where it is 10t no utilised. These blue-dye plants are purely indigenous, and were prob bly the sources of the blue-dye of India long prior to a knowledge in1/\*ila. (The reader is referred to the paragraph on Indigo Substitutes, for further information on this point\* see page 449.) r(j *tftfa* 

But there are other considerations of equal weight. The wo terss simply denotes dark blue colour, and is, with many of the early writh practically synonymous with kdla (black). Adjectively it is  $^{a} ? ^{p}$  is the simple of practically synonymous with kdla (black). Adjectively it is  $^{a} ? ^{p}$  is the simple of the number of the practically synonymous with kdla (black). Adjectively it is  $^{a} ? ^{p}$  is the simple of practically synonymous with kdla (black). Adjectively it is  $^{a} ? ^{p}$  is the simple of the number of the practically synonymous with kdla (black). Adjectively it is  $^{a} ? ^{p}$  is the simple of the number of numbers speak of nila flies, birds, cows (e.g. nflgao, the blue-bull or tax pictus of Zoologists); of blue stones (m'lopala, the Lapis  $^{azui}$  V (ind nilamani, nilaratna, the Sapphire); of blue flowers, rivers, seas, n is, and clouds (nilabha). Nila, nil, nel. is associated with a 1 a  $^{a}$  is plants besides indigorea. Thus we have the blue water-lily Nympnfe Lotus), in Arabic the nilufar, from which we derive the generic.  $^{n} i^{m} f_{fif1}$  a small group of water-lilies, Nuphar. So, again, we have it in the D<sup>0</sup> AJ' cal name for the sacred Lotus—Nelumbium ; and in botanical nomenclature and oriental literature we have the Pharbitis Nil or nabbun-nti or Arabic, tukhme-nil of Persian, and \*// kolomi of Bengal. A curious I. 153

#### **INDIGOFERA** The Indigo Plant of Commerce. (G. Watt) tinctoria. HISTORY. instance (having perhaps a special significance in connection with Indigo since one species is actually used along with indigo) exists in the fact that some of the species of Senna bear as a prefix to their specific names, the syllable nil. But nila carries with it also the abstract meaning of darkness. Mid substantively is the plant which yields a blue or darkcoloured dye. Thus in its range of meanings it passes from the general to the specific, and probably obtained its restricted signification of the blue dyef>orti Indigofera in India, and that too perhaps only during comparatively modern times. In addition to the fact that there are no specific primitive names in the languages of India for Indigofera tinctoria, such as exist for the other species of the genus, there are in some of the languages or dialects descriptive and comparative names for it that would seem to indicate a previous knowledge in other blue uyes. A nus in ....... rese it is ollenili (olle, good) : again, hennunili (female indigo) : in Tamil, aviri (avi, boiled), and karundóshi (black indigo): so also even in Sanskrit out of a long list of descriptive names, besides nild, it is vajranili (hard blue). Even the Gujarati name gait may simply mean " the decoction,' and thus indicate the method of preparation. In part support of this contention for a comparatively modern application of *Nild* specifically, we have the further fact that Indigo did not, except in Portuguese and during the sixteenth century, carry with it to Europe the name Nild. That an indigo or blue dye was used in remote times there can be no doubt since it has been detected in the coloured borders of some of the Egyptian mummy garments, but that the word *Nild* is of alike antiquity, or that the mummy dye was prepared from Indigofera tinctoria are problems that perhaps can never be solved. Dioscorides (A.D. 60) speaks of Indigo as'lvliKov, Pliny calls it Indicutn; and in the Periplus it is 'IVILKOV ptkav or the Indian Black, exported from Barbaricon on the Indus. The word "black" is instructive both from its association with Nild, and from the circumstance that the dye was used as a black colour before its property of affording blue was discovered. In the thirteenth century Marco Polo recorded having seen it at Colium (an ancient port in the Native State of Travancore) where he says, "they also have abundance of a very fine indigo (ynde)." John Huyghen van Linschoten, whose journal of Indian Early mentravel was published in 1596, very carefully describes the manufacture of tion or Indigo in India. what he speaks of as \*' Annil or Indigo, by the Guzuratis called Gait, by others *Nil.''* 154 Conte in the fifteenth century, and Tavernier in the seventeenth, also minutely describe the manufacture of Indigo. Up to the time when the discoveries of the fifteenth century established the new commercial route to India, Indigo reached Europe by the Persian Gulf and Alexandria. In the commercial reports of Marseilles as early asA.D. 1228, it is described as the Indigo of Bagdad. But when first brought into Europe it was used only in small quantities to heighten and deepen the blue colour obtained from woad-a dye which, for several centuries, was the object of an important cultivation and manufacture in Germany, France, Prussia, Italy, and England. Towards the end of the sixteenth century, however, the European dyers had begun to recognise that Indigo afforded the means of a great economy, and that the dye was at the same time of a superior quality. At this period the dyers of Holland were the most famous and prosperous in all Europe. Even down to the beginning of the seventeenth century the English manufacturers sent their white cloths to be dyed in Holland: hence known as Hollands. From this trade the fortunes of the great Dutch capitalists were made; but difficulties with Portugal led to; the Dutch making an effort to procure their supplies direct, instead of through the Portuguese merchants. For nearly a century Lisbon rivalled even Venice as a dep6t for Eastern produce; but

| the name Indigo. The writer is thus disposed to regard Indigo (so f<br>as India is concerned) as having been first manufactured in Weste<br>India—Gujarat or Sind being its home—a region where it is now rarely,<br>at all prepared, but where it still bears its vernacular name, <i>gait</i> . The Po<br>sian and African influences (especially in the dyeing and weaving indu-<br>tries) are so strong on the Western side of India as to give countenar<br>to the idea of Indigo-growing and manufacture having been introduced<br>an idea almost confirmed by the rapidity and completeness of its migrati<br>to other tracts of India subsequently found better suited. Indeed, it m<br>be suggested that an indigenous industry would almost naturally<br>expected to have survived with greater pertinacity than indigo has man<br>fested.<br>A\out the middle of the eighteenth century, the injunctions against four<br>use of Indigo were in most European countries removed, though in Niire<br>burg the dyers were required, so late as the end of that century, to take<br>oath that they would not use it. Gradually the knowledge of the d<br>extended, and it may safely be said that, though attempts have be                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | ar<br>HISTORY.<br>rn<br>if<br>er-<br>is-<br>is-<br>ce<br>on<br>ay<br>be<br>ni-<br>he<br>m-<br>an<br>ye                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| extended, and it may safely be said that, though attempts have be<br>made to discover a substitute, all have failed, and at the present d<br>Indigo is perhaps the world's most important tinctorial re-agent.<br>Two influences, however, early began to militate against the Indi<br>market—the discovery of a source of the dye in America, and the adulte<br>tion practised by the native manufacturers. The high price paid for 1<br>article gave birth to a wholesale system of adulteration, while at the sa<br>time the dye had become indispensable. The colonists, French, Spani<br>Portuguese, and English, accordingly took to Indigo cultivation. Eu<br>pean skill and capital soon placed the enterprise on a footing which kill<br>or all but killed, the Indian trade. The British West Indian colonists, he<br>ever, soon found that coffee, sugar, and other products were more remune<br>tive ; and at the same time the severance of America from Great British<br>left the British dyers at the mercy of foreign countries for their supplies<br>Indigo. According to some authorities, the first efforts to revive an Indi<br>Indigo industry proceeded from a small French factory established m<br>the French settlement of Chandernagore on the Hugli, a few miles for<br>Calcutta. But if the idea had been thus actually entertained, very lit<br>was done until the Directors of the East India Company, seeing the pr<br>pect of renewing their Indigo transactions and at the same time of savi<br>the British manufacturers from dependence on French and Spanish co<br>nists, resolved to take active steps towards starting Indigo cultivation<br>Bengal. European Indigo planters were brought from the West Indies a<br>established in selected districts of Bengal. The Company's officers wa<br>wermitted to trade in the article, and home remittances were made<br>Indigo for a series of years, even although this resulted in heavy loss<br>It was early seen to be unnecessary for the Company to directly or<br>factories. Many gentlemen were found willing to undertake the respo-<br>sibility upon obtaining grants of land on favourable leases, the Compa<br>purchasi | ay<br>an<br>ra-<br>he<br>me<br>sh,<br>ro-<br>ed,<br>ww-<br>ra-<br>nin<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>of<br>an<br>ear<br>an<br>ear<br>of<br>an<br>ear<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an<br>an |

| ndigo purely<br>a European<br>trade.<br>158 | cess of manufacture, and the Company continued to subsidise the industry until the quality of, first the French and then the Spanish Indigo, had beer supassed by the Indian. In 1787 Dr. Hove visited Western India, and it his Journal he describes an Indigo industry on a scale that there no longe exists. Thus the establishment of the *Bengal Indigo trade may be viewed as having given the final blow to the extinction of the Bombay cultivation. Even so late as 1820, Indigo was a fairly important crop in Gujarat, and the number of unused pits near old villages and among the buried cities of the Satpuda mountains bear testimony to the abandoned industry. Early, however, we read that the natives of Upper India had even taken to producing large quantities. The good name earned through the European still and care in manufacture thus began to be injured by the inferiority of the Native stuff that found its way to Europeal along with the highly-prized East Indian European-made, article. The success of the new industry soon also created another danger. European factories multiplied until alarm was felt that the markets were being glutted. The bast India Company then felt called upon to restrict the traffic, especially from territories outside their own possessions. Accordingly in a despatch dated August 1800 we read:—« European skill and enterprise have formed the present indigo manufacture and indigo trade of India. To these both Oudh and Bengal are indebted for the share they possess in the exports of that article, and on these, there seems reason to believe the trade in both countries will continue to depend. A trade thus raised and supported greatly to the benefit of those countries, by persons not natives of 5 m to both countries will continue to depend. A trade thus raised and supported greatly to the benefit of those countries, by persons not natives formed the present Suff and in the receive of the state at a considerable expense—such a trade the Bengal." "In whatever degree, also, the indigo trade of Oudh is ca |

| 1802) the East India Company directly supported the indigo industry,<br>and placed India once more in the foremost rank among the indigo-pro-<br>ducing countries of the world. When pecuniary aid was no further neces-<br>sary, the Company retired from direct ownership of indigo-factories.<br>They, however, continued to make large purchases and to trade in<br>indigo. In 1806 they directed a mart to be established in Calcutta<br>for ready-money purchases in indigo, and they consigned to India test<br>samples' valued by the home brokers "for the purpose of assisting the<br>judgment of our servants in making their purchases." It was, however,<br>subsequently found necessary to make certain money advances to manu-<br>facturers from whom the Company proposed to purchase the dye, so that<br>a certain amount of encouragement was continued, though direct support<br>and Supervision were discontinued. It may be of use to quote here the<br>specification of qualities and prices which in 1810 were sent to India :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | HISTORY.                                           |

| •'The general average of all which is 55. <i>lid.</i> per pound; and as the above term comprises a period when the markets were favourable as well as one in which they were adverse, it may be considered as a fair general average.'' In a ''Statement of Advances on the Remittance Plan '' the Company is shown to have advanced from 1786 to 1804 close on a million pounds sterling towards their purchases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | •                                                  |
| Even at this early stage of the new Anglo-Indian Indigo industry,<br>however,*-an industry directly fostered by the Government and in which<br>many of its officers traded extensively, or resigned the Company's service<br>to become Indigo planters—difficulties had arisen through the competi-<br>tion of rival concerns. The planters desired that the Company should<br>prohibit the establishment of new factories within certain limited distances<br>of those already in existence. The Directors replied that "since the in-<br>conveniences of which they complain may also have contributed to the<br>repeated calls made on the Company to relieve the distresses under which<br>this branch of manufacture laboured, we are the more disposed to wish<br>that ne.V enterprises may be undertaken with prudence, and that the<br>cultivators may avoid collisions by friendly correspondence among them-<br>selves, and by mutually restraining their servants from issuing advances<br>to those rayats who may be under previous engagements." The system of<br>advances made by the Company to the owners of factories against annual<br>purchases was thus not only fully established, but that principle was<br>recognised as applicable to the owners of factories in their dealings with<br>the rayats or actual cultivators. At the same time the Company seem<br>to have appreciated the advantages that would likely accrue from the<br>establishment of native manufacturers. In a despatch dated April 1811<br>we accordingly read:—" It is expedient that your attention should be | Difficulties<br>due to over-<br>production.<br>160 |

| HISTORY.                                                           | directed to the encouragement of the native growers of indigo being proprietors of factories, by issuing advances to them in common with European manufacturers, taking care that the security be sufficiently respectable; as we fully concur in the opinion of our Board of Trade, expresses in their minute of the 28th October 1796, that the cultivation of Indig cannot be considered as decidedly established in Bengal until the Native shall chiefly manufacture it of a quality fit for the European market. <sup>1</sup> Upon a general view of the present appearance of the state of the indigo factories upon our account in the territories under the authorit of the Madras Government; for our apprehension that the market is Europe will be liable to be overstocked by the Bengal produce operate as more than a counterpoise to the abstract principle which wouldothe wise govern our decision, <i>vie.</i> , that it is our duty to promote new branche of trade in any of our settlements to which the soil and climate ma appear favourable."                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                    | In a correspondence between the Board of Directors and the Madra<br>Government, many interesting facts are brought out. For example, in<br>despatch dated May 1791, the Board approve of the Madras $e^{ex}P^{e_{TM}}$<br>ments with indigo seed from Bombay. "A new sort of indigo " is $re * e^{e_{T}} $<br>to and a report on its merit promised. The despatch continues—" The<br>box of <b>Nerium</b> indigo by the same conveyance has been inspected by a<br>eminent broker, and the samples valued at from 2\$ <i>. gd.</i> to <i>js. 3d.</i> a pound.<br>Reference is made to European indigo planters in Madras, but the spir<br>of the correspondence is a recommendation to discourage the expansion of<br>the industry, since the production was viewed as likely sooner or later t                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Difficulties<br>between the<br>Planters and<br>Cultivators.<br>161 | far exceed the demand.<br>By 1837 difficulties had arisen in connection with the relation of the zemindars and planters to the actual cultivators. On this subject <sup>LOW</sup> Macaulay wrote a lucid memorandum of the greatest interest, which seem to have had the effect of preventing the Government from interfering except to organise a greater number of courts so as to obviate the incor venience necessitated by the distance from each other of those already i existence. Lord Macaulay wrote:—"That great evils exist, that g <sup>1</sup> ** injustice is frequently committed, that manyjrayats have been brough partly by the operation of the law and partly by acts committed in defiance of the law, into a state not very far removed from that of partial slavery-is, I fear, too certain." Again, "The regulation, which gave to the Indig planters who had made advances to a rayat a lien on the Indigo crop, seem to me highly objectionable in principle. But I do not conceive th^-frescinding it the Governor General in Council would give any sensible relief to that class of the population whose interests appear to be peculiarly the object of his solicitation. The question appears to be a question be tween the planter and the zemindar. It is not easy to see how it can be C any consequence to the rayat which of the two may distrain on his crop? I have no reason to believe that the zemindars exercise their p.«wer with more justice or how provide the planters." |
| engal Indigo'<br>Disturbances.<br>162                              | more justice or humanity than the planters."<br>Passing over a space of some thirty or forty years, which seem to have<br>been marked only by the continued withdrawal of all official support or en-<br>couragement, Indigo next attracts public attention in the troublous time<br>which culminated in the Bengal Indigo Disturbances of 1860-67. These<br>may be briefly summarised as the outcome of the system of land tenurs<br>which prevails in Bengal, in which a rent-receiver" or zemindar exiss<br>between the actual occupant of the land and the Government. In som<br>cases these zemindars temporarily or permanently sold their rights to the<br>owners of indigo factories, thus handing over to the planters a power of<br><b>I.</b> 162                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| T = 1 + 1 + 2 + 2 = 0 + 2 + 4 + 4 + 4 + 1 + 2 + 2 + 2 + 2 + 2 + 2 + 2 + 2 + 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | nctoria.                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| dictating that a certain proportion of each holding should be annually<br>thrown under indigo. The green produce was contracted for at a fixed<br>rate, but while the value of all other crops had steadily improved, the rate<br>paid for the indigo plant practically remained stationary. Where even<br>the shadow of a legal right to enforce indigo cultivation did not exist the<br>system of making advances to the rayat secured compulsory cultivation.                                                                                            | HISTORY                           |
| Money offered at the season of the cultivator's greatest impecuniosity was<br>a bribe «that few could resist, and it was in the interest of the factory owners<br>to secure a maximum amount of indebtedness on the part of the neighbour-<br>ing rayats. By the law passed in 1830, but repealed in 1835, failure to<br>fulfil contracts could be criminally prosecuted. The effect of that enact-<br>ment was to give the stronger contracting party the protection of law, while<br>no consideration was shown to the weaker, who might have been forced | Advance-<br>System.<br><b>I63</b> |
| into contracts the full meaning of which he did not comprehend. But even<br>without special legislation the system pursued placed the cultivators largely<br>at the mercy of the planters if they chose to exercise their power. Com-<br>plaints of enforced cultivation of an unprofitable crop on the one hand,<br>and of the want of protection against dishonest cultivators on the other,<br>became rife. Expensive supervision and protracted litigation told heavily<br>against the industry and led to unlawful restraint and assault which in      |                                   |
| certain parts of Bengal culminated in a disturbance that necessitated mili-<br>tary protection. A Commission was appointed by Act XI. of i860 to en-<br>quire into the whole subject, and the Report of the Commission revealed<br>the existence of faults on both sides. The Act gave powers to the Magis-<br>trate to enforce the completion of contracts to grow indigo where advances<br>had been made; but where such contracts were found to have been<br>obtained by fraud, force, or unlawful intimidation, the complaint was to be                 | Legislation.<br>164               |
| dismissed. By Act VIII. of 1868, this special "Indigo Contracts Act" was, however, repealed. His Honour the Lieutenant-Governor of Bengal, in reviewing the Report furnished by the Commissioners, said :—"Setting aside individual cases having no connection, or at least no necessary connection, with the indigo system, that system is fairly chargeable with a very notable portion of those classes of offences the peculiar prevalence of which in Bengal has been from the first a blot in our administration. In                                  | •                                 |
| my opinion it is rather the system than the planters individually who are<br>to be blamed. It is to the unprofitableness of the cultivation of indigo at<br>the extremely inadequate price given for it, under the system, necessitating                                                                                                                                                                                                                                                                                                                    |                                   |

spontaneously reform itself from within is not surprising. The chief fault was in the defective, and I fear I must say the not impartial, administration of the law, which allowed such a vicious state of things to exist." Difficulties also arose in Behar in 1876-77, and an elaborate enquiry Difficulties was then instituted by the Bengal Government into all the complaints. But the charitable action of the planters to their cultivators during the famine and the kindly way they were then spoken of by the poor in their neighbourhood, satisfied the Government that no cause for interference existed save to put down with a strong hand any violations of the law on either side that might come to notice. The enactments that are still in force regarding indigo cultivation will be found in the Bengal Code, v»,, Regulation VI. of 1823, and an amendment to it passed in 1830, as also in the Local Act X. of 1836. These provide that if a rayat by contract takes advances to cultivate a certain prescribed portion of land with indigo, he

either a forced cultivation, or the abandonment of the manufacture from Bengal rayaty plant, that this and every other evil connected with indigo is attributable. An individual manufacturer could not live upon a fair and free system, surrounded on all sides by competitors who get their raw produce without paying nearly its full value. That a whole class did not

| Indigo<br>Planters'<br>Association.            | At several periods the planters have formed associations which no<br>since practically been consolidated into the Indigo Planters' Association<br>Important reforms have been effected through the planters mutually a get                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 166                                            | ing to observe certain rules, and the indigo industry has thereby bee<br>placed on a more rational basis. But a migration of a pronounced Kan<br>took place from Bengal, where the action of the Government was four<br>opposed to certain individual interests, and it may now be said that ^ni<br>the best quality of dye is still produced in Bengal, the chief seats of the<br>industry are in Behar, the North-Western Provinces, and Ma. dra<br>The action of Government in removing the import and export duties,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Removal of<br>Duty.<br>167                     | also the tax on the green plant, greatly favoured the development of Indian indigo trade. Previous to the 5th August 1875 there was an <sup>e</sup> *P <sup>51</sup> duty of R3 a maund; but from that date it became R3 <sup>a maun</sup> ?u 8 manufactured indigo, and R3 a ton on indigo leaves, while on the 25 <sup>th</sup> February 1880 the duty was entirely removed. Imported indigo <b>*</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                                | subject to a duty of 7J per cent., but from the 5th August 1875 it becam<br>5 per cent., and was altogether removed on the 10th March 1882.<br>Enough has perhaps been said to convey a general idea of the $10^{16}$ s. $10^{10}$ facts connected with the growth of the indigo industry. The $10^{10}$ figures of trade, in another paragraph, will complete the sketch. It $10^{11}$ figures of trade, in another paragraph, will complete the sketch. It $10^{11}$ seen shown that the earliest European accounts of indigo manufactur<br>are associated with Southern and Western India. That the trade the<br>migrated to the West Indies and America, was restored to India through<br>the enlightened, though monopolising policy of the East India Company<br>but was then established in Bengal. That half a century later it had. t<br>leave some of its most productive areas, through a selfish policy of culfiv<br>vation, and lastly that a new feature arose in the keen competition of the<br>native growers of Madras. An examination of the trade statistics will<br>show how vastly more important Madras Indigo has become within recen-<br>years, thus justifying the far-sighted policy of the East India Company<br>in urging the importance of getting the growers to be themselves manu-<br>facturers of the dye. If one idea more than another came out pointedly a<br>the result of the enquiry of i860, it was that the Bengal planters were ad<br>mittedly paying a very low price to the cultivators for a crop, of which, one o<br>the seasons of cultivation proved irksome to them, since it prevented their de |
| Objections<br>to Indigo<br>cultivation.<br>I6S | the seasons of cultivation proved irksome to them, since it prevented their de<br>voting themselves to their chief food crops. Elpt the cultivators of Madra<br>and of many parts of Upper India are not only not opposed to growin<br>indigo but do so willingly, since in these regions it not only does not conflic<br>with, but improves the food crop with which it is grown as a valued roja<br>tion. In the reports of occupancy manufacture, highly remunerative<br>returns are given. It would appear to richly pay the grower and manu-<br>facturer of small holdings, while it may not be remunerative to a privat                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | GOFERA                                                                                          |

| The Indigo Plant of Commerce $(C Watt)$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <u>ctoria.</u>                                                                                  |
| European factory to prepare the dye alone. But the danger anticipated<br>and carefully guarded against by the East India Company, <i>viz.</i> , the<br>undue production of inferior native indigo, is in full operation to-day;<br>and were the number of the European factories from any cause to be<br>seriously diminished, it seems just possible that India might once more<br>witness a partial migration of the industry to European colonies. The<br>one saving feature seems to be a wholesale reduction of expenditure in<br>manufatture similar to what has taken place in Tea—thus narrowing the<br>profits but paying on large concerns. The decline in the price paid in<br>England for indigo since 1880—a decline of fully 35 per cent.—maybe<br>viewed as, in part, the result of the competition within India itself, a country<br>which enjoys a practical monopoly in the production of the dye; though<br>doubtless, the competition of inferior dye-stuffs, and fluctuations in cur-<br>renc <sup>•</sup> , have also exercised a depressing influence. The competition of<br>Madras, for example, with other parts of India, must have been serious;<br>for within the 25 years ending 1881-82 the cultivation has expanded in South<br>India over 133*8 per cent, and the exports over 116 per cent., while those of<br>Bengal have decreased 3*2 per cent. The exports from Madras in 1855-56<br>were 2,852,713ft, while last year (1887-88) they were 4,794,944ft or an in-<br>crease in 32 years of 68 per cent. From Bengal in the same years they<br>were 10,106,768ft and 9,781,520ft. The exports from Bengal, however,<br>convey a much less accurate idea of the actual Bengal trade than do those<br>of Madras of the Madras trade The Bengal exports include the pro-<br>duction in the North-Western Provinces, and Oudh. Indigo cultivation<br>has seriously declined in the Lower Provinces. In fact the chief modern<br>feature of the so-called Bengal indigo trade is the rapid expansion of<br>cultivation in tracts under canal irrigation and the great increase of<br>factories owned and worked by natives. Tirhút may be described as the<br>most productive indigo area, as it is a | Growth<br>of Madras<br>Trade.<br>169<br>Expansion<br>in Canal-<br>Irrigated<br>Tracts.<br>170 . |
| CULTIVATION.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | CULTIVA-<br>TION.                                                                               |
| Soils, Methods, Yield, Cost/and Prqfit.—The system of cultivation<br>pursued in the various provinces of India is so nearly alike, that it need<br>be necessary only to describe in detail one or two provinces- the<br>notices of the others being more or less restricted to the indication<br>of departures from the general types. Thus, for example, there are<br>three distinct methods pursued in Bengal, characteristic of three import-<br>ant sections of the Presidency, <i>i.e.</i> , Lower Bengal, Northern Behar,<br>and Southern Behar. In Lower Bengal a two-fold system arises from<br>the fact that large portions of the Indigo lands are within the area of<br>Gangetic inundation, while in different districts or portions of the same<br>district, higher lands that become annually submerged by the rainfall are<br>also thrown under indigo. In both of these conditions irrigation is conse-<br>quently quite unnecessary, and, the soil being recent alluvial deposit, a<br>simple system of cultivation with broad-cast sowings is all that is required.<br>In South Behar ( <i>i.e.</i> , Patna, Gay a, and parts of Chutia Nagpur) irrigation<br>from tanks and wells, and in Shahabad from canals, is found necessary, so<br>that the system of indigo cultivation, there pursued, resembles very much<br>that of the North-Western Provinces and the Panjáb. In Northern Behar<br>(Tirhút, Champarun, Sarun, &c), a very high class cultivation with dril<br>sowings is practised, and although well and tank irrigation is available<br>such aid, owing to the fertility of the soil, is very frequently quit<br>unnecessary. To a small extent similar high class cultivation is accom                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 171                                                                                             |

