THE ECONOMIC PRODUCTS OF INDIA.

The Cotton-vielding Plants. (Watt & Murray.) GOSSYPIUM.

GOSSYPIUM, Linn.; Gen, PL, L, 209.

A genus of the Natural Order MALVACEAE, the species of which are widely distributed on both sides of the Equator, and in both hemispheres. On the North they extend, under cultivation, as far as the shores of Southern Europe, and on the South to the Cape of Good Hope.

The limitation of the forms of these very important cultivated plants, to definite species, varieties, hybrids, and races, has much perplexed writers on the subject. The vast importance of the floss, obtained from the seeds, has induced an extensive cultivation, and that, too, under almost every condition of climate and soil. The ease with which climatic conditions originate local forms, and the rapidity with which hybrids are produced, have *both* combined to bring about a degree of complexity that perhaps exists with no other agricultural crop. The departures from original specific conditions are in fact so great as to render it almost impossible to determine whether the cotton-yielding plants have been derived from three or more species, or are all mere develipments from a protean ancestor which possessed indigenous Asiatic, African, and American representatives. This being so, the authors have found it undesirable, at present, to attempt more than a brief review of the botanical literature of the subject. They are conscious that many ambiguities and even errors may be thereby reproduced, but unavoidably so, for, until a thorough and original investigation has been conducted with the living plants, nothing definite can be published regarding the cultivated cottons of India The classification which follows may, however, be accepted as denoting some of the chief forms recognised by us, but the accuracy of the relegation of vernacular names and of the restriction of special properties to definite forms, is open to the gravest doubt. This is due to the authors having been practically limited to a compilation from published works and official correspondence. The primary object of the present effort may in fact be viewed as an attempt to suggest some of the main lines on which a scientific classification of the Indian indigenous and exotic cottons, and of their hybrids, might in the future be conducted, rather than to produce a treatise professing originality. It must, however, be admitted that no real good can be

This knowledge could doubtless be arrived at after the different forms of cotton had been scientifically worked up, and the degree of their hybridisation and the nature of *that* hybridisation clearly established. Indeed, it is at present impossible to write with any degree of confidence regarding¹ this—one of the most important of Indian crops,—since it is often difficult to know what torms are referred to by writers who employ local and vernacular names only, when discussing their properties. *I* hus, for example, a District Officer writing of *Nurma* cotton may be understood to be speaking of some of the forms of G. **arboreum** or of some hybrid between that species and **G. herbaceum**— *Deshi* cotton with purple instead of yellow flowers. Indeed, it seems highly I

ri=

GOSSYPIUM*

The Cotton-yielding Plants;

improbable tfiat any form of Indian cotton can be said to belong, strictly speaking, to the Linnean species, **G. herbaceum**. **On** the other hand, nearly every writer on Indian cotton has denied the existence of **G. arboreum** as **a** field crop, whereas the chief cotton of Eastern and Northern India seems undoubtedly to be a foFm of that species. In fact, in this distinction lies the chief difference between the Indian cottons of the Eastern and Western pennr sulas, the latter being mainly derived from a form allied to, but (juite distinct from, **G. herbaceum**.

sulas, the latter being mainly derived from a form allied to, but (Juite distinct from, **G. herbaceum**. Much has been done to discover the soils suited for cotton generally, and under orders of Government, many valuable experiments have been made, with exotic forms. What would appear to be the foremost and most essential enquiry has, apparently, however, been entirely neglected, namely, a scientific and exhaustive investigation into the existing conditions of Indian cotton. Until this has been done experiment can be but blind groping in the dark, which by chance may now and then fall upon facts of importance, but only after needless expenditure of time and money. To effect improvement in the indigenous cottons would of necessity confer a more lasting benefit to the country than even success in acclimatisation of exotic forms. To accomplish this, the endemic cottons must first be worked up. The climatic and other causes which tend to preserve or destroy good or bad properties must be thoroughly established. The influences of hybridisation must be worked out on a scientific basis, by testing the strength of strain, from this species or that, best suited to the environment. The tendency of retrogression from a prized hybrid to either ancestor should not be a matter of periodic deprecation; it should be understood, and, if possible, prevented or the exhausted stock promptly replenished. When experiment and study have furnished the required data on which to act, it will almost for certain be found, that to preserve the cotto* of a province or district up to **a** required standard, specially grown and artificially hybridised stock will be imperatively necessary. Indeed, the establishment of nurseries or seed farms, for this purpose, on a more rational basis than heretofore attempted, would, in all probability, prove the greatest reform possible for the cotton industry of India. When the quality of stock has been improved, attention might hen be turned to the modes of cultivation and methods of cleaning the fibre, but

It will be observed by a comparison with what **Dr. Maxwell T. Masters** has written that, in discussing the forms of **Gossypium,the** authors have on the whole followed botanically (as is customary in this work) the classification of the *Flora of British India*. **Dr. Masters** recognises four species; — **G. Stocksii Can** indigenous plant met with on the limestone rocks of the Coast of Sind); **G. herbaceum** (the chief source of the so-called indigenous *or deshi* cultivated cottons); **G. barbadense** (the American cotton); and **G. arboreum** (the tree cotton, which, according, to **Masters**, is probably a native of Africa). Dr. **Masters**, and following him many other authors, incline to the view that **G. Stocksii** is the wild form, from which the cultivated **G. herbaceum** has been derived. As opposed, however, to this it may be pointed out that, while the description of the leaf of **G. Stocksii** (as given by **Masters**) would in part support that view, its naked seed and laciniated bracteoles point to an affinity **to G. barbadense**. ^ This so-called wild species is only found, however, near the coast, and hence it may prove but an acclimatised form or possibly one of the numerous hybrids that undoubtedly exist in India. **TodarO** seems, however, to have advanced a new theory regarding the Indian cottons. The vast majority **of the** "mportant growths, he informs us, are hybrids, not true species, hence unaer altered conditions, as, for example, on being removed from one district to another, they manifest a strong tendency to depart from their recognised and valued properties. He has further described many forms as species between which his hybrids have been produced, *and he practically excludes* **G. herbaceum** *from being an Indian species*. Of his species he urges, for example, that

The Cotton-yielding Plants. (Watt & Murray.) GOSSYPIUM.

G. Wightianum has a stronger claim to being recognised as a truly indi-genous Indian plant than G. herbaceum. A variety of G. herbaceum, viz., microcarpum, he informs us, is, however, frequently met with, as also a second variety, G. obtusifolium, but the typical form of G. herbaceum» according to Todaro, does not occur in India. His variety, microcarpum, he affirms, is the Dhnllera cotton of merchants, a plant which, like G. neglectum, Tod, (referred by most botanists to G. arboreum), readily hybridises with G. Wightianum. These hybrids constitute the better class of Indian cottons, such as the Hinganghat, Oomraoti, &c. Dr. Masters follows the usual acceptation of the species G. herbaceum ; and, doubtless according to him, G. Wightianum would be regarded as a variety or hybrid between that species and one or other of the forms of G. arboreum. In *Indian Herbaria* G. Wightianum, Tod., is often named G. herbaceum, var. hirsutum; this is the case, for example, with Kurz's specimens from Pegu in the Calcutta Herbarium. The plant is certainly mote densely hairy than **G. herbaceum**, and the hairs are stellate, which gives it a velvety and ashy appearance. It seems, in fact, probable that much of the confusion regarding **Todaro's** species is due to its having been spoken of ultimately as G. **hirsutum**, *Linn.*, **a** plant to which it has little or no affinity. There is probably no doubt that, whether recognised as a hybrid or species, **G. Wightianum** is of the greatest importance to India, whether much more so than either **G. herbaceum** or **G. arboreum** between which even much more so than either G. herbaceum or G. arboreum, between which in many of its characteristics it is intermediate. **Todaro's** experiments would, however, support the theory of G. Wightianum being an independent species. The hybrids produced with it from G. neglectum or G. herbaceum, var. m microcarpum, were fertile and afforded seed which, in some cases, yielded cotto of a superior quality, but in a ye^A or or two these hybrids gradually lost their merit (if not carefully cultivated), and reverted, in the majority of cases, to G. neglectum, more rarely to G. Wightianum. Experimenting withG. herbaceum and G. Wightianum by growing them in sterile soils and without irrigation, **Todaro** found the latter species to preserve its characteristics even more persistently than the former. Further, he noted that the good qualities of a hybrid were longer maintained when it was grown at a distance from either of its ancestors.

Todaro has, in a like manner, suggested **a** line of enquiry with **G. arboreum**, of the greatest practical importance. He isolates a condition which he designates **G. neglectum** from **G. arboreum**, *Linn*. According to **Todaro**, **G. neglectum** has played a far more important part in the Indian cotton question than the true **G. arboreum**. He cites the following synonyms and plates for his new species:—

G. neglectum, *Tod.*, with the synonyms **herbaceum** (*var.* China cotton of Roxburgh and of Royle, *non-Linn.*); **G. herbaceum**, *Wight*, *Ic.*, t, n; **G. arboreum**, *Parlatore*, *in part*; **Cudapariti**, *Rheede*.

Under his species he also forms a variety with the name **Roxburghianum**, and mentions the following synonyms for that:—G. herbaceum (*var*. Dacca Cotton, of Roxburgh); and G. indicum (*var*. Dacca Cotton, of Royle).

G. neglectum, thus isolated from **G. arboreum**, differs chiefly in being sub-herbaceous, in having broader, less pointed segments to the leaves, and in possessing an acutely pointed ovary. The type form of **G. arboreum**, *Linn.*, is more arborescent, has the segments of the leaves (**Todaro** affirms), bristle-tipped, with the fruit rounded. But in **Parlatore**'s picture, cited as in part **G. neglectum**, the flowers are purple, whereas in *Royle*s III. Him. Bot.*, *table 23, fig. i* (which is *Wight's Ic, t. IT.*, quoted above), the flowers are shown as yellow with a purple centre. **Todaro** states that while **G. arboreum**, *Linn.*, occurs only near temples and in gardens, **G. neglectum** is extensively cultivated as a field crop, and is in fact the chief source of the so-called Bengal cottons of commerce. It is said to have always yellow flowers with a purple centre, and in this respect resembles **G. Wightianum** and other Indian cottons. Hence it would appear probable that all the purple-flowered field cottons of

»^A

GOSSYPIUM arboreum.	The Indian Arboreous Cottcns.
	wrote, ^w is a perennial plant, lasting for four or five years or more. It grows in every kind of soil; but attains perfection only in the light, sandy, gord! lands. The wool is fine, silky, of considerable strength, and fully an • inch long. Hedgerows, gardens, and groves of trees about the abodes of devotees and temples, are the places where the plant is found. Muslins and turbans are made from it. Since the introduction of European cloth, the culture of this cotton has almost entirely ceased. Its yield per acre is estimated at one hundred pounds of clean cotton in the first year, and in the second at from three to four hundred pounds. The great hin- drance to its cultivation is the fact that it requires protection throughout the year. The price of this cotton in the market at Broach is always double that of the common country article. But there are never more than a few pounds procurable!' In the <i>Broach Gazetteer</i> it is added to the above that " <i>Nurma</i> or <i>deva kapas</i> (Gossypium religiosum), would seem to be grown only to a small extent, chiefly near temples and the dwellings H ascetics. It is used in making the caste thread (<i>Jandi</i>). [#] Before passing from this subject it may be pointed out that the above opinion as to the value of <i>Nut ma</i> cotton, is most probably greatly over-estimated. A far more serious error has, however, been made in regarding one of the conditions of this species as a form of G. herbaceum. This has been cleared up by Todaro, who has isolated as species many forms hitherto viewed as but cultivated races. Some of these he has associated with G. arboreum, others with G. herbaceum. While viewing Todaro as having materially advanced the study of the species of Gossypium, we are not pre- pared to agree entirely with him that G. Wightianum and G. neglectum are good species. They are perhaps at most vanetios, if, indeed, they are anything more than hybrids, derived from the two originally Asiatic (or Old World) species, represented by G. arboreum and G. herbaceum. But, whether species, v
3 Conf. with pp. 8-14; 63; 102; 103; • 19; 134; 142.	ed as follows: — n G. arboreum, proper. DIAGNOSTIC CHARACTERS.—Arborescent, cultivated in 'gardens only or near temples; not a regular field crop. Leaves, 5-7 lobed with an extra tooth in the left side sinus (or both sides) of the central lobe; tnick, leathery, sub-glabrous or with short, abortively stellate hairs on the leaves and longer hafrs on the petioles and young stems: lobes bristle-tipped: petiole long, rigid: <i>stipules</i> falcate. Inflor- escence axillary, generally one-flowered; peduncle about \$ the length of the petiole, but jointed above the middle, bearing a small leaf and two stipules at the joint. <i>Flowers</i> small, purple, a little less than twice the length of the bractcoles; brae- teoles medium-sized, base with round ears, apex ovate, acute toothed or sub-entire. Ovary rounded; seeds with greyish black velvet underneath the floss. Todaro figures this plant, as well as C sanguineum Hasskard on Tab'o
	Todaro figures this plant, as well as G. sanguineum, <i>Hasskarl</i> , on Tab'e I.: we regard both these as representing the Linnean plant. The differences in sanguineum are very slight '.—purplish stems, petioles, and bracteoles; lobes of the leaves scarcely constricted at the base, and lower pair much smaller than the others; bracteoles, as a rule, more deeply toothed. Wight's /*, t. 10 (taken from <i>Royle, III. Him. Bot., t. 23, f. 2)</i> , is a very indifferent representation of G. arboreum; infact in hairiness and shape of bracteoles it more nearly resembles the form indicated above as G. sangiineum, $H < isskarl$. G. arboreum is the <i>Nurma</i> or <i>Deo</i> cotton of most writers.

densely coated with long spreading* hairs, and, if hybridised with G. Wightianum, having stellate hairs as well: <i>stipules</i> broad. linear. <i>Inflorescence</i> on short lateral broads 2.4 flowered.	4. Conf. with 9 pp. 8-14; 9 8 102; 111; 118; 129; 134; 143; U7-
An excellent plate of this plant will be found in "The Field and Garden Crops "under the name of G. herbaceum. Par latore's plate of G. arboreum represents, on the whole, the Garo long-boiled condition of G. neglectum except in the colour of the flowers, and Wight's A?., $t.11$ (taken from <i>Royle, Ic</i> $t. 23$, $/\dot{w}$), is a good illustration, except in the fact of the in- florescence being shown solitary flowered, which it rarely is in typical conditions of this species—the <i>rad hi a</i> and <i>martna</i> cotton of Upper India. Todaro says that, having cultivated this plant for fifteen years, he never saw it with red flowers but always yellow and of a brighter tint than in G. herbaceum or G. maritimum—more resembling in fact the flowers of G. Wightianum. But Roxburgh's Dacca cotton, which Todaro refers to this species, has the petals tinged with red. G. neglectum is extensively cultivated in Bengal, the North-West Provinces, and the Panjab, con- stituting to a large extent the so-called "Bengals" of commerce.	Conf. with p. 60.

Habitat.-The typical condition of this species is a low tree or shrub, met with in garden cultivation throughout India. Except, perhaps, in a state of hybridisation it rarely occurs as a field crop, but, as explained above, it seems probable the purple-flowered indigenous cotton crop, mentioned by many writers, is of this nature. The chief commercial form of this species is, however, the plant isolated by Todaro under the name of G, neglectum.

٦

GOSSYPIUM arboreum.	The Indian Arboreous Cottons.
CULTIVA- TION. 6	CULTIVATION. 6. neglectum is existively cultivated as a field crop. It has bright yellow flowers, and deeply palmately segmented leaves, which in shape are scarcely distinguishable from G. arboreum proper, except in that they are more herbaccous and very much more hairy. How far G. neglectum, Tod, may, by future observers, be confirmed as of specific value, we are not at present prepared to affirm. It seems, indeed, quite likely that it may prove but a hybrid between G. arboreum and one of the plants be- longing to the series which we prefer to continue designating G. herba- ceum. But whether species or hybrid, there is nothing gained, but, on the species Todaro refers all the China and Dacca cottons described by Roxburgh as forms of G. herbaceum, but while some of the Dacca cot- tons seem to be of this nature, others most certainly are not. There is, however, a much stronger taint of G. neglectum in the cottons of Eastern and Northern than in Western India, where G. Wightianum becomes the Todaro's description of G. neglectum, and the cottons of the Santal fordaro's description of G. neglectum, and the cottons of the Santal sountry are very similar, though they differ, not only from the Garo cot- who has kindly furnished admirable botanical specimes of the two cottor- sof Manbhum, informs us that they are grown at different seasons, and are other. The Rev. A. Campbell, of the Santal Mission, who has kindly furnished admirable botanical specimes of the two cottor- sor of the homestead lands. It flyvers in November and yields a larger frop than the former (<i>Bhaga</i>), but, as it requires a richer soil, is much less this is more frequently met with from 2 to 3 feet in height. Mr. Campbell divisibed a sample of this we are unable to say what it may be : it is, the flowes is obstich if there share earbore as sufficiently certi- strong and <i>Budh</i> i as seen in the herbarium is, however, so slight the simposible to give a discust the synom as furgued. 	a <mark>rboreum.</mark>
frequently made some twenty or thirty years ago, of assigning to this spe- cies the name G. religiosum, Roxb., but they call it by its most general ver- nacular name Nurma and speak of it as " arboreous, slender, hardy, har- ing the habit of a tree; cultivated rather extensively in the North-West Gujarat as a triennial (?), also in Sind. It derives its name Deo kupas' from being most extensively used for the sacred thread of the Banians, Monj." There would appear to be little doubt that the plant referred to above was a form of G. arboreum. With reference to the remarks below, on Hove's red-flowered cotton of Bombay, it is interesting to notice that Dalzell and Gibson's Gujarat field crop of G. arboreum is very pro- bably one and the same as that described by Hove in 1787. The Transactions and Journals of the Agri-Horticultural Society of India teem with papers and reports on cotton, but only from about the year 1850 do these deal at any length with the indigenous growths. The fof Towing passages may, however, be given in this place as presumably allud- ing to G. arboreum. So long ago as 1837 a Mr. D. F. McLeod of Sconf (Central Provinces) furnished the Agri-Horticultural Society with two samples of tree-cotton, both of which appear to have been G. arboreum, £., as defined in the <i>Flora of British India</i> . These were then known as <i>Munnooa</i> and <i>Deo</i> . The former was a green and the latter a black seeded condition. They were perennials and "yielded their cotton in the hot "These varieties are planted," says Mr. McLeod, *' by the natives near their dwellings, with a view to shelter, and the produce is chiefly used for mak- ing Brahminical threads. The <i>Munnooa</i> is also cultivated extensively in fields on the ranges east of Mirzapore." It may be surmised that the <i>Munnooa</i> totton of the above passage was G. neglectum, <i>Tod.</i> , and the <i>Deo</i> , G. arboreum, <i>L</i> . In 1842, an interesting enquiry was instituted into the subject of the Chanderi (Gwalior) cotton, from which the once famous muslins were made. This was at fir	Cultiva- Tion.

GÖSSYPIUM arboreum.	The Indian Arboreous Cottons.
CULTIVA- TION.	Indian tree cotton. Peruvian cotton, for example, is, like G. arboreum, frequently met with near temples and grows into a large bush or tree. Mr. Blount, Government Cotton Planter, in a report (1845) on the cottons which he found the natives cultivating in Goruckpore near Benares, mentioned, however, what appears to have been the same two forms of G. arboreum. These were known as <i>Bogali</i> and <i>Nurma</i> . The former, he wrote, was grown as a field crop, being sown at the commencement of the rains, and the latter raised near huts only. Both these plants produced their fibre in
Conf. with p. II.	February and March. The ordinary cotton of the district—that most ex- tensively cultivated—he contrasted u ith these, stating that it was known as <i>Kukli</i> . It was planted in February and gathered in June and July. There would seem little doubt but that, like the <i>Munnaoa</i> cotton of the Central Provinces, the <i>Bogali</i> must have been a field crop which nearly, if not ab- solutely, answers to Todaro's G. neglectum. Many subsequent writers dwell on ' the tree cotton,' * the red-flowered cotton,' the <i>Nurma</i> cotton• of the Benares Division of the North-West Provinces—a peculiar and perfectly distinct crop from the ordinary cotton of these provinces.
Conf. with p. 29.	Turning now to Bengal: in a long and most instructive report on the indigenous cottons of Eastern Bengal, written by Mr. T. Allan Wise in June i860, much light may be assumed to be thrown on the subject of Todaro's G. neglectum. From that paper, there would appear to be considerable likelihood that two or three of the Dacca cottons are forms of G. arboreum, one most probably G. neglectum, <i>Tod.</i> Whether that form was actually (as Todaro asserts) the reddish-tinged plant, with pointed leaves (described by Roxburgh as a variety of G. herbaceum), may be open to doubt. Mr. Wise specialises eight forms of cotton as found in Eastern Bengal, vir., (1) Tipperah Hills cotton : (2) <i>Sheraj</i> cotton : (3) <i>Bogga</i> cotton : (4) <i>Borailli</i> cotton: (5) Dacca cotton : (6) Dacca <i>Ta ngari</i> cotton: (7) Common Bengal cotton: and (8) Foreign cottons lately introduced. We shall revert to the subject of most of these cottons under G. herbaceum; but it is desirable to deal here with those that appear to belong te ⁻ the G. arboreum series. The <i>Sheraj</i> cotton, Mr. Wise states, "very probably comes from the Garo hills. It is considered, after <i>Borailli</i> , the second best cotton found in the bazars of Mymensing, and from it the cloth worn by the better class of natives is made. It is bought by the ryots in the bazars for their wives and daughters to spin into thread, which they sell to the professional weavers to make into cloth for the markets." The <i>Boggg</i> was a very inferior sort of cotton, used in making the <i>do~sutti</i> or 4 two-thread " cloth employed for sails. It was said to come from the landed proprietors and wealthy natives are fond of wearing. It is the landed proprietors and wealthy natives are fond of wearing. It is the landed proprietors and wealthy natives are fond of wearing. It is the landed proprietors and wealthy natives are fond of wearing. It is the lands quite clear of inundation. It bears pods every month in the year for three or four years in succession, and being in every way such a different plant frijm any of t

e.

G. 6

of view, they are botanically almost identical. To what extent all the Dacca cottons may, in the same way, be but forms of G. neglectum we cannot discover. That that species (or hybrid) actually does occur in Eastern Ben- gal we have no doubt, but we have seen specimens of what we take to be G. herbaceum, var. obtusifolium, from Dacca, as also others that appear to be hybrids of G. neglectum with G. Wightianum. It is thus impossible to determine to what species, varieties, or hybrids Mr. Wise's eight Dacca cottons belong, more than to discover which of them may have been the Dacca cottons examined by Roxburgh and which Todaro consigns col- lectively to his G. neglectum. It seems highly probable that the Sheraj and Borailli cottons, at least, are forms or hybrids of G. arboreum, while the Dacca Tangort cotton, the cultivation of which is now practically abandoned, may have been G. neg- lectum. Speaking of the Dacca Tangort cotton Mr. Wise remarks that it was grown on high lands and appeared a*species peculiar to the district. "It grows on the high red clay lands to the north of Dacca and attains the height of five feet. It is sown in July and the crop reaped in February. It bears a light crop for two or three years, and is probably the same kind that formed the attraction to Cospassia and the rest cf these jungles which once teemed with a wealthy people who had brick houses, tanks, &c, all now in ruins, but which seem to have been gradually relinquished. Thus only a few years ago at Sodapore, a village to the north-west of Dacca, large fields of this cotton were sown, but now not a single patch is to be found there The rayats say it is too troublesome to cultivate, but I doubt rather they do not manage it properly, do not allow the land to lie fallow every foilrth year as was formerly done, and the crop is consequently aban- doned/' (Agri-Hort. Soc. Jour., Old Series, Vol. XL, I.e.) In a more recent report (written by Mr. H. J. S. Cotton, 1876) "on Cotton Cultivation in the Interior of Bengal," the recognition o		SSYPIU M rboreum.
chi parts of Rajshanye ne wrote. The varieties are locally known under j	cottons may, in the same way, be but forms of G. neglectum we cannot discover. That that species (or hybrid) actually does occur in Eastern Ben- gal we have no doubt, but we have seen specimens of what we take to be G. herbaceum, var. obtusifolium, from Dacca, as also others that appear to be hybrids of G. neglectum with G. Wightianum. It is thus impossible to determine to what species, varieties, or hybrids Mr. Wise's eight Dacca cottons belong, more than to discover which of them may have been the Dacca cottons examined by Roxburgh and which Todaro consigns col- lectively to his G. neglectum. It seems highly probable that the <i>Sheraj</i> and <i>Borailli</i> cottons, at least, are forms or hybrids of G. arboreum, while the Dacca <i>Tangort</i> cotton, the cultivation of which is now practically abandoned, may have been G. neg- lectum. Speaking of the Dacca <i>Tangort</i> cotton Mr. Wise remarks that it was grown on high lands and appeared a*species peculiar to the district. "It grows on the high red clay lands to the north of Dacca and attains the height of five feet. It is sown in July and the crop reaped in February. It bears a light crop for two or three years, and is probably the same kind that formed the attraction to Cospassia and the rest cf these jungles which once teemed with a wealthy people who had brick houses, tanks, &c, all now in ruins, but which seem to have been gradually relinquished. Thus only a few years ago at Sodapore, a village to the north-west of Dacca, large fields of this cotton were sown, but now not a single patch is to be found there The rayats say it is too troublesome to cultivate, but I doubt rather they do not manage it properly, do not allow the land to lie fallow every fciirth year as was formerly done, and the crop is consequently aban- doned/" (<i>Agri:Hort. Soc. Jour., Old Series, Vol. XL, I.e.</i>) In a more recent report (written by Mr. H. J. S. Cotton, 1876) "on Cotton Cultivation in the Interior of Bengal," the recognition of two forms	CULTIVA- TION.

three names, viz., Boya-bonga, Chengta-bonga, and Bura-muri. ...Mr. Fasson, the Joint Magistrate who drew up the report for the district, says:—' There are certainly two strongly-marked varieties, both apparently G, arboreum, though neither answer the description exactly. The first of these is an erect, ligneous, slender-looking plant, growing six or eight feet high, with three or generally five-lobed palmate leaves; lobes acute, elongated, and lanceolate. The flowers large and showy, reddish pink in colour, with purple claws. The bracts of the outer calvx are cordate-ovate, either entire or obscurely tridentate at the apex; capsules large and three-celled; seeds black, slightly covered with greyish fuzz. The cotton is fine and silky, but of extremely short staple. This variety is called Chengta-bonga or Bon kapas.""

Before proceeding to give Mr, Fasson's account of the second form, it may be here remarked that the above plant would seem to be unmistakeably a form of G. arboreum. The fact of its having leaves sometimes three-lobed, and still further of its being a field crop, would lead •to the supposition, that it may have been but a hybrid of that species with one of the G. herbaceum series, and there would seem no room for doubt, that this is the red-flowered form of G. herbaceum alluded to by many popular writers. But in addition to the colour of the flower, we have the character of the seed and the deeply-cut leaves, with acute elongate, and lanceolate lobes-characters that clearly point to its having been either a cultivated state of G. arboreum or some hybrid with a powerful strain from that species. Whether this form still exists we have no means of saying; but the question of a possible improvement of Indian stock would

GOSSYPIUM arboreum.	
CULTIVA- TION.	seem to hinge upon the possession of all the early forms, and this is one well worthy of being followed up. We turn now to Mr. Fasson's second variety. This is described as having had broader leaves, sub-acute lobes, and more deeply toothed bracteoles, the fruit, 5-celled, the staple less plentiful though longer, and fuz of a grey colour. This is the <i>Boya-Donga</i> , and by Mr. Fasson was thought to be Roxburgh's G, obtusifolium: it was, however, more probably G. neglectum. Mr. Cotton's valuable report, from which the above passages have been abstracted, contains much of great interejt regarding the cottons of Bengal; enough to raise the hoge of possible future good work, but not enough to solve all the obscure problems that involve the subject. In Bhagulpore the tree-cotton grown near the villages is said to have been known as <i>gajer</i> , a perennial which yielded a crop for three or four years. The long-boiled condition of the Garo cotton has led to its being oicen spoken of as a kidney-cotton. It is, however, quite different from G. acuminatum, <i>Roxb</i> , G. vitifolium, <i>Latnk</i> , G. brasiliense, <i>Macf</i> , and G. racemosum, <i>Poir</i> , the kidney-cottons. It has in fact & much closer resemblance to G. peruvianum, for in both the seeds have an under-coat of the wool which holds the contents of the capsule together in a mass, often in the case of the Garo cottons, sportuding to a length of three to six inches. The matted character of the Garo cotton suits it, in an eminent degree, to one of the suproses for which it is employed. In weaving a sort of fluit, teutf of wool from a seed is said to be placed, by the hand, within the weft of the texture and thus firmly fixed, on the upper surface, forming rows which in a dense mass, imitate a thick and crude plush. We have incidentally alluded above to Dr. Hove, but it may perhaps be as well to discuss in this place more fully the inferences to be drawn for the tatter and thus firmly fixed, on the upper surface, forming intow this approbation on the beiget of his mission. He lived fo
	G. U

	The Indian Arboreous Cottons.	(Watt & Murray)	GOSSYP1UM
· ·		(Wan & Marray.)	arboreum.

assertion, and he gives no other region as the habitat of the species. Since -the time of Roxburgh, however, no collector has recorded G. acuminatum as found anywhere except in those gardens and farms where efforts have been made to acclimatise exotic cottons. The Calcutta Herbarium possesses specimens dried from plants grown in the gardens. Indeed, G. acuminatum is much less frequently cultivated than G. pemvianum, to which species Royle incorrectly referred Roxburgh's plant. It may, in fact, be said that Peruvian cotton is to some extent cultivated in the Madras Presidency. It is the large-leaved and conspicously flowered species with immense bracteoles, of which specimens have been contributed by several officers in South India. As already remarked G. peruvianum has velvety seeds free from each other, but in foliage, flowers, and bracteoles it much resembles the kidney-cottons.

But Roxburgh, in addition to the three species named, also described O. barbadense (Bourbon cotton), remarking that it had then been only recently introduced. Seeing that Roxburgh practically began to study the cottons of India about the time of Hove's visit, these distinguished botanical pioneers may be said to have found the cotton crops, at the close of the last century, to consist of forms of the plants generally known as G. arboreum and G. herbaceum. Indeed, Roxburgh questioned the former species being ever grown as a field crop, and, as already stated, he appears to have classed the yellow-flowered form (G. neglectum, Tod.) under G. herbaceum. He was, however, in considerable doubt regarding G. arboreum, and probably rightly conjectured that the Cudupariti of Rheede (Hort. Mai, 1., p. 55, t. 31) might prove a distinct species. This Todaro refers to his G. neglectum, but as opposed to this arrangement it may be pointed out that, according to Roxburgh, the most characteristic feature of the Cudupariti is its round fruit, a character which would place it with G. arboreum proper. This confusion may, however, be accepted as indicating a recognition, on the part of Roxburgh, that there were two forms of G arboreum. He does not seem to have entertained the idea that the field crops with " petals tinged with red," and those with yellow flowers but, jyith the foliage of arboreum, might be hybrids of that species, and probably had not seen the red-flowered growths of which Hove wrote. Hove, in fact, found three forms of cotton in Western India, but as his report was not published till 1851, Roxburgh appears to have remained ignorant of Hove's discoveries. The three cottons seen by Hove were—(1) a yellowflowered form which yielded the best staple and was always grown on the lower-lying lands: (2) a red-flowered kind, cultivated on the higher sandy soils which afforded a short but fine staple: and (3) a form peculiar to Kathiawar, which he came across accidentally in a garden. There are many features of Hove's red-flowered cotton that justify the suspicion that it was a hybrid, with a pronounced strain of G. arboreum. He wrote of this cotton in Cambay on the 6th November as then in full bloom with scarlet flowers, and quite another species from the yellow-flowered bush grown at Diroll in Broach, " On my journey," he continues," to Kerwan On Cambay, for the space of 16 miles, wherever I cast my eye, I could *see nothing else but cotton plantations. Where the soil consisted of a heavy clay those districts were planted with the yellow sort, and those which consisted of sand, or were situated higher from the adjacent ground, were planted with the red species." He then goes on to say that in the second year the red-flowered bushes grow to a height of seven feet, but in order to make them bushy and to cause them to yield a large crop, they

3

-1

have to be twice pruned,—once when they are only three feet high, the shoots are', then cut down by a foot, and the second pruning takes place after the first crop has been collected. At Desberah in Broach, he was G: 6 13

CULTIVA-TION.

GOSSYPIUM arboreum.	The Indian Arboreous Cottons.
CULTIVA- TION.	 told, the red cotton was known as Dyva Nerma Cap ass. As seen at Sabermatty it had blossoms of a prodigiously large size, not unlike " the Gossypium arboreum on the coast of Guinea." At Sunerwara the red-flowered species was called Semul. One of the most remarkable features of Hove's account of the Bombay cotton cultivation, one hundred years ago, is the stress he lays upon the necessity for free irrigation, with yellow-flowered cotton, which in this respect differs, he adds, materially from the red. The third form of cotton seen and described by Hove was a form from Kathiawar which he saw accidentally. At Hanley village, close to the river Dahder, he came across a solitary plant of this cotton, which, he was told, had come from Junaghar in Kathiawar. The cultivation of this had been abandoned at Hanley because the plant formed so dense a bush as to kill the grains grown between the rows of the cotton plants. It was large ppdded and a more luxuriant plant than either of the former two sorts. Hove expressed astonishment that it had not taken the place of the yellow and red-flowered ordinary sorts. This was explained, however, for it not only suffocated the grains grown with it in the same Held, but " possessed such a sweetness by nature that the insects destroyed the greatest part before it came to full perfection." It was apparently not so destroyed, however, in Kathiawar, for Hove was told that to the merits of this cotton the people of that region owed their reputation of being the most prosperous in all Guzerat. What cotton Hove here alludes to seems open to grave doubt, but it could not have been an American exotic, or he would most probably have recognised it as such. In the remarks under Bombay it will be found Kathiawar is shown to be, even today, famous for many kinds of cotton and some of great merit. In another passage Hove alludes to the roots of red cotton being much more bitter than those of the yellow, and states that in consequence they were used as a medicine for fever
MEDICINE.	MEDICINE. In the above remarks it may have been observed that Dr. Hove is
Root.	In the above remarks it may have been observed that Dr. Hove is quoted as the authority for the statement that in Bombay the ROOT \Aas
7	at his time used in the treatment of fever, as it had the reputation of being more bitter than that of G. herbaceum. Dr. Dymock says that " in the Konkan the root of the <i>Deokapts</i> (fairy or sacred cotton bush), rubbed to a paste with the juice of patchouli leaves, has a reputation as a pro-
Juice of the Leaves. 8	moter of granulation in wounds, and the JUICE of the LEAVES, made into a paste with the seeds of Veraonia anthelmintica, is applied to eruptions of the skin following fever. In Pudukota the leaves, ground and mixed with milk, are given for strangury." In the United States Dispensatory the bark of the root of G. herbaceum and other species is officinal.