| CULTIVA-<br>TION.                             | plishedin parts of Lower Bengal on high lands but mostly as spring sovings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Objection to<br>Indigo<br>eultIvatio n<br>172 | While, therefore, Northern Behar may justly be described as the head-quarters of the indigo industry, some of the districts of Low Bengal, such as Jessore and Nadiya, still continue to produce the monighly prized qualities. The advance of the industry from Lower $B^{en}$ to the Upper Provinces may, in a measure, be due to the loss of a $P^{oW}$ , to enforce cultivation, but the rapidity with which it has spread into the new or greatly enriched tracts, under canal influence, would seem to point to another explanation—direct gain. It is possible also that exhaustion the soil to indigo, though improvement to rice, may have in some case necessitated irrigation, which was not in every district easily obtamable. At all events through the aid of canals, large tracts can now be cultivatered during a period when the land was formerly left in fallow, and it see 7 highly probable that, instead of being exhausted to rice and wheat, the soil is greatly improved by the extra crop. The rayats of Upper Inai would thus seem to recognise in indigo an additional source of profit with out any serious injury to their other crops. In Lower Bengal* on the other hand, the spring-sown crop has to be attended to at the very time of * principal rice sowings. It is thus not a favourite crop, since it is legremunerative than rice; but to the planter it yields a very superior quain of dye. |
| BENGAL.                                       | IBENGAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 173                                           | 1ST—NORTH BEHAR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Digging.<br>174                               | Preparing the Land.—Mr. W. M. Reid (in his Culture nnd Mannf <sup>**</sup><br>ture of Indigo) urges the necessity of deep and thorough DIGGING $^{u}T$ ?<br>for high non-inundated lands such as those of Behar. This should<br>commenced as soon as last year's manufacturing is completed. " ^n the<br>work of digging deep down will depend," he says, "in a great meas, the<br>the future health and growth of the indigo plant, and it cannot be, w<br>carefully supervised." The digging ended, the PLOUGHING next begin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 175                                           | The ploughs used are the ordinary native wooden plough with an iro<br>ploughshare. Usually five or six ploughs work alongside of each othe<br>passing, say, north to south along the field, while a second set work $a^{ac*05}$<br>the furrows from east to west. In this way the surface soil is complete<br>broken up over the deeper digging which was effected by the hand o<br>using the ordinary large hoe or <i>kodal</i> . When the ploughing has been                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Rolling.<br><i>rjt</i>                        | completed, the field is next ROLLED by wooden rollers, of smooth cylinders<br>or constructed with a rough thread like a screw. By this means in<br>clods are broken up, and the field levelled. For the purpose of rolling<br>the oldest and most worn-out bullocks are employed which, as Mr. Rei-<br>explains, •« not being smart and active enough for ploughing are put to<br>this slow and arduous work in which dead weight tells more than strength<br>and activity. After rolling down the clods, the ground is again plougher<br>up, perhaps three or four times, according to the dryness, stubbornness<br>or clayiness of the soil. The smaller clods which remain are then finally<br>broken by hand by gangs of, from 50 to 100 women and children, boy<br>and girls, in one long row, who keep up a perpetual din, beating time of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Sowing.<br>177<br>Seed-drill.<br>178          | the clods with thick short sticks amidst clouds of dust until there is not<br>a lump left bigger than an ordinary walnut."<br>Sowing.—The land having been thus thoroughly prepared, sowin<br>commences about February. For this purpose a SEED-DRILL is used—a<br>adaptation from a native implement - specially constructed for indig<br>purposes. This has been briefly described (in <i>Gleanings of Science, Mo</i><br><i>i*29h</i> tnus:— The shares cut the furrow, the wheels of the machin<br><b>I. 178</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | DIGOFERA<br>inctoria.                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| turn those of the trough, the slanting holes bored in the wheels of the trough, during their passage through the seed, take up each one or more seeds (seldom more than one), and, in the downward part of their revolution, unload themselves with precision into the hoppers, which lead them into the hollow of the ploughshares, which last deposit the seed in the furrow and enclose the seed in an instant." Mr. Reid gives a more detailed description of the drill, urging that the wheels and trough must be constructed of <i>Shisham</i> wood (Dalbergia Sissoo), the latter lined with galvanized iron. Tc ascertain the rate of discharge of seed, the number of revolutions of the seed-wheels in a given distance is tested and the quantity of seed discharged carefully collected in small bags. If too much or too little seed be distributed, the holes are enlarged or diminished until the desired rate of sowing is obtained. The eight-shared drill is that generally employed, but a four-shared to a twenty-shared drill may be used. "After the drill follows an instrument, drawn by bullocks, like a long bamboo ladder, which smooths the earth over the seeds, and then the lands are left. In from four to five days the seeds germinate, generally on or about the third day, and the two first leaves of the plant peep forth." | CULTIVA-<br>TION.<br>BENGAL.                 |
| Manuring.—As the lands become exhausted by constant indigo cultivation, where renovation is not accomplished by annual inundations from the rivers, it becomes essentially necessary to manure. For this purpose the cheapest and best material is the <i>seet</i> or refuse plant after the indigo has been extracted. This is dried and carefully stacked, as it is not only of value as a manure for the higher lands not inundated, but it is the fuel used in the succeeding- season for the boilers. In Lower Bengal <i>seet</i> manuring is not practised, or only rarely so, since the rivers overflow the indigo fields and richly manure them with fertile deposits. In Tirhút, on the contrary, and the upper parts of the province, <i>seet</i> manuring is regularly followed. For this purpose, it is carted to the fields and deposited in heaps in regular lines all over the field, and is then trenched into the soil.                                                                                                                                                                                                                                                                                                                                                                                                                          | Manuring.<br>179                             |
| <i>Weeding.—By</i> the time the plant is a few inches above ground, weeds<br>will have grown to such an extent as to necessitate weeding. This is done<br>by a small cutting instrument held in the hand and plunged two inches<br>under ground, so as to cut the weeds off without injuring the indigo. The<br>weeds should then be carried to the margin of the field and not piled in<br>heaps on the field, by which latter careless process many young indigo<br>plants would be killed. Weeding may have to be repeated until the<br>indigo crop rises above the height of being injured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Weeding.<br>ISO                              |
| <i>Cutting.</i> —Indigo is ripe when the flowers begin to appear. This generally takes place about June—earlier or later according to the nature of the season.<br><i>Irrigation.</i> —In exceptionally dry seasons irrigation may be necessary, and in Bengal this is generally accomplished by a slung basket worked by two men; holding the ropes attached to the basket they throw the water to the higher level. At other times a bucket suspended from a beam, with a mud weight at the further end, is employed. Occasionally a eathern bag drawn from a well by bullocks running down an inclined plane is used. On the bag coming to the top of the well it is swung over the end of the drain and the bullocks made to step backwards. The bag thus coming to rest collapses and the water runs off. China pumps, Persian wheels, or various steam pumps may also be used, but in Bengal, when irrigation is practised (which is but rarely), the two first-mentioned methods are generally pursued to raise water from a tank or blind canal flowing from a river; except in Behar well irrigation is rare.                                                                                                                                                                                                                                            | Cutting.<br><b>I81</b><br>Irrigation*<br>182 |

| CULTIVATION.<br>BENGAL.<br>Carting.<br>183<br>Steeping-vat.<br>184. | Carting to the factory,—All arrangements for manufacturing <sup>ha</sup> Y''?]<br>been completed the planter fixes a day for commencing cutting. * n<br>lower-lying portions of his estate or plantation are selected for first cu-<br>tings. This is necessitated through the fact that the rivers at this & <sup>a*</sup> *i<br>(June) are liable to rise rapidly and overflow their banks, when many acre-<br>of ripe crop may be destroyed in a few hours. This remark is, <sup>how</sup> 1 <sup>rg</sup><br>more directly applicable to the Lower Provinces than to Behar, <sup>w</sup><br>inundation only occasionally occurs. The crop is cut with' a sickle a<br>tied into bundles. When cultivated by the rayats and sold to the own<br>of a factory, it is paid for by the bundle. The size of the bundle vanes<br>so greatly, however, in the different parts of the country, that much C <sup>A</sup><br>fusion in estimating the outturn is due to this cause. Most <sup>fact0</sup> H <sup>es</sup> cut<br>a chain for measuring their bundles. As soon as possible after being<br>and bundled, it is conveyed to the factory, either in boats on the nyef. the<br>up the short canal leading to the factory, or by carts. On arrival at<br>factory it is packed in the STEEPING-VAT when the cultivators interest<br>the crop ceases, and the operations of the manufacturer commence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 3RD—LOWER BENGAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | LOWER                  |
| The method of cultivation pursued in the Lower Provinces is less elabo-<br>rate than in Northern Behar—the nature of the soil and the conditions of<br>climate alike operating against the necessity for high cultivation. The<br>bulk of the indigo fields are annually inundated, and thus covered with a<br>rich alluvial deposit which, even when dry, does not require a rigorous<br>method of ploughing and clod-breaking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | BÊNGÂL.<br><b>18</b> 3 |
| Sowings*—There are two October sowings, and a less extensive though<br>highly valued crop in April. As the water subsides in September-<br>October from the muddy banks and <i>chars</i> (islands and shallow promon-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Sowings.<br>189        |
| tories in the river bed), the seed is sown BROADCAST. PLOUGHING would                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Dloughing              |
| tories in the river bed), the seed is sown BROADCAST. PLOUGHING would<br>be impossible, but by means of a bamboo or raft of plantain stems, the<br>cultivator is enabled to move about over the soft slimy surface and thus<br>^ scatter the seeds. His supply of seed is carried in a water-tight basket<br>made by winding rattan canes round and round continuously, each coil<br>being fastened hard on the others by ascending ties of split cane. On<br>being plastered with cow-dung these baskets are rendered water-tight,<br>and they are very durable. Floating on the surface of the water or slimy<br>mud the seed supply is thus pushed over the field, and the seed scattered<br>by the hand as uniformly as possible. By its own weight it soon sinks to<br>a depth of two inches, and within a few days, begins to germinate. By<br>this time in some districts the higher <i>char-\ands</i> have dried sufficiently to<br>allow of the ladder-like harrow being drawn over, thus smoothing the sur-<br>face and consolidating the soil around the seeds, but such harrowing is in<br>most cases quite unnecessary.<br>This method of cultivation is in Lower Bengal known as <i>Chit' ant</i><br>(meaning to scatter); and so far it is very cheap, but as the plants spring<br>up there appears with them a rampant growth of weeds, which proves<br>a source of very considerable annoyance, and involves a very heavy weed-<br>ing expenditure. Sometimes cattle are turned on in December and Jan-<br>uary to browse down the rank vegetation, and in the early state of the<br>October sowings little harm is thereby caused to the crop, while a much<br>valued concession is granted to the rayats. But as the banks of the rivers<br>of Bengal are often densely covered with the scrubby plant, Tamarisk(^aw),<br>when this extends over the <i>char-fields</i> (as it only too frequently does), the |                        |
| greatest possible annoyance is occasioned. The roots penetrate, if anything,<br>deeper than the indigo, and if not uprooted early, the crop may often be<br>thus seriously injured if not entirely destroyed. By the time the hot weather<br>in April and May has come round, the <i>char</i> lands have become very dry<br>and hard. They have split up into great squares or brick-like sections—<br>the cracks often gaping two or three inches and penetrating to the tips of<br>the roots of the crop. Further growth is arrested, and the plants wither                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |
| up to a crop of thin twigs, with a few sickly leaves. They are, however,<br>by no means killed, and when the rains in June begin to soften the soil,<br>the invigorating moisture of the first showers is carried by the cracks<br>straight to the roots, with the result that the sickly-looking twigs at once<br>burst into a fresh vigour and produce an abundant crop of highly valuable<br>dye-yielding leaves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                        |
| On more elevated lands the second class of October sowings are made.<br>For this purpose the land is ploughed once or twice and the clods broken                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                        |

For this purpose the land is ploughed once or twice and the clods broken by drawing the ladder-like harrow (the *mute*) over the surface. The soil of Bengal being of a more recent alluvial nature than that of Tiihut and Behar generally, a much less elaborate system of cultivation is neces-

| The letter Plant of Commune (C. Watt) INE                                                                                                                                                                                                    | <b>DIGOFERA</b>         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| The Indigo Plant of Commerce. (G. Watt)ti                                                                                                                                                                                                    | nctoria                 |
| by the other 678) an acre. The bundle of green plant is an ever changing                                                                                                                                                                     | CULTIVA-<br>TION.       |
| quantity, but of Jessore it is said, the yield of dye is 3 to 4, or even 7 maunds<br>per 1,000 bundles. Again, in Mr. Sheriffs report it is stated, "The yield<br>of dye is about 6 cwts. per 1,000 bundles (a bundle weighing about 300ft). | LOWER<br>BENGAL.        |
| This would therefore be 1 in 461, and it is probable from this that 5,53 <sup>2</sup> & <sup>o</sup> f plant were produced per acre. In Mr. <b>Manson's</b> interesting report on                                                            |                         |
| Indigo cultivation in Rajmehal the yield of plant is put down at 30 to 40 bundles per acre and the yield of dye at very nearly 12ft an acre. Dr.                                                                                             |                         |
| McCann, in his <i>Dyes and Tans</i> , fortunately devoted much careful study to the Records in the Economic Museum relating to the yield of dye per acre,                                                                                    |                         |
| riis conclusions have been verified by the writer, with the result that it appears safe to take the yield in the Lower Provinces at 10 to 12& an acre,                                                                                       |                         |
| and in Behar at nearly 20ft an acre.<br>The cost of cultivation has been so variously stated that it is perhaps                                                                                                                              | Cost Of<br>Cultivation. |
| scarcely necessary to review all the figures. The differences proceed main-<br>ly from the view taken as to the advantages or otherwise of indigo culti-                                                                                     | Profit.<br><b>195</b>   |
| • vation. Certain items have been debited or credited in one return and omitted from another; and the system of making advances has been alaimed as a been or pronounced assures according to the projudices of the                          |                         |
| claimed as a boon or pronounced a curse according to the prejudices of the writer. But the system of making advances, however objectionable it might be made in individual cases, is a necessary outcome of all produc-                      |                         |
| tion not intended for homestead consumption, and is carried out by Gov-<br>ernment successfully in the opium industry. Unless a market exists the                                                                                            |                         |
| plant is of no value" in itself to the cultivator, and unless plant be available<br>the capitalist could not be expected to erect a factory. The planter is re-                                                                              | u .                     |
| quired therefore either to own or to lease the land, or is compelled to hold<br>out such inducements to occupancy tenants as may secure a regular cul-<br>tivation sufficient to support his factory. The fault lies, not so much in         |                         |
| the system of advances, as in the monopoly thereby secured to each cor-<br>cern by which the price paid for the field produce is kept stationary, in-                                                                                        |                         |
| stead of being allowed to progress with the increasing value of all other<br>produce. That the price paid until recently was too low there seems no                                                                                          |                         |
| doubt; and the thousands of ruined factories now met with in many parts<br>of the country bear testimony to the natural punishment that befell                                                                                               |                         |
| those who either could not, or would not, correct and reform their system<br>of treatment of the rayats. The loss to the cultivator, as matters stand,<br>is hypothesical. It is a loss of the difference in value of the indian             |                         |
| is hypothetical. It is a loss of the difference in value of the indigo<br>as compared with another crop. The assumption is involved that the land<br>could or would have been required to grow that other crop. It might                     |                         |
| fairly be contended that the increased value of agricultural produce is the outcome of the multiplicity of crops brought about by foreign demands.                                                                                           | 1                       |
| The land is required for oilseeds, fibres, dyes, food-stuffs, &c. The surplus not absolutely necessary for food crops would naturally be thrown under                                                                                        | of Indigo               |
| the most profitable market crop. In many parts of Bengal, where indigo was formerly grown, jute has proved more profitable; but jute and indigo <sub>L</sub> are only two of the crops by which the foreign markets have                     | cultivation.            |
| enhanced the value of the Indian soil and extended the area of cultivation<br>beyond the good requirements of the people. The subsequent compensating                                                                                        |                         |
| influences of indigo cultivation, which cannot be shown on a balance sheet,<br>have to be borne in mind, and are fully appreciated by the more intelli-                                                                                      |                         |
| gent rayats. The cash advance is a distinct gain, coming as it does at<br>the time of the cultivator's greatest impecuniosity. Prosperity is not                                                                                             |                         |
| accompanied by increased rent, as is only too frequently the case with the<br>ordinary zemindar. The crop is easily grown and requires little or no<br>attention, thus enabling the rayat with his limited resources to cultivate a          |                         |
| greater area. Mixed crops are frequently raised on the same fields, and                                                                                                                                                                      | 1                       |
| I 196                                                                                                                                                                                                                                        |                         |

| INDIGOFER.<br>tinctoria               | A The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOWER<br>BENGAL.                      | for these (which afford many requisites of life) the same labour and <b>expense</b><br>would have to be incurred as are necessary for a joint indigo crop.<br>rotation of a leguminous stock such as indigo is essentially necessary.<br>roots penetrate to a great depth and draw their moisture from, so<br>which the cereals never touch. They tend thus to bring a greater depth<br>into bearing. The manure given to the indigo (and debited to the indigo conduction of a fallow, greatly enrich the soil. It is in fact; ""Ver A" J<br>admitted that a better crop of wheat or rice is obtained after indigo that<br>could possibly have been the case after a millet or other minor food cr. H<br>While the indigo crop is young, the fields are freely permitted to be use<br>as grazing grounds by the cultivators, and as the cattle eat the weeds<br>will not touch the indigo, the advantages of this concession are £J <sup>utual</sup> to<br>the rayat and his European neighbour. The presence of a Jj ^ P *a<br>capitalist in a rural district must also have its advantages. He will at ie<br>be a less exacting creditor than the village money-lender, for it is m<br>interest to keep his cultivators and their cattle in good healthy condi-<br>tion. His factory affords employment to a large community who are <i>too</i><br>purchasers, and even the <i>rayat</i> directly participates in some of the collater<br>advantages, for he owns cattle and carts and sometimes even b°ats, and<br>gets paid to convey the produce of his tithe of indigo plant to the "ac" "J |
| Cost of<br>Cultivation.<br><b>197</b> | Mr. Collin reports that in Bengal as a whole, the planter P ^ / fj ^<br>R12 to R15 a bigha for indigo land, including rent of R3 "!J ''L<br>int R4 to R5 is the actual cost of cultivation, and something is P '' a<br>amount R4 to R5 is the actual cost of cultivation, and something is p <sup>riv</sup> ."<br>ly paid to the factory servants, leaving a profit to the <i>rayat ot</i> 1<br>R4 to R7. The net profit on a good crop of rice on the same field *                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| NW. P. 4<br>OUDH.<br><b>198</b>       | be about R8 to Rio, but such a crop could not be continuously ©warn<br>and if all land were under rice the profits would seriously decline.<br>11NORTH-WESTERN PROVINCES AND OUDH.<br>In the commercial returns of indigo, the produce of these provinces,<br>referred to two sections—Benares and the Doab. The former incluage<br>Goruckpore, Ghazipore, Azimgarh, Benares, Jaunpore, and Allahabaa,»-<br>the small tracts of Oudh and Rohilkhand that have indigo; the latter, and<br>places above Allahabad in the inter-fluvial tract between the Ganges and<br>the Jumna, extending to Meerut and Saharanpur, and south of the Jumn<br>to Jhansi. This distinction is made on account of the difference in the<br>quality of the indigo produced in the two regions, and it may be her<br>pointed out that the former is well and tank, and the latter canal, irrigated<br>T his amerence is of considerable importance, for, while the weits filt in the<br>obtained by canal irrigation is heightened, the yield and quality or the<br>is lessened and deteriorated. The valuable communication on J'A & Voo<br>these provinces received from Colonel Pitcher, Director of Land K<br>and Agriculture, contains the following brief massages meanding the                                                                                                                                                                                                                                                                                                                                   |
| Ploughfngs.<br>I<br>Manure.<br>200    | vation of the plant: - <sup>M</sup> The number of PLOUGHINGS in the Doab<br>exceeds two, but in the Benares Division, indigo fields often receive a sam<br>as four ploughings. MANURE is very seldom used, but when possible ina s<br>follows sugar-cane or cotton, and it thus derives some benefit from<br>manures applied to these crops. Experiments in the Government far                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Waterings.<br>201                     | at Cawnpore show that gypsum is a valuable manure for indigo as for $\circ$ the leguminous crops. For indigo sown in spring ( <i>Jamana</i> ) the <i>nurawr</i> waterings vary from one to three according to the dry ness of in weather. Indigo sown at the commencement of the rains ( <i>Asari</i> receives no watering. As already remarked under "Rotation," "Indig often follows sugarcane or cotton, and unless kept for seed it is general followed by wheat or barley the same year." Speaking of the rotation <b>I.</b> 201                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Indigo, Messrs. Duthie and Fuller ( <i>Field and Garden Crops, page 45</i> ) remark :—" The outturn of a <i>rabi</i> crop (wheat or barley) will not be above half what it would have been if grown after a fallow in the rains, but it is only with indigo that this much can be obtained unless the land be manured, the outturn of a <i>rabi</i> crop grown on unmanured land after millet or maize being extremely small." It is most commonly grown alone, as the period of its growth does not coincide with that of any other crop. Occasionally, however, it is mixed with <i>jnur</i> or <i>arhar</i> , and is surrounded with a border of castor plant, or of <i>son</i> (hemp) more with the idea of one crop insuring the other than with any hope of reaping the produce of both. A loam is preferred, but much of the cultivation is on the lightest possible sand in tracts where copious irrigation is possible from                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | CULTIVA-<br>TION.<br>NW. | canal."j " It is essential that the crop be kept free from weeds, and two                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Weeding.                                |
| WEEDINGS are the least that are given.<br>Extended Cultivation in Canahirt{gated Tracts; its Effects*—The<br>Director of Land Records and Agriculture in these Provinces observes:—<br><sup>W</sup> A good deal has been written during the past few years about the per-<br>nicious effects of the method of indigo cultivation pursued in canal-irrigated<br>districts. There is no doubt that the abundance and cheapness of canal<br>water has enabled the cultivator to #row indigo as an extra crop on lands<br>which, before the advent of the canal, ordinarily lay fallow after the Kharif<br>or Rabi harvest until the setting in of the next rains. In the old days,<br>when the sut;ar-cane or cotton crop had been harvested in January or<br>February, the soil had rest for several months. Now an indigo crop is<br>promptly put down, and on being cut in August is followed by sowings of<br>cereals in October or November. The amount of manure received by the<br>land is certainly no greater, and frequently less, than what was given in<br>former times. Many observers have seen in these facts a clear proof of a<br>reckless and soil-exhausting method of cultivation. It may, however, be<br>doubted whether the effects are practically as bad as they at first appear.<br>The long tap-roots of the indigo prevent the plant from trenching- on the<br>food-supplies of other crops which follow or precede it, and after the<br>indigo is reaped the decaying roots and stalks when ploughed into the<br>ground constitute a distinct accession of wealth to the surface soil-bed.<br>This seems the only possible and natural explanation of the phenomenon<br>that the sterility predicted in canal-tracts from the cultivation of indigo | 202<br>Irrigation.<br>203               |
| has not occurred in any material degree."<br><i>Seasons.</i> —In these Provinces "Indigo may be sown either in the<br>spring (March and April) or at the commencement of the rains. In the<br>first it is called <i>Jamana</i> or <i>Chaiti</i> , in the second <i>Asarhi</i> . The former is ready<br>for cutting in August, the latter in September. The stumps of <i>Asarhi</i><br>indigo are often left in the ground till the following rains, when they spring<br>up again and yield what is known as a <i>Khuntt</i> or <i>Ratoon</i> crop. The<br><i>yamana</i> system is commonly followed in the Doab, but in the Benares<br>Division much of the indigo is sown in June ( <i>Asarhi</i> ), In some parts of<br>Gorakhpur indigo is sown in October with Brassica juncea (Indian Mustard,<br><i>lant</i> ) on alluvial land. The mustard is said to protect the crop in winter,<br>but the area under this mixed crop is limited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Seasons.<br>204                         |
| Method of Sowing and Quantity of Seed to the Acre "Seed is sown<br>broadcast and is mixed up in the soil either by ploughing lightly with<br>the native plough or by passing the long clod-crusher over the field.<br>The quantity usually applied is 15ft to the acre. It is essential for<br>germination that the land must be thoroughly moist and the seed must                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Sowing.<br>205                          |