II. Gossypium barbadense, <i>Linn.; Ft. Br. 2nd.</i> , /., 347.	-
11. Gossyphum bar badense, <i>Linn.</i> , <i>Ft. Br. 2nd.</i> , <i>f.</i> , 547. THE AMERICAN COTTONS. For the purpose of the present article, all the American cottons are treated of collectively, but those only in any degree of detail, that have been successfully acclimatised in India. The New World cottons are re- cognised by most authors as the forms with broad (only half-segmented) leaves and ovate obtuse, deeply laciniated bracteoles. The leaves in the great majority are sub-glabrous, those of typical Asiatic origin being very hairy. Todaro puts little faith in the specific value of the under-coat of tofhentum, which clothes the seed (in many forms of Gossypium), but it seems highly probable that that peculiarity was originally confined to Asiatic cottons. The further peculiarity of a series of cottons having the seeds mechanically united into a kidney-like mass would, on the whole, appear also to belong to certain American cottons. The species here viewed as of more immediate American origin, were, at the time of the dis-	10
covery of America, found in a state of cultivation from the West Indies to Peru and from Mexico to Brazil.	
The geographical distribution of the series, according to Humboldt, is from 0° to 34° of latitude, or where the annual temperature ranges from 82° to 68°. The several forms, races, or hybrids, of this assemblage, vary greatly in external characters and commercial value, though botanically it may be doubted how far it is desirable to isolate as species the forms recog- • nised as of pure (not hybrid) origin. Generally speaking, the staple im- proves with proximity to the sea, but it cannot be said that there is any fixed ratio of variability to climate or position within the area of distribution. Thus the cotton of Demarara (14° south) is fairly good, that from Jamaica (20° north) bad, while the cotton of Georgia and Carolina, nearly at rfhe most northern limit of the area, is very superior. Commenting on this variability Royle says, "It would appear, therefore, that not only is tem- perature necessary to be considered, but also the due balance between the supply of moisture to the roots and its escape by the leaves, as well as all the varied processes of a judicious culture in addition to the choice of species or variety to be cultivated in any particular locality." Dr. Maxwell T Masters {Jour. Linn. Soc ₉ XIX., 213) has given an entirely new turn to the enquiry into the so-called American cottons. A manifestation apparently of this type is, he says, the prevailing one in tropical Africa. It has been found, he affirms, by African travellers, in a state of cultivation near lake Nyassa, along the Zambesi, Shire, and the Rovuma valleys, near lake Tsad, in Abyssinia, and on the Somali coast. On the western side of the continent and adjacent islands it is also the	

species principally cultivated. Along the Nile valley, however, extending aiv far as Khartum, G. herbaceum, Dr. Masters states, is the form usually grown. He further describes a new species of Gossypium (G. Kirkii) which, there would appear to be no doubt, is a truly indigenous wild African form. It is interesting to notice that Dr. Masters regards G. Kirkii and G. anomalum as the only truly wild African forms and makes

no mention of G. arboreum. On the other hand, DeCandolle (*Origin Cult PL, 40*\$) writes of G. arboreum :—" It is a native of tropical Africa and has been seen wild in Upper Guinea, in Abyssinia, Sennaar, and Upper

Egypt. So great a number of collectors have brought it from these countries that there is no room for doubt, but cultivation has so diffused

G	OSSYPIUM
The Barbadense Series of Cottons. {Watt & Murray,) ba	arbadense.
This is generally known as Nankin cotton. (Con/, with pages 29, 31, 79, iL2, 130, 134-135-) According to Roxburgh it is closely allied to G. hirsutum, and by Todaro the Indian Nankin plant is placed under that species and apart from G. religiosum, Linn. Roxburgh appears to regard it as having come to India from China. Its peculiarities may be said to be those of a cross between the typical American and Asiatic forms, probably a hybrid which took its birth in India or China. (Cottf. with G. nanking, see p. 290	CLASSIFICA- TION.
but it is feared the existence of <i>khaki</i> -coloured forms of all the Indian species and hybrids, has tended to destroy the advantages that might have been expected to accrue from the careful cultivation of this plant. It seems at least probable that any brown or reddish-brown cotton has been accepted and cultivated as Nankin and hence called G. religiosum, whereas the Selection and development of white qualities of G. religiosum, <i>Roxb.</i> , might prove of great value, but of course apart entirely from the craze for " nature-dyed <i>khaki</i> cotton." (2) Gossypium mexicanum, <i>Tod., Cult, dei Cot. 193, t. VI.</i>	14
 (2) GOSS prim mentation in the road, four, active out 195, it is the MEXICAN COTTON. DIAGNOSTIC CHARACTERS.—Shrubby, hairy, ultimately glabrous. Leaves, deeply cordate, sub-rotund, one-half cut into 3-5 lobes, lower pair very obscure; lobes oblong, triangular, acute or acuminate; stipules deciduous. Flowers, small, yellow or with a purple flush; petals obliquely truncate, often with a very small circular purple spot; bracteoles sub-equal with the corolla, broadly ovate, base rounded or slightly cordate, deeply laciniated. Capsule, small, rotund, slightly acute, 3-4 celled: seeds small, truncate, velvety underneath the floss; fuzz short, deeply rusty-coloured, floss long, pzfte reddish white. It seems probable that this may be the species with small pale-coloured flowers alluded to by certain writers on Indian cotton. Dr. Wight contributed to the Agri-Horticultural Society of India two long papers on Mexican cotton. These will be found in the Journals (Old Series) VI., 189-196; in his second paper he gave the results of experiments with this cotton in the various provinces (jour., Old Series, VII., 194-215). In a still earlier issue (Journal, Old Series, Vol. I., 25-34), Dr. Spry gave it as his opinion that Mexican cotton was admirably suited to Behar. 	
 that Mexican cotton was admirably suited to Behar. B. Capsule large, leaves nlso large and palmately lobed. There are many more forms described by Todaro under this series than need be here dealt with. The following are the more important— (3) G. hirsutum, L. DIAGNOSTIC CHARACTERS.—The description of the Indian form of this plant, as given in Roxburgh's Flora India and the Flora of British India, may be expressed as:—shrubby, tender parts and young leaves softly hairy and of a pale moss green. Leaves, 3-5 triangularly lobed, being cut to one-half their depth. Flowers, large, yellow or yellowish white without a purple spot; bracteoles deeply laciniated, obtuse. Capsule rounded ovate, 4-celled, apex rounded then terminated with a short beak, seeds free, down, firmly adhering, green or grey, cotton, white, fine, and long. 	Conf. with p. 130. 15
² G. 15	

GOSSYPIUM	The American Cottons
barbadense.	
CLASSIFICA- TION.	This species varies greatly in the thickness and colour of its velvety coat (on the seeds) and also in the length and fineness of the staple. Roxburgh wrote of it: "This green-seeded variety has only been of late introduced into India, where the cotton is much admired by the natives." During the past fifty years, however, the cultivation of this cotton has gra- dually concentrated in the Deccan. It is of course also met with in other parts of India, but success has chiefly attended its acclimatisation in Dharwar and the neighbouring districts; the cotton is known in the trade as Saw-ginned Dharwar. This has come by many writers to be spoken of as a form of G. herbaceum, and indeed in the <i>Flora of British India</i> , it appears as a variety of that species. In foliage, flowers, bracteoles, and cotton, how- ever, it clearly belongs to the American series. In the velvety seeds and strong tendency to wooly stellate pubescence on the leaves it manifests an approximation to the Indian cottons, which may be due to hybridisation. Indeed, in the Sutlej Valley, near Sum', a form of G. hirsutum occurs which appears a hybrid. It is there known as <i>Nurma</i> , and its flowers are often quite pink. This is almost identical with the Sahet kaskom cotton of Santal country.
16	Egyptian cotton, at least the plant so called in India, is apparently a peculiar form of G. hirsutum, which in some districts has shown itself fairly suited to this country. Bamia cotton (once, though erroneously, said to have been a hybrid between ordinary Egyptian cotton and Hibiscus esculentus), is, according to Todaro, a hybrid between the Egyptian form of G. hirsutum and G. maritimum—Sea Island cotton. By cultivation in Italy Todaro found that it rapidly reverted to the latter species, never to the former. In Egypt, Sea Island cotton is perhaps grown to an equal extent withftew Orleans. The Bami race, which appeared spontaneously, establishes be- yond all doubt, therefore, that the American series of cottons hybridise amongst each other. Further, if G. hirsutum be itself accepted as a hybrid, it might even be inferred, that it originated from G. maritimum with some plant belonging to the G. herbaceum series, since Bamia reverted to the admitted specific ancestor, G. maritimum, never to the doubtful specific form, G. hirsutum. Indeed, on this line of reasoning, it might still further be assumed that the failures recorded in the effort to fertilize New Orleans with Indian cotton, were due to the G. herbaceum ancestor of New Orleans being distinct from the Indian cotton, or to G. maritimum being the stronger element of its hybridisation, towards which it would readily pass by further crossing or by continued cultivation.

	The Bourbon Cottons. {Watt & Matt	117770111	
In the Journal of the Agri-Horticultural Society of India (New Series), Vol. VL, pp. 72 ^m 73 and 177-193* in the last-quoted passage, Mr. C. L. Tupper (then Under-Secretary in the Revenue and Agricultural Depart- ment), gives a review of all the experiments conducted in India with the vhw of acclimatising Bamia cotton.) Gossypium barbadense, Linn.: Todaro, Cult dei Cot, 234. ¹¹ A fairly good representation of this plant is the unpublished engraving in the India Office Museum collection, bearing the name G. barbadense. This form may possibly be the chief source of the so-called Bourbon Cotton of India. References.—AgriHort. Soc. Ind., Trans. II., ///., i32; V., 183: VI., 23,238', Jour. (Old Series), I., 187. DIAGNOSTIC CHARACTERS.—Todaro, while insisting upon the separation of Conf. with	that Bourbon cotton, which we are told was introduced into Indi belongs mainly to one or other of the forms of this species, or as some writers, to G. barbadense. The term Bourbon is in fi- generic in its significance—at least it is not specific, but inclu- widely different flosses. For many years * Heath's cotton/ Bourbon, found a ready market. It was seemingly the same p yields the staple, known up to the present day, as * Salems.' (7 is referred to the provincial section of this article which deals of Indian cotton, pp. 102-104.) G. maritimuni var. polycarpum, Tad., t. VIII., is the hybrid alluded to which affords the Egyptian cotton known as Bamia. already stated, is viewed by Todaro (Cult., dei Cot., pp. 36-37) as between ordinary Egyptian cotton (one of the forms of G. hirs Sea Island cotton—G. maritimum. While admitting, however is* the nature of the plant in question, Todaro assigns it the po- variety. He defines it as stem rigid, erect, rarely branched; peduncles 1-3 in each axil, the lower one bearing one to two f his introductory chapter Todaro contends that Bamia cottor culturally speaking, very interesting, because, not being branc plants can be grown on a given space, and since more than on formed at each node, the yield is very great. Cultivated in Ital soil, it lost, however, all these advantages and assumed the ord of Sea Island cotton. In a like manner the condition whic designates as variety degeneratum was found naturally produced containing New Orleans and Sea Island, but the seeds were not fertle to allow of its being cultivated for many years. Before dismissing the subject of Bamia cotton it may be that an extensive Inäian official correspondence was conducted, f the year 1877, on that subject. Large supplies of seed were obtain plant was experimentally cultivated in every province of India few years all interest ceased, and it is not known to what extent Bamia cotton is now grown in India (see Proceedings, Revenue cultural Department—Papers on the Experimental Cultivation cotton in India	ia in i8o4> ccording to cact almost udes many a form of olant which The reader with South id already this, as as a hybrid sutum) and c, that this osition of a ; flowering lowers. GOSSYPIUM barbadense.	
CLASSIFICA- TION. Conf. with p. 152.	were the words used by Linnaeus in his descriptive designation of G. barbadense, Linn., which very probably included G. maritimum. Todaro contends,' however, that the confusion regarding this species is mainly traceable to Swartz, who de- scribed cultivated plants and says that in Barbadoes, there is a Gossypium with a three-lobed leaf corresponding closely to the Linnean type, and which could not be included with G. maritimum. He therefore regards the Barbadoes plant as very possibly G. barbadense, Linn. This argument is strengthened, he thinks, by the fact that Sea Island cotton (G. maritimum) was not cultivated in the West Indies at the time Swartz wrote. After a critical inspection of all the plates cited, and a careful considera- tion of the meagre literature of these two plants as separated by Todaro, we do not think that they are likely, in the future, to be retained as distinct botanically. They are doubtless, however, worthy of separate recogni- tion, since they yield commercial forms of cotton, and thus, both agricultur- ally and commercially, are of interest. G. maritimum, <i>Tod.</i> , is an anfual plant, largely cultivated, while G. barbadense is perennial. We possess samples from various districts in Western and Southern India, that appear to be the G. barbadense, <i>Linn.</i> , accepted as such by Todaro. Dr. Prain has also kindly allowed us to inspect a specimen of it which he collected in the Andaman Islands on Mount Harriet. It was there found in an arboreous condition and apparently quite naturalised [*] It seems highly probable that this is, to a large extent, the G. barbadense, <i>Roxb., FL Ind., p. 521</i> , which, he says, had been introduced into India about the beginning of the century from the Island of Bourbon—hence its com- mercial name of Bourbon cotton. His memak regarding its introduction firms Todaro's statement of its having been originally a native oi these islands. There are, however, one or two difficult points regarding Rox- burgh's Bourbon cotton. It is described as having "leaves smooth, wit
	Cult, Cotton in Jnd., PI. III., 7. 2) under the name of Bourbon cotton, has the broader, less segmented leaf of G. barbadense, but the 5-lobed condition of G. maritimum.
18	 (6) Gossypium peruvianum, Cav.; Tod., Cult, del Cot, 240. PERUVIAN COTTON[^] This is said by Todaro to be a native of Peru, and to be cultivated in Spain. We have seen one or two samples of it from various parts of India— notably a good sheet from the Madras Herbarium. This was apparently cultivated at Triplicane by Dr. George Bidie, O.I.E. In foliage and bracteoles it much resembles G. acuminatum, Roxb., but the stipules are very large, being fully.an inch and a half long and the leaves thicker, smaller, and the segments more constricted at the base than in G.
	G. 18

• 'The Kidney Cottons. (Watt & Murray)	GOSSYPIUM barbadense.
vitifolium and G. brasiliense—the kidney cottons—with which it was confused by Royle and, following him, by many Indian popular write. This same mistake has also been made by Masters (<i>Flora of British Ind</i> /., 247) where G. peruvianum, <i>Cav.</i> , is quoted under G. acuminatum <i>Roxb.</i> , a plant which, at the same time, is reduced to a variety of barbadense. Peruvian cotton has the seeds free from each other and coated with thick velvet below the floss. It is thus either a distinct species (and that case a native of Peru) or a Peruvian hybrid between one of the kidne cottons and some of the forms of G. herbaceum. The very large flower and immense deeply gashed bracteoles are its most ready eye-marks wh taken in conjunction with the fact of the seeds being free from each other Mention is made of this cotton in several of the reports, &c, which de <i>With</i> the introduction of American cottons into India, notably in connection with Orissa. II. SYNSPERMIA. (For Section I, see p. 16.)	10
Seeds adherent into a mass—hence the name kidney-cottons. Toda describes eight species under this section, and three of these are met wi in India. There are several very obscure points regarding these plan and, so far as the forms met with in India are concerned, it seems dout ful if they deserve a higher rank than that of varieties, if, indeed, th should not rather be accepted as cultivated races of one species. Ro burgh was the first to describe the plant now known under the nar G _n acuminatum. Regarding the habitat of that form he wrote, "said* o a native of the mountains to the north and westward of Bengal." B the exact location of the region there referred to is extremely difficult, if n impossible. Nepal would perhaps be on the north-west of Bengal as no understood, but if Behar be excluded from Bengal, Roxburgh's senten would then indicate Bundelkhand or thereabouts. But, it should be o served, he gives no exact locality, his words being "said to be a nati &c." It thus seems highly probable that Roxburgh described his speci- from plants raised in the Botanic Gardens, the information given abo being the report furnished to him by his native gardener, who, perhaps, pr cured the seed from some of his friends as that of an interesting ne plant. It is not like Roxburgh's work generally to leave so obscure passage, if it had been in his power to be more precise. Royle (<i>Illustr</i> <i>tions of Himalayan Botany, 98</i>) republished Roxburgh's description at habitat of this species, but apparently had not seen an example of th plant. He, however, described it as distinct from G. vitifolium and for G peruvianum. In his later work (<i>Cult, and Com. of Cotton in India, 14</i> he reduced all the kidney-cottons, including G. acuminatum, <i>Roxb.</i> , to of peruvianum, <i>Cav.</i> —a reduction due very probably to the misconception of viewing G. peruvianum as kidney-cotton. While we cannot accept th part of Royle's work, as remarked above, we consider G. acuminatum, <i>Rox</i> g, vitifolium, <i>Lam. (non Roxb.)</i> , and G. brasiliense, <i>Macf.</i> , as d	ro ith ts, bt- ey x- ne be but iot ww ce b- ve es ve o- ww a a- nd he m 0) G. of is b; ly as is rt p, he b; ly as y- p, he b; b; b; b; b; b; b; b; b; b;

barbadense.	The American Cottons*.
CONCLUDING REMARKS. 23	Concluding Remarks regarding the American Cottons. , To give even the briefest review of the numerous experiments which have been performed, to indicate the purposes for which large sums of money have been spent, or to exhibit the true force of the disappointing reaction, consequent on the fulle efforts to acclimatise these cottons in India, would occupy many pages. Suffice it to say that neither money nor labour have been spared, but nearly everywhere the same conclusion has been ar- rived at, <i>vie.</i> , failure. In one or two localities, however, fairly good results have been obtained, and the Saw-ginned or New Orleans cotton of Dharwar may be said to be the practical outcome of a half century's energies, on the part of the public, the Agri-Horticultural Society of India, and the Govern- ment. Scattered throughout India may now be found the depauperated sur- vivors of all these attempts at acclimatisation, some practically naturalised but others preserved as mere garden curiosities. It may be stated that fhe final verdict has been pronounced, <i>vis.</i> , that, if seed could be annually pro- cured and of good quality, many of the American cottons might be culti- vated in India, but that they all rapidly lose their special merits when grown from Indian-produced seed. Even the Dharwar exotic, though in some respects a superior cotton to many of the indigenous growths, is a sadly degenerated stock from the New Orleans of America and Egypt. What influence, if any, hybridisation of Indian with American or American with Indian may have exercised in this degeneration it is impossible to tell, but, as repeatedly urged, it would seem to us that the natural direction of future experiments should be in the hybridisation and selection of superior qualities from indigenous or naturalised stocks rather than further efforts at Accli- matisation. The first step towards this end is, of necessity, the acquire- ment of detailed scientific knowledge as to the forms of cotton that now exist in India; the second, the establishment of the
	ciety of India, chiefly from the pens of Drs. Wight & Spry, and in the
	Dr. Forbes Watson writes on this subject:—" With regard to improve- ments in selection of seed and in cotton cultivation generally, no per- ceptible progress has been made, in spite of incessant efforts during the past fifty years. The system of Government cotton farms adopted /or years seemed as if specially devised to render abortive the services* of some of the zealous agents employed at them. The plan under which a certain number of acres was for a season taken over from the rayat and appropriated for experimental purposes, the locality of the experiments being shifted from year to year, made it perfectly impossible to attempt any consecutive experiments as to improved methods of cultivation, rota- tion of crops, or improvement of the plant by selection, such as could be carried out at a permanent agricultural experimental station, of the kind to be found in hundreds on the Continent and in the United States, and in

G, 23

-----	-----------	--------	----------	------------------	-----------------------------

CONCLUDING which the cultivation of cotton could be combined with experiments on the general agriculture of the country, with the progress of which the improvement of the cotton staple is indissolubly connected. There appears to be a natural adaptation of the Indian cotton plant to the dry climate of India, which enables it, by means of its long tap-root, to draw sustenance and moisture from greater depths of the soil than is the case with the American variety, with its number of lateral roots spreading near the surface. Hence it is quite as important to proceed with experiments in the improvement of the native staple by selection, as to attempt the introduction of foreign varieties which, whatever their advantages may be, are not so well adapted to sustain the frequent seasons of extreme drought occurring in India.

It may be remarked that there is less reason now than appeared some time ago to apprehend a serious diminution of the Indian cotton trade through the increasing competition of American cotton. The Indian cotton is not only finding a new and rapidly increasing market in India itself, but it also has taken a firm hold of the continental markets, and it is possible that the appreciation of the merits and the extensive use of Indian cotton by the continental manufacturers may be one of the causes which enable them to compete so successfully as they have done of late with the cotton manufacturers of England, among whom the use of the Indian cotton has declined in a very marked manner. It is also due to this continental competition for Indian cotton, that its market value has of late approached more nearly to that of the American than at any previous period.

Finally, the competition of the American cotton is not the only circumstance which regulates the cultivation of cotton in India. Unless the prices should fall much below even their present level, cotton will continue to be largely grown in India, as over a large part of the country it enters into the regular rotation of crops, and being at all times readily convertible into money, is relied on by the rayat to produce a large portion of the cash required to meet the Government rent and other payments. So long as no convenient substitute is discovered which can replace it in this? respect, the cultivation of cotton is in no danger of falling much below its present extent. It may be remarked, too, that a period of low prices is much more favourable for the introduction of reforms in the cultivation and preparation of the cotton, than a period of high prices, in which there is a good demand for the most inferior descriptions which can be brought (Report on Cotton Gins, Pt. /., 30-31.) into the market."

GOSSYPIUM herbaceum

CLASSIFICA-TION. The Asiatic series of Cottons.

nell, Tiele and Yule), Vol. /., 55, 60, 95, 129; Hove, Jour, of Tour in Bombay in 1787, pp. 26-27, 29, 30, 34-35* 36, 37-38, 39* 40-4'» 4h 45, 58, 69, 76, 81, 106-107, '09, M27, 131-132, J49-149, i55-*5t> *58, 161, 167, 169 / Man. Madras A dm., Vol. I., 289-290, 334, 335, 339; Nicholson, Man. Coimbatore, 232-235; Gazetteers and Settlement Reports too numerous to be quoted; Indian Forester, XII., app. 7; XIV., 109.

To prevent any possible misunderstanding, it may again be explained that we use the name G. herbaceum, as the most convenient for a series of forms, one of which (G. Wightianum, *Tod.*) may be of specific interest, but the others, while entitled to lower positions botanically, are nevertheless equally valuable as races of cultivated cotton. Todaro appears to have established one or two important facts regarding these cottons, and these may be briefly summarised :—(1) G. herbaceum *proper* does not occur in India, and indeed the attempts at introducing it have been less successful than were those with the American cottons : (2) The bulk of the commercial cottons of India are hybrids : (3) The species of greatest importance to India is G. Wightianum, *Tod.*: hybrids from that species constitute the better cottons of Western and Southern India : (4) G. neglectum, *Tod.* (a form of G. arboreixm, according to many authors, and of G. herbaceum by others), also occurs in India, and hybrids from that species constitute the bulk of the cottons of the Eastern and Northern divisions of India : (5) Two varieties of G. herbaceum are found in India, *vis.*, obtusifolium and microcarputn. The former is met with chiefly in Bengal and Madras, and the latter is largely the source of the *Dhollera* cotton.

As already remarked under G. arboreutn we regard many of Todaro's forms of this species as mere hybrids, but it may serve a useful purpose to give here the names of the species or hybrids to which we allude and to suggest their possible nature.

III.

{For /. see page 7, and for II., page 16.)

kTHE HERBACEUM OR ASIATIC SERIES OF COTTONS,

25

Habitat.—This form, Todaro says, is a native of Asia, and perhaps also of Egypt. Accepting G. Stocksii as a wild form of it, he gives also the rocks of Sind as one of its habitats, thus extending the area to India. As far as we can judge, the original home of G. herbaceum may have been to the North-West of India proper, corresponding more nearly with the region of its present cultivation, *viz.*, Egypt, Asia Minor, Northern Africa, and Southern Europe. Although now extensively cultivated in the United States, it was probably introduced there from Europe. It was a new cultivation, DeCandolle remarks, one hundred years ago, since in 1774 a bale from North America was confiscated at Liverpool on the plea that the cotton plant did not grow there, but there is probably little or nothing to support DeCandolle's appropriation of that circumstance as a historic fact specially connected with G. herbaceum. It would seem simply to prove that America up to that date was not known to produce cott«n. We know, however, that the G. barbadense series of cottons had been grown there from time immemorial by the aboriginal tribes long anterior to any record of the introduction of G. herbaceum. It would appear also that the incident alluded to by DeCandolle took place in 1784 not 1774.

Todaro, however, admits two varieties as met with under cultivation in India, and if our suggestion proves correct, *viz.*, that even G. Wightianum may be but a hybrid or sport, or at most a variety, of G. herbaceum, *Linn.*, India, as commonly reported, might then be accepted as one of the chief habitats of the species. If, on the other hand, Todaro's views

(z) Gossypiutn herbaceum, Linn.

(Watt & Murray.) 🔪 The Asiatic series of Cottons. regarding G. Wightianum be confirmed by more extended study of the CLASSIFICA-TION, Indian cottons, that plant is probably the original condition from which all the better cottons of India have been derived. Under G. Wightianum mention will be found of a wild form of cotton, found in Rajputana and the Panjab, which appears to be that species, a fact which powerfully supports Todaro's position. DIAGNOSTIC CHARACTERS.—Perennial and bushy in the warmer areas, annual where killed by winter. *Stems* erect, sparsely hairy, branches spreading, the bush sub-pyramidal. *Leaves* pale green, thick, leathery, and larger and broader than in G. Wightianum, half segmented into 3-5, often 7 lobes: lobes ovate-rotund, con-stricted below, the middle one acuminate, all shortly bristle-tipped; upper surface reticulate, pubescent, with longer hairs on the veins and felted below when young with hifd or triffd (not stellate) hairs merging ciliate. *Stimulas* linear longelate with bifid or trifid (not stellate) hairs, margins ciliate. Stipules linear lanceolate, those nearer the peduncles shorter and broader. *Flowers* longer than the bracteoles, petals obovate, unequally cuneate, yellow, with a large purple patch, slightly united together below; *peduncles* about half the length of the petioles; *bracteoles* ovate sub-obtuse, cordate, inciso-dentate, the entire portion sub-rotund, united to each other below, in texture thinner and more numerously veined than in Indian cottons. Capsule ovate-rotund 4-5-celled, cells 6-7 seeded, seeds ovate, beaked at the hilum; undervelvet or fuzz as it is often called short, firmly adhering, whitish-grey; wool fairly long and white. The chief features of this plant, which distinguish it from the ordinary Indian cottons, are its broader leaves, more rounded lobes, the absence of stellate felted hairs, and the shape of the bracteoles, which approach much nearer to those of the American than to any of the Indian cottons. The remark that the seeds are beaked is of considerable interest, since, if specific, this would indicate the inferior quality of cotton, with a spine on the end of the seed, alluded to by Mr. Hare (see remarks below in connection with Berar), as one of the forms of G. herbaceum, Linn. We have seen only one or two examples of what we regard as true G. herbaceum in Indian collections. Of these may be specially mentioned the Gilgit specimens issued as No. 250 from Kew, and a specimen collected by the Editor in a garden on the Nilghiri Hills. But the following are forms which we recognise as possibly only varieties of G. herbaceum, and the forms of the species which alone exist in

This is described as possessing much smaller fruits than the type, and of an ovate, sub-rotund shape, with the apex deeply depressed.

According to Todaro this corresponds to much of the *Dhollera* cotton, a form which is grown in Kathiawar, Cutch, Kaira, and Cambay, &c.

Var. obtusifolium.

Todaro regards this as a species, but we can see very little to separate it. Indeed, like *var.* microcarpum, it is a form that connects in some respects G. Wightianum with G. herbaceum. The description originally given by Roxburgh appears to have been simply reproduced by Todaro, also by Masters in the *Flora of British India*. It is not appalent whether or not these authors have specially studied the plant.

DIAGNOSTIC CHARACTERS OF OBTUSIFOLIUM.—Shrubby, much branched. Leaves small, 3, rarely 5, lobed, lobes ovate, obtuse, entire; stipules falcate; bracteoles ovate, obtuse entire or nearly so. Capsule ovate, 3-celled, with 3 seeds in each cell; seeds free, coated with closely adhering green velvet below the ashy-white wool. T od a r o remarks that it differs from all the other species in the entire bracteoles and in having only three seeds in each cell.

Roxburgh supposed this to be a native of Ceylon, but Thwaites and other more recent writers have failed to confirm this statement. The plant, as recognised above, has, however, been collected by Griffith in Ava, and the Editor came across it in a semi-wild condition on the Naga 26

herbaceuir	
CLASSIFICA- TION.	Hills and in Manipur, found on deserted lands near ruined .villages. Samples have also been obtained from Madras of a plant with small and mostly three-lobed leaves, which appears to be the obtuse-leaved cotton of most writers, and we have grounds for believing that the plant we allude to, at least, is fairly extensively cultivated throughout India, especially in the warmer areas and on poorer soils. Indeed, it seems probable that it is the inferior cotton with beaked seeds referred to above.
28 Conf. with pp. 64, 85, 88, 98, 102, 111 ,	(2) Gossypium Wightianum, <i>Tod., Cult del Cot, 141,</i> This, according to Todaro, is the chief cultivated cotton plant of India, being mainly met with, in its purer forms, on the Western side of the Pen- insula. It is apparently the G. indicum of lire's <i>Cotton Manufacture,</i> <i>p. 126.</i>
118, 129, 152, 142, 147, 150.	DIAGNOSTIC CHARACTERS.—Stems erect, somewhat hairy, branches spreading and ascending. Leaves when young densely matted, with short, thick, stellate lours, which fall off in patches leaving a few scattered all over both surfaces; ovate-rotund, almost obsoletely cordate, 3-5, rareiy 7, lobed, lobes ovate, oblong, acute, constrict- ed at the base into the rounded sinus which in the young leaves rises up as a fold: stipules on the peduncles almost ovate, the others linear-lanceolate acuminate. Flow- ers yellow with a deep-purple patch at the base, becoming reddish on the outside on passing maturity; bracteoles small, slightly united at the base, ovate cordate, acute, shortly toothed : peduncles erect in flower, recurved in fruit, one-fourth the length of the petioles. Capsule small, ovate acute, 4-celled, with 8 seeds in each cell; seeds small, ovate, sub-rotund, velvet very short and firmly adhering, wool white or whitish-red. Syn. —Todaro cites the following references to this form :—G. HERBA- CEUM, WW. OBTUSIFOLUJM, Wight, Ic, t. 0/ G. ALBUM, W. & A.; G. HERBACEUM , Mast, in Hook., PI. Br. Ind., ex parte.
	The peculiarities of the leaves, bracteoles, and capsules of this species
	are contrasted with those of G. herbaceum, <i>Linn</i> , in Todaro's plate IV,
	The leaves of the latter are larger, broader, more rotund and much more
	deeply cordate, with the lobes more rounded, and acute-apiculate, instead
	of ovate, oblong, acute as in G. Wightianum. The bracteole is also broader, much thinner in texture, more deeply cordate and often gashed*
	somewhat resembling the bracteoles of the G. barbadense series. We
	have very carefully examined a large assortment of specimens of G
	Wightianum and have come to put a considerable degree of faith in the
	value of the character of the hairs in isolating that plant not only from G herbaceum, but also from G. neglectum. The latter has long spreading
	hairs and is only stellately tomentose when hybridised with G. Wightianun
	just as that species shows a strain of G. neglectum by the presence on th
	veins, of a few of the long hairs.
	We have had the pleasure of examining in Mr. J. F. Duthie's collect tions of Gossypium, now deposited in the Saharunpur herbarium, on or two specimens bearing on their labels the remarks «'the wild cotton o
,	Merwara," " apparently quite wild in the forests west of Bdr in Merwara. Mr. A. E. Lowrie has also contributed a sample of the same plant found in fruit in Ajmir on the 30th October 1883. Mr. Lowrie remarks of this " the wild cotton I send you was found as a creeper over other trees.
	These samples were kindly examined (in consultation) by Mr. Drummond Deputy Commissioner, Karnal, who thought he could identify therm a the wild cotton alluded to by him in his remarks below, in connection wit
Conf. with	the Province of the Panjáb. Mr. Drummond's description of the Karna • wild plant' would lead to the supposition of its being G. neglectum, bu we have seen no specimen of the plant referred to. We have already inc
p. 119.	dentally alluded to these samples, and need only add that they appear to be the wild, or at least semi-wild, condition of G. Wightianum.
29	HYBRIDS OF THE HERBACEUM SERIES.
	There are numerous hybrids from G. Wightianum, but all w
	G. 29

. The Indian herbaceum Cottons. (Watt & Murray.) h	DSSYPIU Prbaceuu
have examined are hybrids with G. neglectum, more rarely with G. arboreum. These hybrids have more deeply segmented leaves than G. Wightianum, and possess the extra tooth in the sinus which we regard as characteristic of the G. arboreum series. They are either very hairy, if hybridised with G. neglectum (having both kinds of hairs) or almost sub-glabrous, if with G. arboreum. Of this latter class may be mentioned the common'Himalayan crop of which Dr. J. E. T. Aitchison's No. 462 from Kuram Valley may be mentioned as a good type. We in fact regard Todaro as having isolated as species some of these hybrids, for example, the following, taken up in alphabetical order:—	CLASSIFIC TION.
 G. cernum, Tod., Cult dei Cot., 160. This is said to be cultivated in India, its chief characteristic feature being the reflexed upper portion of the bracts. The description of the leaf as given by Todaro mould point to its being a hybrid from G. neglectum with pale sulphur-coloured flowers with a purple spot. The capsule is said to be fairly large, cylindric, acute, 4- rarely 3- celled, cells 7-11 seeded, wool short, white or reddish. 	30
 2) G. indicum, Latnk.; Tod., Cult, dei Cot., 150. This, according to Todaro, is the Cap as of Rumphius (Ami. IV., 33, t. 12). The Linnean species, G. herbaceum, is, he thinks, a combination of the characters of G. Wightianum with the plant he isolates as G. herbaceum, Linn., proper, and G. indicum, Lamk. The present restricted species is characterised by having 3-lobed leaves which are eglandular and shortly pointed, and small bracteoles, sub-entire or slightly toothed on the apex. But that description recalls G. obtusifolium, of which it may be but a form with more pointed leaves^ 	31
 3) G. intermedium, Tod., Cult, dei Cot., 153. * This, Todaro, on the authority of Royle (Cotton in India, 142), says, is cultivated in India, chiefly in the Deccan, and is distinguished by the free re-curved segments of the style. It would, however, appear to be one of the hybrids between G. Wightianum and G. neglectum, in which the segments of the leaves are usually broad as well as the stipules. The flower is large and opens wide in flowering. Capsule ovate acute, rough on the surface, 3-celled, each cell 8-seeded : wool reddish white. 	32
4) G. nanking, Meyen: Tod, Cult, dei Cot., 147. This, Todaro says, is the true Nank'n cotton—a Chinese plant often grown in India under the name of G. religiosum; the Nankin or reddish cotton of India being, he affirms, perfectly distinct and a form of G. hirsutum. The description given by Todaro, however, as also his figure III., suggests its being possibly a hybrid between G. Wightianum, Tod., and G. herbaceum, Linn. The lower leaves are sub-rotund, obsoletely cordate, 5-7 lobed, the lobes oblong obtuse, with the base only slightly constricted; upper leaves 3-5 lobed, lobes ovate obtuse. Flowers pale yellow with a purple spot; bracteoles exceptionally small, ovate sub-rotund; peduncles recurved in fruit, much shorter than the petioles. Capsules ovate acute (in the figure shown as sub-rotund); 3-celled, cells mostly 5-seeded, wool reddish yel- low.	33 Conf. with P. 17.
 5) G. roseum, Tod., Cult, dei Cot., 164. 5) G. roseum, Tod., Cult, dei Cot., 164. This is also said to be cultivated in India and is described as being erect with slender spreading branches. In the description of the leaf it approaches most to G. neglectum. Flowers white or pale yellow with a purple tinge on the outside, petals remaining convolutely tubular, thus never completely expanding-, also united together below : bracteoles rotund-ovate, dentate more or less united below. Calyx constricted at the base. Capsule very small, ovate acuminate, red-coloured, 3-celled, cells 5-6 seeded ; velvet ashy-coloured as also the wool. This would appear to answer to the description of some of the Cottons of Eastern Bengal and Assam. 	34 Conf. witt pp. 10-11
VARIABILITY OF THE CAPSULE AND SEED IN GOSSYPIUM. It will be seen from the above notes on some of Todaro's species that they would appear to possess few, if any, characters that could be accepted as absolutely separating them. They differ mainly in the shape of the cap-	35

	Similar results were obtained by experiments continued in the follow- ing year {Annual Report, 1887-88, pp. 5-7), and commenting on the experi- ments with the American seed it is stated, *• The greatest percentage of pods are in every case pods with 4-cells, the normal number in this class of cottons. The seed from 5-celled pods has, however, produced the greatest percentage of similar celled capsules," The remark regarding the Sindf cottons may also be reproduced :—" In this, as in the American, the percentage of capsules having the larger number of cells is lower than last year, but the tendency seems to be in the same direction,—that is to say, the seeds from pods with the greatest number of cells give the highest proportion of similar celled pods." We are not told the particular growths of either American or Sindf cottons selected for these experiments, but thS inference seems justifiable that all the former shewed a strong tendency to become 4-celled, while the latter became 3-celled. From these facts we may at least assume that these are the chief specific peculiarities of the fruit in the two great series of Gossypium, and learn the futility of mak- ing species out of races or hybrids of Indian Cotton according to the size, shape or divisions of the capsule,

Dye from Gossypium. (Watt & Murray)	DSSYPIUM rbaceum•
DYE FROM GOSSYPIUM AND THE DYEING OF COTTON GOODS. The colouring matter seen in the wild cottons, and also in Nankfn cotton, has been found, by Schunck (Memoirs of the Literary and Philo- sophical Society of Manchester), to be present, to a limited extent, in all forms of cotton. Schunek's paper (l.c.)' On some Constituents of the Cotton Fibre,' investigated the substances contained in or attached to the frame- work of cellulose which constitutes the staple. He found that these sub- stances were almost insoluble in water but soluble in hot alkaline lye. The action of concentrated aqueous solutions of caustic soda and potash had, however, been some time before observed by M. Alkan and turned to practical use by Mr. John Mercer, who patented a process now known as mercerising, by which the fibre was prepared for certain dye re-actions. Mercerising may be expressed as an extreme and powerful process of hydrolysis or bleaching, accompanied with structural changes in the fibre. Not only is cellulose separated from non-cellulose, but the shape or con- tour of the ultimate fibre-cells is altered. Schunck, however, confined himself to the examination of the substances separated in solution by alkaline lye, and which are afterwards precipitated by acids. The acid he employed was an excess of sulphuric, and the copious brown flocculent pre- cipitate when thrown down from the alkaline solution was found to be	DYE. 36
cipitate when thrown down from the alkaline solution was found to be o*337 P ^{er} cent, of the weight of 'Dhollera' yarn employed. Similar yarn of Middling Orleans yielded 0*48 per cent, of precipitate. On examining the material thus obtained, he found it to contain (1) Cotton wax : (2) Margaric acid ; (3) A colouring matter easily soluble in alcohol: (4) A colouring matter sparingly soluble in alcohol: (5) Pectic acid : and (6) Albuminous matter. Of these substances the pectic acid far exceeds the others in quantity, then follow the colouring matters. But it is well known that, on bleaching cotton, it sustains a loss of 5 per cent, of its weight, whereas the total weight of the substances removed by Schunck and afterwards precipita- ted by acid, amounted to only about £ per cent. It is, therefore, assumed that the difference in loss on bleaching, was either removed by the water or not precipitated from the alkaline solution by the acids used by Schunck. It is known, for example, that certain derivatives of pectine are not precipitat- ed by acids. Hence it is not improbable, as contended by writers on this subject, that the substance that escaped observation in Schunek's experi- ments was para pectic acid originally removed is assumed to be possi- bly converted, through the action of the alkali, into metapectic acid—a substance very soluble in water, and not precipitable by acids. These discoveries in the nature of the substances removed from cotton by bleaching and mercerising, have a direct bearing on many of the textile and dyeing industries. They are interesting also from a purely botanical consideration, since we learn that the colouring matter, in cotton, is a nor- mal constituent, which yields to bleaching. The interest in Nankfn or <i>khaki</i> cottons, as supplying a nature-dyed textile of a desired colour, was, therefore, in the light thrown on the subject through Schu nek's discov- eries, very probably mis-directed, since the colour must of necessity be femovable by the ordinary methods of washing with soa	Conf. with p. 79.

species of Gossypium. Recently, through the kindness of Mr. Beheram Shah, Forest Officer, Palanpur State, Bombay, we have had the pleasure of receiving a piece of cotton cloth said to have been dyed with a decoction of the ROOTS of G. herbaceum mordanted with alum. A soft delicate colour has been thereby produced which, if permanent, might be turned to

herbaceum.	
DYE.	much account. It is remarkable that no other Indian writer appears to
Flowers.	have observed the Natives of this country using the root; few even mention the FLOWERS as being so used, which, like those of Thespesia populnea,
	afford a yellow dye. Mr. Liotard, in his memorandum on the Dyes of
38	India, incidentally mentions the flowers as being employed for dyeing pur-
	poses in the Mainpuri district.
	Mr. T. Wardle, in his report on the "Dyes of India," states that the
Í	Collectors of Jacobabad and of Hyderabad (Sind) had furnished him with samples of the flowers. Mr. Wardle obtained from these, according
	to the mordants used, various shades, which ranged from bright yellow,
	greenish yellow, and fawn colour, to orange, reddish, and brownish yellow.
	Commenting on this subject Mr. Wardle wrote, "Cotton flowers are very
	rich in yellow colouring matter. They will give bright yellow colours, and, as a dye-stuff, have much the same properties as Butea flowers."
	It may be here added that the above facts of a knowledge of the dye-
	property of cotton roots and flowers, being practically confined to Sind
	and Palanpur, might be accepted as denoting a more ancient acquaintance
	with the plant. If this inference be justifiable, it might perhaps be viewed as confirming the accuracy of the reports regarding a wild Gossypium in
	Sind, in certain parts of the Panjab, Rajputana, and the hotter localities
	of the North-West Provinces.
Blue Dye.	In Gmelin's <i>Handbook</i> the subject of a BLUE DYE obtained from cotton SEED is discussed. Dr. Warden, in a note on this subject, says,
c ³ Q	"Cotton seeds contain a principle which, by the action of acids, yields a
Seeds, 40	blue colouring matter—cotton seed blue. This blue is not altered by reduc-
40	ing agents, but is at once decomposed by oxidising ones. It is insoluble
	in water. An alcoholic solution gives a fine blue colour to fabrics either mordanted or unmordanted with alum; the colour, however, fades rapidly."
	The subject of DYEING and CALICO-PRINTING is too extensive to be
	dealt with collectively in this article. The reader is, therefore, referred to
1	technical works such as Buck's Dyes of the North-West Provinces: McCann's Dyes and Tans of Bengal : Liotard's Memorandum on the Dyes
	of India : Crooke's Handbook of Dyeing: Hummel, The Dyeing of Textile
l l	<i>Fabrics</i> , &c. Also to the separate articles in this work on the more impor-
\	tant dye materials such as INDIGO, SAFFLOWER, LAC, MADDER, MORINDA,
	&c, &c. FIBRE.
FIBRE.	This will be treated of in detail under the section of this article
41	designated COTTON. It may be as well, however, to give here a brief
	account of the microscopical and chemical features of the floss. The
	cotton staple consists of elongated simple cells, developed around the seed, and is not therefore a bundle of cells or vessels as in the case of Flax, Jute,
	and other commercial fibres. Under the microscope cotton is seen to be
	an elongated cell or fibre, ribbon-shaped, with corded edges, thickest at
	the base (the end of attachment to the seed), and continued upwards without
-	material change for three-fourths of its length, after which it tapers to a point. Each fibre is twisted many times on itself and on transverse section it
	is seen to be a collapsed cylinder, the walls, compared with the calibre, Veng
	of a considerable thickness. This is the appearance of the perfect fibre,
	but there are often found many imperfectly developed or immature oftes,
	which, though twisted like the perfect ones, are thin and brittle, and owing to the deficiency of cellulose do not manifest the double outline of margin.
	The peculiar twistings give strength to the fibre and facilitate the process
	of spinning, the natural twistings becoming interlocked. These twistings
ł	do not exist on the fibre before the dehiscence of the pod. On ripening
'	nourishment from the seed is gradually discontinued, a vacuum is thus
	G. 41

· The Cotton-Seed, Oil, and Cake. (Watt & Murray.) Go	SSYPIUM erbaceum.
left in the interior, first, at the apex, afterwards along the length to the base. The atmospheric pressure occurring on these hollow tubes causes them to twist and collapse. The mean length of the cells (popularly the staple) in Sea Island cotton is 1.65 inch ; in Egyptian 1.50 inch ; in Pernambuco 1.25 inch : in American 1.10 inch ; in Indian 0.90 to 0.65 inches. Cotton floss consists of nearly pure cellulose, together with only i to i J per cent, of inorganic matter. The specific gravity of New Orleans is said to be $1*165$, $a^{\circ}d$ Bourbon I'lio. Cotton is tasteless, devoid of smell, insoluble in water, alcohol, ether, fixed and volatile oils, or vegetable acids. It is soluble in strong alkaline solutions and decomposed by concentrated mineral acids. The action of nitric acid, &c, is referred to in the section under Medicine in the formation of Gun-cotton and Collodion. The colouring matter present in the fibre has already been dealt with and need not be again discussed in this place (Con/, with Dye, p. 32). Cotton exhibits a strong affinity for alumina, hence the use of alum as a mordant in dyeing. Iron stains it a yellow colour which, unless recent, cannot be removed by alkalis or soap. Oxide of tin, which has an affinity for the staple, is frequently used as a mordant in dyeing the fibre. Nitric acid and heat decompose it. It is extremely combustible, burning with a clear bright flame.	FIBRE.
The STEM yields a good FIBRE, which may be separated by retting. Several writers have alluded to this subject and recommended its utilisa- tion, but apparently the people of India are not aware of this fact, since no mention is made of their putting it to any useful purpose. Most malvaceous plants are rich it) fibre, and doubtless the cotton stems are not in this re- spect different from those of Hibiscus, Urena, Pavonia, <i>tsfc</i> . It is probable that in the cultivation for the floss a branched stem is produced which might not be conveniently treated for its fibre. If it could be, the supply would naturally be very great and afford a new source of income to the	Stem. 42 Fibre. 43
people. COTTON-SEED, OIL, AND CAKE.	44
References.—Hawke, Report on Oils of S. India, 39; Cooke, Oils and Oil-seeds of India, 4\$; Useful PI. Bomb., 21\$; Simmonds, Tropical Agriculture, 404-405; Jour. Soc. Arts, 27th July 1883; Indian Agricul- turist, Oct. 12th, & Nov. 2nd, 1889; Edinb. Quart. Jour. Agri., 1854; Spons, Encyclopaedia; Balfour, Cyclopaedia, &c, &c.	
After the floss has been removed, by the process technically known as ginning, the SEEDS are utilised either as cattle-food or as a source of oil. Prior to the American war the seeds were viewed as useless, the difficulty of preparing them as a manure being such as to prevent, to a large extent, their utilisation even as a fertilizer. A writer, in the Report for 1874. issued by the Commissioner of Agriculture, Washington, says: "The seed jn its natural state, or when converted into meal, has greater manurial value than any other single substance." He supports this statement by giving an analysis of the ash of cotton-seed as follows:—	SEEDS. 45
PotishPer cent.SodaMtgnesiaLimeYhosphoric acid<	
In spite of being so valuable a substance immense quantities were in America annually destroyed as useless; to some extent this is the

2 gallons of oil, 481° of oil-cake, and Gib refuse fit for soap-making; another says that one ton of American seed gives 20 gallons of oil; a third, that the oil-product is 37 per cent, of the weight of the kernels; a fourth that 2 gallons of oil and g6lb of cake are afforded by 1 cevt. of seeds, a fifth that 1 ton of cotton material yields at the rate of some 35 gallons of oil." Indian Uses. I NDIAN USES.—I n I ndia cotton-seed is chiefly used as a cattle-food, not as an oil-yielder. Indeed, in this case, as in many other features of cotton cultivation and utilisation, the natives of India do not manifest that in- timate knowledge which characterises their acquaintance with most of the products of their country. While they grow many plants purely as sources of oil, for food, and lighting purposes, they seem to be practically ignorant of the fact that cotton-seed affords one of the most wholesome of oils. In <i>Baljourd Cyclopaedia of India</i> it is stated that " when obtained by pressive its colour, owing to the presence of a resinous substance, is of a very dark red, and to to 15 per cent, is lost in bleaching it. When prepared by steaming the seeds, and collecting the oil by skimming it from the surface of the water, it has a bland, light-coloured appearance. (<i>Faulk- ner.</i>)" In <i>Cooke's Oils and Oil-seeds in India</i> it is stated that cotton-seed is" in some localities considered a better food for the working bullock than grain. It produces, under the action of the native oil mill, 25 per cent, of a good oil, which, by being purified, might grow into an extensive article of commerce. Mr, Bingham does not think it would answer to export* the seed, as, owing to the fibre adhering to it, and perhaps other causes, it is very liable to heat and deteriorate in bulk. The oil is said to be a very useful one, more so than most others for machinery purposes." (<i>Agri- Hort. Soc. Ind. Jour.</i> > XII., 343). The above passage is practically a re- print ot Mr. Bingham's remarks, in his account of the oil-seeds of the Sa	L	
50 as an oil-yielder. Indeed, in this case, as in many other features of cotton cultivation and utilisation, the natives of India do not manifest that in- timate knowledge which characterises their acquaintance with most of the products of their country. While they grow many plants purely as sourcess of oil, for food, and lighting purposes, they seem to be practically ignorant of the fact that cotton-seed affords one of the most wholesome of oils. In <i>Balfourd's Cyclopaedia of India</i> it is stated that "when obtained by pressive its colour, owing to the presence of a resinous substance, is of a very dark red, and io to 15 per cent, is lost in bleaching it. When prepared by steaming the seeds, and collecting the oil by skinnning it from the surface of the water, it has a bland, light-coloured appearance. (<i>Faulk-ner.</i>)" In <i>Cooke's Oils and Oil-seeds in India</i> it is stated that cotton-seed is" in some localities considered a better food for the working bullock than grain. It produces, under the action of the native oil mill, 25 per cent, of a good oil, which, by being purfiled, might grow into an extensive article of commerce. Mr, Bingham does not think it would answer to export ⁴⁸ the seed, as, owing to the fibre adhering to it, and perhaps other causes, it is very liable to heat and deteriorate in bulk. The oil is said to be a very useful one, more so than most others for machinery purposes.' [<i>Agri</i> . <i>Hort. Soc. Ind. Jour.</i> > XII., 343). The above passage is practically a reprint of Mr. Bingham's remarks, in his account of the oil-seeds of the Sasser am district (published in 1862), and it has been repeated in most works on this subject without being in any way amplified or confirmed. The singular silence, on the uses of cotton-seed, in the Gazetteers is practically a proof of the total neglect that prevails throughout loalia. The kapas or cotton with its seed is sold to the dealers who clean it and dispose of the seed as they please, returning a certain amount to the culitivators to be sown in the succeeding	SEED & OIL	2 gallons of oil, 48ft of oil-cake, and 6lb refuse fit for soap-making; another says that one ton of American seed gives 20 gallons o(oil; a third, that the oil-product is 37 per cent, of the weight of the kernels; a fourth that 2 gallons of oil and g6lb of cake are afforded by 1 cwt. of seeds, a fifth that 1 ton of cotton material yields at the rate of some 35
cultivation and utilisation, the natives of India do not manifest that in- timate knowledge which characterises their acquaintance with most of the products of their country. While they grow many plants purely as sources of oil, for food, and lighting purposes, they seem to be practically ignorant of the fact that cotton-seed affords one of the most wholesome of oils. In <i>Balfours Cyclopaedia of India</i> it is stated that "when obtained by pressiVe its colour, owing to the presence of a resinous substance, is of a very dark red, and io to 15 per cent, is lost in bleaching it. When prepared by steaming the seeds, and collecting the oil by skimming it from the surface of the water, it has a bland, light-coloured appearance. (Faulk- ner.)" In Cooke's Oils and Oil-seeds in India it is stated that cotton-seed is "in some localities considered a better food for the working bullock than grain. It produces, under the action of the native oil mill, 25 per cent, of a good oil, which, by being purfied, might grow into an extensive article of commerce. Mr, Bingham does not think it would answer to export* the seed, as, owing to the fibre adhering to it, and perhaps other causes, it is very lashle to heat and deteriorate in bulk. The oil is said to be a very useful one, more so than most others for machinery purposes." [Agri- Hort. Soc. Ind. Jour.> XII., 343). The above passage is practically a re- print of Mr. Bingham's remarks, in his account of the oil-seeds of the Sasse- ram district (published in 1862), and it has been repeated in most works on this subject without being in any way amplified or confirmed. The singular silence, on the uses of cotton-seed, in the Gazetteers is practically a proof of the total neglect that prevails throughout India. 	DSSYFIUM
The Cotton-Seed Oil and Cake (Watt & Murray)	rhaceum.
It is admitted by many American writers that the income derived from the seed has made all the difference between profitable and unprofitable cotton cultivation. If the dealers in the future are to continue to pay the cultivators the same average amount for cotton with its seed, as they did in the past (when the seed was worthless), an undue profit will fall into the hands that least deserve it. In this respect it would seem clearly the duty of those in authority to keep before the eyes of the cultivators the progress made in the cotton-seed traffic. The best incentive to cleaning their own cotton, preserving their own seed, and improving the cultivation generally, would doubtless be secured through personal gain. Some idea of the magnitude of this possible future trade may be learned from the fact that since India produced last year a little over 9 million cwt. of cleaned cotton, that amount must have been obtained from 27 million cwt. of seed. Allowing half to be required for home consumption Snd seed for next crop, over 600,000 tons should have teen available for export, or twice the quantity imported by the United Kingdom from all sources. SPECIAL OPINIONS.—§ "The seeds are given to cattle to increase and improve their supply of milk. The seeds furnish an oil which is used for lighting purposes." <i>[Narain Misser, Kathe Bazar Dispensary, Hoshang- abady Central Provinces</i>). "The seeds are largely used in various parts of India in feeding cows, to increase the quantity and improve the quality	SEED & OIL.
of their milk." (Assistant Surgeon Nunda Lai Ghose, Bankipur).	
PART of this plant contains much mucilage, and has been used as a demulcent. The seeds yield by expression a FIXED OIL of the drying kind, which is employed for making soap and other purposes. The BARK of the root has been supposed to possess medicinal virtues, and is now re- cognised in the U. S. Pharmacopoeia." "Cotton SEEDS have been employed in the Southern States with great asserted success in the treatment 0\$ in- termittents." "A pint of the seeds is boiled in a quart of water to a pint, and a tea-cupful of the, decoction is given to the patient in bed, an hour or two before the expected return of the chill." Ainslie says that the seeds of G. barbadense, in the form of an emulsion, are given in dysentery and are supposed to be pectoral. They yield by expression an oil which is much used, and is considered to have, in a peculiar manner, the virtues, when externally applied, of clearing the skin of spots and freckles. A tea made of the young LEAVES is recommended in lax habits, and for preparing a vapour bath for the anus, in cases of tenesmus. Of the root of G. herba- ceum, Ainslie remarks that he suspects it possesses little real virtue. The Tamil doctors are, however, he adds, in the habit of prescribing a decoc- tion of it in strangury and gravel. Dr. Dymock (<i>Pharm. Ind., /., 22\$</i>) says : "Eastern physicians consider all parts of the cotton plant to be hot and moist; a syrup of the FLOWERS is prescribed in hypochondriasis on ac- count of its stimulating and exhilarant effect; a poultice of them is applied to burns and scalds. OSSYPIUM nerbaceum.	Properties of Gossypium.
MEDICINE.	mended in uterine colic." In the <i>Gazetteer of Bulandshahr</i> cotton-seeds, <i>binaula</i> , are included in a list of the more commonly employed indigenous drugs: the properties assigned to these seeds are not however stated. Atten-
Root-bark, 59	tion appears to have been first drawn to the emmenagogue property of the cotton ROOT-BARK through the observation made by Dr. Bouchelle, of Mississippi, that it was used by Negro females to produce abortion. On this subject Dr. Dymock writes,—"There appears to belittle doubt that it acts like ergot upon the uterus, and is useful in dysmenorrhoea and suppression of the menses when produced by cold, a decoction of four ounces of the bark in two pints of water boiled down to one pint, may be used in doses of two ounces every 20 to 30 minutes, or the fluid extract may be prescribed in doses of from 30 to 60 minims," The above passage is almost word for word as originally published by the discoverer, so that the knowledge of this property is apparently confined to America. This fact may have a historic significance, for, although the people of India seem to have H ad a peculiar aptitude in discovering emmenagogues and aphrodisiacs, they failed to discover any such properties in this case, and the cultivation of cotton might therefore be inferred to be less ancient than is generally supposed.
Preparation of Cotton. 60	A special preparation of COTTON is made, which removes its greasiness and renders it absorbent. This absorbent cotton may be further medicated with carbolic acid, salicylic acid, or boracic acid, and in this form used as an application or dressing to wounds. Its effects are chiefly due to the absorption of effused fluids and the protection it affords from the air. It is similarly used to arrest haemorrhage, its action being mechanical, but for ³ this purpose the special preparation known as 'STYPTIC COTTON' is gene-
Styptic. 61 Gun-cotton. 62	rally employed. GUN-COTTON or PYROXYLIN is prepared by dipping the floss in a mixture of equal parts of nitric and sulphuric acids, and by after- wards washing freely with water and drying. This explosive substance is readily soluble in a mixture of ether and rectified spirit, forming the officinal COLLOOIUM or COLLODION.
CHEMISTRY. 63	^{rt} CHEMISTRY OF GOSSYPIUM BARK.—In the United States Dispensatory, tatcen for the most part from the American Journal of Pharmacy, will be found the chief facts regarding the chemistry of this substance. These opinions are briefly reviewed in the <i>Pharmacographia Indica</i> as follows:—" The bark contains <i>starch</i> , and when fresh, according to W. A. Taylor (1876), a <i>chromogen</i> , which dissolves in alcohol with a fresh yellow, gradually chang- ing to a bright brownish red. The same change takes place on keeping the bark for some time, when it yields a red tincture with alcohol. This substance was examined by Professor Wayne (1872) and W. C. Staehle (1878), who regard it as of a resinous nature. The latter obtained about 8 per cent, of this substance, which is soluble in 14 parts of alcohol, 15 of chloroform, 23 of ether, and 122 of benzol; also in alkalis, from which solution it is again precipitated by acids. The potassa solution diluted with water is of a sage green tint. Glucose was likewise observed, and the aqueous solution of the alcoholic extract contained a principle which gave a purplish-black precipitate with ferric chloride. C. C. D rued ing (1877) obtained also a yellow resin soluble in petroleum benzine, a fixed oil, a little tannin, and 6 per cent, of ash." <i>c</i> SPECIAL OPINIONS—§ " Cotton-wool is a filterer of atmospheric germs preventing their access to wounds, cavities of the nose, ear, &c, and for this purpose is very useful after operations, including those on the eye.' <i>{Brigade Surgeon G. A. Watson, Allahabad</i> . "The seeds largely increase the flow of milk, especially in cows, for whom <i>bandla</i> (sic ? <i>banaulf~En</i> .) is one of the best articles of diet. When given to wome the <i>bandla</i> is beater up in a mortar with a little water; the mass is then strained and the juicc mixed with rice and cooked into <i>khir," {Surgeon-Major</i> C. <i>W. Calthrop</i>

Morar). "The seeds are considered to be a nervine tonic and are given for headaches and brain affections." (Surgeon-Major Robb, Civil Sur- geon, Ahmedabad). "Best application in burns and blisters." (Assistant Surgeon Shib Chunder Bhuttacharji, Chanda, Central Provinces). "The seeds, deprived of their outer coat, powdered and given in milk (in doses of 2 drachms) are used as a tonic. *' (ist Class Hospital Assistant Lai Mahomed, Main Dispensary, Hoshangabad, Central Provinces.) "The young fruit is given to check dysentery." (V. Ummegudien, Mettapollian, Madras.) "The oil from the seeds is used as a liniment in rheumatic affections." (Honorary Surgeon P. Kinsley, Chicacole, Ganjam, Madras.)	
DOMESTIC AND SACRED.	
The sacred uses of cotton have already been alluded to. Except among one or two aboriginal tribes the plant as such cannot be said to be sacred, £ut the thread prepared from the so-called <i>Nurma</i> cottons is that alone prescribed to be worn as the Brahminical string. The STEMS of the cotton bush are largely used for agricultural purposes, being made into baskets in Bombay and other parts of India. Throughout the Panjab they are used in making the wattle sides of carts, being supposed better suited to such purposes than for basket-work. One of the most universal usages of the dry cotton stems is as fuel: this may be seen in all the cotton districts. In <i>U. C. Dutt's Materia Medica of the Hindus</i> (under the Diamond) occurs the following curious passage :—'' Diamond is purified for medi- cal purposes by being enclosed within a lemon and boiled in the juice of the leaves of Sesbania grandiflora (<i>vaka</i>). It is reduced to a powder in tfie following manner: A piece of the root of a Cotton plant is beaten to a paste with the juice of some betel leaves. Both these vege- tables should not be less than three years old. Diamond is enclosed	
within this paste and roasted in a pit of fire. The process is repeated seven times, when the stone is easily reduced to a fine powder. "	}
IV. G. StOCksii, Mast. ; Fl. Br. Ind., /., 346. References.—Tod., Cult, dei Cot., 132; Dymock, Warden, and Hooper, Pkarm. Ind., 224-228; Murray, PL and Drugs, Sind, 64. DIAGNOSTIC CHARACTERS.—Leaves glabrous, palmately 3-5-lobed, segments roundish or oblong obtuse. Bracteoles ^A deeply laciniate, segments linear lanceolate. Flowers small, yellow. Capsule ovoid. Seeds devoid of felted down, covered with yellow adherent cotton not easily separable.	66
Habitat.—A shrub found on the lime-stone rocks of the coasts of Sind. Dr. Masters and, following him, Todaro and DeCandolle, regard this as the wild condition of G. herbaceum. It may, however, be pointed out that the glabrous leaves, deeply laciniated bracteoles, and naked seeds ally it more strongly to some of the forms of G. barbadense. The interest in this observation lies in the fact that the most recently dis- covered wild species in Africa is viewed by Masters as very nearly allied to G. barbadense. Doubt may thus be admissible as to the desirability of a hard-and-fast isolation of the forms of Gossypium into Old and New World types, represented by G. herbaceum in the former and G. barbadense in the latter. Stocks himself, while describing his wild plant, in the <i>Gazetteer of</i> <i>ISind</i> , calls it G. obtusifolium, <i>Roxb.;</i> and thus did not view it as distinct.	
V. Hybrids and Hybridisation. If the character of velvety seeds (below the floss) be accepted as an Asiatic peculiarity, the absence of velvet would have to be added to the col- lective characters given above for the indigenous American species of Gossypium. And if this view receive more support than it has hitherto	HYBRIDS. 67

GOSSYPIUM	
Hybrids,	Hybrids and Hybridisation.
HYBRIDS.	obtained, then the forms of cotton with broad leaves, laciniated bracteoles and velvety seeds (such as G. hirsutum). would have to be regarded as
HYBRIDISA- TION. 68	hybrids. As opposed, however, to this explanation of the velvety-seeded American cottons, there are one or two considerations of importance : Certain writers affirm that it is impossible to hybridise the American naked seeded with the Asiatic velvety forms, or, indeed, the Asiatic with any American. It is further contended that the American velvety seeded cottons were known and even held to be indigenous Western species prior to the recorded introduction of Asiatic cottons in America, which probably took place towards the end of the last century. So again G. hirsutum and other velvety-seeded American forms show little tendency to revert to Asia- tic types, though in India they degenerate to almost valueless states. But, on the other hand, the ease, in certain cases, with which the velvet is in- herited or lost under simple cultivation, would point to its being an acquired and not an originally specific peculiarity, at least in the de- bateable species, the more so since, in the pure types of naked-seeded American or velvety Asiatic, the velvet is neither acquired nor lost. It would thus seem desirable to have the question of hybridisation more carefully investigated. Not having the opportunity of performing such experiments we are compelled to content ourselves with a review of what has been written. That the Indian cottons have been freely hybrid- ised, naturally and artificially, goes without saying. That the same is the case with the American is equally true : the prized New World cottons are in fact mostly sports or hybrids. The debatable point is, can a hybrid be produced, or does such exist, between Indian and American pure cottons? We are bound to admit that there seems, even in the face of all that has been written to the contrary, no good reason for supposing that American and Asiatic species cannot be hybridised. But it may be as well to give here the opinions of writers on the subject. Major Trevor Clarke (<i>Pro- ceedings, Madras Agri-Hort. Soc, June 1871)9</i> in a letter to Mr. H. Rivett-Carnac, for
	the true Indian plant." Mr. W. Walton (<i>in Cotton, its Culture, Trade, and Manufacture,</i> Bombay, 1880) devotes a chapter to the subject of Hybridisation, He seems to have been influenced by so liberal an admiration of Dr. Wight's botanical merits as to accept unreservedly the dictum laid down by that author that hybridisation of <i>any two species of cotton</i> " would be contrary to the laws
	of nature." To do so, wrote Dr. Wight, "it would be necessary to open the flowers before natural blooming, to cut out their stamens before shed- ding their pollen, and then to apply the pollen of the intended male parent to the virgin stigma; if its own pollen had once been applied, the other will not take effect." As opposed to this emphatic statement it need only be said that in India at least the difficulty is to find a cultivated cotton that is not a hybrid. Many authors describe, in great detail, their va- rious methods of hybridisation, so that, in addition to the fact of most of the favourite growths of cotton being botanically hybrids, no such difficul- ty exists as stated by Wight. The failures which Mr. Walton cites, in support of his concurrence with Wight, were failures to naturally fertilise New .Orleans with ^M native Indian cotton." But the difficulty arises, what is native Indian cotton, and even still more so, what is New Orleans ?
	We are, for example, strongly disposed to think the latter a hybrid, as G. 68

.

٥

GO	SSYPIUM
· Unbridg and Unbridgetion (Watt & Murray)	<u>Iybrids.</u>
most of the Indian cottons certainly are; hence Dr. Forbes, Mr. A. Elphinston, and other writers on this subject very probably tried to pro- duce a cross between two hybrids—a matter which might have been an- ticipated to prove difficult. We are therefore unable to support Mr. Walton's contention, that these failures in one line of experiment prove the impossibility of any hybridisation. On the contrary, we believe that few genera are more easily hybridised artificially than, or have been so exten- sively hybridised in nature as, the species of Gossypium. This idea is borne out by Todaro's experiments in the hybridisation of cottons. That careful observer not only crossed many species artificially, but he gives it as his experience that it is almost impossible to check the natural hybrid- isation of Asiatic cottons. For example, he observed that G. Wightianum may be crossed with G. neglectum or with G. herbaceum, <i>var.</i> micro- carpum, and that the hybrids take intermediate forms which connect the «ancestral types. By continued cultivation he found that these hybrids were all fertile, but that they gradually approached their specific types if grown near each other, though preserved if they were kept apart. On the other hand, he noted that G. herbaceum, <i>var.</i> microcarpum, fertilised G. Wightianum and G. neglectum, <i>var.</i> microcarpum, on sterile soils, To- daro noted that that form was far more liable to change its characters than was G. Wightianum when similarly treated. He then adds that in these hybrids it is nearly always G. Wightianum that fertilises G. neglectum, the reversion going to G. neglectum, rarely to G. Wightianum. These are facts of great importance, and doubtless there are many others of a similar nafcure which should imperatively be understood, before good results can be obtained in hybridisation. It would appear to be essentially necessary, for example, first of all to thoroughly establish the characters of the species and to possess stock of the purest strain. Haying done so, experiments might	HYBRIDISA- TION.
In the Annual Reports of the Experimental Farms in the Bombay Presi- dency numerous reports occur on the subject of Hybrids and Hybridisa- tion. An interesting paper on this subject will also be found in the Report for 1872 (North-West Provinces and Oudh) from <i>the</i> pen of Mr. J. Simpson, Superintendent of the Cotton Farm at Bulandshahr. In the Journals of the Agri-Horticultural Society of India numerous papers also appear on this subject. Thus, for example, <i>Volume 1. (Old Series), 183-103\$</i> Dr. J. V. Thompson of Sydney describes his process of hybridisation in letail, and gives particulars of his favourite hybrid between Georgian and Maltese brown cottons, to which he gave the name of <i>Georgia tinta</i> . This was probably a cross between G. barbadense and G. herbaceum, or possi- oly G. religiosum, <i>Roxb</i> . In <i>Volume VI. (Old Series), 149-153,</i> Mr. H. Hamilton Bell discusses certain Indian hybrids. In <i>Volume L (New Series),</i> <i>roceedings 1867, x.,</i> Major Trevor Clarke furnishes particulars of his having been working hard at the subject of getting the arboreous sorts of seed and cross. Speaking of the hybrids Tie had produced, he wrote, '' Many were mere scientific experiments, some were the produce of bad orts, some no hybrids at all, and so on.'' In the same volume (<i>Proceed'</i> <i>Ings for i860</i>), Mr. S. H. Robinson furnishes the Agri-Horticultural fociety with cotton grown at Goosree from seed of a hybrid cotton produced	

HISTORY. 69

History of Cotton. :

HYBRIDISA-TION, by Major Trevor Clarke, a cross between Sea Island and Bourbon [Con/, with the remarks regarding Baxnia Cotton, p. 18 and p. 19.)

It is perhaps needless to quote other passages in support of the contention that hybridisation is possible, or that many hybrids exist. Suffice it to add that we are strongly disposed to regard all American velvety-seeded cottons as hybrids between the American and Asiatic series of forms. When, or how these were produced is quite another matter, but that in India they should show no sign to revert to the G. herbaceum series establishes one peculiarity of their hybridisation, but does not disprove their origin as here suggested. There are many examples of hybrids produced in a particular manner, which invariably, in retrogression, produce one and not the other strain. To arrive at a more precise conception of these supposed American-produced hybrids, it would be necessary to know whether, in the home of their birth, they show a tendency to revert to the G. barbadense series of characters. Their behaviour in India is of lees consideration, since all American cottons degenerate rapidly in this country and often assume perfectly new, though inferior, forms. The acclimatised New Orleans cotton of India has lost, for example, many of its original properties, but is as distinct as ever from either of its suggested ancestors.

HISTORY.

Perhaps no more remarkable example of a sudden development exists in the whole history of Economic Products, than in the case of cotton. The enormous importance, at the present day, of the fibre in the agriculture, trade, manufactures, and daily wants of the people of nearly the whole world, render it difficult to believe that only a few hundred years ago cotton and its products were practically unknown to the civilised nations of the West.

But it is perhaps even more singular that a fibre which has for centuries been the staple article of clothing in India, and elsewhere in the East, should scarcely find a place in the early classical literature of these Nearly all the beautiful and the useful plants of India, if not countries. of Asia, have their" properties extolled by the Sanskrit poets, and indeed are frequently dedicated to the gods, but cotton—the plant above all others which might be expected to have formed a theme for nature worship—is passed by, with only the most incidental allusions to its properties. Indeed, it is only in modern works that the fibre is unmistakeably referred to. Evidences exist, however, amongst certain of the aboriginal tribes of Ind'a of what is perhaps a much more ancient knowledge of the plant. For example, the Khonds grow a cotton-bush in the place selected for a new

"History of Cotton.

•

(Watt & Murray) GOSSYPIUM.

settlement, and in after years the village plant is tended as sacred and carefully watered. This custom is probably of very ancient origin, and may denote a superstitious regard for the plant, probably derived from the knowledge and appreciation of its valuable properties.	HISTORY.
The Sanskrit word translated " cotton " is perhaps first mentioned in the Institutes of Manu, where, in <i>Book II., No. 44</i> , it is stated that, "the sacrificial thread of a Brahman must be made of cotton, so as to be put on over his head in three strings." The word used in that passage and trans- lated cotton is <iiimitft (<i="">kdrpdsi) from which has been derived, accord- ing *o most writers, the modern Hindustani <i>kapds</i>, and even the Hebrew <i>karpds</i> (the "green hangings " of the Book of Esther). The frequent con- fusion in ancient classical terms for textile fibres, which will be further commented on below, has led many to believe that the <i>kdrpdsi</i> of the Insti- tutes of Manu may not necessarily have been cotton. The probability, however, is that it really was so. Not only does the term in general use for cotton at the present day evidently owe its origin to that word, but the brah- minical threads are, up to the present date, made almost, if not quite, exclusively from the fibre of G. arboreum, a plant, in many parts, considered the exclusive property of the Brahmans, and generally planted near tem-</iiimitft>	Cotton in Sanskrit Literature.
ples, or the abodes 01 fakirs. Be this as it may, it is certain that at the time of the Institutes of Manu spinning and weaving were not only known, but the art of starching or weighting a textile was also practised, and the admissible amount pre- scribed. In <i>Book VHL, No. 236</i> , it is enjoined that for "stealing thread, raw cotton, materials for making spirituous liquors, &c," the fine should be "thrice the value of the article stolen. Again, at <i>No. 397, "</i> Let a weaver, who has received ten <i>palas</i> of cotton thread, give them back increased to eleven by the rice water, and the like used in weaving; he who does other- wise shall pay a fine of twelve panas." A still earlier notice of the process of starching probably occurs in the <i>Rig Veda, Hymn</i> 705, <i>v. 8,</i> where the following is to be found: "Cares consume me Satakratu, although thy wor- shipper, as a rat gnaws a weaver's thread." Commentators have explain- ed that the rat's temptation was probably the starch, in which the threads had been steeped to improve their tenacity and strengthen the fabric. The picture thus raised of the character of the textile industries of India, some two thousand years ago, meets its parallel only in the injunctions laid down for domestic life. <i>Book VIII., No. 3g6, of the Institutes of Manu</i>	
deals with the regulations concerning washermen. "Let a washerman wash the clothes of his employers by little and little, or piece by piece, and not hastily, on a smooth board of <i>Sdlmali-v/ood</i> : let him never mix the clothes of one person with the clothes of another, nor suffer any but the owner to wear them." (For <i>Sdlmali-wood cf.</i> with Bombast and Erioden- dron.) We are thus led to believe that not only were spinning and weaving fully understood, but that a civilisation existed in that early age, in which the social habits of the people differed little from those of the present day. Accepting as correct the interpretation of the early <i>kdrpdsi</i> as cotton, we have no alternative but to believe that the arts of spinning and weaving jvere perfectly understood in the East, at a time when the textile industries of the West, through ignorance of cotton, were in a much more backward condition.	
It is extremely difficult if not quite impossible to determine the earliest of	iotton in arly classical iterature.