| writer gives his result as 12 seers of dye from 100 maunds, e.g., 1 in 333 :<br>another 100 maunds of plant to 8 seers of dye, and still another 119<br>maunds to 8 seers. One writer gives the results of careful observations<br>extending over 13 years, in which the mean yield was 1 in 426 for<br>European factories and about 1 in 300 for Native. Mr. Liotard speaks<br>of natives obtaining £lb of dye from 1 cwt. of plant or 1 in 224, while<br>Mr. Reid (in his <i>Culture and Manufacture of Indigo</i> ), who says little<br>of a definite nature regarding the yield of plant or dye in Bengal, gives<br>the average in the North-West Provinces as 300 maunds of plant<br>to one maund of dye. Speaking of the impure indigo or gdd, so largely<br>prepared in the North-West Provinces and many other parts of India (for<br>local use), Mr. Reid remarks, 100 maunds of plant will as a rule yield the<br>planner 2  maunds of gdd. He speaks also of one katcha bigha (about  <br>acre) as yielding 15 to 20 maunds of plant. From these facts it would<br>appear that the acreage yield of dye would be about i8Bb.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | CULTIVA-<br>TION.<br>NW. | III.—PANJÁB,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | PANJAB,                                    |
| Indigo is said to be grown more or less in all districts except Simla,<br>Kangra, Amritsar, Gurdaspur, Sialkot, Gujranwala, Jhelum, Rawalpindi,<br>Peshawar, and Kohat. The chief seats of the Panjib indigo industry are,<br>however, in Multan, Muzaffargarh, and Dera Ghazi Khan. It is entirely<br>grown on irrigated land, but a strong prejudice exists against excessive<br>irrigation; hence lands subject to river inundation are considered unsuited.<br>Mr. Baden Powell gives much interesting information regarding Panjáb<br>indigo, and mentions that it is produced in two of the districts above<br>(Sialkot and Amritsar), which in recent official reports are shown as not<br>producing it. Mr. Baden Powell gives the seed per bigha at 6 seers for<br>the early and 8 seers for the later sowings. The Director of Land<br>Records and Agriculture has furnished a report which embraces the<br>main facts obtained from the three chief indigo districts. On the subject of<br>methods of cultivation he writes :— <sup>n</sup> The land is usually prepared during<br>the COLD SEASON after the winter rains. It receives about four PLOUGH-<br>INGS before the seed is sown and none after. The more labour thus<br>expended the better the crop; but there is no ploughing for the second<br>year's crop obtained off the stems left in the ground from first year's crop.<br><i>Seasons of sowing.</i> —•" The seed is sown from 1st March to 15th May.<br>It is customary to make fresh sowings every year, but sometimes a second<br>or even a third year's crop is obtained off the same plants. The crop | 209<br>Ploughing.<br>210<br>Sowing.<br>2IX |
| takes from three and a half to four months to ripen, before it is cut. To sow<br>the crop the field is first flooded and the seeds then scattered broadcast on                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                            |
| the water. This practice is followed to ensure the seeds sinking into the ground, and that none may remain exposed to the sun. For a month after sowing the field is irrigated every third day or until the plants are a foot high. Irrigation is then given every eighth or tenth day. When the plants are young water is given only in the evening, and then only sparingly, for fear of their rotting from standing in water heated by the sun. Even when older and stronger, the nicest discrimination is required in regulating the supply of water. An over-supply causes the leaves to turn yellow. Continued heavy falls of rain do much injury and often destroy the crops.'' ^ '' For the second year's indigo, less irrigation will suffice, the crop being watered every eighth or tenth day; but the watering must take place early, if possible by the 15th April. First year's indigo requires in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Irrigation.<br>212                         |
| all from 18 to 20 waterings, second year's only 13 to 14."<br>Manure " is not generally used."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Manure.                                    |

| Political Agent is believed to be presently endeavouring to establish there<br>an indigo industry. In Merwara Mr. Duthie found four species of Indigo-<br>fera growing wild; of L argentea var. ccerulea, he says that it is on the<br>Aravalli hills known as <i>nil</i> . The extent to which indigo cultivation is actu-<br>ally carried on in Rájputana cannot be discovered, but in the Gazetteer<br>it is mentioned in a lisi of the chief <i>khdrif</i> crops of Bundi. In a special<br>report on the dye-stuffs of Ajmir, Pandił Bhag Ram says: •« The<br>average 'approximate extent of indigo cultivation for the last <i>five</i> years<br>may be stated at about 500 <i>bighas</i> per annum. Wild indigo is more<br>or less spontaneous in all the forest tracts. It is cultivated chiefly in<br>the lands of Srinagar, Rámsar, Gangwara, and Kikri by native dyers, to<br>meet their own requirements. In the hill jungle of Rájgarh it is found<br>to gnjw spontaneously, which would seem to indicate that the land is fully<br>adapted to the cultivation of indigo; but it is to be regretted that the agri-<br>cultural classes take little or no interest owing to the difficulties with which<br>the dye is extracted. This circumstance accounts for the scanty supply<br>raised in the districts and the total absence of regular indigo factories<br>The Pandit then states, however, that the cultivation leaves a "very small<br>margin for profit." He remarks that it is grown on <i>bardni</i> land, which is<br>ploughed twice or thrice and then levelled. "The seed is sown broadcast<br>early in the month of June, or as soon as the rains set in. When the young<br>plants are above ground, the grass that grows with them is weeded out<br>by the process of hand-hoeing, which is performed about four times. The<br>reaping season commences in October. | CULTIVA-<br>TION.<br>SIND.   |
| Qf the indigo of the CENTRAL PROVINCES very little has been reported.<br>It is mainly grown in the districts of Sagar, Damoh, Narsinghpur, and<br>Nimar, but it seems probable there are not more than 150 acres annually<br>under the crop. The method of cultivation appears to be similar to that<br>in the North-West Provinces. In Sagar the sowings take place in July or<br>August, and the plants are cut when they attain the height of 2 to 25 feet.<br>In Damoh and Narsinghpur the fields are ploughed twice in June; the<br>seed is sown broadcast. The plants are cut in October, and dried and<br>stored. The roots are, however, left in the ground and yield a second<br>and a third year crop, after which they are dug out. In the Upper<br>Godavari, the seeds of the wild indigo, which abounds in this district,<br>are sown at the beginning of the monsoon, and the leaves are picked<br>during the month of September. These plants yield dye leaves for three<br>seasons, and thereafter fresh ground is cultivated. The ground is ploughed<br>twice and is not manured. Mr. Liotard, from whose report on Dyes and<br>Tans the above passages regarding the Central Provinces have been com-<br>piled, adds that according to the local officer," the leaves of the wild indigo,<br>in the neighbourhood of towns and villages, yield a finer dye than the<br>cultivated indigo, because the plants grow up much further apart when<br>left to themselves and are more luxuriant."<br>The writer has had occasion to point out that such references as the<br>above to \yild plants may probably, when carefully investigated, throw<br>much light on the plant, which might be called the original <i>Nild</i> of Sanskrit<br>authors, but there is nothing to justify the opinion that they would prove to<br>be Indigofera tinctoria.                             | CENTRAL<br>PROVINCES.<br>2X8 |
| VBOMBAY.<br>In 1787, Dr. Hove described the cultivation of Indigo in Gujarat as                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | BOMBAY.<br>219               |

In 1787, Dr. Hove described the cultivation of Indigo in Gujarat as follows: "The indigo was partly inter-sown with cotton, and on some plantations with millet and other grains. The lines were divided about 16 inches from each other, in which the cotton shrub stood pretty thick; the above-mentioned grains were scattered without the least regularity. I

|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| followed in the other indigo localities. There may be other peculiarities<br>still surviving of the early methods of cultivation and manufacture that<br>would prove instructive. It is significant of the migration from Bombay<br>to Bengal, that a similar migration has recently taken place from Bengal to<br>the Upper Provinces. In Tirhút and the Benares Division of the North-<br>West Provinces the greatest yield is obtained, and in these regions indigo<br>cultivation is not only carried on more extensively but on more scientific<br>principles, it would thus appear as if Indigofera tinctoria had only just<br>reached the region of India most suited to it—a region u here there is no<br>record of its ever having been grown by natives prior to the European mo-<br>dern efforts, still less of its ever having existed as a wild plant. The infer-<br>ence is, therefore, pardonable, that had it been indigenous to India it would<br>most probably have existed from time immemorial in Tirhút and Benares.<br>Experiments in cultivating indigo have recently been made at Junagad<br>in Kathiawar, and the results seem fairly hopeful. That the Bombay<br>Presidency could produce good indigo seems abundantly proved by the<br>large exports that once took place—and these the earliest recorded exports<br>of the dye as made by the Honourable East India Company—from Surat,<br>Ahmedabad, and Bombay nearly three centuries ago.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | CULTIVA-<br>TION.<br>BOMBAY. |
| VIMADRAS.<br>The Director of Land Records and Agriculture has furnished a series<br>of most instructive reports on the Madras Indigo industry, from which the<br>main facts given below have been derived. In one of these Mr. Mac-<br>leane, Collector of Nellore, writes :—'' Indigo cultivation extends along<br>the east coast from Kistna to South Arcot and inland to Kurnool and<br>Cuddapah. Cuddapah is the principal district for indigo : next Nellore.<br>The crop requires a rich friable soil, neither too moist nor too dry.<br>Bright sunshine favours the development of the dye principle, but fre-<br>quent rains cause a more luxuriant growth. It is generally cultivated as<br>a dry crop. In some parts, it is sown mixed with millet crops, and after<br>the latter are harvested, the indigo shoots up. In dry land, as a rule,<br>one cutting is obtained in October and a second in January. Indigo is<br>also, however, grown on wet land. Here two cuttings are certain and<br>sometimes even a third. It is not unfrequently sown in paddy fields a<br>few days before reaping. On whatever soil sown, the crop, so far from<br>exhausting, is believed to strengthen the soil. The first step in its cul-<br>ture is to plough and manure the ground. A flock of sheep is sometimes<br>enclosed on the ground. At other times the ground is lightly scattered<br>with wood-ashes, cow-dung, &c, or the refuse of the indigo plant from<br>the steeping-vat, or its ashes, are scattered over the fields. The seed is<br>generally sown broadcast. The plant in favourable damp weather, or<br>if lightly-irrigated, makes its appearance above ground in four or five<br>days and ripens in about two months and a half. Great care is taken<br>to weed the plantation thoroughly and to keep the ground moist, but not<br>to weet. When the seedlings attain two or three inches, the fields are<br>weeded. The leaves are cut just before the plant flowers. The first<br>cutting takes place when the crop is three months' old, after which the<br>field is lightly ploughed. The other cuttings follow after intervals of two<br>or three months and are better than the first. | MADRAS.<br>220               |

Other two reports give particulars regarding South Arcot, Kistna, Cuddapah, Kurnool, and Vizagapatam. Regarding Cuddapah, Mr. Sewell writes:— Dry cultiva-tion.

Dry Land Cultivation.—<sup>1</sup>\* After the land has been moistened by

| NDIGOFERA<br><u>tinctoria.</u> | The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | rain it is ploughed and manured. If the April rain is sufficiently<br>heavy this is done then. If not, in July or August, The ground,<br>loosened by <b>ploughing</b> , is allowed to remain unsown for a few days until the<br>next heavy showers when the seed is sown in rows by drills followed by a<br>roller. It sprouts in about three days. In about a month weeding com-<br>mences, which is done by labourers with a sort of spud. On dry lands the<br>crop is entirely dependent on rainfall. The first cutting is taken irong<br>three to five months after sowing, the interval being shorty if rain a<br>abundant and frequent, and longer if it is scanty. At intervals of aDOU<br>three months after the first cutting of the leaves a second and third culture we<br>is taken. It is not usual to attempt to take more than three crops, on                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Wet cultiva-<br>tion.<br>222   | is taken. It is not usual to attempt to take more than three crops, on<br>the plant is allowed after the third cutting to seed."<br>"Wet Cultivation.—This is either under tanks or wells. Under weigh<br>the water supply of which is certain, the cultivation is commenced $i^*$ . Mar<br>or April. The land being constantly under cultivation, if the soil is loos<br>the seed is sown without any previous ploughing, which is, in such cas<br>thought injurious: otherwise under tanks the land is watered, the<br>ploughed and smoothed by a roller. The land is then manured either wut<br>cow-dung or by penning flocks of sheep on it for two or three days,<br>is then watered, and when it has dried again ( <i>i.e.</i> , in three or four day<br>the seed is sown. It sprouts in about three days. If it does not do.sp-t<br>land is watered once to make the seeds germinate. The crop is the<br>watered at regular intervals of not less than a week, or more thanktwen<br>days. The intervals depend on the rainfall and the consequent state of<br>the soil and atmosphere. Weeding commences a month after sowi<br>and continues at intervals of a month. The first cutting is taken tuple<br>or four months after sowing, and the second three months later; when<br>are circumstances permit the crop to be sown early enough, two <sup>cuttin</sup> j J v<br>taken and the crop is then ploughed in, and a food-crop, usually P agay,<br>grown. Indigo is not geown continuously on the same land but is; all of<br>nated with paddy. The refuse of the indigo-vats is much prized a "<br>manure both for indigo and other crops." J-^Q.<br>Having thus dealt with the methods of cultivation in the two chief in dig<br>producing districts of Madras little more need be said. To complete in<br>account, however, a few passages may be here given from Mr. 0. Kougn<br>description of Indigo cultivation in the district of Kurnúl which mayhe <sup>tak</sup> .<br>to represent the districts in the Presidency where indigo is of less import-<br>ance than in Cuddapah and Nellore. The plant, Mr. Kough says, is-a<br>biennial, but is sometimes kept growing for three years. It is sown in<br>black cotton un |
|                                | cuttings lasting into the next season, <i>viz.</i> , two in the first year and the region in the second. Indigo is also grown on land artificially irrigated. When the second is cultivated in paddy land, it is sown in January or February, after the prese paddy crop has been harvested, and one or two cuttings are made be *99, the end of <i>thefasli</i> , and a third cutting in July and August. After the stumps are ploughed up for manure and paddy planted; the ray moreover, almost invariably gets back the refuse after steeping, and this ajs he uses as manure." Speaking of the dry land cultivation, Mr. Kougn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                | further remarks:—" The time of sowing must be selected with care, 10,<br>the chance of a heavy fall of rain caking the surface of the ground and thus<br>preventing the young germs from coming through is considerable, but this<br>difficulty having been got over, when once a fair start is attained, there is<br>scarcely any crop more hardy and less susceptible of damage by drought<br>It escapes damage from grazing of cattle, sheep, or goats, as none of these<br>animals will touch it. Thus the soil, climate, and season are the three<br>I. 222                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>I ne Indigo Plant</b> of <b>Commerce.</b> ((1. Watt.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | DIGOFERA<br>inctoria         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| factors that affect the prospects of the crop. The indigo grown on dry<br>black cotton soil yields dye of a superior quality. The winter crop yields<br>more prolifically than the summer crop. "Weeding/' Mr. Kough re-<br>marks, " is sometimes done by the drill, at other times by hand. The crop<br>is cut four months after sowing when the plants begin to blossom. Two<br>acres fair growth yield about three tons in the first cutting, and will give<br>four or five cuttings, of which the first and the last are usually the least<br>heavy." 3 He gives the cost of cultivation at R14, the price paid for the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | CULTIVA-<br>TION.<br>MADRAS. |
| produce as R20, and the profit, accordingly, as R6 per acre.<br><i>Cost of Cultivation: Field of Plant and of Dye,</i> —In the official<br>reports of the Saidapet Farm a slightly improved process of cultivation is<br>recommended in which the crop is drill-sown after deep ploughing. The<br>danger of the surface soil getting hardened by evaporation after rain,<br>before* germination sets in, is strongly urged. If the sowing takes place<br>in November, the crop will be ready for cutting by the beginning of March.<br>An acre at the Farm was found to yield 200 bundles weighing 12,000ft,<br>and to be worth to the cultivator about R30, giving R10-3-0 an acre as net<br>profit. An acre of land yielding 12,000 ffi of plant was believed to afford<br>2 maunds of dye worth R90, but the report on Cuddapah quoted above<br>states that a fair yield of dye would be 1J to 1} maunds per acre. Of the<br>Kistna district it is said that the net profit per acre on two years' cultiva-<br>tion of indigo plant is R20-8-0. In Nellore 100 bundles of plant are said<br>to give one maund of dye; and in the Kurnul report it is said that ?ID<br>of dye is obtained per cwt of plant. In Bellary, however, the yield of dye<br>is given as only J maund per acre. The Madras maund equals 24*68Ib or<br>in mercantile usage 25ft. It seems probable that these estimates of yield<br>of dye to the acre of land are very much overstated even were a deduction<br>of 50 per cent, made for weight of adulteration. The yield for the Presi*<br>dency obtained by dividing the total production by the ascertained area is<br>only 9'5tb an acre, and this is probably not far from correct. | Cost.<br>223                 |
| VII.—BURMA & ASSAM.<br>In a communication from the Political Agent, Mandalay, dated 1872, it is stated that Indigo cultivation was first commenced in that part of Burma in 1P60, when the King of Burma procured manufacturers from Bengal to teach his subjects the art of preparing the dye. Four factories were established. His Majesty required his subjects to sow a third share of their land within the vicinity of the factories when the land in question was found suitable. It is remarked that "Indigo made from the Burmese f'lant, indigenous to the country, is found not to be equal to the Bengal ndigo." Seed was accordingly annually imported. The Chinese merchants of Mandalay purchased the indigo produced, and exported it to the Shan States and China. It is said to have fetched Rioo per 4^ maunds. Dr. Mason ( <i>Burma and Its People</i> ) says that Indigofera tinctoria, the <i>mat-nay</i> or <i>shan-mai</i> , is much less extensively used as a source of blue dye than Strobilanthes flaccidifolius, the <i>mai-gyee</i> , or than Marsdenia tinctoria. ~An " indigenous shrub," a species of " Indigofera," he remarks, is also sometimes used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | BURMA.<br>224                |

is also sometimes used. In a recent communication on the subject of Indigo cultivation in Burma, it is said to be grown in the Lower Chindwin district. ° There are two crops—the wet weather and the dry weather crop. It grows anywhere. The ground is ploughed up and the seeds scattered over it. The wet weather crop is sown in June and collected in July and August, and the dry weather crop is sown in October and collected in December and January." In the Mandalay district it is reported to grow wild "and the plant is never used for extracting the dye. It is employed medicinally

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | inctoria.                  |
| ready early, <i>i.e.</i> , about the middle of June. The Madras seed yields a crop even earlier than that from the Patna and C awn pore seed. But this is rarely an advantage. The factory operations are dependent on there being plenty of clean water ready at hand, and in May, when the crop from Madras seed is ready for cutting, the rivers are still dry.<br>"The price of seed varies very much, from R4 to R40 per maund." The Collector of Midnapore reports :—<br>"No indigo seed is produced here. The rayats are given 6 seers of seed for each bigha. Last year the seed cost R15 a maund : this year only R5. The high price having induced many to produce it, the supply was greatly increased : hence this decline in price."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | CULTIVA-<br>TION.<br>SEED. |
| is reported on as follows :—<br>"SeveVi seers of seed are sown per bigha in the Gya district. In<br>October a portion of the Asarhi and Jamana are left standing for bearing<br>seed. The plants are kept apart at a distance of 6 inches for this purpose.<br>- There are two kinds of indigo seed sown—that grown in the locality<br>known as dasi, and that of the North-Western Provinces, known as up-<br>country; the latter being sown more extensively, especially in the chief<br>concerns to the south and south-east and south-west of the station of<br>Purneah, where little or no dasi seed is sown. The north and north-west<br>and east of the district have few working factories, and in these the dasi<br>is sown in high lands only. For a seed crop it is grown to the west and<br>north-west only; sown in July and August; reaped in December; sells in<br>January; prices vary according to the demand, averaging about R4 to<br>&5 per bazar maund."                                                                                                                                                                                                                                                                       |                            |
| North-West Provinces.—The Director reports as follows on the subject<br>of seed cultivation:—"When the plants remain stunted and do not pro-<br>mise to fetch much by their weight they are reserved for seed and cut in De-<br>cember, when they yield about 6 maunds of seed to the acre. The stumps<br>of a Jamana crop are also sometimes left in the ground for seed, after the<br>stalks have been cut, and yield about 4 maunds of seed to an acre."<br><i>Madras.</i> —Mr. H. G. Turner, Collector of Vizagapatam, writes:—" As<br>the lands in which Indigo is cultivated are required almost immediately<br>after for paddy, there are no opportunities of raising a crop for seed pur-<br>poses." Mr. C. Kough, Collector of Kurnúl, reports:—"Seeds are col-<br>lected in January and February from plants sown in the beginning of the<br>monsoon, and those sown during the previous year. The latter yields more<br>seed. ^ The plant, when the leaves have been cut after the monsoon is<br>over, is allowed to grow for the purpose of yielding seed. With the seed<br>the leaves are also collected and allowed to dry, and when the seed is<br>separated, indigo is extracted from the dry leaf also."<br>DISEASES AND INJURIES. | DISEASES.                  |
| DISEASES AND INJURIES.<br>In a recent circular, calling for information regarding the Indigo cul-<br>tivation and manufacture as presently practised (which the writer issued<br>through the-Revenue and Agricultural Department), the following replies<br>were received regarding the above subject :—<br>Bengal.—Mr. N. G. Mookerji reported to the Director of Land Re-<br>cords and Agriculture that "the crop suffers from the following causes :—<br>In May and June indigo plants sometimes drop their leaves. This is pro-<br>bably due to droughty weather, but it is only some plants that behave in<br>this way.<br>(2) A green caterpillar, about 1" long, when of full size, locally called                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | DISEASES.<br>227           |

(2) A green caterpillar, about 1" long, when of full size, locally called *malpoka*, appears when plants are mature. The appearance of this caterpillar is in fact a sign of the maturity of the leaf for cutting. If, however,

| INDIGOFERA | A The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | the harvest is neglected for a few days, the caterpillar does great harm b<br>eating away the leaves.<br>(3) A big geometridae caterpillar,   " to 2 <sup>V</sup> long, <i>i</i> " in diameter where<br>full sized, occasionally appears just before harvest, and does <sup>considerran</sup> 's<br>damage. The caterpillar maybe just noticed some afternoon for the n<br>time, and the leaf of a whole bigha of flourishing crop may disappear<br>before the next morning.<br>(4) High winds, hailstorm, constant loading and unloading after na<br>vest, soaking in water, or any other circumstances that spoils the<br>injures the crop for the dye. To get the best result the largest qual'n^<br>of leaf must be gathered when mature and taken as quickly as possible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | the factory house.<br>(5) The crop is very liable to blights of different sorts, and is ascroption<br>jured by extremes of either drought or wet. It is also liable to ^'O^y.<br>insects at different periods of its growth, to Injury from hail, and also<br>injury from severe storms of wind.<br>(6) The indigo is a very hardy plant, but owing to the length nt difference<br>required to bring it to maturity—• a period extending, in the case 01-1<br>crops sown in October, to from eight to nine months '—it is very hable-<br>injury from drought and from the high winds which are prevalent dun<br>the months of April, May, and June. A very severe gale of wind last<br>ing some days, will almost entirely destroy a crop of indigo, stripping it,<br>its leaf, and consequently rendering it useless for manufacturing purpose.<br>The Collector of Midnapur reports :—'' The crop is liable to very as<br>diseases. The spring crop is sometimes eaten by caterpillars and 81, en-<br>hoppers. The autumn crop is too old to be generally attacked by <i>in</i><br>insects. The quality of the crop, however, is sometimes destroyed -oy the<br>untimely drought in June, when all the leaves get scorched up, atte as<br>plant has once started its second growth, or by excessive rain which we |
|            | North-West Provinces and Oldlidh-The Director of Land $   < J_{i} < J_{i}$<br>and Agriculture reports that, "In the early part of its growth it is HaDe<br>the attacks of a winged insect called Gadlie which feeds on the 'oJ''<br>leaves. Another source of damage to the plant is continued wet weain<br>which renders it tall and woody without much foliage, and by a kin a,<br>etiolation prevents the proper development of the dye property in **<br>leaves."<br>Panjdb.—The Director in this province writes :—" As above stated to<br>large a supply of water is fatal. Heavy and continuous rain is also i<br>jurious. The plant is also subject to be attacked by certain insects r<br>sembling blight and by the grass-hopper. But if rain falls in modera<br>quantities the insect dies out. Another disease is also common in its early<br>stages from the 15th to the 30th day, brought on by excessive heat an<br>hot winds, which cause the plant to dry up and wither away. Wet-io<br>too are very injurious."                                                                                                                                                                                                                                                                                   |
|            | <i>Madras.</i> — <i>Mr.</i> L. M. Wynch, Kistna district, writes: -'' The indigo <sup>c</sup> cr<br>is said to be liable to the ravages of several insects, amorgst them bein<br>locusts, the <i>gongali purugu</i> , and <i>kambali purus<sup>A</sup>u</i> (caterpillars). A<br>rayats have no means of destroying these insects. The <i>Buddi ttga</i><br>attacks the crop after it has grown up 6 or 0 inches; if this occurs, the crois ruined and has to be left till the following year.'' Mr. E. J. Se <sup>W</sup> f<br>Collector of Cuddapah, in his reply states that, '' At the age of two month<br>the plant is liable to be attacked by diseases known as <i>Budide-rogane</i> , a<br><i>Agut-mandalaputhegulu</i> . In the former case the leaves turn white, in the<br>latter black, and in both they fall off.'' Mr. C. Kough, Collector of Ku<br>nul, alludes apparently to these diseases, but he speaks of a third form<br>I. 227                                                                                                                                                                                                                                                                                                                                                                |

|   | when subject to the first disease the leaves contract and gradually fall off :<br>when to the second the leaves turn white and the plant ultimately decays :<br>when to the third the leaf is covered with white* matter and the plant dies.<br>"While still young, the plant is subject to the attacks of caterpillars.<br>They attack it when germinating. When the plant attains a height of<br>three inches it is almost free from the insect pest."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | DISEASES.                                                         |
|   | YIELD, AND AREA UNDER INDIGO.<br>With perhaps no other commercial commodity does the inconvenience<br>of a want of uniformity in weights and measures tell more injuriously than<br>with indigo. The <i>Bigha</i> of land in Lower Bengal is one-third of an"acre;<br>in some parts of Tirhút it is six-sevenths; in the greater part of the North-<br>West Provinces five-eighths; and in many other provinces three-quarters of<br>an acr3. The factory maund of dry indigo is 74ft io oz.; the Madras maund<br>25ft; the Bombay maund 28ft; the Government maund for Bengal, the<br>North-West Provinces, and the Panj£b, 82ft. In this connection it may<br>be remarked that it has been found impossible to discover whether the<br>green indigo plant is purchased in factory maunds or in Government<br>maunds. The calculation of yield of plant to acre has been made on the<br>assumption that the maunds of Upper India given by writers on the<br>subject are 82ft. If this be found hereafter to have been incorrect, an<br>alteration from 82 to 74I will have to be made, but this would not affect<br>the yield of dye, which is estimated on a relation of quantity to a<br>unit. The assumption of the maund being equivalent to a cwt., adopted in<br>certain compilations, has led to the greatest confusion and gross misrepre-<br>sentation. | AREA &<br>YIELD.<br>228<br>The Bigha.<br>229<br>The Maund.<br>230 |
|   | In working out the indigo statistics given in this article, the attempt has<br>been made to reduce areas to acres and weights to pounds, but the writer<br>is conscious he may have made some mistakes from the difficulty experi-<br>enced with local returns in determining the system pursued by the original<br>authors. He has, however, corrected these weights and measures with<br>some degree of care, and is hopeful that his results will, on the whole, be<br>found to convey a fairly accurate statement of the indigo industry of<br>India. With regard to yield of dye per acre of crop the very greatest<br>difficulty has been encountered. This has arisen not only from the causes<br>indicated above, but through numerous inaccuracies in the returns, and<br>from a possible desire to avoid definite statements on the part of those<br>most interested. For example, the range of variation of yield of dye has<br>been found to be from 41b to 150B) an acre. Such a discrepancy is<br>obviously due to inaccuracy in compilation or to want of definite in-<br>formation, and not to differences of climate and soil, or method of manu-<br>facture. The writer has arrived at the conclusion that a yield of 12ft an<br>acre for Lower Bengal (and the other non-irrigated tracts, indeed,                                              | ,<br>Dye to Plant.<br>231                                         |
|   | the greater part of India), and of 18 to 20ft for Behar, and certain<br>parts of the North-West Provinces and of the Panjab, would be fairly safe<br>standards.<br>It seens probable that the yield of plant per acre is in direct ratio to<br>the degree of irrigation, but that the quantity and value of the dye                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Plant to<br>Acre.                                                 |

obtained is in inverse ratio. This rather complicates matters, but it accounts largely for th'e greater quantity, though inferior quality, obtained from the canal-irrigated tracts of the North-West Provinces and the Panjdb. A further fact of great importance is that with all Native factories, increased yield is due to two causes: (a) the extraction from the plant of a greater amount of organic but non-indigo materials, and (b) the