	History	of	Cotton.*
--	---------	----	----------

HISTORY. bic Kurpas (probably derived from the Sanskrit), the modern kutn fijiaj and panbah AAJU, of the Persians are all now translated cotton, though their original meaning is doubtful. In Greek the word *karpason* is generally translated "cotton," but has often been rendered " flax." The /3td<ro-o? of the early Greeks was the fine linen used for making mummy cloths, but by later writers it was applied to cotton. The words K(vov and linum have sometimes been translated "cotton," just as karpason has often been rendered "flax." Yates (in his Textrinum Antiquorum) says that some poets assume a license in the use of the word carbasus, and Dr. Robertson points out that doubt may be admissible as to whether cotton was even known to the early Romans, since garments made of that fibre are nowhere specified in the laws de Publicanis et Vectigalibus, while, on the other hand, imported spices and precious stones find a recognised place. It may also be viewed as significant that, with writers at the beginning of the Christian era, it was customary to speak of cotton and cotton goods by names not in use prior to that date. Thus Pfiny refers to the Gossypinos or Gossypion of the island of Tylos, and a misapplication of a term derived from silk became general, Bambacinus (made of cotton), Bambacarius (cotton dealer), &c. e.e. *Bombax* is the generic name given by botanists to the silk-cotton tree. It is thus evident that no reliance can be placed on any of the terms above mentioned as necessarily meaning " cotton," and that it is only possible to identify a reference to it by the context. Herodotus is perhaps the first who seems to refer to the fibre. In his account of India he writes, " The wild trees of that country bear fleeces as their fruit, surpassing those of sheep in beauty and excellence; and the Indians use cloth made from these trees." He further states that the cuirass sent by Amasis, King of Egypt, to Sparta, was " adorned with gold and with fleeces from trees." Ctisias, the contemporary of Herodotus, was also acquainted with cloth made from tree-wool. **^But perhaps the first unmistakeable reference to cotton is by Theo**phrastus, subsequent to the expedition of Alexander into India. Me describes the trees from which the Indians made cloth, as " having a leaf like that of a black mulberry, the whole plant resembling the dog-rose. They set them in the plains arranged in rows, so as to IOOK like vines in a The plant thus described is unmistakeably cotton, and the distance." passage indicates that not only was the fibre known, but that the plant was cultivated, at least in North-Western India, at that early date. Nearchus described the garments made from this tree-wool, stating that the natives wore a cloth " which reached to the middle of the leg, a sheet folded about the shoulders, and a turban rolled round the head," a description which accurately describes the clothing of the people of many parts of the country at the present day. Cotton as an The first mention of cotton, considered as an article of commerce, is article of found in "the Periplus of the Erythraean Sea," by Arrian, who probably Commerce. lived towards the end of the first century. That writer, who was at the same time a merchant and traveller, sailed over the whole of the Arabian Sea, and described in detail the articles of trade of many of the corst towns of India. According to Arrian it appears that, in his time, the Arabs exported Indian cotton to Aduli, a port on the Red Sea, and that a trade was established with Patiala, Ariake, and Barygaza—the modern Broach. From the latter a great quantity of cotton cloth, made in the neighbourhood and also obtained from the remote parts of the country, was exported, Masulia, the modern Masulipatam, was also then, as it is to this day, famous for the manufacture of excellent cotton stuffs. The muslins of

HISTORY. Dacca seem also to have been known. They are described as superior to all others, and are said to have been called gangitiki by the Greeks, a name indicative of their manufacture on the banks of the Ganges.

The knowledge of the manufacture of cotton appears to have extended into Arabia and Persia about the beginning of the Christian era. From these countries cloth locally manufactured, or imported thence from India, may have found its way to Rome and the richer cities of the Greeks. But such supplies must have been very rarely obtained, and the silence of classical authors on the subject is a proof of the want of regular imports of the material. Even after regular commercial intercourse had been established between Rome and the East, cotton, considered as a material capable of being woven, appears to have excited little interest. It may in fact be inferred from the silence of writers of the middle ages that cotton was even then but little known. While they write in full detail of 4he ordinary articles of clothing, of wool, linen, and silk, they make no mention of cotton.

From India, there is no doubt, the cultivation of cotton spread into Persia, Arabia, and Egypt, from whence it probably extended into Central and Western Africa. From Persia the culture migrated into Syria and Asia Minor, also into Turkey in Europe, and thence into other parts of Southern Europe. It is doubtful at what period the plant first crossed the Mediterranean, but the earliest account of its cultivation on the European shores, is to be found in the works of Eben el Awan of Seville, who lived in the twelfth century. He describes the method employed in Sicily and Spain, to which the plant had doubtless been brought by the Arabs. About theeame period cotton stuffs, manufactured in Turkestan and by the Armenians, became an important article of commerce between Asia and the Crimea.

On its arrival in Europe, cotton-wool was first employed in the manufacture of paper, and for padding quilts, cushions, &c. The art of spinning its short staple was only learnt in Europe after the delicate manufactures of the East had permeated the whole world. Thus, long beforS any mention is made of cotton manufacture in Europe, records exist of paper made of cotton being commonly used at Cambridge.

But more astonishing still than the slow progress of cotton to Europe is the fact that China, which, from very remote times, held intimate commercial intercourse with India, should have known nothing of the arts of culture and manufacture of cotton until the thirteenth century, when they were introduced into that empire by the Mongol-Tartar dynasty. Two Arabian travellers who visited China in the ninth century observed, "The Chinese dress, not in cotton as the Arabians do, but in silk." In the sixth century records exist that the Emperor Ou-ti possessed a robe of cotton, which had probably been presented by some foreign ambassador, and was held in great esteem. Towards the end of the seventh century it is known that the plant was grown in gardens for the beauty of its flowers. At first, as in England, there was great opposition to the new staple, but the cultivation gradually increased, until it reached its present importance, being now in China as in India a valued crop. The quantity produced annually as been estimated at as much as 12,000,000 bales. Whether that be a correct estimate of Chinese production or not, the outturn must be enormous, since the lower orders (now-a-days) are all clothed in cotton.

Turning to the New World, we find that cotton has probably been used from the earliest times. It is connected with some of the most ancient beliefs of the aboriginal peoples of South America. Thus, M. Agassiz in his work on Brazil, recounts a strange legend respecting the cotton plant according to which Caro Sacarbu, the first of men and a demi-god, pulled'

Spread of Cotton-to Europe,

to China.

Cotton in the New World.

GOSSYPIUM,

HISTORY.

Spread of the Cotton Industries. History of Cotton:

the ancestors of the human race from the bowels of the earth by means of a cotton rope. Columbus found cotton in use among the natives of Hispaniola, but only in the most primitive way. Cortez found the manufacture in a much more advanced condition in Mexico. The Spanish historian informs us that" The Mexicans made large webs, as delicate and fine as those of Holland. They wove their cloths of different figures and colours, representing different animals and flowers. Of feathers interwoven with cotton they made mantles and bed curtains, carpets, gowns, and other things, not less soft than beautiful. With cotton also they interwove the finest hair of the belly of rabbits and hares, after having spun it into thread; of this they made most beautiful cloths, and in particular winter waistcoats, for their lords."

With the rise of Muhammadanism and the conquests of the Saracens, the knowledge of spinning and weaving cotton probably spread to Europe, consequently we find the delicate cotton fabrics of the Efst first imitated in Italy and Spain, during the twelfth or thirteenth century. From these localities the art of cotton manufacture became diffused and extensively established all along the Southern shores of the Mediterranean, but it was confined to that area till the sixteenth century. The Dutch then succeeded in depriving the Portuguese of their Eastern colonies, and not only extended their own imports of cotton goods, but, towards the end of the century, began to manufacture at home.

From the Low Countries the industry passed over to England in the seventeenth century. On the arrival of cotton goods at the Mediterranean ports, these fabrics became known and valued in England, and gave rise to imitation. Thus Cam den, writing of Manchester in 1590, says, * This town excels the towns immediately around it in handsomeness, populousness, woollen manufacture, market place, church, and college, but did much more excel them in the last age, as well as by the glory of its woollen cloths, which they call,' Manchester cottons.' " In 164.1 Roberts, in his "Treasure of Traffic," writes, "The town of Manchester buys cot*on wool from London, that comes from Cyprus and Smyrna and works the same into fustians, yermillions, and dimities." About this time, however, calicoes began to be imported in greater quantities from Holland, Portugal, and also from India direct, with the result that Indian chintzes became so generally worn (to the detriment of the woollen and flaxen manufactures at home) as to excite popular feeling against them. Disputes arose as to the question of duty on these goods. Thus, in 1664, Pepys writes in his diary, "Sir Martin Noel told us the dispute between' him, as framer of the additional duty, and the East India Company, whether calico be linen or no, which he says it is, having ever been returned so. They say it is made of cotton wool and grows upon trees." In 1678 complaints from those interested in woollen manufactures became louder and a pamphlet was issued, called " The Ancient Trades Decayed and Repaired again," lamenting the detrimental effect of imported cottons. This dissatisfaction steadily increased, till, in 1700, Acts were passed wKch prohibited the introduction of printed calicoes for domestic use, either as apparel or furniture, under a penalty of ^ 200 on the wearer or seller. But this did not prevent the continued use of cotton goods, qiintities of which were smuggled into the country.

Towards the end of the seventeenth century cotton printing was established in England, and English prints began to combine with Indian in ousting woollen goods. Thus in 1708 the *Weekly Review* of Daniel De Foe contained the statement that " above half of the woollen manufacture was entirely lost, half of the people scattered and ruined, and all this by the interference of the East India Trade." Dissatisfaction increased, till in * History of Cotton.

(Watt & Murray.) GOSSYPIUM.

1720, an Act was passed prohibiting altogether " the *use* or *wear* in Great Britain, in any garment or apparel whatsoever, of any printed, painted, stained, or dyed calico, under the penalty of forfeiting to the informer the sum of $\pounds 5$." By the same Act the use of printed or dyed calicoes, " in or about any bed, chair, cushion, window curtain, or any other sort of household stuff or furniture," was forbidden under a penalty of $\pounds 20$, and the same attached to the seller of the article. This Act, however, though confirmed in 1721, appears to have had little permanent effect, since in 1728 we find another author writing of the prevalent evil of the consumption of Indian cotton manufactures, which he ascribed to the " passion of ladies for their fashion."

In 1736 the law, since it struck at the existence of the now rising cotton manufactures of England, was modified so far as to permit the manufacture of calicoes "provided the warp thereof is entirely made of linen thread."

During the succeeding thirty years the mechanical achievements of Wyatt Kay, Hargreaves, and Arkwright, by reducing the cost of manufacture, and contributing to the production of more perfect and cheaper fabrics, placed the English manufacturer in a position to dispense with a considerable proportion of the protective legislation which previously existed. Accordingly, a law was passed in 1774, sanctioning the manufacture of purely cotton goods, rendering English calicoes subject to a duty of 3d. per square yard, but still prohibiting the importation of such goods. The numerous inventions perfected about the end of the eighteenth century, together with the withdrawal of restriction in manufacture, led to so wonderful a development of the cotton trade, that it became not only necessary to seek new markets for English manufactures, but also for more abundant supplies of the raw material. In 1697 the amount of cotton imported into England was 1,976,359 ft, up to 17491/it did not materially increase, in 1751 it was 2,976,610ft, the average from 1771 to 1775 was 45764.589ft; but from 1796 to 1800 it increased to the annual amount of 37>350>276ft. At this period the West Indies appear to have bec9me the best and largest source of supply, and prices seem to have ranged from 2od. to 301/. per ft, though in 1799 the average price of West India and Barbias extra was as bight of 272 per ft and Berbice cotton was as high as 37c?. per ft.

Up to the commencement of the present century America contributed but a very insignificant portion of the cotton consumed. It is stated that "in 17S4 an American ship, which had imported eight bags of cotton into Liverpool, was seized, on the plea that so much cotton could not be the produce of the United States." The imports from America in fact continued to be very small up to the end of the century. In 1790, for example, Europe received 18 bags; in 1791 the total exports of cotton from the United States were 189,316ft, but in 1794 they amounted to 1,601,700ft, and by the year 1800 they had increased to nearly 18,000,000ft.

At the close of the war in 1815, when prospects of foreign trade began to brighten and to lead to an increased demand, the production of cotton in America received a fresh impetus, and the subsequent progress was rrpid and continuous. The lead then taken by the Southern States was A steadily maintained for nearly half a century, and a practical monopoly was eventually established. With increased production came lower prices; cotton worth 22d. per ft two years before fell in 1819 to *is.*, in 1848 to 4|rf. per ft.^

This great increase in the importance of America, as a cotton-growing country, early led the Directors of the Honourable East India Company to commence operations for the purpose of improving the quality and increasing **the** quantity of Indian cotton for export to England. Full information

HISTORY.

HISTORY.

The History of Cotton.

regarding cultivation and trade was called for as early as 1788. In 1790 numerous reports were received which showed the chief districts of the several provinces in which cott6n cultivation was then carried on, and recorded many interesting facts regarding the methods of cultivation. In a "Report on the Proceedings of the East India Company in regard to the Production of Cotton Wool" the following passage occurs:—" From this period great attention was bestowed with a view to the production of a larger and better supply of cotton in the provinces under the Company's Government, as well for the advantage of the native cultivators and manufacturers, as for the benefit of Great Britain. Endeavours were made to prevent adulteration in the cotton purchased from the native merchants; and in order to reduce the expense of freight, screws for compression were brought into successful use, and subsequently carried to great perfection."

The imports into Great Britain from India during the years 1800 to *iSog* averaged 12,700 bales per annum; and owing to the influence on the cotton trade of the American embargo in 1808, the quantity brought over in 1810 amounted to 79,000 bales (27,783,700ft). "In 1818 the export to the United Kingdom amounted to 247,300 bales (86,555,0001b)—the largest quantity exported from India up to 1833." The report continues, "In the import of every year there was generally among the consignments some good clean cotton; but the greater proportion was not suitable for spinning in this country, and was therefore re-exported to the Continent." The Company persevered in their energetic measures for the improvement of Indian cotton, but without much success.

The final result of the contest between America and India in cotton supply is too well known to require any recapitulation in this place. From 1818 onwards the respective quantities of Indian and American cotton in the English market never again approached each other till about the time of the American war. During the first fifty years of the present century, Indian cotton exports were characterised by the most extraordinary fluc-Thus in 1821 the imports from India had fallen to 20,000 tuations. bales; in 1841 they rose to 278,000 bales; in 1848 they again sank to 49,000 bales. America, in short, had gained command of the market, and India was considered only as a supplementary source of supply, resorted to mainly in the event of a short crop from the West. It was not till the blockade of the Southern Ports, during the American civil war, that India again became one of the main sources of supply to the English cotton market. The effect of that war is not only shown by the increase of I ndiair exports but by the extraordinary rise in value. Thus, previous to war, Indian cotton sold for between 2 and 3 annas per pound, and during the crisis attained the high value of II annas 5 pie. With the recovery of American trade, Indian cotton again decreased to its normal value and has since fluctuated between 4 pence and six pence a pound. The following analytical tablesof the imports into Great Britain, and statement of prices will perhaps, however, exhibit, in the shortest way, the striking fluctuat tions of the American and Indian trades during the ten years previous to and following the War of Secession :---

history of Cotton. (Watt & Murray) GOSSYPIUM

The causes of the decline of India's hold on the European market, during the first half of this century, are abundantly shown in every report on the subject. Imperfections in methods of picking, cleaning, and packing, together with extensive adulteration, rendered many of the Indian consignments practically valueless, and largely increased the demand for the clean American cottons, which thus rapidly obtained a stronger hold on the market. The great development in machinery, which coincidently took place, resulted in improvements being directed towards the utilisation of the clean, long-stapled, high quality American cottons. As a consequence, the short-stapled Indian flosses soon became entirely unsuited for Énglish machinery, and thus their market price rapidly fell. With diminished prices, and a bad name, inducement to improve the quality of consignments became less and less, till such a statement as the following became only too true:—" An inferior and dirty article is by far the most profitable artktle of native trade, even so to European merchants.'

Notwithstanding many endeavours on the part of the East India Company, but little improvement was effected. In 1829 a Regulation(III. of that year) was introduced for the suppression of the adulteration of cotton, but with no practical result. Attempts were therefore directed towards the improvement of Indian cotton by the introduction of American seed-attempts which were energetically aided by the Agri.-Horticultural Society of India, and by many private individuals. Thus, in 1830, the Society started a farm of 500 big has at Akra, near Calcutta, for the experimental cultivation of cotton. This endeavour was prosecuted, and acclimatised seed freely distributed till June 1833, when the lease of the farm'having expired, the Society did not deem it necessary to keep up the establishment. In 1837, £200 of the Society's money was set apart for procuring seed, and an annual grant of R 1,000 voted for the same purpose. And the whole of that amount was ordered to be expended on Upland Georgian. The earlier publications of the Society in fact teem with accounts of similar patriotic efforts.

In 1838, ten experienced planters were procured by Government, from the Southern States of America, for the purpose of establishing the cultivation of New Orleans cotton. They were furnished with seeds, ploughs, hoes, and gins, and began operations about 1840-41. Three were»stationed in Bombay, chiefly at Broach; three in Madras, at Tinnevelly and afterwards at Coimbatore; and the remaining four, sent to Bengal, commenced experimental cultivation in the Doab and Bandelkhand. With varying success these cotton farmers continued their efforts, until it became manifest that permanent improvements were not likely to be attained. Besides many natural difficulties, much opposition from the natives was encountered. This was overcome in Dharwar only, the one great instance of success, by the personal influence of the Collector and his assistants. For a full account of these experiments the reader is referred to the publications of the Agri.-Horticultural Society of India.

Notwithstanding the want of success which attended these endeavours, a firm conviction was still entertained that the speediest and surest way to the improvement of Indian cotton was by the extensive use of exotic seed. Large qua*tities were accordingly sent to India by the Cotton Supply Association, and were also distributed by the Agri.-Horticultural Society of India, but with the old result of general failure. Up to the date of the American war, and the consequent cotton famine, it appeared as if Indian cotton would be gradually driven out of the market. At that time, however, merchants in Europe naturally turned to this country for a great part of their supply, and energetic efforts were renewed by Government to meet the demand and improve the quality. These endeavours were materially

aided by private enterprise; notably so by the English Cotton Supply Association. In 1863 a Cotton Commissioner was appointed in the ^{Bom} ME Presidency; in 1864 a similar appointment was made for Berar ana the Central Provinces. A Cotton Frauds Bill was submitted in 1862-03, and

became law as the Bombay Cotton Frauds Act, IX. of 1863. In conclusion it may be said that experiments on the introduction of American seed have been steadily kept up at the Government Farms DUe with little success, and of late years attention has been consequently moand more directed towards improving the Indian staple, by careful 1 seiection of seed and adoption of the best methods of cultivation. Since the reestablishment of the native staple in European markets, consequent on the cotton famine, it has been found that a good market does exist. An exports have remained fairly steady, and should the staple not furthe deteriorate, they are likely to continue regular.

The reader is referred to the article on "TRADE " for information as to the present position of India as a cotton-exporting country. The remarKable increase since 1862, and the present immense importance of the exports, render it manifest that every effort ought to be made to retain ana expand a trade of so much value to this country.

CULTIVATION OF COTTON IN INDIA.

REVIEW OF AREA, OUTTURN, AND CONSUMPTION.

The statistics of area of agricultural crops in India are year by year being brought to a state of greater completion. In the case of cotton special attention has been paid to the subject, with the result that the figures now given* are believed to be fairly accurate. This remark appn^e to most of the provinces and Native States in India, with the exception of Bengal, a province regarding which the available information as to area and outturn is of the most meagre character. An attempt was, however, made, some few years ago, to determine the Bengal area and outturn Of cotton, and the figures then published have had to be accepted in the pre-•sent statement, for the year 1888-89, though everything points to their being under rather than over the mark. In a "Note" on cotton cultivation issued by the Government of India, in 1888, the average area for the-five years preceding 1885-86, was put down at 14,051,800 acres, and the outturn at 6,775,000 cwts. of cleaned cotton. For most provinces of India a certain reduction (as far as possible allowed for in this article) has to be made, owing to the fact that a considerable percentage of the cotton lands is regularly occupied with mixed crops, viz., one or two rows of cotton alternating with a row of one or other of the bushy pulses or some such crop which can conveniently be grown on the same field with cotton. The estimate of yield has, in many provinces, been arrived at, after the conduction of careful crop experiments, and these, on the whole, have demonstrated that in former returns the yield was understated. Moreover, for the races and hybrids of indigenous cotton (Gossypium herbaceum and G. Wightianum), it is now generally accepted that 30: 100 is a safer estimate of cleaned from uncleaned" cotton than 25: 100 as previously allowed. Accepting these opinions as correct, the area under cotton in 1888-89 was 13,998,639 acres, and the outturn 9,219493 cwt. This rxhibits a decrease in the area but an increase in the outturn of approximately 2,500,000 cwt. of cleaned cotton over that given in the "Note" above alluded to. It is believed that these results indicate a departure of a more superficial than actual character, however, being the adjustment

[•] T^{he} year 1888 89 has been chosen (though later figures of foreign trade are available), because it is the last for which corresponding Agricultural and Internal Trade Statistics are obtainable.

53

GOSSYPIUM.

of the error arising from mixed crops, which would restrict the area CULTIVAactually occupied by the crop but raise the acreage outturn. Indeed, it seems probable that, instead of the cultivation of cotton having declined, Area & Outturn• as the figures given above might be supposed to indicate, it is actually on the increase, and greatly owing to the favour shown for mixed crop cultivation. For example, if the standard of least error be taken in determining this point, viz., the total consumption of Indian cotton in the home and foreign markets, we learn that the exports (as a direct result of the American War) suddenly expanded. In 1865-66, they attained the magnitude of 7,170,986 cwt., valued at 1*35,58,73,890. In the year previous, though the quantity exported was only 4,687,972 cwt., the greatest recorded value was then obtained, viz., 837*57,36,370. From the date of the War of Secession the exports declined, till in 1869-70 the? amounted to only 4,953,379 cwt. They again, however, recovered, and attained, in 1871-72, their maximum quantity, namely, 7,225,411 cwt.; but it is noteworthy that this remarkable production of Indian cotton decreased rather than increased the value, for the exports were then declared at only £21,27,24,297. From 1871-72, the exports declined once more and reached their lowest recorded level in 1878-79, a year of famine, when they were 2,966,060 cwt., valued at 87,91,30,458. Since that date they have steadily improved, having been, in 1885-86, 4,189,718 cwt.; in 1886-87, 5>432,648 cwt.; in 1887-88,5,374,542 °wt.; in 1888-89,5,331,904 cwt.; and in 1889-90, 6.328.898 cwt. It may thus be admitted that the foreign exports justify the opinion of an expansion in the production of cotton, the more so since the consumption by Indian mills has manifested during the past five years,—indeed during the past thirty years—a corre-sponding steady increase. The statistics of these mills showed, during the five years ending 1866-67, an average annual consumption of only 210,000 cwt., while last year they took 3,111,024 cwt., being an increase in twentytwo years of 1,381! per cent. These facts may thus be admitted to afford a tangible conception of the cultivation of cotton in India, which can Se elaborated by a review of the figures of internal and foreign trade. Working back from the returns of marine and rail-borne traffic, for example, a powerful confirmation is obtained of the accuracy of the agricultural statistics (in the case of surveyed provinces), and accepting the data thereby arrived at, it becomes possible to fill up approximately accurate figures for such provinces as Bengal, which publish only generalisations regarding their area and outturn of crops. Some years ago an attempt was made to register the road traffic to and from the larger cities of India. This was found both troublesome and expensive and had accordingly to be abandoned. But the more important railways having fallen into the hands of Government, an arrangement has been made by which each province is divided into certain blocks. The interchange of "produce between these blocks is carefully recorded and the traffic published annually. A similar system of registration on rivers and canals having been organised, it has thus, during the past few years at least, become possible to form a fairly clear idea of the major portion of the internal trad ' of the country. Had it been possible to carry out a registration of road trade, an even "more complete conception of outturn would have been derivable from the movements of produce from district to district and province to province. But by bearing in mind the error involved through want of road statistics we are, nevertheless, in a position to arrive at a fairly accurate idea of the intra- and inter- provincial transactions, from the annual reports of the rail, river, and canal traffic. A provincial balance sheet of imports and exports, doubtless, ignores at the same time local consumption, since a product, such as cotton, may be conveyed a few

Review of Area, Outturn, and Consumption

miles from the field to the loom without being carried over any possible registration route. The amounts thus locally consumed would, therefore, escape registration, however carefully road traffic was recorded, but by various analytical methods, figures have been derived, which are believed to approximately express local consumption. The accuracy of these estimates is, indeed, confirmed by an analysis of all trade transactions. net exports over imports being deducted from outturn, the balance shown would be available for local consumption, and that balance, in most cases, represents the actual figure stipulated for by official estimates as the amount requisite. It need only be here added, in this connection, that the most serious error, involved in all tabular statements of the production ana trade in cotton, is due to the season of cultivation and harvest not corresponding to the official year in trade statistics. It does not follow, for example, that the area shown as under cotton, in any one year, ahordea the whole supply for the trade of the same period. Indeed, an annijaj statement for twelve months ending 30th June (the cotton commercial year), would be more correct than a year ending 31st March—the official year. By such an arrangement, however, the relation of the cotton production to the imports and exports of raw cotton and piece goods would be lost sight of. The error here indicated is, at the same time, one that admits of correction by the average of a series of official years being compared with a corresponding average of commercial returns. As this involves, however, considerable labour, scarcely commensurate with the advantages gained, the authors have in the present review of the Indian Cotton Trade preferred to adhere to the official year, even though aware that the transactions in rail, river, canal, and marine returns, for the first few months of each year, refer mostly to the previous year's crop. explained above, this is due to the official year closing in March, whereas the whole of the crop is not in the market before the end of June. Allow''' Jng for this error and for the want of road statistics, it is believed that *the internal transactions in cotton under rail, river, and canal traffic, confirm the agricultural statistics of area, outturn, and local consumption, just as the returns of internal trade are again confirmed by the foreign exports from India.

In 1869, Mr. H. Rivett-Carnac (then Cotton Commissioner for the Central Provinces and Berar) estimated the Indian consumption of cotton at fcoo.ooo bales (of 3[^] cwt.). There were in all only seventeen mills at work in that year, and these used 90,000 bales, so that the local consumption for hand-looms and all other purposes, would on that estimate have been 510,000 bales, or 1,785,000 cwt. The author of the valuable work "Indian Cotton Statistics" has proved satisfactorily that the annual average production of cotton in India at the present day is a little over 2,600,000 bales, or 9,100,000 cwt. There are now at work 124 mills in India, and last commercial year these worked up 388,654 bales. The foreign exports from India, during the official year (which in part only corresponds to the commercial year), were 1,523,401 bales. If it be admissible to add these two quantities together and deduct the total from the estimated average annual production, there would have bep*)left for local consumption in all India, during the year 1888-89, 1871945 ^a'f or 657,807 cwt., a quantity which, there are grounds for believing, would have been considerably under the actual requirements of the country. But the above estimate does not take into account the foreign and transfrontier imports, and thus deals with actual foreign exports, not net exports, from the country. The outturn, according to the most recent official returns, was, besides, about 120,000 cwt., in excess of the estimated average, so that it seems safe to add that the actual supply was

Commercial Forms of Indian Cotton. (Watt & Murray.) GOSSYPIUM.

Below will be found brief accounts of cotton cultivation in each province, the attempt having been made to bring together all available information. In the case of provinces possessing port towns, the provincial transactions have, as far as possible, been kept distinct, so that production might not be confused with markets of supply from which the foreign exports take place. With reference to the port towns, the areas from which supplies are drawn have been exhibited, so that it is possible to judge approximately what provincial cotton goes to each special foreign market; but before proceeding with provincial cultivation it may be as well to say something of:—.

THE COMMERCIAL FORMS OF INDIAN COTTON.

The Indian cotton of commerce is divided into certain well-defined forms, designated according to the localities in which each is chiefly cultivated, and distinguished by certain peculiarities of staple. For an account of the botanickl nature of these forms the reader is referred to the descriptions of the various species in the chapters on Botany (pp. i-39), also to the provincial accounts, in which it has been attempted, as far as possible, with the limited material available, to refer each to its proper botanical position. It is. however, almost impossible to give accurate botanical definitions of these Though the commercial terms may at one time have signified speforms. cial forms of cotton in addition to the port of shipment or the place of production, in the present day they merely denote different standards of quality irrespective of race. Thus Mr. Ozanne, Director of Land Records and Agriculture, Bombay, in a note kindly furnished to the editor, writes, " A bale of cotton classed under any of these standards may contain the produce of different races, provided the staples blend together and are not easily detected. Thus the newly-created standard ' belati⁹ (see Oomras) has been found to contain staples of four distinct kinds, in certain proportions, which often determine the place of a mixture under a standard and consequently its price.*'

In this paragraph a short description of the area under each form (as recognised commercially), the progress made in its cultivation, and the pSrts supplied, will be attempted, but the authors are indebted for much of the information given regarding area, locality, &c, of the commercial growths of cotton, to Mr. Beaufort's valuable compilation of Indian cotton statistics • they have also to acknowledge useful information received from Mr. Ozanne'

"Dholleras."—Is a race of cotton (called after Dhollera, till lately, the chief port of shipment on the Gulf of Cambay), the cultivation of which has of recent years, shown a very marked expansion. It is principally produced in the Native States of Kathiawar, and includes the produce of the two annual varieties *lalia* and *vagadia*[%] and the two perennials *jeria*, and *Yogi*. Mr. Beaufort writes :—'' Excluding the State of Baroda, a portion of which till 1885-86 was not included in the Kathiawar Native States, the acreage has risen from a mean of 1,408,000, acres to 1,996,000 acres/ In the Baroda State, in the last four seasons, it has averaged 168,000 acres, making a total average area devoted to this 'growth ' of 2.547,000 acres. Of this, 1,760,000 acres are in Kathiawar, 360,000 in Ahmedabad, 1,790 in Cutch, 168,000, as stated, in Baroda (districts of Kadi and Amreli), 70, ^00 in Palanpur, and the remaining 14,000 acres in Kaira, Mahi Kant ha, and Cambay." In 1888-89 the acreage was somewhat lower than the average above cited, vi*., 2,469.000 acres. Mr. Ozanne informs us that Dholleras are now sold in Europe under the names of Bhownagtrer Mcwa, Wadwhair, Veerumgaum, and Veraval Cutch. The land is "pre^ pared for this crop in May to June, the seed is sown in June, and picking takes place from February to April, or March to May. The average oun turn is 1,600,000 cwt. of cleaned cotton, of which the average receipts in Bombay are 1,407,000 cwt.

"Bengals,"—| race of cotton grown chiefly in the PanjAb, the North-West Provinces and Oudh, Bengal, Rajputana, and Central India. The area under the crop is the largest returned for any • growth ' of cotton, the average during the past five years having been 3,492,000 acres, y,* this the Panjab grew 860,0c0, the North-West Provinces 1,536,000, Oudn 79,600, Bengal 162,000, and Rajputana and Central India 840,000 acres. The land is prepared in May-June, the seed is sown in June, picking takes place from October to January, and the average yield from the total area is said to be 2,730,000 cwt. "Bengals" from the 'Panjab go to Karachi, Calcutta, and Bombay for shipment; those from the North-West Frovinces and Oudh to Calcutta and Bombay; those from Bengal to Calcutta : and thos: from Rajputana and Central India to Bombay.

cutta ; and thos: from Rajputana and Central India to Bombay. ^{kt} Oomras'' or '' Oomra-wuttee cotton.''—\s divided in Liverpool into three separate growths—Oomras, Khan desk, and Bilatee*} but in the-3ombay market the names of the principal producing districts or provinces are the leading heads under which statistics are compiled. '' Khandtsh '' is produced in the district of that name, also to a small extent in Nassik* The area under the crop in these districts during the past five years averaged 887,400 acres. '' Barsee'' and '' Naggar'' are named after the towns of Barsee and Ahmednaggar, through which the bulk of the cottjin passes, but, according to Mr. Beaufort, the greater portion is actually grown in the Nizam's Territory. The area in the Bombay districts during the past five years averaged 63,600 acres. According to Mr. Ozanne, three forms of cotton are sold under the name of Oomras :--''^a good-stapled form, Akola; a medium staple from Indore and Oojafti, J^{af}* gaum and Dhalia, and third, the short-stapled Bilatee* from Khandeshana Oomrawatti, Shegaum, and Akote. It is practically, however, a mixture of four distinct kinds, banni, jarivaradt; acclimatised American, and the ordinary variety of the Deccan. But Oomras proper is banni and jari ^{oV}^'

ordinary variety of the Deccan. But *Oomras* proper is *banni* and *jari* ${}^{0V_{\Lambda}}$ ' The finest description of ${}^{-1}$ *Oomras*" is produced in the Berars, but the xrea under the crop in that province has shown a decided faliing-off at least during the past twenty years. Thus, in 1878-79, as much as 2,207,889 acres were planted with it, while the average for the past five years has only reached 1,957,200 acres. It is grown in all the districts, the average in each for the same period having been—Amraoti 4.80,000 acres, Akola 479,000 acres, Buldana 300,000 acres, Wun 231,000 acres, Bassein 233,000 acres, and Ellichpur 231,000 acres, making a total of nearly 1,960,000 acres. The total average area under " *Oomras*" for all India, during the past five years, was, as shown above, about 2,910,000 acres. The average crop for the same period was 2,007,000 cwt., of which 1,836,000 cwt. was sent to Bombay for shipment, the rest being retained for local consumption.

The land is prepared for the "*Oomras*" crop in May-June, the seed is sown in June, and picking is carried on from November to March.

•' Westerns''—This race, as its name implies, is one of the chief cottons of Madras, the Nizam's Dominions, and Western India generally. Iⁿ the Madras Presidency, Bellary is the principal district, with 250,000 acres, followed by Kurnul with 205,000, Anantapore with 110,000, and Cadapp^{an} with 100,000 acres, making a total of 665,000 acres. The avenge area under the crop during the three years preceding 1887-88 in the Nizam's Dominions was 973,600 acres, and in Sholapore (Bombay) 25,000, making an average grand total under •' Westerns'' in India, of about 1,660,000 acres. The average outturn for the past five years was 735,000 cwt., of which 112,000 cwt. was sent to Bombay for shipment, the bulk of the remain-

^{*} yUayati-Khandesh or Varadi. This while not. strictly speaking, a commercial form, is now so largely employed for adulteration that it may be viewed as of commercial importance. Conf. with pp. 62, 75,89—91.

Commercial Forms of Indian Cotton. (Watt & Murray,) GOSSYPIUM

der going to Madras sea-ports. The land is prepared for the crop in July-COMMERCIAL FORMS. August, the seed is sown in August-September, and the picking, which commences in March-April, is completed by May or early in June. " Dharivars."—This is an important Bombay cotton, grown principally **Dharwars.** in Dharwar, Bijapore, and the other Southern Mahratta States. The aver-77 age area covered by the crop during the last three years was 277,300 acres, Conf. with of which Dharwar contributed 191,000, Bijapore 25,000, and the remaining pp. 17—185 62—63; 67. Southern Mahratta States, 61,000 acres. The average yield for the same period was 122,000 cwt., of which the greater part went for shipment to Bombay. Dharwar cotton proper is the produce of the American or New Orleans variety, introduced into these districts about half a century ago. The periods of sowing and picking correspond with those of •• Westerns. 'Coomptas.''-This is another Bombay cotton of some importance, grown Coomptas. **78** Conf. with pp. 62; 68. under the same conditions and in the same seasons as *Dharwars*. During the past three years the average acreage was 968,300, a considerable diminution on the figures for the four years ending 1883-84, in which the average was 1,118,250 acres. Bijapore, with 347,000 acres, is the chief district of its cultivation, followed by Dharwar with 287,000 Belgaum with 172,000, Kolhapur with 31,000, and the remaining Southern Mahratta States with 132,000 acres. The average outturn for the same period was 420,000 cwt., of which the great bulk went to Bombay for shipment. It is supposed to be the native race of the Bombay Karnatak, and is named after one of the principal ports from which cotton of that district used to be shipped. In Kanarese (th6 prevailing language of the country) it is called $i < ivdri-hatti=s^*$ country cotton," to distinguish it from the acclimatised American form. Broach. "Broach."—This is the cotton of Baroda, Broach, and Surat. The total 79 area taken up by the crop in the four years ending 1888-89, was 597*000 acres, of which Broach contributed 241,000, Baroda 227,000, and Surat Conf. with pp. 62-63. 129,000 acres. The average outturn for the same years was 525,000 cwt., of which 133,000 cwt. was despatched to Bombay for export. Breach cotton consists for the most part of the lalia form, and is locally known as kahnam, i.e., "black soil " cotton, to distinguish it from the rogi perennial cotton of the light soils of Gujarat. As in the case of most of the other Bombay cottons, sowing is conducted in June, the picking commencing in February and finishing in April. " Coconadas."—A red cotton, principally produced in the Kistna district Coconadas. of Madras, where on an average about 200,000 acres are taken up by it. 80 Nellore also contains about 25,000 acres under the crop, and Godaveri 20,000, making a total of 245,000 acres. The average crop is about 80,500 Conf. with pp.27; 101 cwt., of which nearly the whole is sent to Guntoor to be press(d, and is de-ĪŌ2. spatched from thence chiefly to Coconada for export. A small quantity, however, is transported by the Buckingham Canal to Madras. This, like the other Madras cottons, is grown during the north-east monsoon, being sown in September-October, and picked in February to June. Tinnevellys. "Ttnnevellys."—Are entirely shipped from Tuticorin, from whence 81 nearly the whole is despatched coastwise to Bombay for transhipment to Conf. with jpo; Js in Europe. The average area is estimated by Mr. Beaufort at pp. ioi-102. 742,000 acres, distributed as follows :- Tinnevelly, 320,000; Coimbatore, 250,000; Madura, 120,000; Trichinopoly, 26,000; Salem, 17,000; South Arcot, 6,000; and Tanjore, 3,000 acres. The annual average crop is about 450,000 cwt. It is the latest of the cottons, being sown in Octo-Salems. ber-November, and picked from March to April.