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| systematic adulteration that is practised. The greater weight of indigo<br>obtained from an acre of land by the Native as compared with the Euro-<br>pean methods of manufacture has its explanation in these facts, but its<br>consequence in lessened value. After a consideration of all the facts<br>brought to light by the numerous reports and publications on the subject,<br>it seems safe to infer that the production of indigo by the .European<br>factories varies from 1 in 340 to 1 in 640, the average being $a^{\circ\circ u}$ 1 of dye from 420 of plant. These extreme variations are, due to two<br>causes—the difference in the dye-yielding property of one year's crop a <sup>o</sup><br>compared with another, and the difference already alluded to between<br>indigo plant from canal-irrigated land and that from non-irrigated lana.<br>With native manufacturers the range is 1 in 220 to 1 in 330. Accepting<br>these figures as factors to estimate the yield of crop per acre, we <b>obtain</b><br>for Lower Bengal 420X12=5,040^{^}, and in 'Behar and many parts of <b>the</b><br>North-West Provinces 420 x 20=8,400^{^}. These results are <b>e perf</b> ,<br>ent doubtless on test cases (obtained by well-known factories) and may<br>not be applicable absolutely to every case. On turning, however, to the<br>published figures of actual yield of green plant to acreage, it is found that<br>the above estimates correspond remarkably. Thus, the average 01 ai<br>returns gives the yield as ranging from 50 to 80 maunds, the maximum<br>being 120 maunds to the acre. These returns would therefore be 50 X 82-<br>4.ioofcj 80X82=6,560^{^}, or 120x82=9,840tb of green plant to the<br>acre of land. The lesser quantity of plant required by the native manu-<br>factories for all estimates of outturn per acre. But the application of<br>this system of calculation can be made with safety only where the parts of<br>the system of calculation can be made with safety only where the parts of<br>this system of calculation can be made with safety only where the parts of<br>practised. For example, it would be unsafe to assume that an aver<br>of 20ft an acre was produced in the No |
| the weight of dye. Indeed, in many parts of India, a large trade is done<br>in preparing and selling the peculiar clays that are mixed with the liquid<br>dye, preparatory to its being made into cakes and dried. A much more<br>correct estimate of yield is 25ft of dye to 73 cwt. of plant, or 1 in 3 V <sup>4</sup><br>and that is the yield stated by several writers on the indigo industry of the<br>North-West Provinces; but of course it is the yield of good indigOi not 01<br>the highly-adulterated stuff.<br>Perhaps the earliest attempt to estimate the area of land under Inaige<br>in Bengal was made by the late Dr. H. McCann {Dyes and Tans of<br>Bengal}. His figures were compiled from the reports of local officer<br>furnished in connection with the formation of the Economic Museum<br>Dr. McCann arrived at the conclusion that in 1877-78 there, were <sup>03</sup> 705<br>(or as subse uently quoted in round figures, 700,000 acres of land under<br>indigo. A more recent estimate published in the Statistical Atlas fives<br>the area in 1884-85 as having been approximately 1,300,000 acres. It, w<br>apply the mode of testing these figures given above, the Bengal produc-<br>tion in 1877-78 would have been thus—Behar 297,716 acres, giving 20iD<br>an acre, and Lower Bengal 340,240 acres, giving 12ft an acre, or a totai<br>of 10,037,200ft. The writer has no means of analysing the second esti-<br>mate to discover how much was regarded as Behar, and how much Lower<br>Bengal, but assuming that only 12ft an acre was obtained all over, the<br>I. 233                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| production in Bengal for 1884-85 would have been 15,600,000ft. According to Messrs. Thomas and Co., the actual production in these years was respectively 3,832,605ft or 6ft an acre to McCann's area, and 5,351,806ft or 4* 1 ft an acre to the <i>Statistical Atlas</i> area. It would thus appear that either the area as given by McCann and the still greater area in the <i>Sta* tistical Atlas</i> must have far exceeded the actual area of the years in question, or that the average yield per acre must have been about one-third of what the writer believes it to be. Applying the test of 12ft an acre for Lower Bengal and 20ft for Behar, the area under indigo in Bengal, calculated from Messrs. Thomas and Co.'s returns, would have been 232,682 acres in 1877-78, 316,914 acres in 1884-85, and 401,302 acres in 1887-88. The average of these acreages is probably much nearer the actual ^rea under the crop than either of the above which have been accepted as correct by most recent writers. It is probable that these accepted areas of Bengal indigo were dependent on some calculation based on the Bengal trade in the dye—a trade which drains GO per cent, of the North-West, together with a certain amount of the Panjáb, Rajputana, and Central Province indigoes. There being no available agricultural statistics for Bengal, it may serve a useful purpose to test the accuracy of the estimated area of 401,302 acres for the year 1887-88. According to the agricultural statistics of the provinces of Upper India, the following were the areas under the crop during the year 1887-88 :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | AREA ft<br>YIELD.<br>Bengal. |
| Acres.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                              |
| Panj&b<br>Central Provinces                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                              |
| The bulk of the indigo produced in cakes is exported, and the Gov-<br>ernment returns of exports give the quantities and values that left Bengal,<br>Madras, Bombay, and Sind. These will be found tabulated below<br>(Chapter on TRADE IN INDIGO) for the past ten years. To arrive, how-<br>ever, at an approximate estimate of the actual Bengal share in the pro-<br>duction of the exports, we may analyse last year's figures thus :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                              |

| TOTAL .<br><u>-10.845.184</u>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                              |
| The writer believes that, while a production of $20t$ an acre occurs in<br>many parts of the North-West Provinces and possibly throughout Tirhút,<br>for all the provinces (the acreage of which under indigo has been given<br>above), a yield of I2& would be found fairly liberal. For the 397,671<br>acres it may therefore be estimated that 4,772,052ft were produced. By<br>deducting that amount from the total exports from Bengal, Bombay, and<br>Sind, there would remain the Bengal production, <i>vie.</i> , 6,073,1326, and<br>according to Thomas and Co. Lower Bengal and Tirhút produced nearly<br>800,000lb more than that amount, but of course the whole production was<br>not exported. Bengal supplied other provinces and consumed locally a<br>large amount. In fact in the table below showing the balance of produc-<br>tion over exports it will be seen there remained in Bengal 880,640ft in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | ·                            |

| INDIGOFER<br>tinctoria.                    | A The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AREA &<br>YIELD.                           | 1887-88. During the past five years the North-West Provinces and Oudh have had an average of 397,557 acres under indigo which have produced                                                                                                                                                                                      |
| •                                          | the average of 3,609,029,16 of dye or about 10ft an acre. If the estimated area of Bengal indigo of 400,000 acres (or to guard against any possibility of understating, say 500,000 acres) proves correct, the relatively greater production in Bengal, as compared with the North-West Provinces, shown                         |
|                                            | in the above figures, must be accounted for by the greater acreage yield of Behar, which last year manufactured 5,192,780ft of indigo. *                                                                                                                                                                                         |
|                                            | According to the agricultural statistics of Madras, the Southern Presi-<br>dency had last year 501,721 acres under indigo, the exported produce of<br>which amounted to 4,794,944ft, which (disregarding local consumption)                                                                                                      |
| Total area for<br>all India.<br><b>234</b> | would be 9*5ft an acre. Accepting the estimate of 500,000 acres for<br>Bengal as correct, the <i>total area under the cropfot all India</i> wqpld, last<br>year, have been 1,399,392 acres. The total foreign exports were 15,640,128 <sup>©</sup> ,<br>which shows a total average production per acre of 1 rift, to which must |
|                                            | be added the Indian consumption probably close on 2,000,000ft of dye, <sup>thu</sup> s raising the mean acreage production to i2'6ft. But if the calculated* acreage and actual yield of Tirhut be excluded, the average yield for the rest of India is only io^ft an acre; so that in round figures one-tenth of                |
| Į.                                         | the pounds of dye produced is the acreage of the crop.                                                                                                                                                                                                                                                                           |
|                                            | In conclusion, the writer would add that, although personally satisfied<br>that the above criticism of the published statements regarding yield and<br>acreage will be found far more nearly correct than the opinions hitherto<br>advanced, he is conscious that he has had to be guided by indications more                    |
|                                            | than by direct evidence. Many persons express the yield of dye from $P_{a''}^{a''}J$                                                                                                                                                                                                                                             |
|                                            | as one in so many. But applying the factor thus afforded to find the yieW of plant per acre, in one case it comes out as 2,000ft, in another as i2,000D>. These are the extremes, but in working through many such statements                                                                                                    |
|                                            | every intermediate result has been met with. The yield of dye to acre,<br>where given by writers, is almost invariably twice as great as the yield ob-<br>tained by dividing the total production of the province by the recorded                                                                                                |
|                                            | acreage. It is thus probable that the planters who furnished the figures<br>published by Government gave their own results, and that these are far<br>higher than could be admitted for an average provincial production which                                                                                                   |
|                                            | included Native manufacturers. This error is, however, minimised in such<br>provinces as Tirhut or even Bengal as a whole, where the majority of<br>planters and manufacturers are Europeans, who conduct their operations on                                                                                                    |
|                                            | a uniform and scientific principle, so that the returns published by the few<br>may be accepted as fairly applicable to all. Messrs. Thomas & Co.,. » <sup>n</sup><br>their statement of annual averages, exhibit the relative amounts of Native                                                                                 |
|                                            | as compared to European indigo. Last year, while the latter produced in<br>Lower Bengal 20,946 maunds, the former sent into the market only 1,834<br>maunds. The entire Tirbut production of 69,585 maunds is shown as                                                                                                           |
|                                            | European. A very different state of affairs prevails in the North-West<br>Provinces. Of the Benares indigo, Europeans produced 6,515 maunds,                                                                                                                                                                                     |
|                                            | Natives 5,750 maunds. Of the Doab, the shares were, European 3,ia <sup>°</sup> maunds, Native 24,000 maunds. These facts demonstrate 'why it may be safe to accept the average of 12ft for Lower Bengal and 20ft for Tirhút in estimating area. While some of the European Bengal and 20ft for Tirhút                            |
|                                            | in estimating area. While some of the European Benares factories pro-<br>duce as good a result as those of Tirhut, a yield of 20ft for these provinces<br>all over would be incorrect, as may be seen by the fact that it would re-                                                                                              |
| LAND<br>TENURE IN<br>INDIGO<br>DISTRUCTS   | duce the necessary indigo area by fully one-halt of what is given in the Agricultural Statistical Tables of these Provinces.                                                                                                                                                                                                     |
| DISTRICTS.                                 | SYSTEMS OF LAND TENURE IN THE INDIGO DISTRICTS.<br>Prior to the Muhammadan conquests of Upper India the Hindu law                                                                                                                                                                                                                |
|                                            | I. 235                                                                                                                                                                                                                                                                                                                           |

|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| and practice was for the ruler (whether king or petty chief) to obtain<br>a share of the produce of the land. This share was by Akbar converted<br>into a tax or rent, based on an actual survey and settlement, but the assess-<br>ment was fixed for only ten years, and was subject to a revision every de-<br>cade. In South India (which did not fall under Muhammadan rule till a<br>much later period), the Hindu law prevailed, with the modification that<br>the share to be paid to the ruler was often given in cash fixed at the<br>prevailing price of produce. In Bengal, the Muhammadan rulers intro-<br>duced the system of farming out the tax collection to certain individuals<br>who were sometimes the descendants of the original owners, at others mere<br>speculators. During the period of anarchy between the death of Aurang-<br>zeb and the establishment of the British rule, every power which be-<br>came predominant taxed the land to the utmost, and the system of farm-<br>ing out the tax collection was naturally found the easiest and most effectu-<br>al mode of tyranny and persecution. The collector or <i>zamindar</i> obtain-<br>ed the right over a certain district or tract of land from his being<br>the highest bidder, and it became customary to sub-let or even sub-sub-let<br>the <i>zamindari</i> right, until the land had to support not the Government and<br>cultivator only, but two or three sets of collectors, some of whom did abso-<br>lutely nothing but realise a large personal income. The British early found<br>it necessary to reform this system and to restore more or less the Muham-<br>madan method of direct taxation, based on what is called a "Settle-<br>ment" of the land revenue. It was part of the policy also to encourage or<br>develop proprietorship. But the varieties of land tenure found in existence<br>gave rise to three distinct systems of settlement, since the general rule had<br>to be accepted that the person who had the highest existing interest in the<br>land should be held responsible for the revenue. In some cases peasant<br>cultivators paid, as they do now, their land rent directly to the State. | LAND<br>TENURE IN<br>INDIGO<br>DISTRICTS. |
| Bengal, which early came under British rule, was settled under what<br>is now known as the <i>zamindari</i> system. The peasants who cultivated the<br>lands were accepted as having a tenantry right, but the superior holders<br>(the descendants in some cases of ancient families, in others of military<br>chiefs, or only of the farmers of revenue) were recognised as tax collectors<br>in perpetuity on fixed or unchangeable rents. This system prevails not<br>only in Bengal (excluding Orissa) but in the North-Eastern Districts of<br>Madras, in Oudh, and in the Central Provinces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Zamindari.<br>236                         |
| In the greater part of Southern and Western India there was found to<br>exist no superior class between the Government and the actual cultivators,<br>and in the village <sup>^</sup> communities certain families or persons had always<br>cultivated certain fields. The settlement was therefore made with the<br>peasants on what is now known as the <i>Rayativari</i> system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Rayatwari,<br>237                         |
| A third system of settlement, the <i>Lambardari</i> , was made in many parts of the country, especially in the North-West Provinces and in the Pan jáb, where village communities, more or less united, were found to hold tracts of land. On the members of these communities jointly the settlement was made, and these communities, now recognised as having proprietary rights, can let the lands they do not wish to cultivate to tenants, but the communities, not the tenants, are responsible for the Government revenue. In the <i>Rayatwari</i> provinces village communities own only the fields they cultivate—the waste lands adjoining belong to Government and consequently the revenue may be increased by the cultivation of waste lands or                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Lambardari.<br>233                        |

| LAND<br>TENURE IN<br>iNDIGt)<br>DISTRICTS. | decreased by the non-cultivation of fields formerly cultivated. In <i>samin-</i><br><i>dari</i> provinces the village communities are created actual proprietors on a<br>fixed revenue for a tract of land whether cultivated or not, and this often<br>includes large expanses of waste lands which belong to the village.<br>The above sketch of some of the general features of land tenure has<br>been compiled from Mr. W. Q. Pedder's memorandum on the subject,<br>and it is hoped that it may convey some idea of the position of land<br>tenure as it affects indigo cultivation. It need only be necessary in fact to<br>give further a few passages from writers who specially deal with the ad-<br>vantages of the one and disadvantages of the other system, in their special                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| BENGAL.<br>239                             | <ul> <li>validages of the one and disadvantages of the other system, in their spectal bearings on indigo.</li> <li>Bengal.—Mr. A. P. MacDonnell, Magistrate of Durbhanga, in his Administration Report for the year 1876-77, gives a full account of the indigo cultivation in that district, one of the divisions of what is by planters spoken of as Tirhut. Mr. MacDonnell wrote of the systems of tenure and conditions of indigo cultivation.—" The cultivation of indigo is either <i>Zeraty * Assamiviar or 'Khooshgee,</i>. It is <i>Zerat when the land is</i> in the planter's sole possession, and the rayat employed on it is a mere hired labourer. It is <i>Assatnivar when</i> the land is in the rayat's possession, and when he is compelled (being usually the planter's tenant) to grow indigo on it at fixed rates per <i>bigha</i>. It is <i>Khooshgee</i> when the rayat, under no compulsion, grows the plant as a remunerative crop."</li> <li>The Commissioner of the Patna Division, in his Administration Report for 1872-73, wrote as follows :—</li> <li>In the northern districts of Tirhut, Champarun, and Sarun, the indigo is cultivated, as a rule, in villages let to the planter by the zamindars, and is either <i>Assamiwar on Nij</i>. Under the former system when the lease is completed the rayat sattend the factory and execute agreements to cultivate a specified portion of their uplands with indigo. The common proportion now agreed upon is two to three cottahs per bigha of upland or <i>bhit</i>, though in some tew factories the proportion demanded is larger, amounting to five or six cottahs, which it appears was the rate prevailing, at least in Champarun and Sarun, before the indigo difficulties in 1867. The agreement is generally for the same term as the lease. At the time of executing it an advance is given, which remains unpaid without interest till the end of the term, and during each year the price agreed on to be paid for the size of the bigha. The average rate in Tirhut, where the bigha is about 4.225 square yards, is from R8-8 to R9, inclusive of rent; and in Sa</li></ul> |  |
| I                                          | factory, after which time they are useless for growing indigo, though, as the indigo plant has a long tap-root and draws its nourishment prin-<br>I. 239                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |
|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |

| the hidgo right of connected (G. with.) finc cipally from the subsoil, they are improved for the growth of cereals and green crops, which subsist upon the upper layer, which has had the advantage of a long fallow and of being manured by the indigo leaves. In lieu of the lands thus given up, a similar area of other lands is taken from the rayats for the rest of the term of the agreement, and in some instances a clause is inserted that these exchanged lands shall be selected by the factory from the best of those in the rayat's holding. "Speaking generally, the crop may be said in these districts to be sown in February, and the cutting and manufacture to commence early in July. A second cutting of the <i>khunti</i> crop generally takes place in Septemerer and the land is clear in October, except in the very few instances, and these are mainly on the south of the Ganges, where poppy lands are taken for the growth of a crop of irrigated indigo. No other crop can be grown during the same year: as when the crop is a rich loam, with a good subsoil, neither too sandy nor too stiff, and old river deposits not liable to inundation give the best yield; but fine crops are also grown in inland villages, or uplands or <i>bhit</i> . " In the districts south of the Ganges the system is totally different from that above described. The cultivation is for the most part <i>nij</i> , and is carried on in lands leased by the factory from the zamindars or rayats. The whole expenses of cultivation are paid directly by the planter, who employs his own labourers and bullocks. The seed is sown at the beginning of the rains, and the plant remains in the ground during two years, in each of which it is cut. In strong lands a third year's crop is sometimes taken; but, generally speaking, the land is given up at the end of the second year (when it is said to be eagerly sought after for the growth of green crops) and engagements made for other rayats. The whole expenses for two sets of land, one of which is occupied by indigo, and | OFERA<br>toria<br>NURE IN<br>NURE IN<br>NURE IN<br>STRICTS.<br>ENGAL. |

LAND TENURE IN INDIGO

DISTRIČTS.

N.-W. P.

The Indigo Plant of Commerce.

cut" (Report by the Director of Land Records and Agriculture). Mr. Reid (Culture and Manufacture of Indigo) devotes a special chapter to the systems of land tenure in these provinces. He speaks of indigo as having "flourished under the liberal Government of the North-West Provinces." He states that his experience is connected with the district ot Gorakhpur, which he adds "I emphatically believe to be the direction in which the industry of the blue dye, forced out of Behar^ will, in the near future, compulsorily seek its legitimate development. ΑĤ disputes, of whatever nature, between landlord and tenant, have to be adjusted before the Collector or Assistant Collector, with appeal, if desired, to the Commissioner, or finally to the Board of Revenue. Mr. Reia reviews briefly the conditions on which land may be held in these provinces, but the reader may consult on this subject for fuller details  $I^{ne}$ Rent Law Manual published by Mr. L. W. Teyen. By the provisions 01 the Rent Act (XII. of 1881) the term \* tenant" includes, in addition to the cultivators who inhabit the villages and cultivate the lands pertaining thereto, the sub-lessees and also the sub-sub-lessees. This tenancy, as, Mr. Reid puts it, divides itself into four great sections, (a)  ${}^{0CCU}Pf^{n}/5[$ tenants; (b) non-occupancy tenants; (c) tenants at fixed rates; and (a)ex-proprietary tenants. The Lambardari (from "lambar" a corruption of the English word "number" and dar holding) system, it is contended, gives to the North-West Provinces, a great advantage over Bengal, since every field, plot of grass land, cattle track, and village site has been surveyed and numbered. A tenant by reference to the patwari (or village accountant) can obtain an absolute statement of the fields and iF\*\*\* lands over which his tenancy right extends. On this point Mr. ReidI ad as, "The numbering of each field secures the tenant against the snut of about or exchange of lands and the confusion consequent upon tnis which obtains, with such miserable results, in Bengal. An  $occup \&^{nc} /$ tenant is one who has held unbroken possession of the same is in a s under cultivation for twelve years, or who inherited the same by |egat right. But a gift of land by the landholder confers no occupancy right, nor is an occupancy right transferable. But actual occupation of the land for a time as proprietor, and afterwads continuously as tenant for twelve years, established the rights of an occupancy tenure. Non-occupancy tenants are tenants who have not cultivated the land for a term of twelve years. These can be deprived of their tenures at the will of the landowner, on being served by a written notice of ejectment under the provisions of the Act. Tenants at fixed rates: This class of holdings only; occurs in the permanently-settled districts, and the term 'fixed rates implies the grant of land on terms agreed upon at the settlement. This right is inheritable as well as transferable, and the rate cannot be enhanced except on the ground of increased value of holding by alluvial deposits or otherwise. Ex-proprietary tenants are those who have lost or parted with their proprietary rights, but who retain an occupancy tenant right on the land, holding the same at a rental of 4 annas in the rupee less than the prevailing rate payable by *tenants\*at-\*aill''* 

The above sketch, which more immediately concerns the North-West Provinces, with slight modifications, is applicable to a great part of India—the regions where a *rayatwari*, or a village settlement, prevails.

the regions where a *rayatwari*, or a village settlement, prevails. *Madras.*—The *Madras Mail*, in an article on indigo cultivation, reviews briefly the difference between the tenure of land in the Southern Presidency and that in Bengal. "In Bengal," the *Mail* remarks, "everything is under the so-called *zamindari* system. The whole country has been parcelled out into blocks, and leased, for sums far below their actual value, to zamindars. These persons do not farm their estates but sub-let them I. 241

tinctoria. in blocks or in detail to renters. Under a system of this kind it is of course easy for the European to acquire an estate and grow on it indigo, opium, or what he likes; the proprietor will lease to the man who gives him DIŜŤŔĨČŤS. the best rent and is the most punctual paymaster. Under the rayatwari MADRAS. system as it prevails in Madras, this is impossible. Here we have scarcely any zamindars. The great bulk of the land belongs to the Government and is let direct to the rayats, who are petty farmers holding on an average about io'acres each. To these acres they cling with the utmost tenacity, so that there is no opportunity for the European to step in and inaugurate an enterprise of his own. It is here that the reason why the zamindari system is often called 'the curse of Bengal' is to be found. Though the country is prosperous, the people derive but little benefit therefrom. This goes to the zamindars and their sub-renters for whom the people have to work. In Madras, the rayat is independent: he works for himself and takes all the profits to be derived from his land. This, it is true, is only small in extent, and he pays a higher rent per acre than the Bengali zamindar, but the whole of the proceeds derived from the land is divided between himself and his fellow-rayats, and there are far fewer middlemen to be enriched at his expense." The Collector of Cuddapah, in his report for this work, says: "There is nothing special about the tenure of land cultivated with indigo; the landowner and cultivator divide the crop in equal shares." The Collector of Kurntil says there is no separate assessment for indigo lands: the tenure for indigo cultivation is not distinguished from that for any other crop. The Collector of Vizagapatam says : "We have no particular land tenure here for indigo, as the crop is raised by rayats in common with other crops. The rayatwari system is that observed in the Government taluks of this district." But although the Madras system would seem to throw a larger share of the profits into the hands of the actual cultivators than is the case in Bengal, still the same evils from the system of advances would seem, to some extent at least, to prevail in Madras. In the Settlement Report of the Cuddapah district it is, for example, stated that \*' The poorer rayats will not sow indigo unless they are forced to do so by their creditorsthe rich Reddies and Banians,—who always manage to cheat the rayat of a large amount of the profits which is placed to the credit of interest due on loans."

## MANUFACTURE OF INDIGO.

The process of preparing Indigo from the plant differs but little in the various provinces of India (at least in the hands of European planters and with larger Native concerns), so that a general description may suffice. Departures from the type will be found discussed in the Chapters on \*' The INDIGO OF COMMERCE " and " The CHEMISTRY OF INDIGO."

Briefly, it may be said, the necessities of Indigo manufacture are—a manager who is methodical, shrewd, ubiquitous, with a business turn of mind fitting him alike for office routine and the securing of contracts; a liberal supply of good water; an influence, direct or indirect, over the neighbouring cultivators, sufficient to guarantee a regular supply of green plant; a factory, commonly called "The Concern," comprising certain vats, machinery, and appliances; and a staff of loyal employe's who can be educated to carry out their various duties tidily and promptly. Space cannot be afforded in the present article to treat in detail of every necessity of indigo manufacture. The respective duties of the manager and of his army of employe's must be left untold. A supply of good water and a regular production of indigo plant are necessities without which the Concern cannot exist. In the chapter on CULTIVATION and in that on LAND TENURE,

|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MANUFAC-<br>TURE.      | the production of plant has been fully dealt with, as well as the difficultie<br>which exist in securing a uniform supply. It remains, therefore, to nar<br>rate, as briefly as may be possible, the construction of an Indigo Concern<br>and the manipulation in the various stages of Manufacture.<br>It may be remarked that there are primarily two processes according<br>as WET ( $e^*g_{,9}$ fresh or green) plant or DRY leaf are employed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| WET PRO-<br>CESS.      | I.—WET PLANT PROCESS. "                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Water. 243             | Supply of water.—Proximity to a river or other unfailing source of<br>water is indispensable. In order that the water may be brought on a level<br>with the highest vat in the concern, pumps may be required. The water<br>should be raised to a reservoir, sufficient to contain about 10,000 cubic feet<br>It should be there retained for some hours, so as to allow the sediment to<br>deposit, before being used. Muddy water would of course impregnate the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Vats.                  | dye with a quantity of dirt from which it could with difficulty only be again<br>freed. Stagnant and foul water is found to impart to the infusion (the<br>fecula or <i>mal</i> as it is called) a property which it is extremely difficult to<br>conquer—namely, of retarding the process of settling and drying.<br><i>The</i> Kafr.—Pipes are required to connect the supply of water with the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 244                    | Steeping-vats, the Beating-vats, the Pulp-boilers, and the Engines. The size of the reservoir as well as the number of vats is dependent on the amount of plant which has to be annually treated. We may assume a concern of twelve Steeping-vats. These are built of brick and portland-cement, and are in dimensions $24x18x5$ feet. These should be arranged in a row and have in front and below the floor level, a corresponding series of shallower and wider vats (3 to 4 feet deep) known as the Beating-vats. The Steeping-vat communicates with its Beating-vat by a hole at the bottom into which a large wooden plug is driven from the outside. By removing this plug the infusion prepared in the Steeping-vat is drained into the Beating-vat. In a similar way the Beating-vat has a number of holes with plugs arranged in a vertical series, which open into a drain. When the fecula has been precipitated to the bottom of the Beating-vat these plugs are successively removed so as to draw off the useless surface fluid which 13 allowed to run to waste, or is used as a manure for the fields. The sides of the Beating-vat are made to curve inwards at the top so that the liquid when set in motion may not splash over. When the surface fluid has been carefully drawn off, the thickish deposit is raised by buckets and thrown on a strainer. This removes large mechanical impurities. It then flows by a pipe to a cistern under the boiler pump, sometimes called the Pulp-vat, which has the dimensions of $15 \times 10 \times 3$ feet. Before leaving the pipe it passes through a second strainer in the form of a cloth or bag tied over the end. The mouth of the suction pipe of the pump which dips to |
| Boiler.<br>2+5         | the bottom of the cistern is closed by a sieve or rose which also assists in<br>the process of straining. The infusion is then raised by the pump and<br>discharged through a further cloth strainer into the boiler.<br><i>The Boiler</i> should be of thin copper in preference to iron and placed<br>in a room instead of in the open air as are the vats. If madfc of copper<br>the boiler heats more rapidly and uniformly, and the indigo is less liable<br>to get burned: it also lasts longer and is therefore more economical, though<br>the initial cost is greater. The boiler for a factory of the size described<br>should be 25 feet long by 12 feet wide and 4 feet deep; and this will* if<br>required, produce 5 maunds (374ft) of dye. As soon as the fecula has<br>been discharged into the boiler (or after the removal of any surface liquid<br>$112^{may}$ chave $f_{2TM}^{164}$ ) acertain quantity of clean water is poured into the<br>boiling point. For this purpose steam may be employed in addition to a<br><b>L</b> . ${}^{2}45$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                                                                                                                                                                        | DIGOFERA<br>tinctoria. |

| THEORY OF<br>MANUFAC-<br>TURE.<br>WET PRO-<br>CESS.<br>Packing.<br>251 | probably crack the cakes. This process of sweating improves the brilli-<br>ancy and imparts the much appreciated white skin.<br><i>Packing.—The</i> cakes being thus thoroughly dried (a process which<br>lasts for about three months), they are each brushed and packed into<br>specially prepared boxes of well-seasoned wood, each box or ° Case<br>being filled, if possible, with the cakes bearing the same mark denoting the<br>day of manufacture. The actual number of cakes in the box should be<br>registered, and if it be necessary to mix the different days' manufacture,<br>the number of cakes placed in it bearing, for example, No 5 and those<br>bearing No 25 &c &c should be carefully recorded                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Steeping.<br>252                                                       | bearing No. 25, &c, &c, should be carefully recorded<br>Action of Steeping.—So far we have followed the fluid from the steeping-vat till it is ready for the market, and in doing so we have briefly<br>alluded to the main features of the indigo factory. It is necessary to<br>return to the steeping-vat and discuss the process by which tile $^{\Lambda}CJV^{a}$<br>is extracted and manipulated. The manager, having seen that all the<br>necessary repairs have been made on the factory, that the vats are $^{Clean}$ ,<br>the reservoir full of clear water, the pumps and machinery in good $^{NoT}$ ,<br>ing order, the carts and oxen, or boats, in good condition, and the culti-<br>vators ready to cut the crop, fixes a day for the commencement 01<br>operations. The plant is ready, on the flowers having begun to $j^{err1}$ ,<br>The stems are cut within a few inches of the ground, baled into " bundles,<br>and carted off to the factory as soon as possible. The plant is measured<br>or weighed, and stacked in the shade until the afternoon, when the R <sup>ogy</sup> "<br>ing of the steeping-vat commences and must be completed before " $j^{err}$ .<br>fall. Much difference of opinion prevails as to the best method of pacK-<br>ing the steeping-vats. The most general way is to arrange the bundles<br>in two layers, one standing on the floor on their stump ends, the o <sup>ther</sup> T <sup>err</sup> ,<br>form depth. Most planters hold, however, that the method of pac King<br>is immaterial, so long as two conditions are observed: (a) facility for in<br>fluid to drain readily and completely through the tap; (b) uniformity hori-<br>zontally, bo that when the beams used for fixing the plant are $^{Prouf}t^{ers}$ .<br>From the plant is firmly fixed and compressed. When this has been<br>done water is allowed to flow into the vat until the plants are nearly<br>covered. "The night being moderately fair, and the plant good and mode<br>the vat the plant. By means of beams and levers acting on the side of<br>the vat the plant. By means of beams and levers acting on the side of<br>the vat the plant. By means of beams and levers acting the thas |

If the fluid obtained from the steeping-vat contains,                                                                                                                                                                                                                                           |                                            |
| before beating, the substance known as white-indigo, a piece of cloth                                                                                                                                                                                                                                             |                                            |
| dipped in it and then exposed to the air should rapidly show that it has                                                                                                                                                                                                                                          |                                            |
| been dyed with indigo. In a further chapter, the chemistry of indigo and<br>the explanation of the dyers'-vat, will be discussed; but in concluding this                                                                                                                                                          |                                            |
| brief allusion to the formation of the blue fecula, it may be said that if                                                                                                                                                                                                                                        |                                            |
| the fluid of the steeping-vat does not contain white-indigo, but only finely                                                                                                                                                                                                                                      |                                            |
| divided blue-indigo, the beating can exercise no oxidising influence what-<br>soever, and the patent processes that liberate oxygen within the fluid                                                                                                                                                              |                                            |
| must in that case have, like the cruder methods of beating, only a mecha-                                                                                                                                                                                                                                         |                                            |
| nical, not a chemical, action.                                                                                                                                                                                                                                                                                    |                                            |
| The simplest form of a Beating-vat is that used by the primitive dye                                                                                                                                                                                                                                              | Primitive                                  |
| manufacturers. The plants having been steeped in a large earthen pot<br>are removed, and by means of a date-palm leaf or other such substance                                                                                                                                                                     | Beating-vat.                               |
| the fluid : 3 lashed about until the change takes place from a green to a                                                                                                                                                                                                                                         | 257                                        |

manufacturers. The plants having been steeped in a large earthen pot are removed, and by means of a date-palm leaf or other such substance the fluid : 3 lashed about until the change takes place from a green to a blue precipitate. About this time a certain quantity of lime water is added which is supposed to facilitate the precipitation. The contents are set aside to allow of slow evaporation of the water, and when quite thick and almost dry a lump of lime is generally used to close the mouth of the jar until such time as the dye-stuff is to be utilised. This in principle is the process formerly pursued by all European planters, and by most of the smaller factories even at the present day. The fluid having been drawn from the steeping- into the beating- vat, from 10 to 12 men are sent into the fluid (which is sufficiently deep to rise to about their waists) and, standing in

| <u></u>                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                                        | two rows facing each other, they commence to lash the fluid with wooden<br>oars or staves, or simply by means of their hands. At first slowly and<br>regularly, but as the froth forms and then begins to disappear, the rapidity<br>of beating increases until the liquid is often made to rise in a great wave<br>between the beaters. The higher the fluid is raised into the air the better,<br>so long as irregular beating does not cause it to lash over the sides of the<br>vat and be thus lost. At no time, however, should the beating be violent<br>or spasmodic, but the beaters may slowly move to right and left, thus<br>giving a greater impetus to the movements of the fluid. Violent beating<br>is thought to break the grain of the forming dye too much, and the steadily<br>increased motion is held to prevent coarse grain forming. The exact<br>period of beating cannot be arbitrarily fixed, as it depends on the degree<br>of fermentation that took place in the steeping-vat, and the temperature and<br>the humidity of the atmosphere. In about two to two-and-a-hai/ hours<br>the froth will have disappeared, the vat will have passed from bright to<br>dark green, then purple and ultimately to dark blue. Before the order is<br>given to discontinue the beating, a small quantity of the fluid is taken up<br>by the dipper from near the bottom forming a sharp edge between the<br>sediment and the fluid, the beating may be considered as satisfactorily<br>accomplished. At this stage it was the habit (and in some factories is so<br>still) to throw into the vat a quantity of lime-water (about 6 <i>calsis</i> = i <sup>o10</sup> ,<br>12 gallons). Instead of using lime-water to complete the precipitation or<br>the dye as it is called, a more favourite and modern process consists <sup>14</sup><br>allowing a quantity of pure cold water to be discharged on the surface of<br>the beating-vat from pipes arranged on the walls around thecircumference.<br>This ready supply of water is also of advantage in washing out the vate<br>the beating-vat from pipes arranged on the walls around thecircumference.<br>The explanation may be here offered that the effect of |
| Danger of<br>Heat.<br>261                              | glucoside obtained from the plant remain undecomposed, this would P. <sup>rov</sup> f<br>highly injurious in the boiler, since by heat, it is known to give origin to<br>browns, reds, &c, that depreciate the value of the dye. The beaters are<br>now told to walk round the vat about a dozen times so as to give a rotatory<br>motion to the contents, afterwards to rapidly jump out. In two or three<br>hours after beating according to the state of the weather, the indigo w''l<br>have settled to the bottom and the surface fluid may be slowly drained off.<br>It seems to be universally admitted that the beating oxidises the infu-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Chemleal ex-<br>planation of<br>Beating*<br><b>262</b> | sion. If the oxygen combines with the indigo instead of with other organic materials, we must assume that the indigo (or a certain proportion of it) exists in the condition of white-indigo. The chemistry of the sumstance clearly shows that no other indigo compound can be made to $ bine with oxygen. It was formerly held that carbon was • removed by oxidation from the compound that was thus reduced to indigo. This view seems opposed to the chemistry of the substance, and carbon, w liberated, is not derived from the soluble glucoside (obtained by the maceration of the indigo plant), the compound which, by decomposition, forms indigo. Many writers still hold, however, that carbonic acid is liberated ; and, if so, it must be viewed as a secondary product of the$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Liberation 01<br>Carbonic                              | fermentation, but one not derived from the substance which ultimately<br>affords indigo. The liberation of carbonic acid, it is held, is the cause of the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | DIGOFERA<br>inctoria.                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| lime, at the close of the beating process, is regarded as destroying the fermentation, which, if still existing in the fecula, would cause destructive changes during the period of subsequent manufacture. The boiling which follows is viewed as liberating volatile materials, expelling air, oxygen, and carbonic acid while at the same time coagulating the albumen and concentrating the pulp. The writer, while endeavouring to criticise the various opinions that are held regarding the reactions and decompositions that take place in the manufacture of indigo, must not be viewed as advancing any peculiar theory of his own. The literature of the subject establishes two entirely antagonistic ideas, the one followed by the actual manufacturer and the other inculcated by the chemist. In the absence of the results of a chemical examination of the process, it has seemed to the writer that the best course for him would be to exhibit the arguments in favour of, and the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | THEORY OF<br>MANUFAC-<br>TURE.<br>WET<br>PROCESS.<br>Effects of<br>boiling the<br>Fecula.<br>264.<br>Antagonistic<br>Ideas.       |
| defects in, the practical and the chemical methods of indigo manufacture.<br>Instead of using men to beat the liquid of the oxidising-vat (as it is<br>sometimes called) various patent machines may be employed. For this<br>purpose, for example, the ends of the vat are founded, and on the bottom<br>along the centre lengthwise is formed an interrupted ridge upon which is<br>adjusted two paddle wheels. These are made to revolve by steam power<br>and a free circulation of the liquid is thus set up, the rapidity of which<br>may be controlled with the utmost nicety. By another process air is forced<br>through the fluid, or by still another method it is conveyed to the particles<br>of white-indigo by centrifugal force. To discuss all the patents that<br>exist would take greater space, however, than the writer has at his dis-<br>posal. So also, for example, various patents have been granted for chemi-<br>cal inventions in which the liquid both in the steeping-and beating-vats is<br>brought under the influence of direct oxidising agents. Certain proper-<br>ties have been claimed (and planters have been found to substantiate<br>these claims) for patents in which ammonia, alum, nitre, caustic soda,<br>essential oils, &c, are added to the steeping- or beating- vats. If ferment-<br>ation be a practical necessity of the isolation of indigo from the plant, such<br>patents are probably fully justified, but the chemist holds that fermentation<br>is not a necessity, that simple maceration in cold or hot water slightly<br>acidulated extracts from the plant a soluble glucoside which, by the action<br>of water alone or still more readily in the presence of acids, splits into<br>indigo-blue and a form of sugar. For this decomposition neither oxygen | PATENTS.<br>265<br>Machinery<br>used in Beat-<br>ing.<br>266<br>Chemical<br>methods.<br>Fermentatio<br>not neces*<br>sary.<br>267 |
| nor alkalies are necessary; indeed, the latter are highly injurious, as they cause, at certain temperatures, a decomposition of the glucoside from which indigo-blue cannot again be prepared.<br>In concluding this brief review of the various stages of manufacture and of the probable reactions which take place, it may be remarked that Mr. Richard Olpherts has patented several mechanical improvements that                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                   |

Richard Olpherts has patented several mechanical improvements that seem of much value. He proposes that the dye-yielding parts of the plant only—the leaves—should be introduced into the Steeping-vat. For this purpose he has large iron-wire cages constructed so as to fit carts and so many of them to accurately fill the vat. These are taken to the fields, charged with leaves as tightly packed as possible, and conveyed to the factory. They can then he lowered into or resided from the vat with the factory. They can then be lowered into or raised from the vat with great ease, while the leaves are held at a given depth in the water until the desired infusion has been obtained. Each cage may then be raised and placed on a platform over the vat, where it may be washed out by having the leaves trodden on, while clean water is being poured over. The patentee claims several advantages which are, as it would appear, borne out by a chemical study of the substances obtained. A lesser

| MANUFAC-<br>TURE.<br>PATENTS. | volume of water relative to the bulk of dye-yielding material is necessi-<br>tated, which has its advantages chemically and mechanically, while fer-<br>mentation is irore under control. From the writer's theoretical convictions<br>he would add that the lessened fermentation is probably an immense<br>gain, but the process might be still further perfected by slight improve-<br>ments having in view the prevention of fermentation entirely. On the cages<br>of leaves being removed, the beaters are sent into the steeping-vat, and<br>after a degree of beating, the surface fluid is drained into 'he ordinary<br>beating-vat. It is there subjected to a further beating, whereby a propor-<br>tion of indigo is recovered which, Mr. Olpherts affirms, is, by the ordinary<br>process, allowed to run to waste. The sediment from both the upper ana<br>lower vats is next carried to the pulping-vat, and for most of its stages of<br>subsequent treatment, Mr. Olpherts appears to hold patents for methods<br>of his own. The advantages of Mr. Olpherts' system have been com-<br>mended by Professor Ohurch, who appears to have examined ing<br>improvements. It cannot but be regretted, however, that a chemist of<br>eminence has not reperformed the analysis of indigo with special reference<br>to the various processes in use for its manufacture, since it has to <i>oe</i><br>admitted that the industry is still in an experimental condition, instead 01<br>having matured into one, in which, like soap and candle-making, every<br>stage is dependent on some ascertained chemical fact. **<br>Using boric acid in the steeping-vat. They account for the advantages they<br>claim by affirming that two classes of organisms are always present in the<br>water of the steeper and that these set up two kinds of fermentation. ***<br>and the other probably without the production of any indigo-white what-<br>ever. They also profess to have discovered that boric acid acts as a<br>selective antiseptic preventing the latter injurious fermentation. ***<br>and the other probably without the production of any indigo-white what-<br>ever. They also profess to have |
| PROCESS.<br>268               | good as the boric acid.<br>II.—THE DRY LEAF PROCESS.<br>Instead of rapidly conveying the bundles of freshly-cut plant to the<br>factory, as pursued in Bengal, in Madras it was formerly very 2 <sup>TM</sup> **''?'<br>and to some extent it is still, the habit to dry the leaves before<br>irfaceration. An inferior quality of dye is said to be produced by this<br>system, but it has the advantage of being suited to the necessities of<br>small growers who are themselves manufacturers. Factolies of a PH"?''<br>tive kind are built by speculators, who hire these out to the growers. * ne<br>dry leaf may have in consequence to be carried to a distance, or only one<br>factory existing in a district, each grower may have to wait his turn of being<br>able to enc-Act <sup>er</sup> . In a district, each grower may have to wait his turn of being<br>able to enc-Act <sup>er</sup> . In a district, each grower may have to wait his turn of being<br>able to enc-Act <sup>er</sup> . In a district, each grower may have to wait his turn of being<br>able to enc-Act <sup>er</sup> . In a district, each grower may have to wait his turn<br>dry-leaf process it can be manufactured at the convenience of the owner.<br>In the official report furnished for this work by the Madras Govern-<br>ment, the following rides relation is given of the lary leaf system : " If he<br>full ts throcess is carried out in th<br>same way as the green-leaf, except<br>that the plant is cut, dried, and threshed to collect the leaves separately,<br>I. 268                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                                                                                                                                                                                                                                                                                                                             | IGOFERA<br>nctoria                     |

| kept dry, the leaves undergo, in the course of four weeks, a material                                                                                                                                                                                                                                                       | MANUFAC-<br>TURE.<br>DRY PRO-<br>CESS. |
| with six times their bulk of water, and allowed to steep for two hours, with continual stirring, till all the floating leaves sink. The fine green liquor is then drawn off into the Beating-vat. In this method the fermentation of                                                                                        | C100.                                  |
| the fresh leaves, often capricious in its course, is superseded by a much<br>shorter period of simple maceration." The Collector of South Arcot<br>writes : "I may say that the dry-leaf process is more largely resorted to<br>in this district than the fresh-leaf process of manufacture, seeing that the                |                                        |
| cultivation is carried on chiefly in the dry season, when very little moisture<br>is retained in the leaves; should, however, there be rain at the time of<br>cutting, the fresh-leaf process necessarily takes place." Most of the                                                                                         |                                        |
| wet process. It thus seems probable, that as in Mr. Olpherts' process<br>described above, a much less amount of fermentation is involved than in<br>Bengal; indeed, when the leaves are boiled and a decoction prepared, in the                                                                                             | o Fermenta-<br>tion.<br><b>269</b>     |
| ladigo of commerce), the Collector, Mr. E. J. Sewell, speaks of the fresh<br>leaves as employed, but makes no mention of fermentation being set up                                                                                                                                                                          | Kurpa Indigo.<br>270                   |
| in the steeping-yat. The fluid is, however, subsequently beaten for three or four hours, the liquor changing from green to deep blue with the grains of indigo settling to the bottom. 'He then makes an interesting remark that may have a wide significance. "The juice of ' <i>Neradit</i> * bark, and some-             |                                        |
| times a little gingelTy oil is added in the steeping-vat when bubbles begin<br>to rise." "The adulteration with blue mud, which has become so common,<br>is done in the boiling process." The <i>Neradu</i> is perhaps the bark of<br>Eugenia Jambolana, the bark which Mr. C. Kough says is used in Kur-                   |                                        |
| ntil for the same purpose. That gentleman adds that—"In some parts,<br>before heating the water containing the decomposed <i>indican</i> , sweet-oil is<br>mixed in order that the <i>indican</i> may sooner be separated. A small<br>quantity of decoction of <i>Netadi</i> bark (Eugenia Jambolana), or of <i>Tugarsa</i> |                                        |
| seed (Čassia) and lime-water are mixed to improve the quality of the indigo." The writer in another part of this work (see Cassia Tora, <i>Vol. II.</i> , <i>p. 225</i> ) has already dealt with the somewhat puzzling use of the seeds of                                                                                  |                                        |
| Cassia Tora along with indigo. The knowledge of this property is so wide-<br>spread as to demand more careful consideration than has hitherto been<br>paid to it. It is mentioned by authors writing of the Panjab, of Bombay,<br>of Madras, of Bengal, and of China. Mr. Wardle found these seeds to                       |                                        |
| contain by themselves a useful yellow colour, and it may be assumed<br>that they have something to say, from this property, to the formation (along<br>with the indigo of a species of Rhamnus) of at least one of the forms of<br>Chinese green-indigo. But that they are regularly collected and sold to                  |                                        |
| the indigo manufacturers of Madras, and not for any purpose of making green-indigo, is a fact, and a fact that has to be accounted for. They seem to be of special use in the preparation of <i>Pala</i> indigo, a dye prepared from                                                                                        | Oil used.                              |
| the leaves of Wrightia tinctoria, though, as Mr. Kough informs us, they<br>are also used in the boiling stage in the manufacture of the indigo of<br>commerce. What action oil can serve is difficult to see, but Mr. Akitt<br>has patented the use of <i>essential oils</i> which he claims, serve as vehicles to          | 271                                    |
| convey oxygen to the white-indigo. But demonstrated science, it may be<br>remarked, has done so little for indigo that the dye manufacturers of<br>Madras must be credited with practical and useful discoveries.                                                                                                           | SHORTT'S<br>PROCESS.                   |
| Dr. Shortt, in his prize essay on Indigo, describes a process of manu-                                                                                                                                                                                                                                                      | 272                                    |