In passing, it maybe remarked that the cotton known as ^{IC} Salems" or *• Coimbatores " of older trade returns, was a race grown from Bourbon seed, which was at one time cultivated to some extent in Coimbatore and

Salems. 82 Conf. with pp. 19; 102GOSSYPIU VI.

believed to be very nearly correct. But the Presidency of Bombay imported and exported cotton from and to other provinces, and, at the same time, consigned large quantities to its port town, which were destined mainly for the foreign traffic from Bombay. The balance of all these transactions on outturn, resulted in a net surplus remaining in the presidency of 593,986 cwt.—the amount available for local consumption. Similarly, all transactions to and from the port town showed a net balance for the local market (chiefly the power-mills) of 1,617,104 cwt. The total balance left in Bombay Presidency and its port town, therefore, amounted to 2,211,090 cwt. It must be here urged that the error due to the overlapping of outturn and traffic for the months of April May, and June of any action score	Conf. with p. 161.
and traffic for the months of April, May, and June, of any cotton season with the official statistics of trade of the year ending 31st March, is a con- stant factor which prevents actual comparison between commercial and official statistics. But in dealing with the possible sources of error in Bombay cotton statistics, the Director of Land Records and Agriculture drew attention in 1889 to an even still more serious error :—« It must be noted, that in the estimates of outturn, the produce of over 100,000 acres, representing the area of unsurveyed villages, is not taken into account. If the produce of this unsurveyed area be added, the estimated outturn will leave a considerable margin, for the excess demand of the well-to-do classes and other miscellaneous uses, after meeting the full demand for local consumption."	P. Yor
In Bombay there are working, at the present moment, 55 mills in the island, and up-country 21, The former consumed, during the year ending 30th June, 1,973*055 cwt., and the latter 363,888 cwt. The total of these figures would give a greater consumption, were the official and commercial figures to be arbitrarily compared, than the available balance shown above, The imperfection of road statistics has, in most provinces, however, a serious influence. Thus large quantities are carried by road, across provincial frontiers, to collecting centres, particularly near the railways, and these appear in statistics of rail-borne trade without having been shown as exports from their actual areas of production. Thus, for example, large amounts of cotton from the Nizam's Dominions arrive at Sholapur and	consumption 89
Ahmednagar by road, and are then conveyed by rail to Bombay. The totals of the entire cotton transactions of India, however, when earned over a number of years, so completely agree with production and trade, as to justify the inference that while errors exist in this province, and that, more serious in one case than in another, the figures herp given may be accepted as fairly correct. This recommendation of accuracy would appear more \$sp£riafly applicable to Bombay, since the relation of area, outturn, and yield, bears a close approximation to all available statistics of the sales and movements of cotton to and from the presidency. In a recent official correspondence regarding the cotton trade of Bombay and its Native States, it has been estimated that 20.000 cwt. are con	

bay and its Native States, it has been estimated that 20.000 cwt. are con-sumed for wicks, about 80,000 cwt. for beds and cushions, and about 619,400 cwt. for cloth of local manufacture, thus making a total of 719,000 cwt. Were a similar statement to that in the table, p. 56, to be worked but

G. 89

n.

Area, Outturn, and Consumption of

CULTIVATION for the past five years instead of one, the annual average left for local conin BOMBAY. sumption in the presidency (excluding its port) would be found to have been 702,200 cwt. As already remarked, the up-country mills in Bombay Presidency consumed, in the year 18258-89 (ending 30th June), 363,888 cwt., and their annual average for the past five years, is found to have been 310,780 cwt. Deducting that amount from the total estimated annual average we learn that the Bombay Presidency, excluding its mills, consumes 387,42° cwt. a year. By a careful comparison, of outturn and total estimated consumption, of Bombay-grown cotton, the Director of Land Records and Agriculture has arrived at the conclusion that the average consumption ot purely local cotton, per head of population, is 3*62fl), which, on the assumption of its all being made into cloth of the Bombay texture and weight (^{vit} 4j yards to the pound of cotton), would be equal to 15 yards. This would allow for loss on manufacture, but deducting the equivalent for consumption of cotton in minor usages, an average of 13 yards is arrived at a? probably moT5 nearly the correct consumption. On this further factor the Bombay statistics may again be confirmed : hence it may in fact be safely said that about four parts are exported, and one part remains to meet the local consumption. Chief These are indicated by the following figures for the year 1888-89 :---Districts. 90

In the other districts of Bombay proper, the cotton area is very small. The following passages, extracted from the *Gazetteers*, give particulars regarding the cotton grown in the more important of the above regions. While not an exhaustive selection, it is believed the facts narrated in these passages convey the main features of the growths or races of Gossypi^{«m} met with in Bombay.

Speaking of the cotton grown in Khåndesh, for example, it is stated that, in 1878-79, there was a tillage area under *kapds* of 590,703 ^{a. cres}; Cotton was even then regarded as the chief crop in Khåndesh. The local form, known as *varhddi* or *berdr*,* was thought to have come to the district through Málwa. The author of the *Gazetteer* says: "It is short-stapled, harsh, and brittle, and has lately been largely supplanted by two foreign varieties—Hinganghát of two kinds, *banni* and *jen*; from the Central Proyinces, and Dharwar or acclimatised New Orleans, from Dharwár." *J a **footmote**, the *banni* is said to bboan earlitter are the *jeri*, a later form (coming into the unarket a mouth or six yeeks later), is whiter and freer from leaf, but has a poorer staple. TV: wn-er goes on to say that the Dharwar is slightly longer in staple but much weaker than the Hinganghát, which, if well picked and cleaned, fetches a higher price. Dharwar cotton, with larger and fewer pods, is the more easily picked. Being close-podded it can also be picked cleaner than Hinganghát, but from its larger and more clinging seeds, it is more apt to_bg

	Bombay Cotton.	(Watt & Murray.)	GOSSYPIUM.

stained in ginning. Of Dha'Wa'r, it is remarked, there are three kinds of in BOMBAY. cotton grown, viz., Gossypium arboreum, dev kdpas (God's Cotton), used in making sacred threads and temple lamp wicks; G. indicum, jvari-hatti, that is, country cotton ; and G. barbadense, vildyati-hatti or American cotton. Of these three forms, G. arboreum, a perennial bush, 8 to 12 feet high, is grown occasionally all over the district-in gardens, beside wells and streams, and near temples. " It is much like the Brazilian or Peruvian cotton plant, and, though this is unlikely, it is often said to be an American exotic." The jvdri-hatti, generally known in the Bombay market as kumta (Coompta) coiton, is largely planted all over the black-soil The vildyati-hatti, commonly known as SAW-GINNED DHARWAR, plain. which was introduced by the Government in 1842, has thriven well and has come to occupy about a quarter of the district cotton area. Among thejxrtton-producing districts of the Bombay Karnatak, Dhá>wár stands first, and both its American and its local cotton are highly esteemed. All evidence goes to show that with fair treatment in preparing them for the market, the two varieties grown in DhaYwa*r will rank among the best cottons of India. In Bijapur, the same forms of cotton appear to be grown as described above in DhaYwaY.

Of Broach, it is remarked, there are two forms of cotton—the annual of black soils, *Idlia*, and the triennial of light soils, *jdria*. These are the chief forms, but, according to the Gazetteer, two others are less fre-quently met with, viz., roji and nurtna. The latter appears to be Gossypium arboreum, which will be found described in various passages throughout this article, more particularly at pages 5-15. The roji is an inferior cotton, grown mainly in Baroda ferritory and brought into Broach district, chiefly with the object of being mixed with the regular Broach cottons. Of Ahmedabad, it is remarked that no foreign cotton is grown. " The local varieties are, in the Viramgaum sub-division, jatvaria ; in Dholka, bhdlia and vagadia 5 in Dhandhuka, Idlia and vagadia; and, in small quantities near the city of Ahmedabad, jaria. Except *idxfa* these, are all varieties. The *jdria* is allowed to grow for four seasons.' The *jdria* is grown along with millets; the other kinds are never treated as mixed crops. The vagadia is a hard-shelled cotton, which must be picked with the pods, the other kinds ought, in picking, to be separated from the pods. But this is nowhere the practice, and, in consequence, the shell, broken and mixed with the wool, greatly lowers its value. Mr. Ozanne informs the writers, in a recent note, kindly furnished on the subject, that the Sanitary Commissioner attributes the high death rate at Viramgaum and other places where the *vagadia* is cleaned by hand, to the diseases which result from the practice.

The Native State of Kathiawar is a most important producing area in the cotton supply of Bombay. Within the past few years, the area under the crop has been remarkably expanded, and the amount of Dhollera cotton brought to market accordingly greatly increased. Kathiawar, with Baroda, Ahmedabad, Cutch, Palanpur, Kaira, Mahi Kantha, and Cambay constitutes the region from which *Dhollera* cotton is derived, and during 1888-89, 2,547,000 acres were under that crop. In the Gazetteer of KatX'owar it is stated that two kinds of cotton are grown, viz., vdgria or dhdnknia, and pumadia or Idlia. Vdgria is almost solely grown in the north and east districts in Jháldvád and Dhandhuka, and Idlia throughout the rest of the province. The pod of the vdgria does not open when ripe so as to allow the seed-cotton to be picked. It only slightly bursts and continues to clasp the cotton tightly, so that the pod and all has to be picked. The *ptimadia*, when ripe, bursts open, and the cotton is easily picked from the pod as it hangs from the tree. The *vdgria* cotton, though Vagria OF vagadia cotton, 91

Cotton pod which does not open. 92

CULTIVATION in BOMBAY. Chief Districts. **Races of Bombay Cotton.**

inferior to i_{4} pan, by careful handling, be prepared so as to look very much like *pumadia* Vdgria has the advantage that the pods can be stored during the rains without injury.

Vdgria cotton stored and cleaned in December is called navlodh. It is whiter than *pumadia*, but, in other respects, poorer. The chief varieties of exported cotton are locally called after the division from which they come, as Hollar and Jhalavad. The best cotton comes from the Palitana State. The whole crop of Pálitána cotton is only about 2,100 tons, but it is by far the best prepared for the market, being well cleaned and free from adulteration. It is bulky, of a good bright creamy white with a yellowish tinge, and the staple is even, fine, and fairly strong and long. It classes from good to fine. The cotton grown in the Bhavnagar districts is called desdn. It closely resembles Politana but is not so well prepared and is occasionally damped to add to its weight, or is mixed with seed, especially when prices rise beyond the rales at which the cotton is usually sold. The Bhavnagar crop averages about 9,800 tons, and most of it classes m Bombay and Europe as good. With care it could easily be made as fine as Palitana. The cotton grown in Wadhwan, Limbdi, Halvad.Chuda, and Gujarvedi is known as vdgria Jhalavad, and is grown from a peculiar seed. When properly picked and cleaned, it is reckoned good cotton, being a bright white which does not readily fade. Its staple too is strong, fairly long, and even, and has much body and bulk. Spinners readily buy it to mix with other kinds of cotton which lack these qualities. It» seldom properly prepared, most of it being full of fine-powdered leaf, which, after a certain stage, it is almost impossible to remove.

Jatvad cotton, grown between Wadhwdn and Viramgaum, finds its way into the Kathiawar markets; it is of a very low quality. Mahuva cotton, grown chiefly in the Mahuva, Lilia, Amrefi, Kundla, and Talaja districts, closely resembles Pálitána cotton, and, like Pálitdna, classes as good and fine. What specially recommends it to buyers is its purity and cleanness. ". In Bh&l and the neighbouring district of Dhandhuka, a better cotton 1* known as *pumadia* or *Idlia*." "The bulk of the crop from these districts, as well as that from Limbdi, Ranpur, Borsad, Cambay, and Dholka, is marred by leaf and is known as sakalia. A weak, flimsy cotton finds its way into Kathiawar from these districts and is known in Bombay as sagar. It harsh, short-stapled, and of a dirty white, much like wool in appearance and touch, and mixed with salt and clay. It is known at once by J^{1s} smell. The cotton of Sorath and Hdlar is inferior to that grown in other parts of Kathiawar, and is known in Bombay and Europe by the names ot its place of export, Veraval and Mnngrol. It is soft and flimsy, of a bluish white, and though the staple is fairly long and silky, it is weak and much mixed with dark broken leaf and seed. Here, as elsewhere, except in Mahuva and Palitana, adulteration is common and most difficult to stop.

The above passages, taken almost at random from the *Gazetteers*, indicate the complex nature of the subject of the Bombay cottons. It seems probable that roost of the forms mentioned are local cultivated races that owe their peculiarities to selection and methods of cultivation, continued over many generations, if not centuries. For an account of the botany or the indigenous races oi Bombay cottons, the reader is referred to the special Chapter on that subject (pages 9, 12—14,17, 28.). It need be only here added that by far the most prevalent form is the plant now known as G. Wightianum. (Conf. with pp. 88, 129).

It is also perhaps needless in this place to allude to the forms of exotic cottons that have been tried in Bombay. The history of the experiments with exotic cottons will be found detailed below, and it is probably enough to add that two or three forms have assumed acclimatised, though degeRaces of Bombay Cotton. (Watt & Murray.) GOSSYPIUM.

CULTIVATION nerated. conditions. These are G. hirsutum, Roxb.—New Orleans cotton, in BOMBAY. for the most part called saw-ginned Dharwar cotton : G. acuminatum, Roxb.—the kidney-cotton, most generally met with in the presidency—and Conf. with G, peruvianum, *Čav.* The two last-mentioned exist mainly as garden crops; pp. 20, 22. they grow, for the most part, into trees, and have thus come to bear the vernacular names of G. arboreum, the floss indeed being used in the pre-Chief Districts. paration of the sacred Brahminical thread. To some extent, also, the remains of the cultivation of other exotic cottons exist, the Georgian, Sea Island, and other forms being occasionally met with in degenerated and neglected conditions. The difficulty that exists, in accounting for the special properties of each of the Indian races of cotton, or of establishing the causation of inferiority or superiority, must remain in the obscurity that involves many features of tha cotton industry, until definite experiments have been made with the view of ascertaining the features of each species botanically, and the taints of character, injurious or otherwise, that have passed into the races or hybrids now grown in the country. Such experiments, if conducted coincidently with chemical and meteorological investigations, would afford the key by which many obscure problems might be solved, and a tangible advancement made towards the improvement of the cotton supply. It would almost seem as if this much-to-be desired object had been retarded, through experiments at acclimatisation taking the place of selection and improvement of existing forms. The fact that so many races of cotton occur in one district, as have been mentioned above, in connection with Kathiawar, seems

to show that India need not be dependent on America for new and improved forms of cotton. These remarks are not, however, intended to throw doubt on the propriety of attempts at acclimatisation, but rather to deprecate the false impression that too frequently exists in India, *vis.*, that no other methods of improvement are open to the agricultural reformer.

CULTIVATION.-SOILS: ROTATION OF CROPS: PLOUGHING: IRRIGA-TION : &c-One of the earliest and, at the same time, one of the best derailed accounts of Bombay cotton is that written by Dr. Hove in 1787. Linschoten, and also Rheede, 200 years before ihe date of Hove's visit, briefly described the cottons of India. The former traveller made special mention of the muslins of Cambay and of Dacca, and of the cotton of Coromandel and the calicoes of various places in the Madras Presidency. The distinguished Polish traveller (Hove) came, however, to India for the express purpose of studying the cotton question, and his report is replete with interest. The botanical results of his study have already been briefly discussed under G. arboreum (to which the reader is referred, p. 12). Hove found, in Guzerat and other parts of Bombay, cotton cultivation relatively in as flourishing a condition as it is to-day. For miles and miles, as far as the eve could see, plantation after plantation of cotton stretched, across Cambay. On the lower-lying lands a form of G. herbaceum—the yellow-flowered cotton as he calls it —occurred, and on the higher sandy soils G. arboreum—the tree cotton with red flowers—was grown. One of the most striking features of Hove's account is the fact that G. herbaceum was apparently often grown on inundated land or even in brackish swamps. The fields were banked up to retain the rain-water, and wells were dug, in their vicinity, from which water was drawn by crude Persian wheels or leathern buckets elevated by bullocks. His description of the methods of well irrigation is, in fact, identically that pursued with other crops, though, at the present day, only rarely resorted to with cotton in Bombay. In 1789, it would thus appear, the cultivators regarded a high state of irrigation as an essential to successful cotton cultivation. Within the past few years this idea seems to have been returning to Bombay; but, for at least half a century, it has been Method. 93

Method.

Area, Outturn, and Consumption of

CULTIVATION the habit to grow cotton only on soils possessed of deep-seated moisture, in BOMBAY. or in districts subject to rain at the season necessary for cotton-growing. The degree of inundation, which Hove seems to have witnessed, is abundantly exemplified by his statement that with yellow cotton, rice was often grown between the lines of bushes, whereas, with the red cotton, bajra, juar, or gram were grown. The yellow cotton was sown, he remarks, in the end of the rains, so that it might not be destroyed by too great inundation. It consequently "ripens a month later than the red cotton, $g^{r} \mathfrak{L}^{w}$ " on the higher lands and having the advantage of the powerful dews, which refresh the pods and promote vegetation, the wool gets not only com-pacter and finer, but likewise produces a greater crop. But the higher grounds, on which cotton ripens in the cold season, are not without some advantages. The dews falling on the wool that discovers itself by the elasticity of the capsula bleaches it, by the assistance of the sun, and jcontributes, in some measure, to its fineness. But where they have not the conveniency of water to support it in the period when the pod begins to swell, the crop is but poor and inferior in quality to those that have either a succour by freshes or are situated lower where the rains may have more influence." The idea of the necessity of artificial irrigation at the time the fruit is forming, has, within the past few years, begun to be felt, and many writers hold that the defect of harshness complained of against Indian cotton as a whole, would be remedied by a return to the system of cultivation which prevailed in the last century, where water, if not obtainable naturally, was supplied freely by artificial means.

Dr. Hove gives an interesting account of the method of ploughing and sowing cotton, as witnessed by him at Gorga, where, he says, the produce was the finest. As soon as the rain ceased, they ploughed all the high lands in the following manner : " A man measures the lines out by walking at the distance of 10 yards before the plough, drawing a line by a hooked piece of wood that scratches the earth which the ploughman follows, ind indents a furrow at the depth of six inches by an iron cutter, which is in the shape of an elephant's tooth mounted into a solid piece of wood. The car at the bottom is hollowed on both sides into a beading by which the furrow is widened, and the earth both pressed on the sides and prevented from falling back and filling it. The beam the oxen or buffaloes are fastened to, may be placed agreeably to their size, and the reins are passed through a hole in the upper part of the plough tail. The plough is so light, the cattle so well trained, and the earth so very brittle and mild, that it is more a play-work than labour, both to the farmer and cattle. " They do not cover the seeds but leave it to the first shower of rain which fills the furrows with the turned out earth, and the plantation is as level as a table.'

In the Bombay Gaeetteers and Agricultural Department Annual *Reports* much valuable information will be found regarding the method of cultivation pursued at the present day. The limited space at our disposal prevents us from even reviewing all the available information, but the following passages, selected under certain important sectional headings, will be found to exhibit the main features of this important branch of **Bombay agriculture.**

In the Khandesh Gazetteer it is stated that "cotton grows both in black and light soil. It is seldom sown in the same field oftener than once in three years, the intermediate crops being wheat and millet. With a moderate rainfall the black-soil crop, and with a heavy rain-fall the lightsoil crop, is the better, There is no special ploughing of the field for cotton. After the first or second rainfall, the heavy hoe, vakhar, is passed over the field to loosen and clean it. Manure is seldom laid down imme**Bombay** Cotton.

(Watt & Murray.) **GOSSYPIUM.**

diately before sowing, as the natives hold that it should be in the ground a year before the seed is sown." In the account of the Bijapur district it	In
is stated, that "No crop takes more out of the soil than cotton. It never thrives in the same field for two successive years, but must be rotated with Indian millet, wheat, or gram. The cotton fields are enriched with the ordinary manure. Fresh manure is believed to heat the soil and, therefore, applied to the land the year before the cotton is sown. Prior to sowing partly by the hand and partly with the hoe, the field is cleared of the stumps of the previous crop, and if the field is overgrown with the <i>karige</i> grass, it is ploughed with the larger plough or <i>neglai</i> .	BOMBAY. Method.
After the ground is cleared, the clods are broken by a heavy wooden beam. In the latter part of August the land becomes fit for sowing.	
The seeds are rubbed in fresh bullock dung and water, and are then dropped through the hollow tubes of the seed drill or <i>kurgi</i> . The seed	
drill is immediately followed by the hoe which closes the drills. The seed leaves show in six to eight days, and in about a month the plants are	
three or four inches high. The farmer then works the grubber between the rows of seedlings, rooting out young weeds and grass, the surface is	
turned, and the soil is heaped at the roots of the young plants. Weeds are also removed by labourers with a sickle. The crop is ready for picking	
late in February or early in March. A good crop yields five and some- times six, pickings; a poor crop not more than three or four." Of	
Ahmedabad it is said that " of the three varieties of soil, mixed, <i>besar</i> , is the best, black, <i>kali</i> , the next, and <i>light</i> , <i>gorddu</i> , the least suited to the growth	
of cotton." *' Manure is used in light, but not in mixed, soils. Even in light soils it improves the crop only after a good rainfall. In July, when	
the land is ready, the seed cleaned by rubbing with earth and ashes in a crude frame, is, at the rate of ten pounds the acre, sown from a drill-	
plough with three or four tubes or feeders. The watering of cotton, common a hundred years ago (December 1787), but apparently in 1850 gone out, of	
use, has again come into practice in Viramgam Hholka, and Dhundhuka. Watering much increases the outturn, but is open to *he objection that it	
makes the crop more apt to take harm from frost. When full grown the plants stand from 3J to 5 feet high. Fields sown in July, flower in Sep-	
tember and October, and pod in December. In light soil, before the time of flowering, cloudy weather, or even slight rain, though it somewhat keeps	
back the picking, does good. Much rain increases the size of the seed and lessens the outturn; and after the pods are formed and when near	
bursting, rain harms the crop." In the <i>Dhdrwdr Gazetteer</i> an interesting account is given of acclima- tised American cotton, from which the following passage may be given	
regarding the soil and climate of the district: "The upland plain of	
Dhárwár enjoys the unusual advantage of two rainy seasons, the south- west between June and October, and the north-east or Madras between	
October and December. The north-east rains give the country a fresh supply of moisture in October, and often again in November, and a small	
degree still later on. This moisture, with the cool November nights, has had a large share in successfully acclimatising New Orleans cotton. In the Deformation of the property resident response from 25 to 20	
the Dha'>wa'> cotton plains, the yearly rainfall ranges from 25 to 30 inches. During the cotton-growing months, that is, from September to Each way the returns for the first recent of 1882, show a supertext heat	
February, the returns for the five years ending 1882, show a greatest heat of 97° in February, and a least heat of 58° in December. For cotton to	
thrive, the soil should be loose and open enough to allow the air and sun to pass below the surface, and still more to let excessive and untimely rain drain from the roots. These qualities the anympling gaping soil of	

>

-

drain from the roots. These qualities the crumbling gaping soil of Dharwir has in an unusual degree. The Dhdrwdr husbandmen describe

G. 93

Area, Outturn, and Consamption of

CULTIVATION their cotton lands as of two kinds: *huluk-yeri*, which is a mixture of black and red soil, and y*>ri₉ pure black soil. Both local and American cottons BOMBAY. are planted in both thebe soils, but huluk-yeri, or black and red, is gene-Method. ally considered best for New Orleans cotton, and yeri or pure black for local cotton. The black and Ted is considered the richer of the two, but in a bad season, blight and other diseases show themselves sooner, and ta a greater extent, in black and red than in pure black. The great ment of these two soils is the surprising length of time during which the undersoil keeps moist. It is this underground dampness that enables the cotton plant, especially the American form, to mature as late as March and April. When the surface of the field is baked and gaping with the heat the cotton bushes are still green, because their tap-roots are down in the cool moist under-soil. Cotton is seldom grown in red soil; the outturn is too small to pay at ordinary prices." In a foot-note to the above passage^thet chemical analysis of the Dhárwár cotton soil is given as follows:—"An analysis of the best cotton soil showed in 4,500 grains 3,324 grains of very fine soil, 936 grains of impalpable powder, and 240 grains of coarse pebbles like jasper, with pieces, like burnt tiles, strongly retentive of moisture* The impalpable portion consisted of 18000 grains of water, 0*450 of organic matter, 0.083 of chloride of sodium, 0.007 of sulphate of lime, 0'027 of phosphate of lime, 0'0450 of carbonate of lime, 0'013 of carbonate of magnesia, 15'200 of peroxide of iron, 16'500 of alumina, 0'085 of potash,48*000 of silica combined and free as sand, and 1*185 loss; total 100'000."

Seasons.

94

SEASONS OF SOWIKG AND PICKING BOMBAY COTTONS.—The *Oomraivuttee, Dh oiler a, and Broach* growths are sown in June, the land having been prepared during May-June. The first pickings commence in December and continue till April and May.

The *Oomrawuttee* is the earliest in maturing, the pickings being complete in March. This is followed by the *Dhollera*, the pickings of which commence in February and are completed in April. The *Broach* begins to yield in March, the harvest being finished in May. It will thus be seen that a large portion of the Bombay cottons grown on the acreage of one year's statistics are included in the trade returns of the following-year owing to the official year ending 31st March.

The *Coompta and Dharwar* are much later still. The land is prepared in July and August, the seed sown in August, the first pickings made in March, and the crop completely gathered in May. The whole of the yield of this class of cotton, from the area of one year's returns* therefore, appears in the trade transactions of the succeeding year.

appears in the trade transactions of the succeeding year. Of Ahmedabad it is stated, that "beginning in early years in January_r but oftener in February, the picking season lasts till the end of March and sometimes till April. Except the Dhandhuka *vågadia* or hard-shelled cotton, which must be picked with the pods, the other kinds ought, in picking* to be separated from the pod. But this is nowhere the practice and, in consequence, the shell, broken and mixed with the wool, greatly lowers its value. The one-year plant yields two and, sometimes, three picking^, the three-year plant always three. The picked cotton is gathered in heaps and at the end of the day carried to the yard near the cultivator's house. Here the pods are broken and the wool drawn out by the hand_r and, to loosen and free it from leaf, it is laid on a rope framework or on the ground, and beaten with sticks." In the *Broach Gazetteer* it is remarked : "The time when a crop of cotton harvest is early, after a heavy fall it is late. If the rainfall has been light, picking begins about the 20th of December, and is over by the 10th of February. If the rainfall **G. 94**

(Watt & Murray.) GOSSYPIUM.

has been heavy, the pods do not burst till the middle of February, and CULTIVATION the cotton is not all housed till the last week in April. In an average BOMBAY, season the picking begins about the close of January and ends in March. Seasons. Before all the cotton is secured, the field has generally been thrice picked, with a fortnight's interval between each picking. The average proportion in weight of seed {kapdsfia}, to cleaned cotton (rut) is one-third of cleaned •cofton to two-thirds of seed." *' Before the time 'of picking-, some of the cotton grows over-ripe, and, falling to the ground, takes up dust and leaf. In this way a portion of the cotton is damaged before it leaves the growers' hands. But the intentional mixture of dirt and earth to add weight to the cotton is not the work of the cultivator but of the dealer, wabhdrio. Cleaned cotton is divided into two classes, the better, *tumel*, and the inferior, *rdsi*, or poor." » COST OF CULTIVATION AND PROFIT.-The estimated cost of cultiva- Cost ft Profit. 95

tion per acre on an average field in a good season is stated in the Khandesh	
<i>Gazetteer</i> (1880) to be as follows for two of the chief cotton-producing dis-	
tricts :	
Khandesh. Broach.	
Khandesh. Broach.

In the former district (with the prices then current) the cultivation left a net profit of 145. Sd. an acre, in the latter 16s. $j^{A}d$.

In the Gazetteer for Dhárvtár it is stated (page 28\$) that "the cost of growing cotton is difficult to determine. Much depends on the grower, the number of cattle he owns, the area of land he holds, the number of persons in his house, and many other conditions which more or less affect his actual cash outlay in growing cotton. Roughly, the acre cost of growing American and local cotton is Us. 4|rf. {R5-11-0}. As the value of the American crop may be set down at £1-105. (R15) and the value of the local crop at £1-45.-9^. (Ri2-6-0), the American leaves a net profit of 18*. l/d. (R9-5-0) and the local of 13\$. l/d. (R6-11-0). To the net profit on the country cotton a small amoint may be added, as in many cases the husbandman's family themselves clean the cotton."

In the *Khdndesh Gazetteer* it is stated that the cotton crop is usually mortgaged to the money-lender, who receives it in the raw or unginned state, and gives back to the cultivator such seed as he may want for feeding his cattle and for sowing. This system prevails more or less throughout the presidency. The local dealers get loans from the larger; buyers; from these they, in their turn, make advances to the growers, so that a state of indebtedness, dependent on the crop, prevails more or less in every grade of the cotton transactions.

MIXED CROP CULTIVATION.—On this subject In 1886-87 the Director of Land Records and Agriculture wrote as follows:—" Respecting the cultivation of cotton and the merit of the local expedient of intersowing occasional rows of *jovsari* or *tdr*, experiments made in the season under report prove that the cultivator, even in a good cotton season, secures a larger profit from the mixed sowings than from cotton alone, and that in a year unfavourable to cotton he ensures a fair return. But, on the other hand, the experiments do not show a similar merit in the local practice of ploughing up poor cotton and following with a late crop. It is better to Mitersow gram or linseed between the rows of poor cotton*" Many writers i

Conf. with prices, pp. 5° &51.

Vixed Crop. 96 GOSSYP1UM.

Diseases of

CULTIVATION allude in similar terms to these advantages as justifying the growing In tendency to extend the Cultivation of cotton as a mixed crop. The habit BOMBAY. is certainly less injurious to the cotton industry than the reckless admixture in the same field of two qualities of cotton by which means adultera-Mixed Crop. tion of good and bad qualities becomes unavoidable. It would seem, however, that even this pernicious practice is rarely a wilful action on the part of the cultivator, but is due, either intentionally or accidentally, to the buyer of the staple returning seed to the cultivator from a mixture obtained by ginning the cottons purchased from many growers. It would seem that this mixing of seed is only too frequently an intentional action, the dealer being thus saved the trouble of mixing bad cotton with good. SELECTION OF SEED.—Forbes Watson expressed the opinion that the Selection of seed from four and five-celled pods would produce a better yield and a. seed. better staple than that from the ordinary three-celled condition. Experi-97 ments have been made, at the Hyderabad Sind Farm, to test this theory, and the results of the trials may be seen by reference to the tables on p. 3 Whatever merit can be attached to the information therein tabulated there would appear to be no doubt that much greater success would be attendant on careful selection of seed than on experiments in acclimatising foreign prize varieties. If there be a demand for cheap cottons, as seems the case (both in India and Europe) care should be taken that the cultivation and trade in such staples be kept distinct from the good growths. The mixing of the seed of two qualities is not only direct adulteration but the surest way to secure, through hybridisation, the degeneration of the better stocks of Indian cotton. DISEASES TO WHICH BOMBAY COTTON IS LIABLE.—In DhárwSr it is Diseases. stated that the cotton crop is liable to two classes of disease. Benithgt 98 rog is brought on by continued hard, cutting, easterly winds. The leaves turn red and become blighted. The flowers and pods fall off without maturing and the plant slowly dies. *Karaghi rog* is brought on by easterly winds accompanied with morning dews and fogs : it disappears if a westerly" wind sets in before the disease has gained too strong a hold. Similar diseases are alluded to in most district reports. The following account of the diseases to which the crop is liable may be abstracted from Mr. Walton's History of Cotton in Bombay :-- Cotton is naturally a very hardy plant, and stands some wonderful vicissitudes of climate and weather, but, notwithstanding this, there are some sudden atmospheric and other changes, which seriously affect it. The most trying consequences are produced by untimely, sudden, and heavy falls of rain, frequent changes of, and trying, winds, and cloudy weather; frost also injuriously affects the plant, but this seldom happens in the Kaladgi and Belgaum country. The rayats often say their cotton plants are struck with rog (disease), when nothing of the kind has really occurred. One set of circumstances which causes this mistake, is when unusual heat comes on with an excessively dry atmosphere; and the roots of the plants have not reached down to a moist sub-soil. When this happens the branches and leaves first droop, then dry up, and eventually turn brown, getting the appearance of having been burned up. It is this brown appearance that the farmers sometimes mistake for blight, when the phenomenon has in reality occurred from the above causes only. Cotton is essentially a sun plant, and if the sub-soil of the fields,

where it is sown, is in proper condition for imparting the required sustenance through the tap-roots, no more rain is needed, and at most times, especially if heavy, any rain that falls after the bushes are about a foot high is injurious. If the fall is heavy, even before that time, it almost **G.** 98

* Bombay Cotton.

(Watt & Murray.) GOSSYPIUM.

always does serious harm. Anything and everything that happens to cotton, and makes the plant look unhealthy, if even for a time only, is called by the native cultivators <i>rog.</i> According to the local farmers, there are some five or six of these diseases to which cotton plants are liable, and they are given below in the order in which they may affect the staple in its gradual stages of growth as follows:—	CULTIVATION in BOMBAY, Diseases.
(1) <i>Banti roga</i> , or 'yellow disease.' This is caused by untimely and excessive rain flooding the fields. The effects are worst where drainage is defective. The stems and branches become a dirty yellow colour, the leaves red, and the bush droops; and if the disease is not arrested by the excessive moisture getting away in time, the plant dies.	Banti roga. 99
(2) <i>Banji roga</i> , or • barren disease.' This is brought about by hard eas\$ winds blowing night and day, together with cloudy weather. The progress of the plant seems to be arrested; it ceases almost entirely to show fresh leaves, and the development of flowers and bolls quite stops.	Banji roga. 100
(3) <i>Gugari roga</i> : this name literally means "half-cooked grain," and implies that the state of the soil and atmosphere has had the effect of partially boiling or cooking the plants. It is brought about by excessive moisture, and dull oppressive weather, with heavy clouds overhead, and but little and variable winds. The leaves fold and dry up.	Gugari roga. 101
 (4) Shidihayu.—This rog is caused by long.continued harsh north-east winds, and is characterised by the leaves drooping; it is seldom fatal to the plant. (5) Kari jigi roga, or the 'black sticky disease.*—This is quite the 	Shidi hayu. 102
worst of all the ailments that the cotton plant is liable to, since, when it has once taken hold of a field, and the plants are far advanced, they hardly ever recover. It is produced by long continued dews and unceasing easterly winds, and shows itself by a thick, dark, gum-like substance covering the plants. This so entirely covers and closes up the leaves, that they, the flowers, and the half-developed cotton-bolls, all die and drop off, and, in a short time, a field, that had the appearance/>f strong, green, healthy bushes, shows nothing but some charred-looking dirty sticks. Both descriptions of cotton are liable to all these ailments, but the acclimatised American may be considered the more susceptible of the two. The plants show their wonderful vitality and innate hardiness by rapidly recovering from disease, when the causes, which have produced it, are removed. All the diseases cease when a favourable change occurs, and genial, seasonable weather ensues for a'sufficiently long period. If any of the ailments have attacked the plants in the earlier stages of their growth, and they recover, no eventual harm is done. The case is, however, different when it happens at a late stage of their cultivation,—the yield of cotton is then affected both in quantity and quality, the fibre is almost sure to be short and weak, and often dull in colour. (<i>History of Cotton, 113-114-</i>). In 1867-68, a great part of the cotton-crop of Bombay suffered from blight, the effects of which were investigated and fully described, by Dr. Forbes . Thecause, he believed, to be exceptional climatic conditions similar to those detailed above; the effect was drooping, withering, and final death of the plants. Dr. Forbes sums up his report as follows :— "This wind-blight is the bane of the southern districts. I have seen seasons pass without the slightest appearance of it, but of late, its occur- rence has been more frequent, and its influence progressively more severe- ly felt * * *. It may be described as the effects of a hot wind, mo	103

G. 103

Picking of Bombay Cotton.