| ever, that the process would be improved by the introduction into the<br>beating-vat of an acid to assist in the decomposition of the <i>indie an</i> into<br>indigo-bluc and indigo-sugar. It is even probable that through the aid of<br>acids beating might be found to be altogether unnecessary, though its<br>mechanical action of agglutinating the particles of the insoluble blue<br>dye may always be found of practical advantage. The idea of oxidation,<br>however, either by beating or by direct chemical means, must be rejected as<br>inadmissible, since in a cold or hot acid infusion, where fermentation is<br>prevented, indigo-blue is at once formed, and there is nothing, therefore,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | MANUFAC-<br>TURE.<br>SHORTT'S<br>PROCESS.<br>Fermentation<br>Injurious.<br>276<br>Indican de-<br>composed Into<br>non-dye-<br>yielding com-<br>pounds.<br>277 |
| INDIGO-GREEK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | INDIGO-<br>GREEN.                                                                                                                                             |
| Recently, Mr. Richard Olpherts has taken out a patent for the pre-<br>paration of both indigo-green and indigo-blue on a new principle. By<br>gentle pressure of the fresh dye-yielding parts of the plant, which, baled<br>in compressible cases or sacs and deposited in the steeping-vat, on being<br>subjected, under water, to the necessary pressure, yield the dye-substance.<br>The pressure requires to be sufficient to burst or break the tissue of the plant.<br>For the preparation of indigo-green the fluid is run off before fermentation<br>and for indigo-blue after fermentation has taken place. In both cases<br>the liquor is beaten in the lower vat, as already described, the fecula<br>washed, strained into the pulp-boilers, and after being boiled is made into<br>green or blue cakes by the usual process. Many years ago M. Char-<br>pen tier DeCossigny drew attention to the fact that a green indigo could<br>be produced by a process somewhat similar to the above, one of the<br>features of which consisted in crushing the plant. Indeed, so long ago<br>as 1790 Mr. Prinsep sent to England a green indigo which Bancroft pro-<br>nounced a substance analogous to chlorophyl, mixed with a certain pro-<br>portion of ordinary indigo. The exact nature, however, of the green dye<br>obtained from the plant on being crushed by Olpherts <sup>1</sup> process has not been<br>determined. Indeed, the chemist will have to furnish other facts than<br>have as yet been made known before the simple act of crushing can be<br>accepted as producing so remarkable a change in the dye-yielding juice<br>of the plant. | GREEN.<br>278<br>0] herts'<br>Process.<br>279<br>Crushing the<br>Plant.<br>280                                                                                |
| Olpherts has also taken out a patent for manufacturing colour-<br>ed indigoes by chemical means from the waste water of the beating vat.<br>The whole ^subject of the indigo-reds, browns, greens, and yellows,<br>is too imperfectly understood to allow of their being discussed in the<br>limited space at the writer's disposal. The first Aniline dyes (the <i>mauves</i> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | By-products<br>of the Indigo<br>Factory.<br>281                                                                                                               |

| NDIGOFERA<br>tinctoria. | The Indigo Plant of Commerce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INDIGO-<br>GREEN.       | with alcohol, was dissolved with oxalic acid, the filtrate (carrying the green in solution) being next treated with carbonate of lime to remove the oxalic acid. By filtration the lime is separated, and by evaporating to dryness the purified green dye is obtained. This substance is solular in water and may be used direct as a dye. Chevreul also obtained green substance which was found to be a mixture of indigo-brown and indigo-blue. The examination chemically of the green dye salid "?, obtained by Mr. Olpherts <sup>1</sup> process, and by a similar method by Mr. Tytic should commend itself to the attention of the chemist. If a green dye carbon dye is simplicity should secure its universal adoption, and it is probable large market may yet be found for an INDIGO-GREEN if such can be act ally manufactured. (See para, below on Green Indigo of ChinOt)                                                                                                                                                                                                                                                                                                                                          |
| COST&<br>PROFIT.<br>282 | COST OF MANUFACTURE AND PROFIT.<br>It is impossible to arrive at any very definite conclusions on this<br>subject, but all authors agree in the opinion that, even at present Pare 4,<br>pays very well to manufacture the dye. Some writers adduce in support<br>of this statement the well-known fact that the planters are often<br>pay heavy interest on borrowed capital and still obtain remumer,<br>returns. Under these circumstances it seems enigmatical that indebted<br>should exist at all, and it is more probable that, as with tea and other<br>fustries, indigo manufacture pays, but does not give the cent per-<br>returns which have been asserted. It is commonly maintained that<br>Madras cultivators are better off than those of Bengal, because the<br>also manufacturers, and that R40 to R60 which they obtain for the math<br>of dye gives them a handsome return. Their capital invested is pro-<br>less proportionately to that of the European, who obtains R200 for<br>same quantity, seeing that the latter also produces a purer artifer.<br>The following statements regarding indigo manufacture are extra-<br>from the report furnished by the Director, Land Records and Agncunu<br>Bengal: |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | IGOFERA<br>nctoria.  |

| what enormous profits can be made out of the indigo industry—profits so<br>large that the planter can afford to borrow his capital and pay 22 to 23<br>per cent, for charges and interest." The writer regards the above<br>balance sheet as absolutely misleading, though it has been confidently<br>published and republished by several writers since it originally appeared.<br>In addition to the obvious misprint, to which attention has been drawn<br>above, parenthetically, the yield of dye is estimated at three times as high<br>as we ha/e any data to believe it could be, even in Tirhút. The factory<br>is said to have cost about Rso,ooo.<br>The following particulars from a recent official source may be here given<br>regarding the number of employe's and the salaries paid to the same at a<br>Bengal factory:—"The number of persons constantly employed in a fac-<br>tory runs from 25 to 40, but at the manufacturing time there will be from<br>200 to 300. The native employe's are paid from Rio to R30 per month;<br>the more subordinate servants from R4 to R8 per month; coolies from R4 to R6 per<br>month, and at the manufacturing time as high as R8 and R9 per month. | COST ft<br>PROFIT.   |
| "The following are the employe's in a factory at Gya: -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Factory              |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Employes.            |

| In Madras a large number of small native factories are returned<br>simply as "Vats," while in the North-West Provinces a very large number<br>are returned as "Factories," which probably have as little claim to that<br>designation as the vats of Madras. Accepting the returns as they stand,<br>there are in all India 2,762 factories and 6,032 vats, and these give employ-<br>ment to 356,675 persons. The greater proportion of the employe's, however,<br>are daily labourers, being engaged during the working season of the<br>factories only. The above estimate of the persons who find employment<br>at Indigo factories does not of course include the rayats who cultivate the<br>plant, although many of these doubtless earn an additional wage from<br>serving as temporary hands at the factories.                                                                                                                                                                                                                                                                                                                                                                                        | 284                  |
| MATERIALS USED IN THE CONSTRUCTION OF INDIGO CASES.<br>The principal Wood for this purpose is the mango, but others may also<br>be employed, but of whatever wood made the cases should be tarred. It<br>is urged by planters that the wood employed should be seasoned for at<br>least one year, since the effect of unseasoned boxes is to cause a difference<br>in the weight at the factory, at Calcutta, or at London. For a list of the<br>woods suitable for Indigo chests see under the heading PACKING CASES.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Indigo Cases.<br>285 |
| COMMERCIAL INDIGO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                      |
| ITS FORMATION, ISOLATION, VALUATION, AND PRICE.<br>This substance is chiefly a product of vegetable origin, but it is found<br>also, under certain conditions, in the blood and urine of animals, and even                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | ISOLATION.<br>286    |

**Commercial Indigo.** 

(G. Watt.)

**ISOLATION.** Schunck next proceeds to deal with the effect of boiling or heating "There is another very remarkable property, he says, which I Indican. have to describe—a property the knowledge of which will probably throw great light on the process of manufacturing indigo. If *indican*, in the form of syrup, as obtained by evaporation of the watery solution, be heated for some time in the water-bath, or if its watery solution be boiled or even moderately heated, it undergoes a complete metamorphosis." When this change has once been accomplished, *indican*, he affirms, " ceases to give the least trace of indigo-blue with acids." It has, however, chemically only taken up the elements of water; but does so more readily if the indican be heated in the presence of alkalies. Instead of indigo-blue and its allied red-colouring matter, it now yields substances which possess no tinctorial property. It may, therefore, fairly be assumed that if the temperature of the sleeping-vat be raised too high, not only will indican be decomposed into indigo-blue, and that substance still further reduced to indigo-white, but that a certain proportion (probably sufficient to materially injure the value of the dye product), will be completely destroyed through its entering into chemical combination with water. And this danger is possibly not confined to the effects of the heat of fermentation in the steeping-vat, but may also take place with the *indican* that may not have been reduced, but carried to the boiler, where the syrupy mass is concentrated. It may, however, be emphasised that these changes can only take place in *indican* as such, and not in the blue indigo obtained by the decomposition of that glucoside. If the fermentation adopted idoes not at once reduce the whole of the *indican*, and the temperature" of the fluid be allowed to rise, the metamorphic change may take place in the vat, or, if undecomposed *indican* passes over to the boiler, it will there undergo a change, producing- dark-coloured compounds to the detriment of the indigo with which it will then be mixed. The enquiry thus seems justified as to whether a process of fermentation in the steeping-vat is the most convenient, economical, and expeditious. In the laboratory Schunck found that *indican*, while undergoing decomposition with acids, "splits up immediately into one equivalent of indigo-blue and three equivalents of sugar." It is, however, possible, he says, "that these three equivalents of sugar may not be eliminated all at once." He concludes his first paper on this subject by three inferences drawn from his experiments with woad :-" i. The Isatis tinctoria does not contain indigo-blue ready formed, either in the blue or colourless state. "2. The formation of the blue-colouring matter in watery extracts of the plant is neither caused nor promoted by the action of oxygen or of alkalies. "3. Indigo-blue cannot be said to exist in any state of combination in the juice of the plant; it is merely contained in them potentially. Indigo is thus one of the colouring materials which, in the passage quoted above, Schunck affirms, can be derived only by a decomposition caused through fermentation or by means of acids. Indican is decomposed even by certain dilute acids in the cold, and more quickly when heated. This decomposition is, for example, induced by tartaric and oxalic acids, and less easily by acetic acid. Schunck gives it the formulae of  $C_{26}$  H<sub>31</sub> NO<sub>17</sub>, and expresses its decomposition thus: CajHaiNOtf +  $_2H_3$  O = C<sub>8</sub> H<sub>6</sub> NO + 3C<sub>6</sub>H<sub>10</sub>O6 Indican + Water = Indigo-blue + Indiglucin. Without experimentally testing the views which a study of the chemistry of this subject induces, it is impossible to suggest practical reforms; but it would seem as if a system of adding dilute acid to a steeping-vat, after a few, hours' maceration, so conducted as to prevent fermentation, might

Isolation of Indigo by means of acids. 289

| ISOLATION.<br>Native me-<br>thod without<br>fermentation.<br>290 | result in the immediate decomposition of <i>Indican</i> and the formation of Indigo-blue, and thus dispense with the expensive and laborious process of oxidation at present pursued. Indeed, it is probable that the waste product <i>Indiglucin</i> might be utilised as the material from which to manufacture the acid necessary. Were such a system found practical* there can be little doubt but that it would result in the production of a purer article, and one freer from adulteration with the Indigo reds, browns, yellows, and greens which so materially lessen tlu value of the dye as manufacured at the present day. The facts here published seem well worthy the attention of the planter. The old woad manufacturers of Europe extracted their indigo by means of tepid water and lime, a process which rendered fermentation impossible. The use of lime, while precipitating rapidly the indigo-blue when once formed, dqubtess acted injuriously, in that it caused the destruction of a large amount of the <i>indican</i> . Throughout India, wherever the European planters' influence has not extended, the natives extract their blue dyes by a very similar process to that formerly pursued by the woad manufacturers. Thus the Madras method of boiling, as described by Dr. Shortt in the passage quoted above under the Chapter on "Manufacture of Indigo" (p; 43 <sup>*</sup> D) is practically that experimentally tried by Roxburgh and is in principle identical with the old woad method. So in the various provinces of India, a primitive system of manufacture (as it is called) is $^{\text{CM}}$ of as pursued by the Natives, in which fermentation is prevented. 'inus, for example, of the Godavery we read, " a fire-place of mud is constructed sufficiently large to hold sixteen <i>chatties</i> , and in these $^{\text{Chaf}}$ , the plants are placed, and water being poured upon them, the $wfl^{0_{\text{R}}}$ is boiled for an hour and a half. The stalks of the plants are tinent taken out of the <i>chatties</i> and the liquor is poured into large jars fn which it must be well stirred for two hours, the scu |

It is not quite clear what object is served by the subsequent beating<br>of the liquor, but it seems evident that the decoction from the wood which<br>is uccleance auguary producibly contains some acid principle, since * « • • • • • • • • • • • • • • • • • •                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| separated from the fecula, and the addition of foreign substances, like gum, T<br>to assist fermentation, result in the production of indigo very inferior to<br>that made up in factories so called, however well suited to the moderate<br>requirements of the dyers of the country "[ <i>Report of Musaffarnagar on<br/>Dyes and Tans of North-West Provinces</i> ). If would seem highly im-<br>probable that so powerfully astringent a gum as Bengal kino (the gum<br>used in the above process) could assist in fermentation. The process as<br>narrated vould, moreover, lead to the supposition that by cold maceration<br><i>indican was</i> extracted from the twigs, and that the Butea gum assisted<br>in the decomposition of that substance into its blue indigo and sugar.<br>Mr, Sherfff <i>in the Report furnished by the Director of Land Records and<br/>Agriculture, Bengal</i> ) says: "Formerly cold water or weak lime-water was<br>added to the water in which the indigo plant was steeped, to hasten the<br>precipitation of the dye, or as a substitute for beating. But this practice is<br>not followed now by the European manufacturers, nor by native manu-<br>facturers who prepare the stuff for the European market. The use of lime<br>is said to make the indigo hard and red. It is, however, still employed by<br>village dyers in Bengal, who prepare their own dyè. In the manufacture<br>of <i>kachha</i> indigo, or the dye prepared for consumption in the country, the<br>gum of Butea frondosa is added in some parts of the country to hasten the<br>precipitation. Some times the bark of Eugenia Jambolana or of Zyzyphus E<br>Jujuba is also used for the same purpose." The danger of using lime or<br>any other alkali in the steeping-vat, and its utter uselessness for the pur-<br>pose, causing the decomposition of <i>indican</i> into <i>indigoin</i> , has already been<br>deatt with, but the habit of throwing a quantity of cold water into the hot<br>extract or fermented decoction seems well worthy of more careful examina-<br>tion. The three plants mentioned above, as used in Bengal to cause the<br>formation of indigo-blue, are, curiously enough, employed for the sa | Ictoria.<br>SOLATION.<br>ids to preci-<br>pitation.<br>Butea gum.<br>292<br>Lime.<br>293<br>Cugenia bark.<br>294<br>Cold water.<br>295<br> |
| necessary to the decomposition of <i>indican</i> , nor for the formation of its result-<br>ant compounds— <i>Indiglucin</i> and <i>Indigotin</i> . Oxidising agents in the<br>steeping-vat are therefore not only unnecessary and wasteful, but may be                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 296                                                                                                                                        |

| INDIGOFERA<br>tinctoria.                                | A Commercial Indigo.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tinctoria.<br>ISOLATION.<br>Aids to pre-<br>cipitation. | absolutely injurious. An alkali added at this stage to the hot decoction<br>would, however, cause its reduction into three or four useless non-dye-<br>yielding compounds. The juice of the plant is naturally acid, however,<br>and this may be thereby prevented. The solution of Eugenia bark most<br>probably contains the acid necessary to accomplish the complete decom-<br>position of <i>Indican</i> into <i>Indiglucin</i> and <i>Indigotin</i> (blue-indigo), a decom-<br>position which would take place to a certain extent in water alone. This<br>decomposition had better not be fully started however, until iffer a short<br>stage of maceration or careful heating so as to remove the <i>indican</i> from the<br>plant and not decompose it within the tissues, as might take place if boiled<br>at once in a strong acid fluid. The absurdity of fermenting the decoction<br>in order to reduce <i>Indigotin</i> to <i>Indigogen</i> (white-indigo) only to have to<br>reconvert <i>that</i> back by oxidation, either by means of beaters <r patent<br="">chemical processes, is abundantly exemplified by the above simple'process<br/>which, in the hands of a careful manipulator, would, chemically speaking<br/>produce blue-indigo by the direct decomposition of <i>indican</i>.<br/>Eugenia bark could be cheaply enough procured, but its chemical<br/>analysis would reveal the nature of the acid which, in a hot decoction<br/>reduces the <i>indican</i>. The immense volume of indigo-sugar which, from<br/>the factories, is annually poured on the fields as manure, would, "<sup>NOW</sup>X?f"</r> |
| VALUATION.<br>297                                       | suggest the desirability of testing the writer's suggestion of the possibility<br>of utilizing that by-product as the source of the reducing acid.<br>TESTING AND VALUATION OF INDIGO.—AS met with in the market the<br>approved form of the dye occurs in small cubic pieces; when of good quali-<br>ty these are so light as to float on water. They are of a violet-blue cowj <sup>*</sup><br>and assume a coppery aspect when rubbed with a hard polished $y^{0/2}$<br>They are free from flaws or cavities and are not traversed by veins $\alpha$<br>white or brown. Good sorts contain from 50 to 60 per cent, of •>>><br>gotin <sub>2</sub> but in addition to the existence of other products of the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| adul tera-<br>tion.<br>298                              | position of <i>indican</i> , such as red-indigo, brown-indigo or indigo-gu <sup>111</sup><br>mechanical impurities are to a certain extent unavoidably present. 1 <sup>144</sup><br>percentage of dirt is, however, greatly reduced by careful and clean manu-<br>facture. The inferior sorts of indigo contain a large amount of fraudulent<br>ly, added dirt, such as sand, peculiar muds, starch, powdered lead, *c<br>1 he decline of the Bombay indigo manufacture is generally attributed to<br>the adulteration practised. Of Khandesh it is said, for example, that wood<br>ashes are used in adulteration. In the Manual of the Cuddapah district<br>Madras, it is reported that there occurs a sort of bluish mud which isuses<br>in adulteration of indigo. "The demand for the silt is so great that <u>i</u><br>has become an article of commerce : it is collected and sold in the bazar<br>and is readily bought up by some native vat-owners during the manufac<br>turing season at 8 annas a maund." A number of similar paf?***<br>might be quoted from nearly every district of India where native mdigo i<br>made. It may have been inferred from what has already been said tha<br>the Indian dyers recognise two primary kinds of indigo : (a) that made DY<br>or on the principle pursued by, European planters, namely, of boiling down<br>the decoction to a thick syrup and compressing the same into cakes, A nes<br>is generally spoken of as "boiled" or "English indigo;" (b) that made<br>faf the <sup>10 c &amp; 1 market</sup> <sup>in wn</sup> ch the decoction is thrown into moulds ana               |
| PURIFICA-<br>TION.<br>299                               | allowed to dry slowly at the ordinary temperature of the atmosphere. A n<br>latter IS^ generally known as gad indigo.<br>Various methods exist of preparing pure indigo for laboratory pur<br>poses and of estimating the actual percentage of <i>indigotin</i> in commercia<br>cakes It may be purified from most of its foreign matters by treating i<br>successively with dilute sulphuric or hydrochloric acid, with boiling water<br>and with alcohol. But the most thorough method is to have resort to th<br>I. 299                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| principle of the vat, in making soluble indigo-white, removing the insoluble materials by filtration, and from the filtrate throwing down the insoluble blue-indigo. The weight of the dry indigo-blue to the original weight of the sample is relatively the amount present. The sample should be first dried over the water-bath to ascertain the amount of moisture present. In good samples this should not exceed 3*5 to 6 per cent. The amount of ash may next be determined by calcining a certain amount in a platinum crucible. <sub>0</sub> Good indigo generally yields only 7 to 10 per cent. The exact amount of sand or other mechanical impurities may be discovered by washing out the soluble ingredients of the ash. The detection of the presence of starch is more difficult. If the starch has been coloured blue by iodine the indigo cake is pale coloured, has a great density and friability. The actual presence of starch may be demonstrated by treating the indigo with sightly alkaline water, neutralising the filtered liquid with a few drops of acid and testing with iodine. The characteristic blue <sup>r</sup> eaction will be restored proving the presence of starch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DECOMPOSITIONS OF INDIGO.—Indigo-blue melts and boils when heated<br>in contact with air. At high temperatures it burns with a bright and<br>smoky flame. Dry chlorine does not act on it between o° and ioo°C,<br>but if indigo-blue be stirred up with water in a paste, and chlorine passed<br>through it, the mass becomes first green then yellow. A similar decompo-<br>sition takes place with bromine and with iodine when heated. When<br>boiled with nitric acid it is converted into <i>isatin</i> with the evolution of gas<br>Concentrated chromic acid immediately decomposes it with violent evolu-<br>tion of carbonic anhydride. Sulphuric acid acts as a solvent forming the<br>so-called INDIGO-EXTRACT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 300                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PRICE <i>OF</i> INDIGO.—There is perhaps no other article that fluctuates so<br>much as does indigo. The mean annual price varies from year to year<br>according to production and demand, but the outturn of each factory also<br>varies from day to day, depending mainly on the condition in which the plan<br>reached the factory, the nature of the available water, the temperature a<br>the time of steeping, and the success or failure of the manufacturers' in<br>structions as to steeping, fermenting, beating, boiling, drying, cleaning<br>and packing. One point on which all writers agree is, that the yield and<br>quality of dye is greatly injured if fermentation be set up in the leaves be<br>fore maceration, and accordingly wet leaves are never collected. It seem<br>quite possible that wet leaves closely packed together would originate<br>certain amount of decomposition of <i>indican</i> within the tissue, the insolubl<br>blue-indigo becoming imprisoned as it were, and the leaves according!<br>dyed. Considerable experience is also necessary as to the exact age a<br>which the plants should be cut, for it seems established that there is a period<br>of maximum yield beyond which the leaves give less and less, and befor<br>which they also afford an inferior yield and quality of dye. All these dan<br>gers and precarious conditions have to be guarded against, and hence, wit<br>no chemical apparatus to forewarn him, the manufacturer must offen fa<br>and thus produce one day an article of much less value than another. In<br>carefully worked factories each day's manufacture receives a current num<br>ber, and the various days' productions are never mixed, so that each cas<br>of indigo may be depended upon as being of one quality. This has gread<br>ly raised the reputation of high merit for Bengal indigo, and enables larg<br>consignments to be sold on approved samples. With Native manufacturers, each producing a few maunds, or it may be only pounds, this<br>quite out of the question, and consequently Native indigo often fetches re<br>latively a far lower price than it merits. The whole traffic in Native Ind<br>go is, a | <b>301</b><br><b>301</b><br><b>5</b><br><b>1</b><br><b>-</b><br><b>5</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>s</b><br><b>a</b><br><b>e</b><br><b>y</b><br><b>t</b><br><b>1</b><br><b>-</b><br><b>e</b><br><b>b</b><br><b>i</b><br><b>i</b><br><b>i</b><br><b>i</b><br><b>i</b><br><b>i</b><br><b>i</b><br><b>i</b> |

each small consignment for the actual amount of dye it contains. One

| · PRICE.                                | sample may be sold for relatively more than it is worth; another for con-<br>siderably less. Fraudulent adulteration is the main cause of the low<br>prices realised for Native indigo. The prejudice against it is in fact<br>likely to survive long after any possible education into the advantages<br>of producing a cleaner article, so that the course of reform is necessarily<br>slow. The small Native manufacturer, obtaining, as he does in Madras,<br>some R30 to R70 for a maund of his adulterated article, is handsomely<br>rewarded for his labour and capital expended, and he is but <sub>r</sub> little inter-<br>csted in the news that his Bengal contemporary can earn R200 a mauna<br>more than is obtained for Madras indigo.<br>The price of the dye will be found dealt with in various places in this<br>brief summary of the main facts regarding Indian indigo. The reaaer<br>referred to the chapter on the History of the Dye where the valuations are<br>given of samples of good quality in 1810 as furnished by the ^?^ <sup>r</sup> _js.<br>Directors of the East India Company. In the chapter on the "Chemi-<br>try" and also on the "Trade in Indigo" the prices ruling <sup>bot</sup> /V"<br>England and India have been discussed. Mr. d. E. O'Conor .ot inc<br>Finance and Commerce Department has obligingly furnished the followi "5 |  |  |  |  |  |  |  |  |  |  |  |

### **INDIGO SUBSTITUTES.**

SUBSTITUTES.

Blues derived from Coal Tar.—Mr. Alfred H. Allen {President of the Society of Public Analysts) has done a good service to the indigo industry, by making known the exact position of the chemical investigations which have been conducted with the aim of producing chemical indigo from coal tar. The complete success that attended the artificial production of madder, and the consequent collapse of the European trade in cultivating the plant (Rubia tinctorium) and in manufacturing the dye, gave to the enquiry into artificial indigo a seriousness that could not be ignored. The result wzs awaited anxiously; but, for the present at least, it may be said that the Indigo Planter is left master of the situation. Mr. Allen has pronounced the chemists' endeavours as unsatisfactory from a practical point of view; for, while he can now produce "Indigotin," he cannot do so at a price to compete with the natural product. The following interesting passage may be here given from Mr. Allen's report:—

'• If a piece of cotton be introduced into a vat, containing the solution of reduced indigo, the liquid penetrates to the interior of the fine tubes constituting the fibres of cotton, and on subsequently exposing the material to the air, oxidation takes place, the insoluble blue-colouring matter is formed, and, being in the interior of the fibre, the goods are dyed a fast blue, incapable of removal by washing, and wholly unacted on by light, soap, or diluted acid or alkaline liquids. By chloride of lime the colour may be bleached, but this has a distinct practical advantage, for a white pattern may be produced on a uniformly blue ground by restricting the treatment with the bleaching agent to those parts of the cloth from which a discharge of the colour is desired. Some years since, by a series of highly complex and ingenious processes, artificial indigotin was obtained from Coal-tar. Owing, however, to the extremely tedious character of the preparation and the unavoidable loss occurring at certain points of the process, resulting in the formation of a large proportion of valueless products, the production of indigo from Coal-tar has not proved an industrial success, and the manufacture has been almost discontinued, and doubtless will be entirely so when the present stocks are exhausted. The artificial indigo from Coal-tar is identical with the natural product in every respect, and it is merely a question of *price* which has prevented it from superseding the colouring matter made in nature's laboratory.