CULTIVATION in BOMBAY. Cotton picking,

104

accompanies it; its action upon the cotton plant is direct and speedy, and no amount of moisture in the soil will avert it."

COTTON PICKING-In Bombay, the picking of indigenous cotton usually commences in December and is completed in May. In the Presidency, as a whole, it would seem that the above dates are correct, although slightly different periods are recorded, in works treating of this subject^{*}. Thus, cotton picking in Khandesh is said to extend from the middle of October to the middle of January (Gas., 154). According to Mr. Beau fort (Indian Cotton Statistics, 24) picking commences in December ana is usually completed in March. The difference between these statements may be due to the introduction, since the date of the *Gazetteer*, of forms or cotton which mature later. "The average proportion of clean to seedcotton is one to three. Seed-cotton, fallen on the ground, contains a certain amount of dirt, which is partially removed by beating it on the *jhanji* or *thdtri*, a bamboo or cotton stalk wicker-work frame." *{lia*etteer*). In various passages, quoted above, the picking¹ and cleaning o^{*} cotton has been incidentally dealt with, and the habit of criminal adulteration laid mainly to the charge of the dealer, not the cultivator. In the paragraph below, on the Improvement of Bombay Cotton, the legislative measures formerly taken, and since repealed, to check adulteration, will be found briefly reviewed. The final conclusion arrived at by most writers seems to have been that careful selection of seed on the part of the cultivator, and stringent measures by the wholesale dealers to bar systematic adulteration from the market, would effect a complete reformation in the Indian cotton industry. It has been contended that the matter rests more with the merchant than the Government, and that what impurities are due to the primitive methods of collection would soon be naturally reformed if the necessity for such reform were made to be felt not only by the primary dealers but by the cultivators. Pressure brought to bear on the local dealers, by those at the centres of baling, would go a long way towards giving a new life to Indian cotton cultivation.

Improvement. **IO5**

G. 105

⁴ IMPROVEMENT OP BOMBAY COTTON.—LEGISLATION TO CHECK AD-ULTERATION.—In the "Note" on Cotton, published by the Revenue and Agricultural Department, the following passages occur regarding the history of the legislative measures taken to prevent the injuries effected on the cotton industry through the practice of adulteration, that for some years prevailed to an alarming extent :—

"The subject of the improvement of the cotton culture and trade of the Bombay Presidency has occupied the attention of Government and of the commercial public for more than half a century. The introduction of American and other forms commenced seventy years ago. "But the evil existed then, as it does even at the present day, of mixing indigenous with exotic, thus bringing discredit on the industry. It was not till after i860 that measures were planned for endeavouring to stop this evil. In that year the practice of mixing local and New Orleans brought the Indian-grown form of the latter into disrepute. (Shortly alter, Government, however, appointed a Commission to enquire into the subject. I he Commissioners found that— during the season in which the enquiries were made, little or no local or American cotton had been shipped clean or unmixed. Besides the mixing of different varieties of cotton the dealers admitted that their cotton was mixed with seeds and other rubbish, and that it compared badly with the exports of other years. Many of the local dealers were anxious that the trade should be regulated by law and placed under inspection. In tileir report the Commissioners stated that the evils of the Dharwar cotton trade were beyond usual remedies, and affected not only local but general interests. Nothing but the energetic action of Government could check so widespread an evil. Existing laws were insufficient; a fresh Act was required. With their report they submitted the draft of a Cotton Frauds Rill. This measure became law in July 1863 as the Bombay Cotton Frauds Act, IX. of 1863. The first Cotton Inspector appointed for Dharwar was Captain (now Colonel) R. Hassard of the Bombay Staff Corps, who had already received charge of the Dharwar factory from Dr. Forbes on his appointment as Cotton Commissioner." (Dhdrwdr Gazetteer, 2Q4—2QS) Improvement of Bombay Cotton. (Watt & Murray.) GOSSYPIUM.

"The Act proved more or less inoperative. The Inspector found it very difficult CULTIVATION to establish the mixing, at the gins, as Iraudulent under its provisions, and its operation thus brought to light a defect in the provisions regarding fraudulent mixing. To BOMBAY. thus brought to light a defect in the provisions regarding fraudulent mixing. To be fraudulent, mixing mustItake place in cotton either offered for sale or offered for pressing. There were no presses in Dhárwár and the cotton was sold, not in Dhárwár but in Bombay. So the Inspector might see in a ginning yard a heap of local, a heap of American, and a third heap of seed to be added as a make-weight, and yet fail to secure a conviction.'' *{Dhdrwdr Gazetteer, 2gs}* 'Ihe result was that out of many prosecutions, all of which were aggravated cases, clearly within the spirit of the law, very few convictions were procured. In 1873, the European merchants of the dis-trict as well as the local officers consequently pressed for a more stringent Act. In 1874, Government appointed a special Commission to enquie into the necessity for continuing the law to suppress cotton frauds. ' The majority of the Commission after collecting a large amount of evidence were of opinion that though it was not advisable to annul the Act it was preferable.to place it in abevance for a time. When the matter Improvement. to annul the Act it was preferable to place it in abeyance for a time. When the matter was referred to the Secretary of Stdte, the Bombay Government were directed to pre-pare a fresh Act with the object of remedying the defects of the existing measure.¹ (*Dhárwar Gazetteer, 2gg.*) ¹⁴ Act IX. of 1863 was repealed by Act VII. of 1878. These Acts appear to have been extended to Berar but not to the Central Provinces (*Cotton Commissioner's Banear for 1869 (0)* 275). In Soutember 1870 Legislation.

Report for 1868-69, 275). In September 1879 the Government of India recom-mended that all special legislation for the suppression of cotton frauds should cease. The Secretary of State did not then agree with the view held by the Govern-ment of India, though in March 1880 he sanctioned its proposals and desired the Bom-bay Government to do away with the special cotton fraud prevention establishment. Act VII. of 1878 was repealed by Act I. of 1882. 'According to Mr. Walton (Cotton Dependent) the opinion of the logal European Agents and Nation more than the special European State and State State

Act VII. of 1878 was repealed by Act I. of 1882. 'According to Mr. Walton (Cotton Inspector) the opinion of the local European Agents and Native merchants was opprsed to the giving up of Government efforts to check frauds. According to Mr. P. Chrystal, a Bombay merchant who is well acquainted with the Belgaum and Dhárwár cotton trade, the Bombay dealers and merchants in Ameiican Dhárwár and Coompta cotton think (18S3) that the Cotton Frauds Act failed to stop adulteration in the ttombay-Karnatak. Mr. Chrystal thinks that since the Act has been stopped, there has been no noticeable increase in the adulteration'' (*Dharwar Gazetteer, joi*). CAUSES OK ADMIXTURE.—The Collector of Khandesh, when referring to this admixture in 1878-79, pointed out that admixture begins with the sowing. The Khandesh ryots do not keep a portion of their crop for seed, as is customaiy in the Deccan, but depend for seed on the *bania*. The *bania* receives all kinds of cotton. That purchased from the pickers, who receive their wages in kind, must often* be mixed. He sells this and what he has received direct from the cultivators to the large dealer, who has it ginned and pressed. The admixture so far may be done in ignorance, but on Mr. Robertson's authority I say that wilful admixture takes place at the hands of the large dealers and of the agents of the large ginning and pressing ignorance, but on Mr. Robertson's authority I say that wilful admixture takes place at the hands of the large dealers and of the agents of the large ginning and pressing factories. At no single stage of this complicated business would honest and wise conduct succeed in preventing the evil. If the rayats sow pure seed, and keep their seed pure, the *banias* will mix it. If the *banias* were to guarantee good seed and to sell only such, they would have to charge a higher price for it, and the rayats would probably prefer using cheaper stuff which they would manage to find. If the large firms were to reject mixed cotton, their factories would be idle. Combined action is essential, but as unlikely as it is essential.'' "The Director of Land Records and Agriculture, Bombay, in his annual reports (the main facts from which may be here reproduced) has repeatedly discussed the

(the main facts from which may be here reproduced) has repeatedly discussed the subject of adulteration and its possible prevention :-

"1884-85.—The subject of adulteration is of such importance that I feel it my duty here to state carefully the whole case before Government, for only a full statement can explain the final deliberate decision that practically nothing at all can

be done. "The Secretary of State forwarded a communication received from the Liverpool "The Secretary of State forwarded a communication received from the Liverpool Chamber of Commerce calling attention to the increased adulteration of East India cotton—a subject of very great gravity—a growing evil which seriously imperils the foremost staple of India, at the same time affecting and disturbing most grievously the cotton trade. In due course the opinion of the Bombay Cotton Trade Associa-tion was solicited. This body informed Government that their attention had already been directed to the matter in such a way that they had been induced to appoint a special Committee to consider the question of mixing and adulteration in all its bearings. The conclusion arrived at was then announced—

will not stop mixing, it will, in my humble opinion, be incumbent on Government to seek to stop it without permitting interference with the trade or the obstruction caused by Inspectors, to weigh against the demands of the country and the welfare CULTIVATION BOMBAY. Admixture.

of the ray at. But I am anticipating. , _, , , _ . tuci.1.1 ur "The Collector of Khandesh, Mr. W. H. Propert, was the first to lay before Government his estimate of the practicability of the advice offered by the Association.

"He pointed out that no effort had been relaxed by the Revenue officers—(1) to prevent the extension of *varadifi*, for he had oftentimes gone near overstepping the bounds of legal authority to check its spread; (2) to encourage the cultivation of im-proved varieties, for at the Maheji Exhibition handsome prizes had been yearly proved varieties, for at the Maheji Exhibition handsome prizes had been yearly awarded for the best samples of exotic cotton; and (3) to supply pood seed, for the Government Farm had for its main object the production and distribution of as much good seed as possible; but that in 1882 the rayats got out of hand for two reasons, first, they had become fully aware that no restraining authority remained in the hands of the Collector, and, secondly, the price given for *varadi* had reached or nearly reached that accorded by the trade to the better staples of the Dharwari (ac-**Climetre** d Am©r (can) and Hingangháti. u !**JTE** showed that the producer has very little voice in the question as to what crop snouid be sown. He gets his seed from the middleman, and his crop is virtually dis-posed of, seed and all, before it is grown.

He admitted that the ryot prefers to grow the indigenous variety, which is reared with far more ease and yields a heavier crop. When the demand rose for this commodity, it was very easy indeed for the middleman to extend its growth at will. and he asserted forcibly that if for one season (1883) the merchants had refused to <u>3my varadi</u>, or had at any time, within the past three or four years, assisted him in his snorts to sustain the good name of Khandesh cotton, the *varadi* cotton would have been virtually stamped out.

. "Next, turning to the question of the distribution of good seed, he indicated his reluctance to look again to the Berars, because there was evidence that the system of admixture had worked harm there as well as in Khandesh, and there was little prospect of advantage from the re-importation of this Hingangh&ti variety, which is not BO valuable or generally suitable as the Dirarwari. And so with regard to Dharwar; the fact of Mr. Crawford's movement to improve the cotton of that distiict shows that the staple has deteriorated there also. Therefore there is risk in applying for seed thence. But Mr. Propert argued that in Khandesh itself it is possible to collect a large quantity of good seed by separately picking the bolls of the exotic cotton grown in and among the indigenous crop, relying on the fact that the former ripens earlier than the latter. than the latter.

... "I may parenthetically remark that good cotton can be procured from Dharwar. Experience has shown that seed acclimatized there succeeds better in Khandesh than freshly-imported seed; and though the Dharwar seed has deteriorated, its transfer to Khandesh will almost certainly give fair results. The plan recommended by Mr. Propert of collecting seed in Khandesh, too, is feasible. But, as is clearly argued, there is no possibility, under present adverse circumstances, of getting good seed sown. By the kind offices of one of the leading merchants in Bombay I was informed that his up-country agents could not, if they would, at present induce cultivators to sow the exotic cotton. Perhaps this opinion should be received with caution ; for, as all the reports tend to show, the rayat is not the arbiter in this matter.

" Mr, Propert sums up with his advice that dishonest mixing should be made penal. He holds out the alternative that the Bombiy merchants for one year should refuse to buy the mixed cotton. But the reply to this is that the merchants cannot

anord to consider any such scheme. "The Commissioner Mr. E. P. Robertson-after, I think very wisely, Insisting that the coercive measures adopted by Mr. Ashhurner some years, $fg^\circ \operatorname{TM}\mathfrak{L}^{a-1}\mathfrak{L}$ gether over-estimated as regards their good results-says that Government mayefull Fight to interfere by dictating to the people what cotton they il ^ d • » $\mathfrak{c}r^{a}\mathfrak{r}_{a}$ if supports the demand-for a law to punish ^ r t t j w - w g ^ peir vehe-that the merchants can hardly plead for the re-imposition of ^ the ^aw^{TM}\mathfrak{L}^n $\int_{inced that}^{inced that}$ ment opposition caused to be abolished, however much they may De convince that law is wanted.}

"Independently I represented my view of the question. The object of my letter "Independently I represented my view of the question. The object of my letter was to show that the advice of the Cotton Trade Association is futile, based on a misconception of the position of the rayat. I tried also to give reasons why the method of improvement initiated by Mr. Crawford in Dhárwár would do no good in Khandesh.

• Varadi in Khandesh- Vilayati-Khandesh in Berar Conf. with pp. 58s 89-9¹-

G. 107

Admixture of Bombay* Cotton.

I called attention to the late discussions in the Berars, and to the late Mr. Ridsdale a CULTIVATION In able review 'of the whole matter, in which he showed that interference with the BOMBAY. rayat is not justifiable on either administrative or economic grounds. This review was called forth by the resolution of a meeting that the action of Mr. Ashburner in 1873 had secured wonderful results in Khandesh, but had been detrimental to Admixture the Berars, in that it caused an influx into that Province of the seed of the » stapled variety ousted from Khandesh (which in the Berars is called Khan* deshi, and which in Khandesh is called Berari or *varadi*), thereby woiking much harm, and that the imitation of the policy of Mr. Ashburner would rehabilitate the cotton of the province. The Government of India, Revenue and Agricultural Department, prevented any action being taken by the plain statement of the pia>n fact that Mr. Ashburner's policy in Khandesh had not secured lasting results. I endeavoured to make it clear that though the Dhaiwari cotton does well in soⁿ parts and some soils in Khandesh, it is not suitable to otheis-that it would be an evil to attempt to stamp out varadi (or Khandeshi cotton), inasmuch as that vane, v is the only paying one in its peculiar soils. Further, that the production of *varaat* has its recognised and justifiable value, though the cotton is useless for'*export, except for purposes of admixture. *1 ventured to suggest that the earnest desire of the Cotton Trade Association to evolve a workable method of preventing fraudulent admixture, and the no less earnest anxiety of the District Officers to assist in the movement, would be best fostered by the appointment of a Joint Commission of merchants and revenue officers to enquire into and discuss the whole matter. On the one hand, the meichants would see how unworkable the advice offered by them really is, and, on the other hand, the Revenue Officers would learn much as to the most feasible method of meeting the evil without disturbance of the trade. "With well-sifted information on the various points noticed, the Commission, I thought, would be in a position to recommend a feasible working-plan. chants would then be entitled to call on District Officers for co-operation, and the District Officers would know what support they could expect from the trade. AC present in their eyes, in spite of the enlightened and well-intentioned declarations and. warnings of the organised mercantile associations, the trade is doing everything it can to checkmate their efforts at every step. "1 casually hinted at the feasibility of establishing warehouses near the ginning and pressing factories where cotton received should be sorted and cleaned. I neea only say that this plan is universally declared to be unpractical, and I do not wish to . pretend that I am able to elaborate a scheme in connection with it. "All these papers were considered by the Chamber of Commerce and the Cotton Trade Association. They were practically a challenge to the trade, and the trade could not take up the challenge. The former body explicitly stated that the admixture is due to a demand in Europe for inferior stuff. "So long as there exists a demand in the consuming market of Europe for the inferior descriptions of cotton, so long will merchants continue to purchase, mid lie-men to mix, and growers to cultivate it. No good end could be served by attempt* ing to interfere with the natural course of the trade. The Chamber went on to urge that there are signs of a re-action against mixed cotton, and advised Government to take energetic steps to distribute good seed throughout the districts, presumably to be ready to meet an improved demand. "The Cotton Trade Association, indisposing of the reference, con tended that there are buyers in Europe of adulterated and mixed stuff on its merits, and that merchants are bound to deal in it. It is, therefore, presumable that much of the adulteration which now goes on is not fraudulent. Certainly the former proceedings of the Association give me, at any rate, a different idea of the matter. It seems to me to be merely removing the fraud one stage further on, for these buyers in Europe of adulterated and mixed stuff on its merits, paying the high price they do for the chief ingredients (worthless 'on its merits) of the mixture, cannot be credited with honest dealing. "The orders of Government were that no steps to stop the supply of a coromodity which is grown to meet a demand by consumers can be taken. As regards the latest advice of the Chamber, it was pointed out that, till the improved demand for good cotton docs arise, it would be premature to distribute good seed. It must be drawn from these orders that Government do not approve of any legislation to check fraudulent mixing. * The course of events must be watched; but whatever is done in the matter ?^u f^a b^c-^{done} Without consultation with the trade. It is, in my humble opinion, hardly fair to ask the merchants to show how the rayats can be protected from byinjury resulting from the course of the trade. On the other hand, the perusal of the G. io7

Admixture of Bombay Cotton. (Watt & Murray.) GOSSYPIUM.

deliberations of the Cotton Trade Association gives the fullest confidence that whatever can be done on their part will be done.

ever can be done on their part will be done. "The Commissioner, N. D_A Mr. G. F. Sheppard, brought to the notice of Government a specific instance of the importation into Broach of 179 tons of *dhol lera* cotton to be ginned. It may be presumed that this was for the purposes of admixture. Clean cotton cannot be successfully mixed. Mr. Sheppard also noticed that annually a very inferior variety of cotton is exported to Dhollera from the Kaira district. He enlarged on the greater danger from deterioration of the seed than from mere, admixture of staples, and urged that the subject demands consideration in the interests, *not* of the trader, but of Government itself. "He contended further that it is easier to prevent admixture of seed at the begin-

"He contended further that it is easier to prevent admixture of seed at the beginning, than to restore the high character which a crop has once lost. He advised that the Collectors of Broach, Surat, and Ahmedabad should be directed to watch importations of interior *kapds* and authorised to buy up the seed either pure or mixed. I here can be no objection to such a plan. The seed would be useful for cattle food and tlje loss nothing, because it may be presumed that a lot of seed, stigmatized as mixea, would not knowingly be used for sowing. I trust that the Commissioner will carry his suggestion into practice.

"Mr. Stormont, of the Bhadgaon Farm, made a short tour chiefly to ascertain the extent of admixture *in the field*. The following may be quoted from his report :—

**Tour in Cotton Districts.—About the beginning of February the Collector T Li 1,1 A 1 • x-r ** directed me to make a short

					AVERAGE MIXTURE.					
PLAC	Е.				Varadi.	Hingan- ghati.	American			
Pachora				_	Per cent. *5	Per cent.	Per cent.			
Yaval Arrawad	:		•	•	58 70	40	43 6			
Chopda Dharangaon			•		75	30 25 20	30			
Erandol		•	•	•	50 58	20 29	13			

directed me to make a short tour in the eastern talukas with the object mainly of finding out to what extent mixed cotton seed was sown by the cultivators; also whether, as a alleged, merchants were paying preference prices for the short-stapled *varadi*. ^ My inspection embraced a circle of districts including Fachora, Bhusaval, Savda, Chopda, and Erandol. The results of the analysis of numerous samples are c>ranged in the margin.

"A glance at the table will show that the crop of Khandesh still contains a fair percentage of good cotton. At Pachora it is nearly half American; the short-staple being only a quarter of the whole. This is admittedly due to the spare farm seed being annually sold in the neighbourhood. At Bhusaval no reliable sample was obtainable, but about Yaval the American element diminishes to o per cent.; at Arrawad and onward to Chopda it altogether disappears, until the vicinity of Dharangaon is reached, wherewith the Hinganghati it makes up half the crop. Coming southward by Erandol the varadi again predominates, being just outside the circle under the influence of the farm.

⁴⁴ Opinion of Cotton Merchants.—At Dharangaon a number of merchants and others met me to discuss the question of cotton improvement. The smaller class of local dealers were strongly opposed to any measures of restraint, declaring that although the price of varadi was comparatively low, still the cultivators liked to sow a certain mixture, it being the more reliable poor man's crop.
"The Bombay buyers, on the other hand, were unanimous in opinion that only

"The Bombay buyers, on the other hand, were unanimous in opinion that only the operation of an Act could ever restore the reputation of Khandesh cotton and the consequent prosperity which its producers enjoyed for so many years. All, however, were agreed as to the beneficial results which must necessarily follow the distribution of large quantities of good seed.

⁵⁶ "It seems to me that Mr. Stormont has missed one point, deducibie from his enquiry,—that is, that the further he went from the railway and from cott n centres (*e.g.*, Dharangaon) the less the percentage of good staple. '1 his fact would seem to show that the suitability of the indigenous variety, apart from the support accorded by the demand for admixture, has a strong bearing on the increase ot *varadi*. The deduction may be wrong, but if it is correct, it is a warning that a place for this variety must be recognised as necessary (see paragraph above).

1885-86*—" I have very little to place on record respecting this important staple. No further movement has taken place in the direction of check against admixture,

Introduction of Better Oualities of

and I have no district agency to record the damage done by carting seed-cotton from districts, where the staple is bad, but the colour good and the cotton cheap, to $b^{\mathbb{C}}$ ginned with superior cotton. That this admixture goes on I have no doubt, and it is certain that the mixed seed is sown in the localities where the ginning is done, to the treat detriment of the crop. One circumstance, however, is worthy of note. The Liverpool Chamber of Commerce has established a new standard which will be known as *bilati*. It will include the short-stapled *omra-wattee*, and will apparently be a direct check against the export of the short-stapled varadi as it is called in KhAn-desh, or Khandeshi as the Berar people chose to denote it, under the standard of omrawattee. It remains to be seen from the quotations and trade returns the price which the new standard will command and the proportion it holds to the whole crop.

In concluding this series of quotations from the best sources regarding adulteration and the measures that have been taken to repress the practice, it may be added that the modern demand for Indian cotton, consequent upon the great trade created by the American war, was not the primary cause of these measures. From the earliest records of the Indian "export traffic (somewhere during the last decade of the eighteenth century j up to the present time, complaints have been rife. Thus, **Dr. Hove** in 1787 wrote, "I observed to-day, when they were embaling the cotton, if they" (the dealers at bynapoor) " adulterate it with any ingredients as it is reported in Bombay. But in justice to the inhabitants, I must say that they paid a particular attention that nothing impure was communicated, in which state they deliver it to Broach, where the cotton *is* adulterated with their own inferior sorts and that of Baonegar, Bodra, and Dolea to make it resemble that of Ahmood, which is first mixed together, as I am informed, and then passed again through the cylinders, by means of which it is so intermixed that the ablest connoisseurs mistake it for the original. To this adulteration the merchant has nothing to say and is very glad to obtain it in that tion the merchant has nothing to say and is very grad to obtain it in that manner. But the same on coming to Surat is adulterated by Europeans in such a manner that all this which was sent from here of late on our Company's account to China lies unsold and for which they paid the contractor a most exorbitant price who gained unlawfully, by the mformacjon I had here, no less than £25,000 sterling. As the method of adulteration of adulteration of the sentence tion was not secretly enough performed, it was of course immediately communicated by the agents to their correspondents here, that they might also adulterate it and send it in that manner to Broach. The method which the well-known contractor for that cotton practised was as follows : he purchased a large quantity of old cotton seeds which is sold publicly in the bazars as food for cattle, then opening the bales he intermixed a certain quantity of it with some other rubbish, and closed it in the first state in which he delivered the contracted quantity to the respective commanders on the Company's account for China."

INTRODUCTION OF BETTER QUALITIES.

In referring to the introduction of exotic cotton into the presidency, the Director of Land Records and Agriculture says in his report for 1884-85 :-

m "(a) American.—The valuable staple acclimatized from American seed is well established. Its cultivation is liable to fluctuations with the rise and fall of the demand for good stapled cotton, but it will not disappear. Us hold is especially strong on the three talukas of Bankapur, Karajgi, and Ranebennur in Dharwar, and the large areas of the surrounding Native States. It does not do well in the deep black-soil talukas. Its advantages are:-

- (2) its outturn becomes sooner certain, and advances can, therefore, be earlier secured on the crop;
 (3) cleaned by the saw-gin it economizes manual labour, and this
 - at the time when this labour is in great demand ;
- G. 108

"(4) >n good years its yield is very high; "(5) though more liable to blight than the indigenous variety, it	CULTIVATION in
possesses greater power of recovery.	BOMBAY.
*' The question of introducing this variety into neighbouring districts,	Exotic Cottons.
fcjp"., Bijapur, is very important."	Cottons.
The experiments with exotic seed, however, appear to have proved unsatisfactory in 1884-85 and 1885-86, but further trial was subsequently	
made with fresh seed imported from America. This was tried in Khán-	
desh also, but the Director, in his report for 1886-87, states that it had been	
clearly demonstrated that it would be unwise to force exotic American	
cotton on the KMndesh cultivator as the soil and climate of the district	
was unsuited to its growth. (b) Egyptian,—The Egyptian black-seeded cotton was tried in Dh4r-	
wdr in 1884-85 but failed. It has apparently been also tried in several	
districts without success.	
m(c) Nankin.—In June 1884, the Government of India supplied the	Conf. with
Director with Nankin cotton seed to test the suitability of the Nankin or <i>Khaki</i> coloured action which it was contamplated should be used for the	р. 17.
<i>Khaki-coloured</i> cotton which, it was contemplated, should be used for the summer clothing of the troops in place of dyed cloth. A guarantee was	
given that the produce would be purchased at 4 annas per ft of cleaned	
given that the produce would be purchased at 4 annas per ft of cleaned cotton. The Director wrote in 1884-85 regarding this experiment:—"The	
cultivation of Nankin cotton in this presidency has not got beyond the	
experimental stage, and even experimental cultivation is in its infancy. The only instance known of a farmer growing this cotton on his own	
account is in the Shevgaon Taluka of the Ahmednagar district, where	
one Narayan Raghunath, a Brahman holder of some means, cultivates	
it yearly as a garden crop to the extent of five gunthas. The seed is said	
to have been imported from Delhi about twelve years ago. The cultiva-	
tor manufactures the produce into cloth for his own use. "On the whole, although the outturn under experiment was smaller than	
that of the local variety, it is not to be doubted that as large an area ?	
may be desired can be grown with this cotton if the Government of Thdia continues its offer of 4 annas per ft of clean lint; but without such a	
continues its offer of 4 annas per ft of clean lint; but without such a	
stimulus it is not at all likely to be grown at all. I am very much averse to any attempt at forcing this variety on the country. It may injure our	
staples by hybridisation. Its seed may get mixed with the other varieties,	
and a most harmful, undesirable mixture will result, which, once establish-	
ed, will take long to remedy. No alacrity is shown by the Military De-	
partment to utilise the natural <i>khaki</i> cotton in lieu of the dyed material, and it is not unlikely that a mordant may soon be discovered which will pre-	
vent the now unsatisfactory variations in the colour of dyed <i>khaki</i> . Again,	
experiment has yet to be carried on to decide whether the colour of the	
Nankin cotton can be relied on. I have instituted experiments on this point	
at the Hyderabad Farm. The Nankin cotton has no merit as to staple or yield; and my advice on the matter, as it stands at present, is that all	
attempts to force its growth should be abandoned. I earnestly ask that	
pressure may not be brought to bear on me to do more than experiment	
with this variety.	
•" The following extract from a letter of the Chamber of Commerce^	

•" The following extract from a letter of the Chamber of Commerce^ to whom a small sample of the Shevgaon cotton which was decidedly superior to that grown on the Bhadgaon Farm, was sent—also supports my view :—

view :— "• The staple is short, irregular, and wasty, and would be most unprofitable stuff to work. Under the circumstances, the Committee would strongly advise that the cultivation of this description be confined to those places where it is indigenous, as there would be great danger of its hybri-

GOSSYPIUM	Introduction of Better Qualities of
CULTIVATION in BOMBAY.	dising with the local varieties to their detriment if introduced largely into this presidency.''' The experiments regarding the possibility of securing a uniform colour
Exotic Cottons.	in Nankin cotton by selecting the seeds from bolls of the desired tint, were concluded in 1886-87, when the Director stated that—" The result ot adequate trial is that it is very difficult to obtain clean cotton of a uniform colour, though it is possible to do so with great care in selection of seed; but as the variety of cotton is poor in yield and undesirable in every respect,
	the conclusion is not of great importance. The Military Department has now withdrawn its special encouragement of this variety by experimental results." Perhaps the first person who saw khaki-coloured cotton in India was the late Dr. Hove, who, in 1781, came across fields of yellow-coloured cotton. At first, on being shown the cotton, he thought it had been d}"^d, but
	afterwards he had abundant proof that this was not so. In the attempts narrated above, history seems only to have repeated itself, for, if unknown in 1884, the knowledge in the cotton had only died out. It was perfectly understood a century ago.
Continued Experiments. 109	CONTINUED EXPERIMENTS WITH AMERICAN COTTONS.—The Director found that the exotic cotton seed (acclimatized American) had degenerat- ed, and he therefore determined on importing fresh seed from America. The following extracts from his reports refer to the subject : — 1884-85.—'' I noticed in my report last year that there was a spontaneous
	demand for fresh seed in Bankapur of the <i>white-seeded American variety*</i> the only one of very numerous kinds which has really shown itself worthy of support. But I found that no further action had been taken. The seed has degenerated. It is harder and smaller than it was. Though a good year seems to check this degeneracy, there is, no doubt, need for new im- portation. The demand for new seed is not confined to Dharwar. From Kolhapur I have received a large indent. 1 have placed myself in commu- • nication with the Chamber of Commerce, and fresh seed will be imported.
	"But I have decided on adopting a slightly different plan from that followed heretofore. Fresh seed is very expensive. It never does well the first year. 1 propose therefore to sow the seed in that part of the dis- trict <i>{e.g.</i> , Bankapur) where the variety succeeds best (I may notice that in the deep black-soil talukas of Ron and Navalgund it gives a poor crop in comparison with the yield of the lighter black districts of Bankapur, Karajgi, and Ranebennur) and to distribute the produce at a moderate charge. This plan 1 shall recommend to the Kolhapur State. Specific proposals will be made to Government for sanction to hire land for one year
	tor the purpose." On the subject of the soil best suited to American cotton, the Director wrote: "Dr. Royle pointed out (184.0) one result of experiment which wills I believe, by all be recognised as correct, <i>viz.</i> , that the black soil is no so well suited for American cotton as the poorer soils. I cannot but think that attempts to introduce the improved varieties without regard tc ^{this} fact were so far misguided."
	This opinion should be compared with that arrived at regarding the soils of the*Central Provinces found best suited for American cotton. 1886-87.—" I described last year the new importation of seed and its distribution. I am now able to give a very satisfactory account of the results. In Dharwar in six villages of selected talukas, <i>i.e.</i> , talukas where the exotic cotton has held its own without the aid of official pressuie, sow ings were made by Mr. Price. A little delay arose owing to an untoward break late in August 1886. The season was, on the whole, favourable The average yield was 158U) per acre of seed-cotton. The proportion of

" I have, under the head, farms, shown the result of experimental sowings at Bhadgaon. A large portion of the new seed was taken over by the Kolhapur Agency. In some States the season was unfavourable. The report received from Miraj Junior states : ' The cotton plant raisect from the new American seed is 3 feet high as compared with 2f feet in the case of the old cotton. The pods are fewer but larger, about in the pro-portion of 2 to 3, but the weight is greater, ten pods of the new weighect 102 to 4 mir of the source number of the old mirighed only 81. These step 103 tolas, while the same number of the old weighed only 8J/ These notes

correspond with Mr. Baines' observations. "In the Panch Mahals Mr. B. A. Dalai sowed the, new cotton. It gftve a poor yield, but he likes the quality of the sample.

CLEANING OR GINNING OF COTTON IN BOMBAY.-Mr. Beaufort writes under this subject:---'' The Broach and Dhdrwdr growths are the only ones which are entirely cleaned by steam or hand saw-gins, but the quantiby of *oomras* and *dholl'eras*, thus treated, is 'yearly increasing. All other descriptions of Indian cotton are hand-cleaned by the native *churka* or foot-roller.'' The following extracts from the annual reports issued by the Director of Land Records and Agriculture give the most recent informa.

GINNING' ZIO

Dictionary of the Economic

GOSSYPIUM,

Cleaning or Ginning of

GINNING tion on the subject of saw-gins and the extent to which they are at present used in Bombay Presidency:-BOMBAY. 1884-85.—" One of the most important questions in Dh[^]rwar is with respect to the saw-gin. A reference to the Gazetteer* will show the various steps which led to the introduction of this necessary concomitant of the American cotton, which has established itself in the district, and the reasons why the management of the saw-gin factories still remains in the hands 01 Three years ago it was discussed whether Government Government. could not safely retire from the direct manufacture, distribution, and repair of the gins; but it was resolved to await the advent of the railway, when it might reasonably be expected that steam saw-gins would be set up ov, private firms. The railway is opened, but there is no indication yet ot any such enterprise. There are steam gins at Hubli and Gadag, but the roller pattern is used. "I sought to ascertain whether the people could not now be left to themselves to arrange for the repair of their gins. There is a great deal of discontent among them. The factories are made self-supporting by a subscription of R6 per annum per gin from each owner. The tax may be evaded by the deposit of the saws and spindles at one of the factories. The owners are entitled to the services of trained hands on payment, over and above the general subscription, for wages and material. The complaint is that the trained workmen kept are too few, and that only those villagers who live close to the factory get any benefit. On the other hand, more labourers would entail a larger subscription, and apparently the people are not careful to have their gins repaired in the slack season, but wait till the ginning time comes, and then, finding something g^o wrong, all clamour lor the factory-men. At Hubli and Ingalgi the rayats assert that they can make their own arrangements, provided Government will assist them in procuring new saws and certain working parts and new gins when required ; but everywhere else there was a consensus of opinion that .»Government must keep the factories, and I believe this is a necessity. It can only be hoped that private steam saw-ginning factories may yet be started. There is one gin worked by bullock power at Halyal near Hubli. At Devgiri I saw another being set up. There is a third, now unused, also near Hubli, and at Ingalgi there is a prospect of another. This utilisation of bullock power must be encouraged. It will reduce the labour now falling on the factory workmen, for the rayat who works a gin with bullocks is in a position to employ his own skilled hand. It may be advisable to seek to introduce Gordon & Co.*s bullock power into this district. This machine has no place to fill in Khdndesh, but there may be benefit in Dharwar. " A new pattern of saw-gin has lately been introduced into Dharwar. It is a great improvement; but the people, I think naturally, complain that the improved grid might have been adapted to the old frame-work and other working parts instead of necessitating their purchasing an entirely new gin. They do not like the new grid. It is too good, and cleans the cotton too well to suit the degenerated demands of the trade. The larger outturn of the old grid is solely due to the large percentage of seed carried through. The same feeling shows itself also in respect to the foot-roller. This rude implement worked by women can compete, and does compete, successfully with the steam-rollers, because the trade is not particular, and prefers buying cheaply half-clean stuff to giving a remunerative price for well-cleaned cotton. " I may mention that the foot-roller-for indigenous cotton only-I^s the implement used all over the Southern Mahratta Country, but that • Dharwar Statistical Account, Vol. XXII., 366-373. G. no

strange to say, the *hand-charka*, very similar to the Khåndesh *charka*, is again found in the very south of the district."

1885-86.—"I am glad to report that the Haliyal saw-gins are now worked by steam instead of by bullock power. This is, however, the only place in the whole Presidency except the two Government farms, where the steam saw-gin is used to clean cotton. No change has taken place regarding the manufacture, repair, and distribution of hand saw-gins in Dharwar, described in last report.

" At Bhadgaon, now that Mr. Stormont has a steam engine, he will work saw-gins to clean the farm cotton and the small amount of the Dhárwa'V-American still grown in the neighbourhood from farm-seed. At Hyderabad, an experiment with the saw-gin for cleaning the indigenous cotton has been most successful The whole of the farm crop was ginned wite* the improved saw-gin sent from the Bhadgaon Farm driven by a six horse-power engine. Mr. Strachan reports that the cost was Ri-3-1 per maund of 84ft as compared with $\pounds 2^{\wedge}$ to R2f for the native hand-charka. The clean cotton sold for R15 per maund, while the ordinary native was selling for R13-8. The seed could have been sold for Ri-10 per maund, but the price of the clean cotton alone was more than would have been got for both cotton and seed had it been sold unginned. The outturn of • the gin was 18 maunds per day of nine hours. The Karachi Chamber reported, • saw-ginned Sind native cotton from selected seed appears to be a great success. The staple does not show any signs of having suffered from the process of ginning, and is valued at about Ri£ to R2 more than the average native *tattda.'* The hand-ginned samples of selected Sind cotton, *i.e_m*, grown from the selected seed, were valued at Ri to Rij- above the then existing average selection of Sind. It is noticed further by Mr. Strachan that the saw-gin does not crush the seed, and that the percentage of clean cotton is greater than that obtained by hand-cleaning.

1886-87.—"The Dha'Wa'r Factory is languishing. Perhaps the defeneration of staple in the exotic cotton is the cause. The extra pr>ce oes not encourage or repay the use of the rather expensive gins. Private enterprise has not, as was hoped, relieved Government of the necessity for maintaining the factory. It has been decided, however, that if the Local Boards will not take over the factory, they will be closed on 31st August 1889. By this time the newly-imported seed may alter the prospect of affairs.

"This gin is wonderfully appreciated in Sind for indigenous cotton. It is only used in Dha'rwa'r for exotic. I have in former reports given details of the working in the Sind Farm. Saw-gins were exhibited at the Shikarpur Show and were much liked. But a further indication of approval must be recorded. A large cotton dealer at Hyderabad, Sind, has contracted with the Government farm to gin considerable quantities of cotton with the saw-gin driven by the farm engine. The result of this working is not yet known."

ANALYSIS OF LAST YEAR'S TRADE.—The total imports into the Bombay Presidency in 1888-89 amounted to 457,470 cwt., of which 119,949 cwt. came by rail, 287,553 cwt. by road, and 53 cwt. by coast, from external blocks; 47,900 cwt. by rail and 1,925 cwt. by coast, from Bombay port. The largest amounts received by rail were from the Central Provinces, Rajputana, Central India, and the North-West Provinces and Oudh; by road, from the Nizam's Territory.

The exports amounted to 3,427,184 cwt., of which 3,372,925 cwt. went to Bombay port, a few cwt. only going to Madras, the Madras seaports, the Central Provinces, Berar, and Bengal. Of the total exports by rail to Bombay port (2,130,897 cwt), Khándesh, Násik and Ahmednagar contri-

Sind.

Method.

the world, would seem to be an increased length of staple and greater cleanliness. These improvements, it is believed, might be effected by more careful attention to the culture of the plant, and to the picking and cleaning of the wool " • « . , . , . , . - »

Even so early as 1839 we "find the cotton of Sind referred to by Sir Edward Ryan as a very flourishing phnt, " cultivated in Upper Sind with great care by the aid of irrigation from the Indus."

Like most other commonly cultivated Indian cottons, that of Sind appears to be G. Wightianum, *Tod.*, or hybrid forms of that species. The hybrids are extremely variable, tending to reveit to G. arboreum, and, in doing so, to deteriorate and give rise to local races with marked differences in quality of staple. Thus, the Superintendent of the Experimental Farm at Hyderabad writes:--- During the past season I have had a better opportunity, than ever previously, of comparing the cotton grown in different districts of Sind when it was brought in for ginning, and from no district did I see cotton so good as that grown on the farm from selected seed. This fact, I believe, is generally admitted. The Tanda cotton is best for length of staple; Hála comes close to it for length, and tops it for outturn of clean staple to seed; from the other districts the cotton is inferior to these. The poorest of all comes from Jhudda, in the Thar and Párkar districts. The seeds are smaller than those of the Sindi proper, but much more numerous, while the covering of cotton on them is very short and very thin. Thisyear some of the farm-selected Sindi cotton has been sent for trial in the Thar and Fárkar district, and I trust it will give such satisfaction as will induce the Deputy Commissioner to call for more of it next year." It may be noted in passing that the experiments at Hyderabad seem to have been attended with an unusual amount of success, most of which appears to have been due to the evident appreciation of native cotton on the part of the management of the farm. By careful selection of the best seeds, and attention to the best methods of cultivation and cleaning, a very exceptionally large outturn of a good fibre was obtained, which sold at $\pounds 2$ over the market rate, and which, at the same time, yielded good seed that could be sold for R2 per miund. There can be no doubt that the distribution of such seed, sold at only a little over the bazir rate, would greatly improve the cotton of the province generally.

Conjointly with these laudable endeavours to improve the local races of cotton, numerous experiments were conducted with the object of determining the suitability of foreign seeds lo the climsie and soil of Sind. The result of these has been to prove that no seed can in any way compete, under the local conditions of soil and climate, with the commonly cultivated Sindi race. Bourbon cotton, the exotic chiefly experimented with, gave a crop of only 3i6fl> in one case, 152ft in the other, of seed or uncleaned cotton to the acre. Native cotton, on the other hand, yielded, in the same year iwith similar care in cultivation), 1,775ft of uncleaned cotton to the acre.

SOIL, MANURING, AND METHOD OF CULTIVATION—The following account is extracted from the *Sind Gazetteer* : "Cotton is cultivated in two *ways*—*sailabt* and *bosi*. The first requires frequent watering after being planted, and the seed is sown on the sides of ridges after the surface has been inundated, the holes being made at a distance of about a foot ard a half from each other

"The second description is sown on the surface of the lands left by the inundation; no alter-waterings are required, the dew. which falls heavily, affording sufficient moisture. The only care required is to keep the earth about the stems loose and free from weeds. Cotton is sown in Upper Sind at the end of February or beginning of March, sometimes in May or

{Watt & Munay.) GOSSYPIUM.

GOSSYPIUM. Cotton Cultivation in CULTIVATION June, and picked in July and August, also in November and December. After picking, the cattle are turned in to graze, and the crops left for a SIND. second year. Cattle dung is used as a manure in the proportion of about Method. 12 maunds to a bighå. In other parts of Sind, cotton is not cultivated till the canals fill in June, and the crop, *m* consequence, is not picked till November or even December. The crop is liable to injury from bug" (? cotton-borer), "frost, and locusts." The rainfall of Sind, as is well known, is excessively small, so the greater part of the cotton, as of other crops, is cultivated by irrigation. Watering is effected by what is called charkhi' or wheel irrigation. Cultivation at the Hyderabad Experimental Farm has proved that, to ensure a good crop, (1) rotation ought to be kept up; (2) sowing ought to be broadcast, and should be carried out before the end of June. It was also proved that late cotton is very liable to the attacks of g. een fly in October. CLEANING—Is, as a rule, performed by the ordinary native charka, Cleaning, which is similar to that described elsewhere. Recent experiments have 117 proved that Sindi cotton is easily and more cheaply cleaned by the sawgin than by hand; that the percentage of cleaned cotton so obtained is greater, and that the produce fetches R2 per maund more than the market rate It appears undoubted that the introduction of saw-gins, together with the efforts to improve the stock by careful selection of seed, may do much to improve the quality of the Sindi cotton of commerce. ANALYSIS OF LAST YEAR'S TRADE.—With the increase in importance of Slnd Trade. Karáchi as a commercial centre, the trade in cotton from the province has 118 undergone a remarkable increase. Sind formerly imported the cotton it required, to the amount of thousand* of cwt annually, principally from Kachh and Gujarat, indeed, it was not until 1840 that the plant began to be at all extensively cultivated in the province itself. The fibre at first held a very -poor position in trade, and in 1863 shewed a difference in value as compared with "Fair Dhollera" cotton of from \d. to 6d. per pound. In 1870, it had so far improved as to reduce this difference to *id*. or ||d. In the year under consideration (18S8-89), ^{t n e} average value of the exports per cwt. amounted to over R20, an amount almost equal to that obtained for the average cwt. of Bombay cotton in the same year. The outturn has steadily increased, until last year, as already stated, it reached a total of 189,600 cwt' The imports amounted to J7, ojq cwt., of which nearly the whole, vis,, 74,012 cwt., was derived from the Panj£b, the small remainder came from the port town of Karáchi, and trans-frontier from Lus Bela, Khelát, and by the Sind-Pishin Railway. The exports amounted to 224,927 cwt., of which a small amount went to the Panjab and trans-frontier to the localities above-named; all the rest, viz., 224,330 cwt., was sent to Karachi for shipment. **CULTIVADON** 3. BERAR. in References.*"Rivett-Carnac, Rep. on Operations of Cotton Dept, 1867-1869; Annual Reports, Cent. Provs. and Berar Cotton Dept.; Hume, Note on Cotton in Berar (1885); Official Corres. and Reports; Agri.-UorU BERAR. IIQ Society of India, Jours. (Old Series), XI._x 456, 472; XII., 22-29! (New Series), I., Proc, Ixi. REVIEW OF THE AREA, &C.-This province, after Bombay, has the Area. largestarea under cotton; but, in comparison to the total cropped area, the 120 fibre is grown much more extensively in the latter than in the former tract. The cultivation of cotton in Berar reached its maximum in 1878-79, when as much as 2,207,839 acres were planted, but two years later a minimum,

G. 120

				<u></u>
•	•	Berar.	(Watt & Murray)	GOSSYPIUM.
 			<u> </u>	

for the last fourteen years, of 1,755,046 acres was recorded. Since that date it has again gradually increased, and, in the year under consideration, attained 1,991,551 acres. Reference to the table, p. 56, will show that the total outturn in the same year was 1,276,061 cwt. of cleaned cotton, an average of 71'68ft) to the acre. Comparison with similar figures for 1887-88 shew a very marked increase in the production per acre, the total outturn in 1888-89 being nearly double that of the former year, while the area increased less than 100,000 acres. By a similar calculation to that followed in the case of Bombay and other regions, the total amount available for consumption in the year under consideration, is found to have been a minus quantity of 48,448 cwt. This fact is only to be explained by the absence of registration of road traffic, and by the error which necessarily arises from considering statistics for on[©] year only. On this subject the Commissioner of the Hyderabad Districts writes:—

*' The replies received from Deputy Commissioners shew that information as to imports and exports cannot possibly be given, as there are no statistics of road-borne trade in Berar. Information on consumption and outturn is included in the statement under submission, but the figures are only approximate. It is difficult to come to any conclusion as to the consumption of indigenous cotton per head of population, as no attempt has yet been made to ascertain what quantity of cotton is reserved by cultivators and others for local consumption. In the Amraoti district the consumption is estimated at one-tenth of the outturn, while in the Basein district the proportion, which estimated consumption bears to outturn, is 1 to 32. With such estimates arrived at by tahsildars, the figures must certainly be untrustworthy."

The Deputy Commissioner of Amrdoti, commenting on the grave error which must arise from want of road trade returns, writes :—" The figures of yield and consumption given above are for Berar, but in addition cotton is poured into it on all sides from the Central Provinces an&the Nizam's Territory. In Amrdoti district alone the cotton markets of Amraoti, Dattapur, Karinja, and Murtizapur receive annually thousands of hundred-weights of cotton from the Nimar, Wardha, and Chanda districts of the Central Provinces, and from the Nizam's territories south of the Paingunga river, Rajur, Ealabad, Bela, and, perhaps, even more western taluks."

The exports from Berar, on the other hand, go principally to Bombay port for shipment, and are consequently nearly, if not quite entirely, represented in the rail-borne trade statistics.

With such an error in the available trade-returns of the province, it is obviously necessary to arrive at an estimate of the local consumption by some other means. This has been done in the recent note on cotton, supplied to the Government of India, from Berar, by accepting the estimates of tahsildars as approximately correct. These, though not as absolutely correct figures, may perhaps be accepted as fair approximations to the truth, and shew that the average in the year under consideration was 4ft per head, indicating a total consumption of 103,725 cwt. This large amount, however, leaves only 1,172,337 cwt. to meet the net export of 1,324,482 cwt. The road imports alluded to must, therefore, have been over 150,000 cwt.

It appears probable, however, that the above estimate of 4ft of cotton per head may be considerably in excess of the truth. The figure is certainly a very large one in comparison with that arrived at for other provinces, and is commented on, as follows, in the recent report above referred to : "The Deputy Commissioner of Ellichpur is of opinion that

CULTIVATION Then came the shortin •BERAR. Races.

(Watt & Murray.)

"Akote used to be famous for its jari. district: stapled houri which, being a heavy cropper, partially displaced the *jari*. In the last two or three years both have been replaced by a new variety called kateli, from a thorn on the seed*, which is much more profitable to sow than either of the others. This is probably a hybrid, and, if so, an attempt might be made to improve it still further, as the staple is not good. The cultivators have not the slightest idea where it came from." The remarks about a new variety threatening to displace the famous Jari cotton of Berar is of interest, and it is to be feared that this *kateli*, from the poorness of its staple, may be productive of much harm. Specimens have not been received and consequently the authors are unable to determine the botanical nature of this race. It seems possible, however, that it may be either a form of Vilayti-Khdndesh, which is known to be rapidly spreading 3n Berar, to the certain detriment of the once famous staple of that province, or the "Dhirwar" cotton referred to below. Dr. Hume, in his note on cotton (1885), describes three additional forms to *bani* and *jari*. The first of these is a *rabi* crop of *jari*, grown at the same time as wheat, and picked in March and April. It is sown on marshy and water-logged land, which, though quite uncultivable during the rains, retains water, and is thus available for cultivation in the cold weather. The soil is rich and deep, and supplies the cotton with water well into the hot weather. The crop, however, is not so heavy as that of kharif jari.

The second form is "Dhdrwar," an acclimatised American cotton. Dr. Hume describes it as follows: — The staple is rather shorter than that of the usual cotton. It is not grown as a separate crop, but plants of it appear at intervals in a cotton field. The natives call it 'gogli jaris' the *large jari* or large-seeded *jari*. As a market cotton it has no separate existence, owing to the small quantity of it grown and the admixture of it with other cotton during the picking of the crops. Since the merchants have made such a determined stand against the Khandesh cotton, this American cotton is becoming more extensively cultivated than it ever was before.'

The third breed is Vilayti-Khdndtsh, which, according to Dr. Hume, came to Berar, principally because the Collector of Khindesh forbade its cultivation in his own district. He adds:- '• The Khandesh variety is being grown largely to the ousting of the other varieties, and the most certain ruin of the Berar cotton trade. At present they obtain from Vilayti-Khdndesh* an early crop, also a large one, getting three or four pickings instead of two or three as they get from the indigenous cotton. They receive R3 or R4 a bale less in price than for the indigenous cotton, but the greater bulk compensates, and much more, for this small loss. Hut this apparent prosperity will be short-lived, for it is only by mixing this Vilayti-Khandesh cotton with the indigenous cottons that merchants get it accepted in Bombay, and mixing cannot be carried to a greater extent than a third of the quantity with bani and a much smaller proportion with jari. When this Khandesh cotton has succeeded in ousting the bani and jari, there seems every prospect of extensive distress and ruin. The Khdndesh variety is getting better than it was when first introduced, according to some people; but however good the Khandesh may become by hybridisation, it can never be as good as the old jari and bani; any hybrid of Khdndesh must be a deterioration on them."

" It is a coarse hardy plant, that will grow almost anywhere that cotton will grow, and produces a large crop; but the staple is short and Vilayati-Khandesh. Conf. with pp. 58, 75.

^{*} The seed of most forms of **G**, herbaceum proper is beaked Con/, with p. 27.

f It seems highly probable that Vilayti'Khdndesh or Varadi is a hybrid form, very probably derived from G. herbaceum var. microcarpum on G. neglectum! The authors, however, have not seen an authentic botanical specimen.

BERAR.

Races.

Cotton Cultivation in

CULTIVATION hard and is objected to as cotton in the home markets, and consequently in Bombay. It is a bad variety, and is doing a lot of injury, by its cultivation in Berar, to the Berar cotton reputation. The plant looks 'jungly;' the high split leaves show want of breeding and cultivation, which is borne out by the short-stapled fibre."

The following history of the attempts to extirpate the Velayti-Khdndesh in Berar is of interest, and may be quoted in entirety horn the Note on Cotton issued by the Revenue and Agricultural Department, Government of India :-

' This inferior cotton formed the subject of correspondence between the Resident, Hyderabad, and the Government of India in 1883-84. The Resident, Mr. J. Q. Cordery, reported in August 1883, that vigorous measures were adopted in 1875-76 for the extirpation of this variety (Vilayt*)* which possesses no staple but is a very prolific crop, costs less to pi aduce, and is clean and good to look at, an3 is, therefore, largely used for purposes of adulteration. It was added that the admixture had of late years been in some markets carried too far, and that it was apprehended that unless its growth could be discouraged, the reputation of Berar cotton would be much injured. The measures taken in 1875-76 were successful for the time, and proved, it was said, permanently successful in Khan-desh. The cultivators who possessed adulterated or inferior seed were induced to receive in exchange for it seed of the same indigenous variety. Advances were made in Berar for this purpose amounting to R 18,000. It does not appear that the agriculturists were compelled to accept the proposed exchange, but a special officer was deputed to the work and much attention and enquiry was needed for its successful execution. It was stated that the reason why the success was not permanent in Berar was probably the fact that, in January 1878, instructions were issued by the then Resident, Sir R. Meade, to Deputy Commissioners that no future attempts should be m.ideto control cotton cultivation, and hence A was supposed by the growers that (iovernment had become indifferent about the matter. The evil was said to have spread to the Amr&oti district. Mr. Cordery was inclined to return to the policy formerly adopted, and he, therefore, asked sanction for another advance (R 15,000) to purchase the seed required for the elimination of the vilayti seed from Berar."

To this application the Government of India replied in 1883 as follows :

" I am directed to acknowledge the receipt of your letter on the present prospects of cotton in Berar and the increasing extent to which an inferior staple known as vilayti, and originally introduced from Khandesh, is being grown by cultivators. You refer to the measures adopted in 1875-76 in Berar, and previously in Khandésh, for the extirpation of this variety of cotton by the distribution of superior seed, by money advances, and by executive orders. And you consider that, though these measures produced no permanent results in Berar, and were abandoned in 1878, yet the large interests at stake, and the success which attended similar measures in Khdndesh, justify further efforts in Berar You accordingly solicit[^] the sanction of the Government of India to the expenditure of Ri5,000 in'advances for seed, of which sum you are disposed to think that not more than one-half might be recovered by Government.

" In reply, I am directed to say that, after giving the subject of your letter its careful attention, the Government of India has come to the conclusion that any attempt on the part of the State to make the Berar cultivator grow one class of cotton when his immediate interests prompt him to grow another, is almost certain to end in failure. The measures taken in G. 122

Berar.

(Watt & Murray) GOSSYPIUM.

Khandesh have not been permanently successful any more than in Berar. CULTIVATION The steps taken by Mr. Ashburner in 1876 succeeded at the time, but as soon as the vigorous measures to which he had to resort ceased with his departure from the district, the cultivators of Khdndesh returned to the inferior variety of cotton. Writing in 1882, Mr. Propert, the Collector of Khandesh, was obliged to confess that all his endeavours during six years of office to discourage the cultivation of the inferior cotton had been practically fruitless.

Under these circumstances, the Government of India, before sanctioning any expenditure on the purchase and distribution of seed in the Berars, would like to be assured that there is some probability of the experiment being productive of more lasting results than have been achieved hitherto. If there is any difficulty in procuring good seed, the Government of India will not object to the institution of any agency for obtaining and distributing it. But the Government of India is unwilling, in the face of past experience, to countenance a system of advances year after year on the mere chance of the cultivators of Berar being thereby induced to abandon the cultivation of a description of cotton for which they have shown a decided preference. Indeed, it appears to the Government of India that it has yet to be shown that the cultivators are wrong and do not know their own interests best. The short-stapled cotton appears to possess certain advantages in regard to soil and climate over the long-stapled variety: it is said to require less rain, and the facts seem to indicate the possibility of greater economy and profit in growing it. These are points which appear to the Government of India to deserve investigation, and I am to suggest that they might profitably form the subject of a series of experimental trials (which should from year to year be carefully watched and the results recorded) in a limited area or in a small number of villages. Proof cannot but eventually be forthcoming as to which cotton returns most profit, and it is by the test of the profits to be derived, rather than by any action on the part of Government that the cultivator will be influenced m his selection of staples."

Mr. Cordery in October 1884 again wrote as follows:—

"1 have the honour to forward what appears to me to be a careful and able report from the Officiating Commissioner upon the manner in which the Province of Berar is affected by the large and increasing admixture of an inferior variety of seed with that which produces a longer staple of cotton.

" If, as Mr. Ridsdale asserts, the new crop has created a market of its own with a designation known in Liverpool and commanding a sufficient profit, there can be no need for any action whatever. The question has, of course, been represented in a very different light by other officers; but the conclusions drawn by the Officiating Commissioner would appear to be more in accordance with the probabilities deducible from the recent extension in the growth of this variety than those based on the statements of traders disappointed in not finding the better variety which they desire to purchase. In such cases the term adulteration is not truly applicable: there is no concealment on the part of the cultivator, and the buyer is not ^deceived. The substitution of an inferior staple for one which formerly ^deceived. "enjoyed a better reputation and a larger price must, under these circumstances, be held to be due to natural causes, against which it is useless to contest.

••The suggestions, therefore, made in my letter No. 368, dated 17th August 1883, were based on the mistaken belief that the complaint lay against an adulterated article being brought to a market, which (if this course were persisted in) would ultimately be closed to Berar. And on the fuller information before me, I have no desire to press them further.

In BERAR.

,

	Cotton Cultivation in
CULTIVATION BERAR. Races.	 The Government of India replied that it agreed with the Resident that a case had not been made out for State interference. "In the Land Revenue Administration Report on Berar during J386-87 it is mentioned that <i>vilayit</i> cotton is fast driving the old <i>bant</i> cotton out of the fields to the great grief of all cotton merchants who like <i>bum</i> because of its long staple, which fetches a higher price than the shorter staple produced by the hardler plant. The large introduction of the latter around Amrafoti is stated to have caused the present cotton known as <i>umras</i> to be looked on as very inferior to what it was a few years ago. It is asserted that the reasons for its superior popularity are, besides its extra productiveness, the fact that the plant is not so easily injured by either excessive wer or drought: it is an earlier crop, and does not come into bearing all at once. These facts have been proved from experiments carried out for some time now on the Amrafoti Experimental Farm. The Deputy Commissioner of Amrafoti considers it necessary to endeavour to substitute, if possible, a variety combining the hardihood of the <i>vilayti</i> with the long staple of the <i>bant</i>, and he suggested that Government should obtain the services of a scientific agriculturist to see if anything could be done towards this end. The Commissioner, in remarking that the suggestion was a good one, added that the value of the profuct was sufficient to warrant the expenditure of a large sum in making such experiments, and supported the proposal met with the approval of the Government of India, the advice of Mr. Ozanne, Director of the Agricultural Department, Bombay, was solicited, and seed was obtained from that department for issue to the <i>rayats</i> in 1888. ⁹ It is to be hoped that these efforts maybe productive of good in exterminating the inferior exotic breeds which, during the past few years, has been steadily obtaining a stronger hold on the agriculture of the prounce, air j at the same time ousti

GOSSYPIUM. Cotton Cultivation *lA* CULTIVATION The above remarks refer to the finer form of cotton known as bant. BERAR. Jari is cultivated, in much the same way, but is sown some fifteen days later, and takes longer in coming to maturity, so that the first picking seldom comes off before the 15th of December. Injuries. INJURIES.—Mr. Hobson writes to the following effect: «^c Cotton requires 127 rain shortly after sowing, otherwise it does not germinate; on the other hand, if there is too much rain, the plants rot. Should it rain during Swatt Nakshatra, i.e., the dark quarter of October or the beginning of November, it is generally supposed that the crops will be seriously injured. The natives have a proverb, «Pad6 swatr kapus na mile" wati/ which, freely translated, means, 'should it rain during swati, you will not be able even to get cotton for wicks." "The bolls are subject to attacks from insects (cotton-borers), and a promising crop early in the season thus not unfrequently ends in failure and disappointment. White-ants, too, sometimes attack the plants, but, as a rule, the cotton is a hardy plant, and, given a fair monsoon, there is little to fear.' CLEANING.—The instrument employed in cleaning and separating the Cleaning. fibre from the seed is called *retsa*. It is similar to the *charka* elsewhere 128 described (p. 115), consisting of two horizontal rollers, one of which is sometimes iron, but usually both are of wood. Generally, this is of such a size that it can be worked by one woman, but a larger kind is occasionally to be seen which requires a woman at each end to work it. After being cleaned the cotton is scutched. This process is somewhat peculiar, and is described as follows by Mr. Hobson :---" The scutch, called *Kamdn*, is a wooden instrument about 3[^] feet in length, embellished at each end with traditional signs and carvings. To the kamdn is attached a bow-string made of sheep-gut, termed *tdt*. Scutching is termed dhunkna, the person who works the instrument, pinjdri. Having fixed one end of the kamdn to a beam with a string called dhani, he seats himself with the loose cotton in front of him and the *tdt* resting on it. He then passes his left arm through a roll of cloth called hdthd, which goes over his elbow and gives him a purchase. With the left hand he holds a piece of stick called *dhunduri*, which is tied to the *kamdn* to steady the whole instrument; with his right hand he takes a kind of elongated dumb-bell called *dastara*, the end of which he catches in the bow-string, and constantly twangs the latter. This causes the *tdt* to strike the cotton at each twang, thus separating the fibres. The floss, by this process, becomes loose enough to be subsequently twisted by women round pieces of wood, forming spools called These are afterwards worked into spinning thread." nelu. YIELD PER ACRE.—" AS already stated, the average yield per acre for Yield. 129 the year under consideration, as derived by dividing the total outturn by the total acreage, was 71*688)." The following figures, however, subject to the errors indicated at pp. 53—54 & 87, are given as the actual outturn in each district:-OUTTURN PER ACRE OF CLEANED COTTON

{Watt & Murray.) GOSSYPIUM, The outturn per acre shews a very large increase over that of the CULTIVATION In BERAR. previous year, perhaps due, in part, to the increased cultivation of inferior but more productive races *{cff.* p. 92). COST AND PROFIT OF CULTIVATION.—Mr. **Hobson** writes, "Preparing, sowing, and weeding cost on an average R7 an acre, but much depends, of course, on the district, and whether sufficient hands are Cost of, 130 obtainable when wanted. Some small farmers sow a much larger surface than they can afford to use and clean properly; the crops naturally are poor, and the owner becomes disgusted and consequently careless of

saving even a portion of his crop. Such men are said 'to try a large mouthful, having only a small mouth,' "Picking and Weeding are heavy expenses; the cotton-pickers are not paid in cash but in kind; the rates vary according to the market, the average may be said to be one-tenth of the first picking, one-sixth of the second, and one-third for the third, equal to from R3 to R4 an acre. Separating the fibre from the seed by passing it through the *retsa* is paid for, sometimes in kind, to the value of annas 5 to 7 per maund (28IB) of seed cleaned, which equals R2 to R3 an acre. The total cost may be taken at R13 to R15 an acre, depending greatly on the district, leaving the cultivator a fair margin of profit. This, of course, again depends on the demand.

"Kapds when cleaned gives 26 per cent, of cleaned cotton. Besides the cotton, the cultivator has the cotton-seed, sarki, to feed his bullocks upon, and cotton stalks, which are used for numerous purposes, such as roofing grain stores, &c, but cotton is not the crop the ray at now pins his faith on; it is being driven out of the field by the more profitable cereals.'

PRESSING AND PACKING.—In 1866 there was not a single cotton press at work in Berar, at the present time there are said to be 31 such presses. (Indian Cotton Statistics.) The following description of these presses and their effect on the cotton trade of the province may be quoted from Ahe Berar Gazetteer:-

But it was the introduction of pressing that promoted as much as, or more than, any other reform the safe and expeditious consignment of our inland cotton to the seaport. In 1866 there was not a single cottonpress at work in Berar, though it seems that as early as 1836 Messrs. Kikaji and Pestanji, merchants of Bombay and Hyderabad, had set up one screw at Khamgaon. During the year 1867, thirty-two half-presses and two full-presses were set up, and the subjoined statement details subsequent progress:-

		 	TEARS				Full-Presses.	Half-Presses.
> ⁸⁶⁸	•	•		-		•	14	81 125
≪869 ''870 = >					:	:	19 19	125 74

* During the season of 1869-70 the number of half-presses has very sensibly diminished, because the railway rates of carriage have been raised on half-pressed bales to an amount that renders full-pressing very much more advantageous. The effect of this change has been to throw most of t the cotton into the hands of the merchants who buy for direct export to England, since the Bombay market does not like to invest in bales that cannot be opened out for examination of the cotton. Therefore most of

	3i'cwt., or equal to 104,723 Bombay kandis.
Berar Trade. 132	" In the market of Berar all the cotton is sold, between producer and dealer, by the <i>boja</i> of 280ft, or 266ft nett; about three of them go to the Bombay kandi. The word means generally a load, and in the Berar cotton trade it meant particularly the load of a pack-bullock. "In the half-pressed bale the cotton is condensed to about 12ft the cubic foot, and in the full-pressed bale contains generally 3J cwt., but Kham-gaon presses now usually succeed in getting 3 cwt. within the bale. The half-pressed bale sometimes contains as much as 5 cwt., but then it is nearly three times the bulk of the full-pressed. In these inland districts the dry weather makes cotton so elastic that the best presses find much difficulty in obtaining the density of a bale pressed on the sea-board. " The full-pressed bale and half-pressed bale are equal to about half a Bombay kandi, and the <i>dokra</i> to one-third of a bale." The advantages of full-pressed for shipment at the seaboard. ANALYSIS OF LAST YEAR'S TRADE.—The imports into Berar by rail during the year under consideration, 1888-89, amounted to 8,704 cwt., the exports to 1,333,186 cwt. Of the imports nearly the whole were derived from the Central Provinces ; but Bombay, the North-West Provinces and Oudh, Irtajputana and Central India, and Bombay port contributed small amounts. As already remarked these rail-borne imports represent but a very small fraction of the total, thousands of cwt. being received by road at the great markets of the province from the Central Provinces and the Nizam's territories. Regarding the latter Mr. Hobson wrote in 1887 '• "** former years large quantities of cotton used to come across from that part of His Highness' Dominions, and doubtless the cotton export may return to its former average." Of the total rail-borne exports, 1,290,807 cwt. went to Bombay for shipment, leaving only 42,379 cwt., of which nearly all was exported to the North-West Provinces and Oudh. Very small quantities were received by the Central Provinces and Oudh. Very small quantitie

CULTIVATION RAJPUTANA. The average area under the crop during the two years 1885-86 and 1886-87, was returned as 886,419 acres, and the average outturn as 877,607 cwt. These figures show an average yield per acre of nolb. Later figures are not available for Central India, but in Rajputana alone the area in 1888-80 is returned as $45S^{25}$ acres, the outturn es 493,206 cwt. The acreage during that year was less than the average, because the rains were late and less was sown. The yield was also much under the The net exports from Rajputana and Central India in 1888-89 average. amounted to 596,631 cwt., leaving (on the assumption that the crop for that year equalled the average given above) 280,976 cwt. for local consumption, or dividing this sum by the population, *v6fb* per head. This closely corresponds to the estimate of 255,000 cwt., given in the "Statistical Tables." The average outturn in Dholpur is stated by the Gazetteer to Se64ofli of uncleaned cotton per acre.

RACES OP COTTON.—All the cottons exported from Rajputana and Central India are included commercially in the group of "Bengals," and are probably nearly all forms of G. herbaceum as that species has been described in the *Flora of British*. India. Numerous references are to be found in the publications of the Agri.-Horticultural Society of India, to a particularly fine cotton called barareea, cultivated near Chanderi and employed in manufacturing the fine cloth called *mahmudL* Major Sleeman describes this fibre ^is coming from Indore to Chanderi, and also as being produced in a few fields in the villages of Herawal and Singwara in the district. He states that" if the seeds of the barareea cotlon be sown in any other fields of that district, the cotton produced is found to be like the produce of the ordinary seed, and to lose all the peculiar qualities of the barareea cotton." In a more recent communication by Mr. Hamilton Bell it is stated, that the imported *barareea* floss is superior to that locally produced. In another article on the subject Mr. Fraser states, that the greater part of Chander Races, **I36**

Cotton Cultivation in

CULTIVATION in RAJPUTANA,	cotton is imported from Berar, and in yet another Dr. Irvine writes that a considerable portion is derived from the Saugor district.
Races.	These statements appear to be supported by the name of the cotton— barareea, and point to the fact that the floss in question was probably the produce of a fine quality of bant, i.e., G. Wightianum, Tod.
1	Several writers allude to what appears to be still another kind of cotton* and very probably G. neglectum, <i>Tod.</i> , as cultivated in Malwa.
Soils.	SOILS AND METHOD OF CULTIVATION.—The soil of Southern Jaipur,
137	Tonk, and Ulwar is fertile though light; that of the extensive plains of the Meywar plateau is fertile when irrigated. In the latter region almost every village has its artificial lake or tank. Behind the retaining embankments, or in the beds, also wherever there are wells, large crops of cotton, wheat, opium, and sugarcane, are raised.
	Localities which are free from inundation are usually selected. The seed is sown in the months of April and June; the first sowings are watered by wells and yield a spare crop; the later depend on rain. Picking com- mences in October and is completed by the end of the year. The seed is sown broadcast, the land is immediately afterwards lightly ploughed, and
	when the crop has reached some height the plough is again drawn in parallel lines. Land thus prepared is said to require little weeding, for the plough furrows deep and removes roots of grass, &c. Weeding which may be required is done by hand, and is again turned up by hand with the trowel or <i>koddli</i> .
	Maize and cotton are the only <i>khan</i> / crops which are manured. About eight cart-loads of manure are applied to the <i>bigha</i> . Night-soil, cow, goat, and sheep dung, ashes, and all sorts of refuse are heaped together near villages, and afterwards utilised as manure. The best kind is the dung of goats and sheep. Fuel being so dear in Rajput- 'ana, cow-dung is only utilised in the rainy season when it cannot be made irtio cakes.
	No definite information is available regarding rotation or associated crops in Rajputana and Central India as a whole. In Dholpur the crop is said to be generally mixed with <i>urid</i> , <i>til</i> , <i>arhdr</i> , and <i>san</i> .
	The following account of the method of cultivating the fine Chanderi cotton may be quoted from Dr. Irvine's article on the subject [Trans. Agri.m Hort, Soc. Ind., VIII., 64). "Chanderi cotton is sown, as usual elsewhere, in June. After the first fall of rain the ground is ploughed, another shower is allowed to fall, when the ground is manured and worked in with the harrow, then again ploughed, after which the seed is sown broadcast and the ground again harrowed, which is nearly the course of the usual cultivation. The seed is then left to spring up under the influence of the rains, when at a moderate height the young plants are carefully hoed, and during the growth the hoeing is sometimes repeated until the matured plant is just about to flower.
	"Should a cessation of the rains occur, then an artificial irrigation is twice or thrice resorted to in September and October. Each <i>bigha</i> requires four people to hoe and do other requisite labour. The result on the same land is by no means equal—some <i>khêts</i> are five times gathered and some seven times. The cotton fit for <i>mahmtidi</i> is never collected oftener than three times, the remainder is common."
Cleaning. 138	CLEANING.—The ordinary <i>Bengals</i> cotton of Rajputana and Central India is cleaned by means of the native gin or <i>charka</i> . Chanderi cotton, however, when destined for the manufacture of the fine muslins of that district is said to be entirely cleaned by hand-picking,

ANALYSIS OF LAST YEAR'S TRADE.—The exports from Rajputana and Central India are increasing yearly; in 1885-86 they were only 399,285 cwt., while in 1888-89 they amounted to 600,411 cwt. The greater part is received by Bombay port, which derives much the largest proportion of its "Bengals" from Rajputana and Central India. The imports from these States into Bombay by rail during the five years ending 1886-87 averaged 387,000 cwt.; in the year under consideration they amounted to 497,311 cwt. Of the remaining exports, 23,136 cwt. went to Calcutta, 38,201 cwt. to the North-West Provinces and Oudh, 38,824 cwt. to Bombay Presidency, and small quantities to the Central Provinces, the Pan jib, Berar, and Bengal. As already stated, the road trade with neighbouring states and provinces is large.

The imports are unimportant. In i888-8g they amounted to only 3,780 cwt., of which 129 cwt. was derived from Bombay Town, 2 cwt from Calcutta, 2,328 cwt. from the North-West Provinces and Oudh, 955 cwt. from the Central Provinces, 133 cwt. from the Panjib, and 122 cwt. from Bombay.