'• But this question of price has been settled, for the present at any rate, in favour of the natural products. The case is not parallel to that of Alizarin, the colouring matter of madder, the synthesis of which from Coaltar has resulted in the complete abandonment of the cultivation of madder.

| suited to Indigofera tinctoria. Should this idea be<br>indigo-production might be greatly extended and le<br>from an internal rather than an external influence<br>be found of three indigo-yielding plants which are<br>as a source of dye. Thus under the Chapter on "<br>allusion has been made to samples of Nerium ind | essened prices re<br>e. Brief notices<br>e regularly emplo<br>History of Indi | esult<br>will<br>oyed<br>go'' |

Wrightia tinctoria, the *Pala* indigo of Madras) as having been sent from Madras to the Board of Directors of the Honourable East India Company for examination. This easily-grown tree yields a large supply of leaves annually, and might be made a source of dye at a nominal cost. Numerous papers will be found on this subject in the earlier volumes of the Journals of the Agri-Horticultural Society of India, but Mr. Fisher's report, Vol. IV. (Selections), 129–131, may be specially consulted.

In the "Chapter on Cultivation of Indigo" two other indigo-yielding plants have been mentioned. Under the account of Bombay and of Ráj-, put ana reference has been made to Tephrosia purpuiea. The Indigoes of Egypt and of the Niger in Africa, are obtained from species of that genus, and it is probable Tephrosia mipht be successfully grown in many parts of India where Indigofera would fail. In the account of Indigo cultivation in Assam, a brief passage has been quoted from the writer's account of the *Rum* dye of the Eastern side of India—the produce of Strobilanthes flaccidifolius. It does not seem necessary to comment further on this subject, suffice it to add that much of the dye of China is obtained from this source, and that long ago Fortune (*see Chinese Indigo by R. Fortune*<sub>9</sub> *Jour, Agri.-Hort. Soc. hid., IX., Sel. 34*) urged the value of this plant. It was apparently first botanically made known to Europe through Dr. W. Griffith, who found it in the Mishmi Hills.

Besides the above there are other Indian plants known to yield the dye. The hill tribes on the Himálaya extract indigo from several plants, but more especially from Marsdenia tinctoria (the ryom of the Eastern division), a creeping Ascjepiad.\* In Java M. parviflora is cultivated as a source of indigo. The Yoruba Indigo of West Africa is obtained from Lonchocarpus cyanescens, Bth. Isatis tinctoria—the woad—yields the Indigo of Afghanistan and of some parts of China. In Burma two plants not as yet mentioned are said to afford indigo, vie., Gymnema tingens, an extensive asclepiad climber, and Acacia rugata, a small tree, probably only a variety of A. concinna, the soap-nut tree. In Cochin China a composite plant, Spilanthes tinctoria, is cultivated as a source of indigo. Many other plants are also reported to yield the dye, though little advantage is taken of these sources of blue-dye. Thus, for example, the leaves of the custard apple, Anona squamosa, and of the gram plant, Cicer arietinum, yield indigo. In Russia, Polygonum tinctorium is grown as a source of the dye, and it is probable several of the Himalayan species might be so used. The fruits of two or three Polygonums afford a pulpy substance which dyes the fingers blue on being squeezed, and the young cones of Abies Webbia<sup>^</sup>a afford a curious purple dye, which is probably a form of indigo. The tree is known to the hill tribes of the Western Himalaya as the Indigo-fir.

The study of all the indigo-yielding plants should commend itself to the attention of planters.

GREEN INDIGO OF CHINA AND OTHER REPUTED GREEN DYES.

GREEN DYES 306

In the concluding paragraphs of the Chapter on the MANUFACTURE OF INDIGO reference has been made briefly to the processes of making Indigo-green. That substance should not be confused with Chinese

a \* For further information on the Indigo from Marsdenia> see Vol. V.

| GREEN DYES.                             | green-indigo, which, in all probability, is not obtained from the Indigo<br>plant at all; if, indeed, it can be accepted as anything more than a com-<br>bination of two materials resulting in a green dye. This subject is,<br>however, 2t present too Hitle known to allow of a succinct review of the<br>literature, and little more therefore can be here done than to furnish the<br>reader with references to the chief works which treat of it. The writer,<br>in his Calcutta International Exhibition Catalogue, referred to four re-<br>puted Indian green dyes, <i>viz.</i> , Baccaurea sapida, Gymnéma tingens,<br>Hedyotis capitellata, and Jatropha glandulifera. These will be found<br>treated of in their respective places in this work. But the two former are<br>affirmed to be used in conjunction with other substances, so that they may<br>be set on one side. The two latter, on the other hand, are reputed to yield<br>a green dye without the aid of any other dye-stuff. Gamble, and ais <sup>9</sup><br>Schlich, speak of Hedyotis as the Lepcha green dye. <sup>n</sup> The green leaves<br>are put into water and infused and the cloth to be dyed is steeped in the<br>infusion." Dr. Thomson, in the Journal of the Agri-Horticultural <sup>Srovie</sup> v<br>of India (1862), described the process of preparing the green dye trom<br>Jatropha, and it is somewhat remarkable that neither of these green dye<br>they been put to any practical use. If it be the case that Jatropha g? <sup>adtro</sup><br>lifera yields the dye said to have been prepared from it, an unlim <sup>4</sup> te-<br>supply mierht be obtained in Bengal, since the plant is one of the <b>most</b><br>prevalent of roadside weeds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Green Indigo<br>Of China.<br><b>307</b> | Subsequent to the appearance of the Catalogue cited above, the wn of<br>published in the Colonial and Indian Exhibition Catalogue an account<br>what promises to be another subject of future interesting investigation,<br>A sample of Kampti green dye was procured, the plant from which for<br>said to have been obtained proving the common pulse Vigna<br>and the transfer of the same and twigs were reported to yield on dec<br>for a fluid which, with the fruits of Garcinia pedunculata, produced<br>indigo which, with the fruits of Garcinia, would form green,<br>a recent communication, however, Mr. H. Z. Darrah (Director, L'ar<br>Records and Agriculture, Assam) throws some doubt on the *ccreation<br>the above information. He describes an Assam green Prepare?, 111<br>ram-indigo with turmeric and the leaves of <i>urohi mahorpat</i> (* Vig *>><br>He adds that the leaves of the common plum may be used in place <i>QI</i><br><i>urohi</i> ; the plum referred to is probably Zizyphus, a plant allied to Rhammus.<br>Major Hannay (Note on the Dye-stuffs of Assam, <i>Jour. AgrirHorty</i> **;<br><i>Ind., VI. (Old series), p. 69</i> ) describes another Assam green prepared with<br>r <m-indigo, <i="" being="" employed="" the="" yellow="">Mishmi-teet (Coptis 1 estator).<br/>Throughout India, however, greens are produced with indigo and some<br/>vegetable yellow, so that little novelty exists in observations of that nature.<br/>In an account of the Resources of Pegu {Jour. AgriHort, Soc., 1**<br/>SeL 54,) it is stated that the leaves of Photinia serratifolia (? a form 01<br/>P. Notoniana, W. fcf A.) yield a green dye. The writer can find no con-<br/>firmation of this statement. Mason alludes to the above plant (on in<br/>authority of McClelland) as the <i>donk-yat</i> of the Burmese, but he, de-<br/>scribes in another page a green dye as prepared by the Burmans trom<br/>turmeric and the leaves of the soap-nut Acacia. In Volume II. 1*.'''<br/>Series), p. 251, mention is made by Mr. A. H. Landers (Vegetable ana<br/>other Products of the Shan Country) of a green vegetable dye of a fading<br/>colour, which, he remarks, would no doubt be lasting with mordants.<br/>Turning now to the info</m-indigo,> |

| Commercial Indigo. (G. Watt.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | INDIGOFERA<br>tinctoria.                                                                                                                                                                                                                  |

| of the AgriHorticultural Society of India. In Volume VIII., Old S (1854), 232, Mr, T. F. Henley addressed the Secretary of the Soc recommending that Mr. R. Fortune's attention (during his contempl travels in China) should be directed towards investigating the so of the famed green-indigo. Mr. Henley referred the Secretary to M sieur Persoz's account of the substance which had then only, recompeared ( <i>in Comptes Revdus de V Academie des Sciences</i> , October 1 A copy of M» Persoz's memoir was furnished to Mr. Fortune along a grant of £50 to be spent on plants and seeds including, if possible, to of the green indigo shrub ( <i>Proceedings, clxxxiii.</i> ). In vol. IX., is published Mr. Fortune's "Account of the Chinese Green Indigo I with specimens of the dye." Mr. Fortune in the above paper expr his satisfaction that the green dye plant forwarded by him had received in safety by the Society. He then proceeds to say that he f that the seeds of a cultivated along with a wild form of the plant used in producing the dye. He performed the experiments for hi as described by his Chinese informants. "The extract," Mr. For wrote, "from the seeds of the cultivated species which I have evapor on paper, is yellowish in colour, while that from the wild kind is of a plish or violet tint, and apparently very beautiful. These mixed tog give a green of various shades, according to the proportion of each and this colour is much varied and improved by the addition of a sulphate of iron, and such substances used as mordants by dyers. | tinctoria.<br>eries<br>GREEN DYES.<br>Green Indigo<br>of China.<br>ource<br>Mon-<br>ently<br>852).<br>with<br>those<br>105,<br>Plant<br>esses<br>been<br>ound<br>were<br>mself<br>tune<br>rated<br>pur-<br>ether<br>kind,<br>alum,<br>The |
| Chinese invariably informed me the seeds were em ployed" to paper<br>and that cotton and silk fabrics were dyed with the bark." Mr. For<br>after sonte trouble found that the chief seat of the green dye (or <i>La</i><br>manufacture was at Kia-hing-fu situated between Hung-chon-fu<br>Shanghai, and as he was unable to visit that city he communicated<br>Dr. Lock hart, who entered warmly into the investigation. Mr. For<br>then adds that on reaching Shanghai later in the year he found tha<br>Rev. Mr. Edkins had, on passing through Kia-hing, procured a bu<br>of the chips. Speaking of these chips he remarks:" Dr. Lockhart had<br>pared the extract by boiling down a decoction obtained from them."<br>page 274 a further communication from Mr. Fortune is given whe<br>furnishes a passage from a letter received from Dr. Lockhart in whic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | only,<br>tune<br>okao)<br>and<br>with<br>tune<br>t the<br>undle<br>pre-<br>At<br>re he<br>h the                                                                                                                                           |
| process of preparing the dye is carefully described- The barks of<br>wild plant called WHITE and of the cultivated called YELLOW are bin<br>in iron pans.<br>.'' The residuum is left for three days, after which it is placed in<br>earthen-ware vessels, and cotton cloth prepared with lime is dyed w<br>several times. After five or six immersions the colouring matter is way<br>from the cloth with water and placed in iron pans to be again boiled.<br>colouring matter is taken up in cotton yarn several times in succe-<br>and then washed off and sprinkled on thin paper. When half dry<br>paper is pasted on light screens, and thoroughly exposed to the sun.<br>produce is called <i>Luk-kaon</i> . In dyeing cotton cloth with it ten par                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | boiled<br>large<br>vith it<br>ashed<br>The<br>ssion,<br>v, the<br>The                                                                                                                                                                     |
| <ul> <li>mixed with three parts of sub-carbonate of potash in boiling water."</li> <li>dye obtained "does not fade with washing, which gives it a super over other greens"</li> <li>In the same article Mr. J. Me Murray, Head Gardener to the So described the process he had pursued in cultivating the plants and of the Chinese green dye, obtained from Mr. Fortune. Dr. Tho (then Superintendent of the Royal Botanic Gardens) identified the as a species of Rhamnus. Reprinting from the Pharmaceutical Jo and Transgestions the Agri Hortigultural Society in their Salestions</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | The<br>riority<br>ciety,<br>seeds<br>mson<br>plant<br>punnal                                                                                                                                                                              |

tion from the other species *p4-pi-lo-chou* is continued for ten days. Each GREEN DYES. of the decoctions is used separately, and on each occasion lime water is Green Indigo of China. The fabric is dipped in the former decoction seven to ten times added. and in the latter three times, but the fabric is allowed to dry between each immersion. The drying is effected on meadows where the cloth is spread out at about night-fall and left until noon of the next day. Only the side of the fabric exposed to the sun becomes coloured, from which circumstance it L inferred that sunlight is indispensable to the formation of Lo~ kao. The process of preparing Lo-kao as a pigment or dye-stuff (described above by Fortune) is thus quite different from the process of dyeing with the fresh barks as employed by the Chinese. In the former a fabric is used to remove the dye, the excess being brushed and washed off and then exposed to the sun on paper so as to cause the change necessary to its formation. In the latter the change effected by the sun takes place on the fabric, the exposed surface being dyed. In M. Michel's experiments with Rhamnus Catharticus, as with the Chinese Rhamnus barks, the surface of the fabric exposed became green coloured, but if prepared Lo-kao be used as a dye both surfaces of the fabric are dyed, since the tinctorial agent employed has already been acted on by the sun.

The berries of a species of Rhamnus are sold in Europe under the name of Persian Berries. These are largely used in calico-printing for steam-orange, olive, green, &c, and this dye exhibits certain actions under the influence of light analogous to the reaction indicated above in the formation of *Lo-kao*. This is especially seen when copper sulphate has been used as a mordant. The olive colour imparted by the berries gradually becomes deeper in colour, but after twelve months' exposure to light the olive green produced becomes as fast to light as vat indigo. These berries are obtained from several species of Rhamnus, wild or cultivated, in France, Spain, Italy, Turkey, the Levant, or Persia. In addition to the works named, the reader may consult the following:—*Crookes, Dyeing and Calico-printing*, 428—435; Hummel^ the Dyeing of Textile Fabrics, 366 i Spans' Encyclopedia 2 Balfour, Cyclopaedia; Linn, Soc. Journals, &c

### CHEMISTRY OF INDIGO.

#### THE EXPLANATION OF ITS TINCTORIAL REACTIONS.

The Indigo of Commerce varies greatly in quality and purity, and its value, therefore, depends upon the proportion of actual colouring matter contained. Thus good indigo, according to Mr. A. H. Allen, ranges from about 45. to 55. 6d. per Jb-the proportion of colouring matter being about 50 to 70 per cent. Good Kurpah (Cuddapah) indigo ranges from 2s. gd. to 35. qd. per lb, and usually contains 33 to 52 per cent, of colouring matter. Oudh is generally similar to Kurpah in price and richness. Good Java indigo contains from 60 to 80 per cent, of colouring matter, and ranges in price from 5s. to 6s. 6d. There are many low qualities of indigo as, for example, the so-called "Fig "Indigo, which sometimes contains only 6 to 9 per cent, of colouring matter. "From a list of the prices and richness of various parcels of indigo sold in London, it appears that the lower qualities usually fetch a higher price per unit of colouring matter contained than is the case with better kinds. On the whole, it may be taken that the unit of colouring matter in indigo has a present market value of about *id.* per lb, or perhaps, more strictly, 15–12 of a penny. There are many exceptions, however, as some dyers are will ing to pay rather more for a particular quality, which their experience or fancy leads them to prefer. In some cases, certain dyers will cons.der that Oudh indigo gives the best results, and they will buy Oudh indigo only; while others doing exactly the same kind of work, find that Oudh

|                         | will not answer their purpose, and will use only Bengal indigo, and so on<br>The dye-colouring matter of the commercial articles has been subjected to<br>the most careful chemical analysis, and, as stated, has received the "*" of<br><i>Indigotin</i> . The commercial article contains, however, in addition the sub-<br>stances known as indigo-red, indigo-brown, indigo-gluten, and a num<br>of brown residus products which have not as yet been fully determined.<br>Without entering into the history of the development of our knowledge A<br><i>Indigotin</i> further than has already been indicated, it may suffice to sthe-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formula C <sub>8</sub> H <sub>5</sub> NO (or C <sub>16</sub> H <sub>10</sub> N <sub>2</sub> O <sub>2</sub> ). It is insoluble in water, <i>at</i> , hol-<br>formitian supplus and partities at a boiling heat, but on cool-<br>maniline, also dissolve small quantities at a boiling heat, but on cool-<br>ing <i>Indigotin</i> is re-deposited : chlorine and hypchlorates destroy its blue coord.<br>Crookes remarks on the insolubility of <i>Indigotin</i> as follows : |
| METHODS OF              | METHODS OF DYEING WITH INDIGO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DYEING.                 | COTTON VATS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                         | The above phenomena, vulgarly called "reduction," requires ${}^{\text{the h3}}_{f}$ and ${}^{transmithermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermittermitte$                                                                                                                               |

| <b>ÆTHODS OF</b><br>DYEING.<br>axony Blue.       | tinting. The colours are fugitive, but their ease of application is a great recommendation, and animal fibres may be dyed on being simply steeped in the slightly acidulated hot extract solution. The colour is much brighter than can be obtained from a vat-dye, but it does not stand milling. Silk to be dyed with the extract is sometimes mordanted with alum, in order, on the addition of cochineal, logwood, or orchil, to produce reddish shades—purples or violets. Indigo-carmine is produced by the addition of sodium sulphate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Vats for<br>Woollens<br>and Silks.<br><b>311</b> | Indigotin is also applied to woollen goods by means of a vat contdirt-<br>ing a special preparation of white-indigo. These vats are prepared of<br>"set" in various ways, but in all, the indigo is reduced in the presence, ot<br>some organic substance such as woad, madder, molasses, bran, &c. Ane<br>organic material undergoes fermentation when macerated in water with<br>the application of heat. The hydrogen evolved by the fermentation<br>transforms the <i>indigotin</i> , and this is dissolved in the vat by the addition<br>of some alkali or alkaline carbonate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Woad Vat.<br>312                                 | The Woad Vat—The woad plant itself, formerly employed as a source of<br>blue, is now used entirely as a fermentation agent in the woollen vat, but it<br>is probable that cabbage leaves might be equally serviceable. The vat is<br>first partly filled with water, and crushed woad is then added, the whole<br>being well stirred and the temperature raised to $50^{\circ}$ or $60^{\circ}$ C. This <sup>tem</sup> j*j <sup>ra</sup> j<br>ture is maintained from 24 to 30 hours; bran and madder are now added<br>and half the total required quantity of lime. After being well stirred, the vat<br>9 covered over and left for 12 to 24 hours. By this time fermentation na <sup>5</sup><br>been established, the surface of the fluid becomes covered with a coppery-W <sup>u</sup> e<br>scum, and on being stirred the liquor is seen to be of a greenish yellow <sup>coro</sup> ? 6<br>interspersed with blue veins of restored indigo. If the bottom of the vat D<br>disturbed a froth will appear on the surface, and the sediment, if brougnt<br>up, will smell sour. A piece of wool dipped in the bath and then ex-<br>posed to the air is coloured blue. All these indications denote the favour-<br>able progression of fermentation, and it now becomes necessary to JI/AJf<br>the further stages under control. The remainder of the lime is <sup>adde</sup> T<br>by degrees, vigorously stirring the contents of the vat all the while. <sup>1</sup> Y<br>the course of 24. hours if the fermentation is checked by the addition of<br>lime, or if too slow it is accelerated by the addition of bran. The dyeing<br>power of the vat is maintained by the daily addition of bran. The dyeing<br>power of the vat is maintained by the daily addition of bran ana<br>every other day of indigo. After three or foir months, or when the vat<br>sediment becomes bulky, no further additions are made, but the vat is used<br>for lighter shades until its indigo is exhausted, when it has to be emptied<br>out and a fresh vat started.<br>The above account of a fermentation-vat has been compiled from<br>Professor Hummel's excellent work on the subject, and for fuller details |
| Potash Vat.<br>313<br>Soda Vat.                  | and quantities of the ingredients the reader is referred to the original text.<br><i>The Potash Vat</i> , which contains indigo, madder, bran, and carbonate ot<br>potash, is not so liable to get out of order owing to its not containing so<br>highly nitrogenous a substance as woad. It also dyes more rapidly and<br>gives deeper though duller shades of blue. The colour does not come oil<br>so much on milling with soap and weak alkalis. It is, therefore, best<br>adapted for very dark shades of navy blue and is better suited for silk-<br>dyeing than a vat containing lime. The best silk vat is, however, one in<br>which indigo is reduced by powdered zinc and ammonia.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                                  | The Soda, or German Vai contains indigo, bran (or treacle), carbonate of soda, and slaked lime.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| The Urine Vat is used by dyers who have to resort to vat dyeing or occasionally. It contains stale urine, and common salt, heated for seve hours up to $50^{\circ}$ or $60^{\circ}$ C. Madder is then added and indigo, fermentat being allowed to proceed as before until white-indigo is produced.                                                                                                                                                                                                                                                                                                                                                                                                                                             | nly ME<br>ral D                                                                                                                                              | THODS OF<br>YEING.<br>ine Vat.<br>315 |
| NATIVE VATS, OR THE PROCESSES of REDUCING INDIGO PURSUED<br>THE PEOPLE OP INDIA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | BY Na                                                                                                                                                        | tive Vats,<br>3l6                     |
| Though crude in comparison with the vats prepared in Europe,<br>native dyers of India are fully aware of most of the processes of render<br>indigo soluble, and in fixing it by making it again insoluble within<br>tissue of the fabric. The vat most generally preferred, however, is a<br>mentation-vat. A pound of powdered indigo is soaked with three pour<br>of lirne and four pounds of impure carbonate of soda in water; four our<br>of sugar are added. If fermentation does not commence in seven or ei-<br>hours, more lime and sugar are added, and if the weather be cold the<br>is heated to encourage the fermentation. When the reduction has tal<br>place the vat is used in the ordinary manner ( <i>Buck, Dyes and Tans</i> | ing<br>the<br>fer-<br>nds<br>ces<br>ght <sup>1</sup><br>vat<br>ken                                                                                           | ·                                     |
| North-Western Provinces),<br>In the Nasik Gazetteer an interesting account of indigo-dyeing,<br>practised in Bombay, will be found. "To prepare the solution of ind<br>the dyers have two vats—a salt vat, <i>khdra pip</i> , for dyeing cotton, in wh<br>poor indigo, and a sweet vat, <i>mitha pip</i> , for silk, in which good indigo<br>used." The vat employed is an open-topped wooden barrel or eart<br>vessel sunk in the ground, and large enough to hold 300 gallons of wat                                                                                                                                                                                                                                                           | ligo<br>lich<br>), is<br>hen                                                                                                                                 |                                       |

| METHODS OF<br>DYEING.<br>Sweet Vat.                | be not attended to the indigo rots, has an offensive smell, and is unfit fo<br>dyeing ( <i>Dr. Ndray an Daji, Dyeing in Western India, 23</i> ).<br>In Bengal sugar is used in only one or two districts as the fermenta-<br>tion agent. In Darjeeling the refuse water obtained in washing sheep<br>is employed in the vat. In Rajshahi district the twigs of Monnda<br>tinctoria are added to the vat, apparently much after the same manner ar-<br>madder is employed in Europe. In Malda the seeds of Cassia Tora are<br>added to the vat. This subject has been alluded to above in connection<br>with the manufacture of Indigo in South India and is apparently of much<br>interest, since the employment of these seeds is so widely known. For a<br>similar purpose apparently the seeds of a plant known as <i>icht-bicht</i> are<br>used in Chittagong ( <i>Dr. McCann, Dyes and Tans of Bengal</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Indigo-Dyeing!<br>and Calico-I<br>Printing.<br>319 | INDIGO-DYEING AND CALICO-PRINTING.<br>The principle of indigo-dyeing has been indicated by the foregoing<br>remarks regarding the chemistry of the drug, and the formation of dye-vats<br>The fabric or yarn is immersed in the reduced indigo solution for the required<br>with a sufficient amount of white-indigo. Care must be taken not to bring<br>the fabric or yarn above the surface of the vat when " hawking" it in the<br>fluid, nor of course should it be allowed to touch the sediment. If raised<br>above the surface, it will be at once oxidised and the portions so acted upon<br>will receive a different colour from the rest. Cloth dyes best in a vat in<br>which moderate fermentation is preserved. After the necessary degree of<br>immersion the fabric is hung up to drain, and is thereby exposed to the a in<br>when the oxygen combines with the excess hydrogen to form water, and<br>this evaporates away, leaving the insoluble particles of <i>indigotin</i> in <i>i</i> be<br>interior of each filament of the texture. If the exact shade has not be<br>obtained the process is repeated. The greatest difficulty is in 'egulating<br>the fermentation bath, and considerable experience is required to know<br>when it is right. Woollen materials should be first boiled well in 2007<br>purpose of allowing the damp fabric to dye evenly and prevents the ad-<br>mission into the vat of too much air which would oxidise the indigo-write,<br>Before beginning to dye, the blue scum should be taken off the surface off<br>the liquor of the vst; otherwise spots will be given to the parts of the tex-<br>ture coming first in contact. After dyeing, the fabric should be rinsed in<br>acidulated water and washed thoroughly. In order to remove every <sup>1</sup> A for the<br>fabric should be boiled in a solution of alum or bichromate of potash and<br>tartaric acid. Some dyers also regard a boiling of the dyed £° ds JL<br>barwood, sanderswood, or camwood as necessary to completely fix the<br>fabric should be boiled in a solution of alum or bichromate of potash and<br>tartaric acid. Some dyers also regard a boiling of the dyed £° ds JL<br>barwood, sanderswood, |

printing or pencilling white-indigo upon the surface. The\* alkali employed to hold the dye in solution is washed out as soon as the *indigogen* has been absorbed by the tissue and the oxidation produced by washing trans-

| forms the dye into its insoluble form, thus exhibiting the patterns printed.<br>"Fast-blue" prints are obtained by precipitating from a paste of indigo<br>and a strong reducing metallic oxide (commonly hydrated protoxide of<br>tin), a too rapid oxidation of the white-indigo being prevented. The paste<br>is printed on the fabric which is then passed through an alkali bath of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | METHODS OF<br>DYEING.<br>Indigo-dyeing<br>and Calico-<br>Printing. |
| lime-water or soda solution. The alkali replaces the oxide of tin, forming<br>a soluble combination of white-indigo, which penetrates and is fixed by<br>oxidation. "China-blue "* prints are somewhat similar. Indigo previously<br>pulverised is printed on the tissue and the fabric placed under the influence<br>of reducing agents; when absorbed the white-indigo is oxidised. But<br>parti-coloured goods may be produced having a blue ground colour by<br>either of two processes technically known as <i>resist</i> and <i>discharge</i> . In the<br>fornyir the fabric, prior to immersion in the indigo vat, is printed with a<br>substance which, either chemically or mechanically, prevents the <i>mdigogen</i><br>penetrating into the fabric. After being dyed blue on the exposed parts<br>the <i>resist</i> is washed off and the white patches printed with any other<br>colours or patterns. In the latter process ( <i>discharge</i> ) the <i>indigotin</i> of the<br>uniformly dyed fabric is removed by chemical agents which are printed<br>in the desired pattern. The mechanical <i>resists</i> , generally used, are wax<br>or pipe-clay (much after the manner in which the <i>Palamput</i> calicoes of<br>South India are dyed) and the chemical <i>resists</i> are powerfully oxidising<br>agents, such as salts of copper or bichloride of mercury, which convert the<br><i>indigogen</i> of the vat, coming in contact with the printed portions, into | Resists.<br>320                                                    |
| <i>indigotin</i> which is deposited mechanically on the surface, instead of being<br>absorbed into the substance of the fabric. <i>Resists</i> printed on a blue<br>ground and the fabric again plunged into the vat results in a pattern in<br>shades of blue. The <i>discharges</i> are in many respects inconvenient, as they<br>do not give sharp prints and very strong vats are required to prevent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Discharges.                                                        |
| running. Chromic acid is the best discharge, but chromate of lead is often<br>used. Red prussiate of potash and caustic soda also form a useful dis-<br>charge to indigo.<br><i>Defects.</i> —All fermentation-vats are subject to derangements by which                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Defects.                                                           |
| <i>Depects.</i> —An termentation-vats are subject to derangements by which<br>they become more or less useless. Deficiency of lime is the most common<br>cause, the fermentation being thus unchecked and allowed to proceed<br>until the liquor is useless. This may be recognised by the scum disap-<br>pearing, the liquor becoming muddy, and the escape of a disagreeable<br>odour. The only remedy is to heat the vat to 0,0°C and add lime. If<br>this does not check the fermentation the preparation is useless. Another<br>danger, according to Professor Hummel, is too rapid working of the vat.<br>The colours become faint and the liquor gives off an ammoniacal odour.<br>The third defect is too much lime. The indigo-white is precipitated and<br>the liquor becomes of a dark-brown colour, while the healthy odour and<br>the scum disappear. If noticed in time this may be corrected by the addi-<br>tion of a little ferrous sulphate or dilute sulphuric acid to precipitate the<br>lime in an insoluble condition.                                                                                                                                                                                                                                                                                                                                                                                                                                             | 322                                                                |
| TRADE IN INDIGO.<br>It is perhaps unnecessary to endeavour to carry the modern trade in<br>Indigo further back than one hundred years. The total imports into                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                    |

.`

It is perhaps unnecessary to endeavour to carry the modern trade in Indigo further back than one hundred years. The total imports into Great Britain were, in 1782, 495,100ft, of which the States of America furnished 161,216; the West Indies 64,309; British Continental Colonies 128,640; Flanders (Austrian) 78,070; Portugal 27,308; Asia 25,535 (including, of course, India); Ireland 6,373, and Spain 200ft. In the year following, the imports were 1,284,565ft, Asia contributing 93,047; the States of America 518,980; the West Indies 204,645, and 117,235ft from Holland. From that year the British imports steadily increased

| TRADE.<br>Restoration<br>of Indigo<br>Trade to<br>India.<br>324 | till 1788, they attained the magnitude of 2,096,91 lib, of which Asia furnished 622,691ft; the States of America 1,060,164; Spain 204,461, and the West Indies 94,550ft. In 1795 they amounted to 4,368,027ft, of which Bengal furnished 2,955,862ft. In a Despatch, dated 1792, the Board of Directors congratulated the Indian Government, that, as the British imports of Bengal Indigo increased, those from the Spanish and French colonies declined, while at the same time a large export trade from Great Britain to the Continent had been established. In 1790 the're-export trade amounted to close on a million pounds of the dye.<br>It may thus be said that in less than 20 years, from the date of their first effort, the East India Company, by the enlightened action they took, completely restored to India its indigo industry. It is also noteworthy that whereas the total imports of indigo into Great Britain were in 1782 lees thart half a million pounds, the production of a superior quality at a cheap rate, in Bengal, had so increased the demand that ten years later Great Britain alone received over four million pounds. This brilliant result is fully borne out by the statistics of the present indigo trade. The French and Spanish manufacturers have practically ceased to exist. In 1888 the United States of America furnished Great Britain with 123 cwt.; Central America with 6,769 cwt., and Holland gave to England a small amount, derived most probably from Java mainly. With the single Dutch exception, however, the other European nations that are annually shown as participating in the British supply may be viewed as re-exporting Indian Indigo* Practically nine-tenths of the Indigo trade is now Indian. Thus, for example, out of a total of 78,128 cwt. (8,750,336ft) of indigo, imported by Great Britain last year (1888), India furnished 69,416 cwt. The Philipp <sup>1</sup> TM <sup>6</sup> } |
| •                                                               | expand. It is doubtful how far any other country (except perhaps<br>China) could ever compete with India. We possess a complete $m \circ n \circ $                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Commercial Indigo. (G. Watt.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | INDIGOFERA<br>tinctoria.                                                                                                                                                                                                                                                                                                                            |

| months, vis., November to February; though it is lessened by the that the whole of the indigo intended for the foreign markets has left I by the end of March. The foreign transactions of each official year would seriously overlap the commercial. most important error, however, lies in the fact of Government figures b the gross weight of cases containing indigo, while the commercial are for weights of actual indigo. It would, in fact, be a safer mode of comparit therefore, to take the Government gross maund of 82ft as correspond to the commercial and the commercial are tweight in factory maunds of 74ftc—the differ being the weight of packages, &c, but merchants put down the differ in the two returns as equal to 25 per cent. While bearing in mind t sources of error, an average of several years would give a fairly trustwo mode of estimation, more so at all events than the actual figures for indigo trade of any one year. In 1813 Milburn stated that the European demand for indigo amo ed to three million pounds, but that, if required, Bengal alone might fur five times that amount. It is somewhat significant that the Indian duction is today a little over its prophesied possibilities. The aver annual exports of indigo from all India during the past ten years H been 134,798 cwt. (15,097,3761b). According to Messrs. Thomas & do not take into consideration. These sources of supply increase slig the returns for Bengal, but there exists a sufficient correspondence in commercial and official statistics to confirm the accuracy of both. According to the official returns of Bengal the production <i>flue</i> sets in the same time exports, whether by land or see, have averaged 9,460,8781b, thus leavin balance of 396,8571b in stock or available for local consumption. It se probable that the Bengal local consumption averages from 230,000 $400,0001b$ annually. A similar analysis might be worked out for Mad but it is believed the figures of trade in the four tables here given will diver a sufficiently comprehensive idea of the Indian indu | ndia<br>puld,<br>rnal<br>The<br>eing<br>rnet<br>son,<br>ding<br>ence<br>ence<br>hese<br>rthy<br>the<br>unt-<br>nish<br>pro-<br>rage<br>nave<br>o.'s<br>past<br>oab<br>hree<br>t of<br>tral<br>Co.<br>htly<br>the<br>ord-<br>nave<br>all<br>ng a<br>ems<br>6 to<br>ras,<br>con-<br>nay,<br>the<br>pro-<br>lass<br>d a<br>s of<br>ngly<br>nds<br>e on |

| 8,483 cwt., and Bengal 839 cwt. The coatwise EXPORTS during the speriod, were 9,584 cwt., valued at R 12,69,305. Of these exports Sind tributed 8,477 cwt., and Madras 1,038, the bulk of the former goin Bombay and of the latter to Bengal. The railway-borne trade she inter-provincial transactions of an even much larger amount than coast-wise. The total imports were 43,513 cwt. and the exports 44 cwt. Sind (including Karachi) received from the Panjab, for exar 5*703 cwt., and Bengal drew from the North-Western Provinces 2 cwt. The railway returns of indigo conveyed from district to di within each province was also very considerable, amounting to 9 cwt. A very large trade is also conducted by road and river, and haps a considerable annual production is consumed by the local configure produced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | con-<br>lg to<br>bwed<br>the<br>5,681<br>nple,<br>7,235<br>strict<br>9,235<br>per-<br>lyers                                                |
| where produced.<br>The trans-frontier trade is of some importance: the exports avera<br>value close on five lakhs of rupees, and the imports five or six thou<br>rupees. Of the exports across the frontier, the Panjab last year sent<br>maunds, valued at (^3,08,275, of which Kabul alone received more<br>half that amount, Kashmir and Bajaur each taking about R 40,000 v<br>of the dye.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | sand frontier.<br>2,916 <b>326</b><br>than                                                                                                 |
| It is however, practically impossible to arrive at an absolutely de<br>statement of the production and consumption of indigo in India, A<br>large amount is probably produced by primitive manufacturers and<br>up by local dyers of which nothing can be learned. The mover<br>of the dye from province to province both by sea and land overlap<br>other and are thus returned time after time. Thus a given quanti<br>indigo comes into Calcutta from Madras and is recorded in the coast<br>statistics. How much of that re-appears in the railway exports<br>Calcutta to the provinces of Upper India, or in the trans-frontier exp<br>or still further again and again in the transactions between district<br>district cannot be discovered, but each transaction is marked by the e<br>in marine, rail, road, and river returns. The large rail-borne quar<br>shown as conveyed from the districts in Bengal to Calcutta and also<br>the Provinces of Upper India to Calcutta figure again as the for<br>exports from that port. The only constant factor therefore, from<br>a definite conception can be drawn as to the condition of the trade i<br>nished by the total foreign imports and exports. The latter repre-<br>the surplus over-consumption for all India but is by no means the su<br>over local production. | very<br>used<br>nents<br>each<br>ty of<br>-wise<br>from<br>ports,<br>and<br>ntries<br>titles<br>from<br>reign<br>which<br>s fur-<br>esents |
| Inga dulcis, see Pithecolobium dulce, Benth.; Vol. V.<br>INK AND MARKING NUTS.<br>Various substances are used by the Natives of India in making INF<br>usual process being to mix some astringent principle such as galls or r<br>balans with one of the iron salts or oxides. The charcoal of rice wir<br>and gum arabic is, however, employed in Madras, and the Muhamma<br>generally prepare the ink they use from lamp-black, gum arabic, an<br>juicejof the aloe. The following are the plants specially mentioned a<br>juncts in the formation of inks :—<br>(1) Alnus nepalensis, D. Don. Bark forms an ingredient in nativ                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | nyro-<br>h lac<br>idans<br>d the<br>s ad-                                                                                                  |
| inks.<br>(2) Cordia Myxa, <i>Linn</i> . Stewart says the unripe fruit is used                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | as a                                                                                                                                       |

- (2) Cordia Myxa, *Linn*. Stewart says the unripe fruit is used as a marking nut, though its colour is less enduring than that from Semecarpus.
- (3) Phyllanthus Emblica, *Linn*. Fruits largely employed in making black ink.

- (4) Semecarpus Anacardium, Linn. f. The MARKING NUT is used by all the Indian washermen to mark the linen given them to wash. The juice of the unripe pericarp with lime forms the ink, but as it is apt to cause severe inflammation it has to be used with caution. Without the addition of lime it is often employed as ordinary writing ink.
- (5) Terminalia belerica and Chebula, the unripe fruits of either species, or indeed of any Terminalia, is combined with iron in making inK.
- (6) In schools, and even by the village merchant, black boards are  $em_{f}$ ployed, the ink being a white soft clay mixed with water ana applied with a reed.

## **INSECTS, SPIDERS, &c.**

Insects. With the exception of the silk-worm, the bee, the cochineal, and lac, and the gall-forming insects, the INSECTA are not of very great economic importance. They belong to the great sub-kingdom of Arthropod\* or Antichletta, windon Khynnfödern ~/zoologists: is Jdivided into two seations-" water breathing and air breathing. The former corresponds to the class Scorpions, and Mites), Myriapoda (Centipedes and Millipedes), and insecta (insects proper or articulated animals with three pairs of legs, borne on the thorax). The INSECTA are referred to three divisions—Ametaboia, Hemimetabola, and Holometabola, according as they attain the adult condition without passing through a metamorphosis, or have an incomplet or a complete metamorphosis. The insects of the first division are parathe Hemiptera, Orthoptera, and Neuroptera. The Hemiptera are para-sitic on plants and animals such as the Plant-lice (Aphides), Field-bug (Pentatoma), the Cochineal, Lac, and Wax-forming Insects (Cocci), &c. To this order belong some of the gall-producing insects such as those on the lime leaves and the peticles of the puplar. Chinese galls of commerce are stated to be produced by Aphis chinensis (on Rhus semialata) and the \* n e Pistacia galls are known to be formed by Hemipterous insects. Orthoptera includes the Crickets, Grasshoppers, Locusts, Cockroaches, &c. Although some of these are eaten by man, interest in them is more connected with the destruction they often effect to crops. The Migratory Locusts (Acrydium migratorium) of Africa and Southern Asia causes  $\mathfrak{S}_{\mathfrak{L}}^{\mathfrak{v}}$ . S $\mathfrak{L}^{\mathfrak{v}}$  as  $\mathfrak{S}^{\mathfrak{alnst}}$  which human ingenuity has practically proved power Ant-The Neuroptera are the Dragon-flies, Caddis-flies, May-flies, the most lion, and Termites. The last mentioned, the white-ants, are, in imparts of India, highly destructive to timber. They live in communities like the Bee and the true Ant (see Hymenoptera), but the workers are individuals of no fully developed sex, whereas among the ants they are undeveloped females; on emergence from the egg the young termite does not pass through a quiescent stage.

The third division Holometabola includes all the insects that pass through a complete metamorphosis, *i.e.*, they exist in a larva stage between the egg and the perfect condition. The orders embraced by this division are Aphaniptera-the Flea and the Chigoe, Diptera (one of the largest orders of INSECTA embracing the House-flies and Flesh-flies, Gnats, Forestflies, Crane-flies, Gad-flies, &c.; Lepidoptera— the Butterflies and Mothsy the most beautiful and, as embracing the silk-worm, the most useful of an insects; Hymenoptera-the Bees, Wasps, Ants, Ichneumons, Saw-flies; ace.; btrepsiptera, an order of small parasitic insects found on bees and other Hymenoptera; and lastly, the Coleoptera or Beetles. | Commercial Classification of Insects. (G. Watt.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | RODUCED<br>Plants                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| Many of the Hymenoptera are of considerable use to man such as<br>the bees and the gall-forming species, of which Cynips gallae-tinctoria,<br>forms the Oak-galls of commerce.<br>The above sketch of the classification of Insects may help to bring out<br>the natural affinities that should exist in an arrangement of the Economic<br>Products derived from the insect world. But the following popular and<br>commercial classification may be given, as it will serve to direct the reader's<br>attentior to the positions in this work where fuller details may be found :—<br>(1) Resin, White-wax, Bees-wax, &c—These products are formed by<br>Hemipterous and Hymenopterous insects See Lac (also Coccus), Wax,                                                                                          | INSECTS.<br>COMMERCIAL<br>CLASSIFI-<br>CATION. |
| <ul> <li>Honey, Oils, &amp;c.</li> <li>(2) Dyes and Tans.—These are afforded by Hemipterous, Dypterous, Hymenopterous, and Coleopterous Insects. See Coccus, Galls, &amp;c.</li> <li>(3; Fibres.—The most important insect fibre is, of course, SILK (which see), but as a curiosity it may be added that some of the spiders spin a web of such strength as to be possible of utilisation as a textile.</li> <li>(4) Medicine.—The beetle known as the Spanish-fly and the Cochineal are the chief medicinal insects. See Cantharis and for Indian substitutes see also Mylabris. The distillation of ants yields Formic acid. Galls are also employed medicinally, and the beetle Melee trianthema is sometimes collected for its medicinal oil.</li> </ul>                                                        | 329                                            |
| <ul> <li>(5) Food.—The most important food substance afforded by insects is, of course, Honey (which see, as also Bees). Grasshoppers, Locusts, and Termites are eaten, and according to the Rev. A. Campbell, the red-ant is by the Santals viewed as edible. (See ANT-GREASE.) Many of the aphides also cause the excretion of Manna (which see). In Burma a grub found in palms is considered a great luxury by the Burmans and Karens.</li> <li>(6) Ornament.—The wing- cases of beetles, but especially of Buprestis viltata, are employed for ornamental purposes, and a considerable trade is done in these., They are used to ornament <i>khas-kkas</i> fans, baskets, lace, muslin, &amp;c. The brightly coloured back of an Ichneumon is often placed on the foreheads of married Hindu .women.</li> </ul> |                                                |
| <ul> <li>(7) Pests.—A large number of Insects belong to this section, for a description of which the reader is referred to the article Pests in another volume, and to the remarks under Insect diseases in the articles on Coffee, Cotton, Indigo, Rice, Tea, Wheat, &amp;c.</li> <li>(8) Destructive Insects.—In this section has to be mentioned the whiteants, weevils, wood borers, &amp;c. Although these mostly attack dead wood or grain, they have been described along with those that infest living structure.</li> </ul>                                                                                                                                                                                                                                                                                 |                                                |
| (9) Scavengers.—Excreta injurious to man are buried deep in the earth by the useful dung-beetles which belong to the genera Coprida and Dynastida. The Necrophaga are carrion feeders. The scavenger beetle of Burma is not a pellet roller; it selects for its abode a bed of ordure which it excavates and carries to a chamber two or three feet below the surface. (10) Sacred Insects.—The Hindus do not reverence any insect, though many other animals are held sacred together with a large list of plants. Among some of the aboriginal tribes, however, beetles are viewed with religious feelings. The Máis of the Rajmahal hills bury in the ground small vessels of water into which they place the large black scavenger and other beetles.                                                            |                                                |
| INTRODUCED ECONOMIC PLANTS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 330                                            |
| To give an exhaustive list of all the introduced plants found in India would occupy many pages and, perhaps, after all, serve a very unimportant purpose—at least from an economic point of view. Of the more important                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                |
| I. 330                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                |

It will suffice, however, to convey some idea of <i>A Sf A j j</i> debtedness to other countries and more especially to America. 1 he <i>f i j j j j j j j j j j</i></li></ul> |
|                    | INULA, Linn. / Gen. PL, II, 330.<br>In India some 20 species of Inula occur, many of them extremely abund-<br>ant plants, as, for example, I. Cappa, DC, a shrub met with on the Temperate<br>Himalaya from Kumaon to Bhutan, chiefly between 4,000 and 6,000 feet, but<br>in some localities ascending <sup>1</sup> even to 10,000 feet; also distributed to the Khasia<br>Hills, Manipur, Burma, China, and Java. No distinct record exists, however,<br>of any of these being used as substitutes for the Elecampane, though by »<br>mistake in synonymy, apparently, some writers regard the species below<br>as the Indian form of that drug. In Kashmir the root of I. Roylcana»<br>DC, is used to adulterate kút (see Saussurea Lappa).                              |
| 333                | Inula racemosa, Hook./.; Fl. Br. | MEDICINE.    | resembling Orris and Camphor; in flavour they are slightly bitter, and<br>their action is as a mild tonic. They also possess diaphoretic, diuretic, ex-<br>pectorant, and emmenagogue properties. By the ancients Elecampane was<br>much employed in the complaints peculiar to females, and in America the<br>drug is still resorted to in the treatment of amenorrhoea, while it is found<br>to be sometimes beneficial in chronic diseases of the lungs when complica-<br>tions of general debility or want of tone in the digestive organs exist. In<br>France #nd Switzerland it is used in the distillation of Absinthe; see Arte-<br>misia Absinthium, Vol. I., 323.<br>[odine] see Barilla, Vol. I., p. 399, also Fucus, & Gracilaria, Vol. III.,<br>451, and IV., 174.                                                                                                                                                       |

| Root.<br>338 | Medicine.—According to Ainslie the LEAVES and tender STALKS are<br>used by the natives of Southern India as a demulcent. They are em-<br>ployed in decoction and electuary in conjunction with some mild oil, in<br>preparing a cool liniment for the head. Of the decoction, he adds, about<br>an ounce and a half is given twice daily. Dr. Moodeen Sheriff (in his<br>forthcoming work) says it is demulcent and refrigerant and is useful in<br>some cases of gonorrhoea and of scalding of urine. According to the Rev.<br>A. Campbell the Santals employ the ROOT in bowel complaints of children<br>accompanied with black excreta. In the <i>United States Dispensatory</i> it is<br>stated that the root of a species of Ionidium has attracted some attention                                                                                                                                                               |
| 339          | in the treatment of elephantiasis.<br>Chemistry.—According to the <i>Pharmacographia Indica</i> , "The root contains an alkaloid soluble in ether, and alcohol, not easily crystallized; its solution in the form of a salt, which it readily forms with the mineral and vegetable acids, is precipitated by potassio-mercuric iodide, iodine in potassium iodide, tannin and the alkalies. It also contains quercitrin, allied to the viola-quercitrin of Man deli n; and another colouring matter soluble in water, but insoluble in amylic alcohol, an acid resin, and quantity of mucilage and oxalates."<br>Sir W. O'Shaughnessy failed to detect the least trace of the active principles emetine or violine in samples of the plant procured from the Koyal Botanic Gardens, Calcutta.                                                                                                                                         |

|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
|                                                                                                                                                               |                      |
| Food.—The young SHOOTS, LEAVES, and ROOTS of this floating aqua-<br>tic species are universally eaten as a vegetable in the region m which                    | FOOD.<br>Shoots.     |
| it is found. In Lower Bengal, where a superabundance of stagnant                                                                                              | 345                  |
| water occurs, in the form of tanks, it is to be found throughout the year, but<br>in other parts of the country it is more or less cultivated. At times bunds | Leaves.              |
| are made across the outlets of marshes to prevent their being drained, and                                                                                    | Roots.               |
| cuttings of the plant are then placed in the mud all over the swamp. In<br>this semi-cultivated condition crops are obtained, where otherwise the plant       | 3*7                  |
| could scarcely exist. In Madras and Ceylon, however, it is regularly culti-<br>vated and trained to exist on fields not inundated. In a circular letter       |                      |
| addressed to Local Governments, in which information was called for on                                                                                        |                      |
| the Economic Products described in this volume, full particulars were<br>rerprded regarding this vegetable. The following abstract of these replies           | 1                    |
| may be here given :                                                                                                                                           |                      |
| Bengal.—Found wild in tanks: is regularly eaten as a vegetable.                                                                                               | {                    |
| Assam.—An aquatic weed which grows in almost all tanks and jeels or                                                                                           |                      |
| low-lying tracts covered with water. The weed generally begins to grow<br>with the commencement of the rains and remains till January or February             |                      |
| when it begins to wither on the top of the water. In <i>jeels and</i> tanks where                                                                             |                      |
| the water never dries up, this weed is found all the year round. The leaves                                                                                   |                      |
| and stems are gathered, cut to pieces, boiled in acid, alone or with fish,                                                                                    | 1                    |
| and eaten by the Assamese with rice. They are supposed to have a very cooling effect if boiled on the previous night and eaten the first thing in             |                      |
| the morning. The weed is considered to be very wholesome for females                                                                                          |                      |
| who suffer from nervous and general debility.                                                                                                                 |                      |
| <i>Madras.</i> —In the Madura District alone the extent of cultivation is said to be about 600 acres. The kind produced is to a large extent that with        |                      |
| white roots. It is sown in August and harvested from December to March,                                                                                       | ļ                    |
| The creeper is cultivated in Padugat, Senval, and Karisal soils. The land                                                                                     |                      |
| is ploughed three times, manured, and ploughed again, then plots are                                                                                          |                      |
| formed and watered. Thereafter the creepers are planted in small pieces<br>of six inches at a span's length from each other. Ten loads of the creeper         |                      |
| are required to plant one acre. The creepers are first grown amidst <i>ragi</i> .                                                                             |                      |
| Weeding is done after one month. The cost of cultivation is R20. The roots are sweet and after being boiled largely eaten.                                    |                      |
| Burma.—In the Pegu District it is found growing wild as a creeper<br>floating on tanks, fields, streams, &c. The Burmese eat it, and it is                    |                      |
| so much a favourite that many persons are engaged collecting and selling                                                                                      |                      |
| it. The price of a bundle is one or two pice, and being very plentiful<br>only a small profit of a few rupees can be made on it.                              |                      |
| In the Akyab District the area of cultivation is about 30 acres. It is<br>first a spontaneous growth in tanks, swamps, &c. Slips are broken off and           |                      |
| about June are planted out. It is fit for use in three weeks and continues                                                                                    |                      |
| growing nearly throughout the year so long as there is water. Cost of cul-                                                                                    | .                    |
| tivation about Rio or R15 an acre. Profit about R60 or R70 per acre-                                                                                          |                      |
| Portions of land are embanked by which the water is kept from escaping<br>and the cuttings are then put down. It is used as a vegetable.                      | \$                   |
| In the Mandalay District it is found in abundance in tanks and marshy                                                                                         | r <b>i</b>           |
| localities, and is extensively used as one of the most favourite vegetable diets.                                                                             |                      |
| In the Thongwa District it grows wild and is largely eaten by the people. In the Maubin Sub-division the annual produce is about 1,000 baskets.               |                      |
| In the Bhamo District it is commonly met with and is much used by<br>the natives in^making curries for which the leaves and tender tips are em-               |                      |
| ployed. Similar information has been communicated regarding the Upper                                                                                         |                      |