Cotton Cultivation in

CULTIVATION MADRAS. Area.	were grown in Government villages, 419*249 acres in Inam villages, and 755924 in zemindari villages. The area returned for the first may be accepted as fairly accurate, but the figures for the two last, more especially those for the zemindaris, are less reliable. The cultivation of cotton is steadily increasing in the presidency, the total area, for the year under consideration exceeding the average of the three years preceding it by 90,000 acres. The total outturn in 1888-89 is calculated to have been 801,120 cwt. The net export deducted from this amount leaves 309,343 cwt as available for local consumption, a sum which, when divided by the population, gives an average of only i21b per head. The Madras Board of Revenue, in a recent report to the Government of India, make the following statement:—* On the question of the amount of clothing required to supply the wants of the population, the Board has made careful enquiries, and finds, that as a rule, the people in the Telegu districts use more than those in the Tamil districts, and that, while the lower classes in all districts get on with very little clothing required for a whole year. For juvenles, male and female, excluding children under five years who practically go without any kind of clothing required for a whole year. For juvenles, male and female, excluding children under five years who practically go without any kind of clothing the net imports of piece goods and wrist from this amount, the total amount of raw cotton used in spinning locally is arrived at , and in the year under consideration, is found to have been 28,7 is 370 ke or 257,780 cwt. As already stated, 309,343 cwt. is found, from calculation based on the outturn, to have been left in the presidency as available for local consumption, so 257,780 cwt. As plears to be well within the mark. The 50,000 cwt. of excess is probably partly exported to Madras seaports by road (not included in the trade returns), partly consumed locally for purposes of upholstery, padding, &c. Of the 257,780 cwt. loc

(Watt & Murrav.) GOSSYPIUM. Madras.

RACES OF COTTON IN MADRAS.-AS already stated in describing the CULTIVATION commercial "growths" of cotton, there are four kinds grown in Madras, IN MADRAS. vis., Tinnevelly, Westerns, Coconadas, and Salems. Of these, "Tinnevelly" is produced in the Tinnevelly district and the southern portion of Madura; "Salem " in Salem and the Coimbatore districts; "Westerns" in Bellary, Anantapur, portions of Kurnúl and Cuddapah, and in the Nizam's Dominions near Raichore and Lingasagor; and "Coconadas" Races. 144 in the Kistna district. According to a note by the Madras Chamber of Commerce, dated September 1889, "Tinnevelly" is the most valuable of these. It has a strong, though not particularly long staple, and a very pure white colour. It is, accordingly, in considerable demand among spinners at home for mixing with Americans, and is one of the few Indian cottons suitable for this* purpose. "Salem" is inferior, and is considerably used in adulter-ating the more valuable "Tinnevelly." "Westerns" have been subdivided into "Westerns" and "Northerns," the latter being the chief cotton of Cuddapah and Kurnul. The principal markets for "Northerns" are Tadputri, Prudatur, Jangalpille, and Koilkuntla; for "Westerns' Bellary, Adoni, and Raichore. The staple of Westerns is rough, but fairly long and strong and of a good white, but, owing to imperfections in cleaning, always contains a considerable proportion of broken leaf. "North-erns" much resembles "Westerns" in length and strength of staple, but is silkier, and were it not for the slightly reddish tinge which it commonly possesses, would be in greater demand. The staple of "Coconadas" is fairly long, strong, and silky, but, owing to its redness, this cotton, also, is used by comparatively few spinners. It is, however, employed in the manufacture of lace, and is said to take dyes more readily than other growths. In the Provincial cotton report for 1882-83, the races found in Madras ^w There are two forms of indigenous cotton usually grown in this presidency—the one depending on the south-west monsoon, and the other on the north-east. The former is sown between May and July, and the latter between September and November. In Tinnevelly, however, both species are sown in the same season, *i.e.*, October to November. They are known in the Telugu districts as the white and the red species, and in the Tamil districts as uppam or ukkam and ladam or nadam. In the Ganjam and Vizagapatam districts, they are also known as the punasa prath (frattt means cotton) and paira or burada prattu The latter is grown on irrigated lands in the Ganjam district. In all other districts, the crop is grown

on dry or unirrigated lands and is often sown with dry grains. The white or the uppam kind (short staple) is sown in black cotton soil, and its fibre is considered superior to that of the yerra or red cotton. The plant lasts from six to twelve months. The ladam species is grown generally on red or gravelly soils and lasts from three to four or five years in the Tinnevelly, Coimbatore, and Salem districts. The Collector of Tinnevelly reports that this crop yields about 62Jib of uncleaned cotton per acre in the first year the tenth month after sowing, and about 125ft per acre in each of the second and third years from the ninth month after the picking of the previous crop. The fibre is said to be thin and fine, and to be used in the manufacture of superior cloths. The plants grow to a height of from five to six feet, and in Salem yied two harvests in the second year—one in September, the other in Januay. In the third year, the plants are lopped at a height of one foot from the ground, and then only one crop is obtained."

CULTIVATION in MADRAS.

Races.

Races of Cotton in

Royle describes the *uppam* race as a superior form of G. herbaceum, with a staple which more nearly resembles that of American Upland than does any other indigenous cotton. *Nadam*, on the other hand, he describes as a triennial plant yielding a much inferior staple, which is also more difficult to clean. The same writer states that plate 11 in Wight's *hones* is an accurate representation of *uppam*. The plate in question, according to Todaro, is typical of his species G. neglectum.

Specimens of *uppam*, however, which the authors have had the pleasure of receiving from Madras, appear to be typical of G. Wightianum, *Tod.*, a species figured in Wight's *Icones*, *t*. p.

In the absence of a complete set of specimens of the commercial forms of Madas cotton it is extremely difficult to determine the botanical nature of each, but, from information available, it would appear that the better/;lass, •' Tinnevellies " and " Westerns," are produced for the most part by uppam, that" Salems "are derived from a degenerated form of G. barbadense (see p. ig), and that the other inferior cottons of the presidency may be nadam. It appears impossible to correctly determine the latter. In the above description everything points to the plant being G. neglectum, Tod., but on the other hand specimens seen by the authors, bearing the vernacular name of *nadam*, are typical G. herbaceum, *var*. obtusifolium. Specimens of nearly typical G. herbaceum, and of G. arboreum, have also been obtained from different parts of the Madras Presidency, but whether they are regularly cultivated, or would be included under the general term of nadam, the authors cannot say. Between G. herbaceum, G. Wightianum, and G. neglectum every intermediate condition seems to exist. Variations from G. Wightianum towards G. neglectum are much inferior to those towards the G. herbaceum series. Of the former may be mentioned a form known as karumkanni, of the latter that known as villaikanni.

The differences in value and quality of the several commercial forms may, after all, depend, as much on local variations of soil, climate, methods of cultivation, and processes adopted in cleaning, as on any racial distinction.

Besides these Indian races, small quantities of various exotic cottons are grown in certain localities, the results of numerous experiments which have been carried on in Madras for many years. Of these, the only one of commercial importance is "Bourbon cotton" (G. barbadense), which at one time produced the commercial "growth" known as "Salems," and which is still grown to a considerable extent, though in a miserably deteriorated condition, in Coimbatore. The Collector of that district furnished an interesting report on the origin and progress of this exotic, from which the following is extracted :—

"The *Shem parutti* (? *Seemai paruthi*) is that known as Bourbon, and will last as long as five or six years; it grows only on red or gravel soils, especially the calcareous and quartzose; hence* *one* reason why it is extensively grown in Erode Taluk, in which there is not an acre of black cotton soil.

"Bourbon is found in Erode and Dhárá'puram Taluks, especially in the Perundurai and Kángyam Firkas. The following explanation has been given me of its spread in those taluks : about 1820, Mr. Heath bought the cotton godowns in this part from the East India Company and introduced the Bourbon cotton ; he was succeeded by Mr. G. D. Fischer in 1824, and this firm, trading largely in Bourbon cotton, induced extensive cultivation. Gradually the firm's dealings fell off, and consequently, for reasons to be noted, the cultivation of Bourbon declined. The firm's godowns were chiefly at Erode, near Perundurai, Chennimalai, and in the Kangyam Firka. The whole course of the cultivation and trade is a striking com.

G. 144

Madras.

G. 144

{Watt & Murray.) GOSSYPIUM.

ment on the importance of private enterprise and British capital in developing the country and improving cultivation."

In a subsequent report the Collector of Coimbatorfi wrote :---

"Messrs. Stanes & Co. also inform me that Bourbon, though of excellent quality and much in demand if properly cultivated, is now, as grown in Coimbatore, of miserable quality and hardly worth buying. The reason is to be found in the wretched cultivation, the lack of manure, the continual cropping of the same ground, the complete removal of the plant, stem, lint, and seed from the ground, and the deterioration of seed from want of renewal. It is understood that Messrs. Fischer & Co. used to obtain and distribute fresh seed, and the rayats, as regards their indigenous cotton, expresslj state that seed costs more than the market price because they have to choose only good seed. Apparently the exotic cotton deteriorates unless *fre\$i* seed is supplied; whether this should be the care of the Agricultural Department of be left to the enterprise of merchants is a question. But there can be no doubt that all cotton outturn in Coimbatore has much deteriorated, and that the quantity and quality of the lint and seed are poor.

" It may also be noted that the cotton going south is intimately mixed with Tinnevelly cotton and exported as such, and that the admixture has been detected by the home brokers. It is a pity that such risks should be run by the trade when every effort ought to be made to improve the name of Indian cotton."

The above report elicited the following remarks from the local Board of Revenue :---

"The Board regret to learn that the quality of the Bourbon cotton is declining in the Coimbatore district. From Mr. Nicholson's report its diminished quantity and deteriorated quality are plainly due to exhaustion of the soil resulting from the continued cropping of unmanured land. The superiority of Bourbon cotton to the indigenous variety has been clearly demonstrated to the rayats of Coimbatore, and no expenditure by Government on the importation and distribution of fresh seed would have ^any permanent effect_nor indeed be justifiable, so long as the rayats pursue their present exhlusting methods of cultivation."

It may be of interest to note that records exist of Bourbon cotton in Coimbatore as early as 1804. In the Selections from the Records of the East India Company, dated 1812, a report occurs by the Collector of Coimbatore in which it is stated that there were three forms of cotton at that time in the district, known, as they are now, as *nadam, coputn* (*? ooputk*), and *shem parutti*. The first two are evidently identical with those bearing the same vernacular names. The last, described as a "large plant cultivated in gardens, and used only for spinning Brahminical threads," would appear to have been a form of G. arboreum. The application of the name at one time used for G. arboreum, to the exotic American plant of the present day, is interesting. The Collector then goes on to state that Bourbon cotton had been introduced eight years before, but he appears to have been very sceptical as to any good results ensuing.

^ The above-quoted remarks of the Board of Revenue completely sum up the history of many years of earnest endeavour on the part of Government and also of private enterprise. Good seed has been procured, has been found with careful cultivation to do well, and has been distributed, time after time, to the rayats. As far as can be gathered from available literature, the only result has been that the stock thus introduced has either completely died out in a few years, or, as in the case of Bourbon cotton in Coimbatore, has given rise to a race of cotton much inferior to that natural to the country. So inferior is the produce obtained, that, instead of fetch103

in MADRAS.	using it to adulterate Tinnevelly cotton.
MADRAS. Races.	The following remarks on the subject of the introduction of new cottons by the Madras Chamber of Commerce are of interest:—" The Chamber is led to suppose that most varieties of seed have been tried from time to time in nearly all districts, and that the variety at present grown is the one that has been adopted owing to its ascertained suitability to the climate and soil of the particular districts. In the sowing time of 1886-87, a systema- tic attempt was made to introduce Broach cotton into the Bellary district; but the plants mostly withered before maturity, and generally the rayats sustained loss over it. Any attempt at the introduction of new seed on a large scale should be deprecated unless the seed has first been experiment- ed with in the same climate and soil for more than one season. Failure generally results, and, even when the plants thrive, the introduction of a new variety is not always satisfactory, as it is some time before the proper market value can be determined by buyers and sellers, 'ind the new variety is often so mixed with the old, that buyers will not pay the same price for the mix- ture as they would for the cottons were they sown separately. The fact of there being in one district two classes of cotton, one of which may com- mand a better price than the other, leads to the extensive adulteration of the better quality by admixture of the inferior." Notwithstanding these facts, numerous experiments were again made at the Saidapet farm, for some years preceding 1886, with all sorts of exotic seed. These once more abundantly proved that with due care and a judicious use of manure, it was possible to grow cotton of a finer quality than the produce of the indigenous races. But there appears to be little reason for believing that, if the Yea valley, New Orleans, or Egyptian cotton, which were all cultivated with great success on the farm, were distributed amongst
Soils. 145	 the rayats, the result would be in the least more satisfactory than that obtained from the Bourbon in Coimbatore. o. METHOD OF CULTIVATION; SOILS, AND MANURES.—Dr. Shortt writes as follows in his •• Essay on Cotton":— "In the culture practised by the native planter, the soil selected is black, soft, porous, and composed of decomposed basalt. It is well known as the <i>regur</i> or 'black cotton soil.' Manure is seldom used, but in some districts the usual dung-heaps or wood-ashes are lightly scattered over the ground, and should cattle not be allowed to enter the fields, the leaves and write of the armitication of the provide the provid
Irrigation.	and twigs of the previous year-are frequently permitted to remain on the ground." IRRIGATION.—As a general rule, cotton fields are not irrigated,—the rayat has, therefore, to depend for the successful growth of his crops, on
Sowing. 147	the periodical rains. SOWING.—The seed of his own growth or of the same district is sown over and over again, each successive year, and this appears to have con- tinued for centuries. It is prepared for sowing by being steeped in a solution of cow-dung and dried in the sun to prevent sticking together, mixed with dry grain or pulse and sown broadcast; in some districts the seed is sown in parallel lines, alternately with pulse, by means of a drill.
	Sowing takes place in some districts as early as June, but seldom later than September, depending, to a great extent, on the particular seasons. The seedlings appear between the third and seventh day. When they are f ^t J ^{eeweeks 00} ** plantation is hand-weeded, which process is re- peated some two or three times during the growth of the plant. Madras.

(Watt & Murray.) GOSSYPIUM.

CULTIVATION fruit at about the sixth month of its growth, but in some rare instances, this MADRAS. does not take place until the eighth month. In the *Coimbatore District Manual* it is stated that *uppam* is Sown in Sowing. October-November, and yields its harvest in March-April. Occasionally, if there is good rain in April, it is interploughed and a small crop taken again in July. It is usually sown with Bengal gram in lines, or mixed with thenei and coriander, and the whole sown broadcast together. The nadam is sown either in July-August mixed with kambu and pulses, or in April-May with cholam and castor, or ginjelly and dhal; sometimes with gram in September. In any case the cereal or pulse crop is reaped in the usual way, and the young cotton plants which have grown up under their shelter are left. In the first and third cases, the first cotton cro[^] is picked in the following¹ July. In the second a crop is got in February, and then not again till the following February. Thenceforward the crops per year are obtained. The crop in the third year yields a small outturn, and is interploughed as often as possible, gram, kambu, and sdmei being sown. In a memorandum furnished by the Revenue Dep?rtment, Madura district, it is stated that, "sowing begins in October and ends in December. Picking is carried on twice in the year from March to April, and from June to July. The land is prepared by ploughing it into time after a shower, and is ploughed over after sowing. The seeds each time after a shower, and is ploughed over after sowing. The seeds to July. The land is prepared by ploughing it five times before sowing, are sown in kerisal, black cotton soil, red soil, and portal. should be manured well, ploughed thrice at least, and the seeds then sown. After the plants have grown to the height of nearly a span, weeding is performed thrice. Ten measures of the seed will sow an acre.' The naturally rude and careless manner in which the native is known to conduct all his agricultural operations is pre-eminently shown in the cultivation of cotton, a circumstance which at once accounts for its usual deficiency in quality. It is surprising to witness, even under these disadvantages, what a large amount is turned out in a tolerably fair season. PICKING.—Dr. Short continues, " The pods, as a rule, are not collected Picking. as they ripen, but are allowed to remain until the whole crop of the field is I48 $f^{a(ty)}$ indeed, so little importance is attached to the speedy collection of the harvest, that even then the rayat consults his own convenience rather than the importance of his duty. In many instances he is either unable to procure labour, or has not the means of doing so; often he is not permitted to gather his produce in small quantities as the fruit ripens, but has to await the pleasure of the merchant from whom he has received an advance. Fre* quently, also, the crop has to be assessed before he is permitted to gather it, during which delay, in most instances two-thirds of the produce fall to the ground where it becomes mixed with dust. Should it happen to rain during this interval, 50 per cent, of the produce is irretrievably lost. In some districts the rayat gathers the early pods, so as to be enabled to come early into market. It is then cleanly gathered. But when the cotton season has fully set in, the price fluctuates, and the rayat being in no hurry to enter the market, thinks the produce may just as well lie in the field •£« in his house. "When the cotton at last is gathered, no care is evinced in removing the dried leaves and other extraneous substances found attached to it. It is generally taken off with all these impurities still clinging to it, thrown into some receptacle, generally a large open bamboo basket, and carried to the stack yard, where it is heaped up amidst the dust which necessarily abounds there. I have often witnessed heaps of cotton, both cleaned and uncleaned, thus lying exposed to wind and weather.

CLEANING AND GINNING.—The produce thus collected is next freed from

105

G. 149

Ginning.

GOSSYPIUM.

Cleaning of Madras Cotton.

CULTIVATION seed. This operation is, as in most other localities, conducted by means of an in MADRAS. Indian *churka*. The cotton, as brought in from the field, is freed, to a certain extent, of its capsules, stalks, leaves, &c, and then submitted Ginning. to the churka. In most districts the cotton is previously spread out on a common charpoy or country cot and beaten with switches, when a portion of the minute particles of earthy or other extraneous matter still adhering falls through; but from the slovenly mode of gathering the cotton, no effort, however persevering, can afterwards entirely free it from its impurities. This seating or thrashing is more intended to loosen the wool from the seed (to which it adheres somewhat tenaciously), in order to facilitate the operation of ginning, rather than to clean the cotton. The operation of ginning is generally performed by females, who hold the seed in the left hand to feed the cylinders, and with the right simultaneously turn the churka. A woman, by manual labour alone, car? clean only about four pounds of cotton, whereas with the churka, she can free from about twenty-five to thirty pounds in a day of ten hours. The Madras Chamber of Commerce, in their report referred to above, state that much of the Westerns cotton of commerce is deficient in cleanliness, owing to the common practice of cleaning the fibre by rolling it on stones with iron rods. This is called "stone cotton" in contradistinction to *churka-desLned* or "jowari cotton." The remark is made that a large proportion of the Westerns crop, owing to this system of cleaning, contains too much seed, and is, accordingly, not readily marketable. It appears to be highly desirable that this laborious and ineffectual process of stone-cleaning should be replaced at least by the *churka*. PACK ING.—Dr. Shortt gives the following description of the opera-Packing, tion of packing :- To a strong, perpendicular, wooden post, a cross piece 150 like the balance of a scale is suspended, the post being partly buried in the ground. To the cross piece, a bag of *cumhly* or gunny is attached, intended as a covering to the bale. From five to six maunds of cotton are now thrown in and compressed by men who jump into the gunny and stamp down the cotton with their dirty feet. From six to ten men are sometimes thus employed, whilst others are engaged in bringing the sides of the covering together, and securing them by sewing. In some places the gunny bags are hung by three ropes from the roof of the house; a fourth also, attached to the roof, hangs free in the centre, to which the men stamping the cotton hold on. These bales vary in size and shape, according to the mode by whch they are to be conveyed to the nearest market for export, and which may be either pack bullocks or carts. From the time of picking to that of export, cotton is liable to adulteration on the part of every one of the many through whose hands it passes. DISEASES — The cotton crop in Madras appears, from Dr. Shortfs ex-Diseases, haustive essay, to be remarkably liable to the attacks of numerous insects, **I5I** especially aphides and larvae of moths, and to one or more fungous parasites. Space cannot be allowed for a full description of these in such an article as the present. To prevent the ravages of insects Dr. Shortt re-commends smoking the plants with tobacco, sulphur, or damp straw, or

> and may have to be got rid of by trapping, poisoning, fcc. In the Coimbatore District Manual, the diseases which attack cotton are said to be known locally as sunndmbu, pen (asugani or poriyan), *inversion* to be known locally as summand, per (asignit of portyan), *inversion* and *adakkei*. The first-named is distinguished by brownish- M^{1} ? $f \land f^{Old spois on the leaves and bolls, and greatly diminishes the$ $5.fmT. Cost and Profit of Cultivation. (Watt & Murray.) GOSSYPIUM.

CULTIVATION murulei by sickly drooping, "roughness of the leaves and brownish-yellow in MADRAS. spots." From the description they would seem to be due to fungoid pests, possibly resembling the cotton-rust and cotton-blight (Cercospora gossypina) of America. The fourth is said to be due to excessive rain, the plant runs to wood, and numerous hard bolls are formed, but no fibre. SEASONS OF SOWING AND REAPING.-The subjoined particulars as to Seasons* the time cotton is sown and harvested in the chief producing districts has been taken from a report furnished by the Government of Madras in 1878 in reply to the enquiries made by the "Famine Commission : —

Districts.	Sown.	Reaped.	
Bellary	3rd July to 23rd September.	9th March to 19th June.	
Kistn£	August to October.	January to April.	
Kurnúl	August.	March.	
Anantapiir	July to September.	March to June	
Cuddapah	July.	3rd, 5th, and 7 th months	
Coimbatore	15th July to 14th September.	after sowing.	
Madura	October or November.	14th June to 14th August.	
Tinnevelly	September to January.	January to April.	

Judging from the above table sowings take place from July to Jan-uary, and the crop is harvested from January to August. In the Provincial cotton report for 1882-83, however, it is stated that uppam is sown between May and July, nadam between September and November, the former depending on the south-west monsoon, the latter on the north-east. On the other hand, the Collector of Coimbatore reports that in his district uppam is sown in October-November, and reaped in April-May. From these conflicting statements it would appear that both varieties may be sown either during the north-east or the south-west monsoon.

COST AND PROFIT OF CULTIVATION.—The annexed statement shows t}ie cost of cultivation per acre as given by Collectors in 1882-83 and the value of the average outturn of cleaned cotton at annas 3-6 per ft :-

GOSSYP1UM	[.	Trad	e in •			
CULTIVATION In MADRAS, Cost,	The Government of Madras commented on the above table as follows:— "Analysing the details of the items given in the district reports, it observed that the value of seed varies from 2 to 3 annas in Kurnúl, Belary, Anantapur, and Kistna, to more than double that rate in Cuddapa South Arcot, Tanjore, Trichinopoly, Coimbatore, and Salem. The cost of ploughing is given at more than R3 per acre in South Arcot, as again					
Madras Trade. 154	 bioughing is given at more than KS per acte in South Arcot, as again less than half the amount in several of the other districts. There a similar disparities in the other items also. The total average cost for Ganjam district is more than double that given in Fasli 1291 (1881-8 The explanation furnished by the Collector is that many of the items not involve actual outlay. In Mr. Nicholson's report the cost of cultition in black cotton soils is worked out at R7 per acre, which is probal nearer the truth." <i>[Paragraph 8, Cotton Report, ISO^-SJ)</i>. If it be assumed that the average outturn be proportionately equal value to the exports from the presidency by rail, the average value per a in the year under consideration may be arrived at as follows. The average exports by rail were 433,925 cwt., value R 1,06,31,102, therefore the va of 1 cwt. was approximately R22. The value of the average outturn (50 was therefore Rg-i3» an amount which, assuming the above cost of R7 pace, would leave R2-13 to cover the cost of cleaning, packing, and to g a small profit. ANALYSIS OF THE TRADE.—The great proportion of the cotton product in the Ceded "Districts (Bellary, Anantapur, Cuddapah) and Kurr is sent to Madras by rail for export. Some portion is also sent Bombay. The cotton produced in Godavari, Kistna, and Nellore is s by canal and road to Cocanada, and since the opening of the Buckingh. Canal a part goes by that route to Madras. The produce of the South districts is exported from Tuticorin, to which it is conveyed, partly gail and partly by road. The following statement, which has been extracted from the provinc cotton report for 1882-83, shows the mode in which the fibre is convey to the ports of shipment from the interior of the presidency :— 					
	DISTRICTS.	To what Places sent.	Mode of Conveyance.	In what shape carried.		
	1	Madras		Mostly in pressed bales.		
	Bellary Canara, South .	Madras and Bombay Mangalore and Bar- kur.	Do By road	In pressed bales. In impressed bales.

(Watt & Murray.) GOSSYPIUM.

CULTIVATION It is impossible, from want of perfect statistics regarding road, river, and canal traffic to make an attempt at giving complete figures regarding the provincial trade of Madras. The following statements must, therefore, be recognised as referring to rail and sea traffic only. Probably the road transactions in cotton are comparatively small; but, on the other hand, the canal-borne traffic is large and important. Much of the cotton produced in the western part of the Presidency finds its way to Guntur, whence it is despatched in great part by canal to Cocanada, Masulipatam, and Madras. The only figures available for this traffic are those in the Administration Report of the Public Works Department, Irrigation Branch, from which it would appear that 10,276 tons of raw cotton were registered in 1888-89 as passing up and down the Godavari, Kistna, Kurnul, Cuddapah, and Buckingham Canals. Of this amount 7,947 tons passed down towards the seaports, of which 1,496 tons went down the Buckingham Canal towards Madras. Though it is impossible to give a complete analysis of this trade, its importance must be remembered in consulting the following figures, as it probably greatly increases the exports from the province to the seaports, and may, in part, explain the apparent deficiency in the amount available for consumption in the town of Madras.

The total registered exports by rail and sea in 1888-89 amounted to 592,865 cwt., of which 575,980 went to the seaports of the presidency for shipment. Of the remainder, 12,259 cwt* went to Bombay port, 3,043 cwt. to Mysore, 1,577 cwt to Bombay Presidency, and 6 cwt. to the Nizam's territory. The exports by rail to Madras seaports amounted 10417,040 cwt., and were made up by 235,275 cwt. to Madras town, 155,832 cwt. to Tuticorin, 14,786 cwt. to Calicut, 7,102 cwt. to Pondicherry, and 4,045 cwt. to Negapatam.

The total imports amounted to 98,039 cwt., of which 52,966 cwt. were derived from the presidency seaports, 45»°73 from other Presidencies and provinces. Of the latter amount 30,226 cwt. came from the Nizam's territory, 14,787 cwt. from Bombay, and 60 cwt. from Mysore.

REVIEW OF AREA, & C-AS will be seen from the table, p. 56, the total area under cotton in these Provinces in 1888-89, including mixed crops, amounted to 1,399,388 acres. As already stated in discussing the races of Indian cotton, the average area has shown a marked increase during the past twenty years. In the year under consideration, however, a considerable falling off is exhibited, the average during the five years preceding having been 1,615,600, and the maximum in 1886-87, no less than 1,885,487 acres.

The total outturn in 1888-89 was 706,344 cwt., giving the average of about 60ft per acre. A comparison of the total import, 112,006 cwt.,

Area.

Cotton Cultivation in the

with the total export, 825,734 cwt., shews the net export to have been 703,728 cwt., a quantity very nearly equal to the estimated total production. Thus, by deducting the net export from the total production, only 2,616 cwt. are shown to have been left for local consumption, a result which is obviously highly erroneous. In a report on cotton, dated 1889, by the Government of the North-West Provinces, it is explained that this error is due to the unregistered road traffic, a great deal of cotton being imported by road from the Panjab and Rajputana to take the rail at Agra, Hathras, and other cotton-pressing districts. In 1877-78, a fairly compre-hensive registration system for trade by road and river was enforced, with the result that the net import by these channels was found to average 200,000 cwt. a year. Assuming that this import continues, the figures above given, as available for local consumption, will be supplemented by a credit of 200,000 cwt. per annum in favour of the province. This will represent fully two-thirds of the estimated home consumption (300,000 cwt.), the remainder could be accounted for by very slightly raising the estimate of yield. The writer of the report above referred to, commenting on these facts, writes, "The weak point in this argument is, that possibly with im-proved railway communication with the Panjáb and Rajputana, road imports may have fallen off since 1879. As to this I have no figures. There is no doubt, however, that cotton still travels largely by road even where the railway competes directly with this mode of conveyance, and that all but a very small portion of the cotton exported from Agra city by rail finds its way into it by road. As the rail exports from Agra city average about one-third of the total rail exports of the province, this fact is significant." From these arguments it appears safe to assume a local consumption of approximately 300,000 cwt., which, when distributed over the population of 43,268,599, gives an average of a little less than '81b per head, or, taking Indian cotton cloth at 4*3 yards per fc, about 3'44 yards to each individual. Commenting on the small average consumption of local cotton, the author of the above-quoted report writes, "Although the estimated home consumption of raw cotton is put at 300,000 cwt. a year, it is quite possible that, for a series of years, it may fall below this if the prices of cotton are high and the demand active in Calcutta and Bombay. This has been the case during the last few years. The native weaver then finds it cheaper to buy imported yarn, and the poorer classes economise in the matter of quilts and cotton-padded garments. These are the two chief uses to which raw cotton is put in the province, and the magnitude of the imports into it of yarn and piece goods of all kinds show how readily a substitute for the demand of raw cotton can be found. I will give the leading figures of the yarn, twist, and piece goods trade. The net imports of piece goods into the North-West Provinces and Oudh represent an average value of 450 or 500 lakhs of rupees a year, the net imports of twist and yarn average 40 lakhs a year. As 300,000 cwt. of raw cotton are worth, at most, only 60 lakhs, it is obvious that the home consumption of raw cotton is a comparatively minor item in the total annual expenditure on clothing of the population of these provinces."

Of the 300,000 cwt. allowed above for local consumption, a considerable proportion is worked up by the five cotton mills which at present exist in the provinces. In 1888-89;^{tnese a re} returned as having consumed 94,766 cwt., of which, however, a certain amount may have been imported as yarn or twist.

N.-W. Provinces and Oudh. (Watt & Murrav.) .GOSSYPIUM.

Races of Cotton.—The only cotton of commercial importance grown in the North-West Provinces is the form known as' Bengals, which probably consists of hybrid forms between G. Wightianum and G. neglectum, and is almost identical with many of the Panjdb forms with short white staple. In addition to this, however, purer forms of G. neglectum, Tod., and G. arboreum, are sparsely cultivated in parts of Oudh and the more eastern districts of the North-West Provinces, where the latter is ordinarily known as *narma*, the former as *manua*. A good illustration of G. neglectum, Tod., the manua cotton, is given in Duthie and Fuller's Field and Garden Crops under the name of G. herbaceum. A superior forn* of manua grown in the Allahabad district is called radya {cff. the account given under G. arboreum for Mirzapur and Goruckpur cottons, p. 10). Both these differ considerably from the ordinary cotton in the season of their growth, not bearing cotton till the hot weather months, instead of at the end of the rains. In a recent communication on narma and manua collectively, the Government of the North-West Provinces reports that " the area in a single holding rarely exceeds a quarter of an acre, and its total area in the United Provinces does not exceed 13,000 acres. In outturn and other details it does not differ much from the ordinary variety of the province."

The hill cottons of Kumaon and Garhwal are. like those of the Paniáb-Himálaya, hybrids with a strong strain of G. arboreum on G. Wightianum.

Numerous attempts have been made by Government to introduce the finer varieties of American cotton into this, as into other, cotton-growing regions. The following exhaustive account of these experiments may be quoted in entirety from the Note on Cotton by the Revenue and Agricultural Department:-

" Experiments were undertaken at the Cawnpore Experimental Farm in 1881-82, in which trials of Hinganghdt cotton and of the varieties of American cotton known as New Orleans and Upland Georgian, were made on two classes of soil, a light loam and a heavy loam, against two varieties of country cotton—one, grown in Bundelkhand and known as kulpahar, and the other, that commonly cultivated in the Cawnpore district. The results went to show (1) that for light soils the indigenous-cotton is by far the most proRaces. 158

N. W. Provinces and Oudh.	(Watt & Murray.)	GOSSYPIUM.
In the <i>kharif</i> season of 1884 three variaties of N	nkin cotton were tr	ed CULTIVATION

In the *kharif* season of 1884 three varieties of Nankin cotton were tried In N.-W. P. & OUDH. on the farm, vt5.;-(1) With seed procured from Yarkand. (2) With seed received from China through the Government of India. (3) With seed acclimatised on the farm. Races.

In reporting the results the Director of Land Records and Agriculture wrote as follows :--- "There is a marked difference in the habits of the three varieties. Nos. 1 and 2 appear to be of the Oriental variety, having few bunches and small deeply-indented leaves similar to the ordinary cotton of these provinces. No. 3 is distinctly occidental or similar in growth and habit to American cotton. Germination in case of the China seed was very irregular. Fields sown at the rate of 18 to 20 seers (36 to 40ft) of seed per acre had not as many plants as fields sown with 3 seers of the acclimatised variety* The plants were very stunted; most of them died before October, and those which survived bore scarcely any cotton. The fate of plants raised from the Yarkand seed was not much better. The fields sown with acclimatised seed fared comparatively well."

Samples of American and of country cotton cleaned in 1882-83 with the Burgess (Emery) saw-gin and with the ordinary country *charkhi* were submitted to the Manager, Elgin Mills, Cawnpore, for opinion. His report is as follows :-

" After carefully examining the samples and comparing the cotton ginned with the native *charkhi* in the ordinary manner with that ginned with the Emery saw-gin, I have arrived at the conclusion that the staple has not been injuriously affected by the latter process, *i.e.*, cut, broken, or otherwise appreciably damaged; while the superiority of the saw-gin over the old primitive method is very marked, so far as opening out and cleaning the cotton is concerned, as applying to Upland Georgian and New Orleans. The effect of the saw-gin on the short-stapled country cotton, however, is that the seed is partially broken in the process, and small particles adhering to the fibre are passed through the machine, which materially reduces its value for spinning purposes. I am of opinion, therefore, that the Emery saw-gin, while doing its work admirably on the long-stapled varieties, is not so well suited for cotton grown in the North-West Provinces and usually known as * Bengal.'''

The Director of Land Records and Agriculture adds:—^M• I may note that a sample of the country cotton cleaned by the sawgin and sent to the Cawnpore market was rejected by the dealers, not on account of any supposed injury to the staple, but on account of its clean appearance, the dealers suspecting that it was old cotton cleaned with a Belna's bow.'

In the *kharif* season of 1887, experiments with cotton of two varieties, (1) Louisiana, and (2) Egyptian, were tried on the farm, before and after the rains. The early-sown plots gave more satisfactory results than those sown late. In each case the Egyptian variety is said to have proved more suitable to the climate and soil of the north-west than the other. In two plots country cotton, and in two other New Orleans, were sown. In both cases the yield with gypsum and kainite was greater than without thsm. New Orleans gave an outturn of 145ft clean cotton per acre, and country cotton 121 ft.

Nankin cotton was also tried; the points to be determined were—(a) for how many years the plants will continue to bear; (b) whether the yield is equal to the annually-sown crop or not; (c) whether there is any change of colour in the produce of the annual and perennial plants; and lastly (d) whether rationing makes any difference? With regard to (a), it has been sufficiently proved that the Nankin cotton plant is perennial, and will yield

8

Cotton Cultivation in the GOSSYPIUM. CULTIVATION and stand for several years. If kept long, it thrives well, becomes more bushy, and produces more pods. But compared with the fresh-sown cotton N.-W.P.& a greater number of pods do not yield fine cotton. It is also shown that with the age of the plant the seed becomes smaller and smaller, and there-Baces. fore the percentage of clean cotton on seed increases. With regard to (b)tthe unfavourable nature of the season interfered much with the experiments. One of the plots sown this year yielded 1721b cleaned cotton per acre, and the other only 40ft, while the produce of the plots sown three years ago was 85th per acre in each case. With regard to (p) and $\{d\}_{g}$ there was apparently no difference between the colour of the produce of the two kinds of plants, nor was there any difference between the results of ratooned and unratooned plants. The foregoing trials have con-clusively shown that early sowing of all *kharif* crops, especially cotton, is advantageous. SOILS AND MANURES.-Messrs. Duthie and Fuller write," Cotton land Soils. may be either the very best or the very worst in a village. As a rule, .159 cotton is grown on good land, a loam being preferred, and is either manured itself, or reaps some benefit from a manuring applied to a crop which preceded it. District returns show that about 32 per cent, of the cotton crop is grown on land manured specially for it, 39 per cent, on land manured in the previous year or two years, and 38 per cent, on land altogether unmanured. A very large proportion is grown with manure, but, on the other hand, it is a common crop on poor soils, such as the raviney calcareous tracts in the neighbourhood of great rivers, which is said to actually improve by the manure of the leaves which fall from it. When sown on high class soil it is generally grown alone, while on poor ground it is almost invariably mixed with a large proportion of pulses and oilseeds. Hardly any of the Bundelkhand cotton, which is by far the best in the provinces, receives manure, nor does the black soil on which it is generally grown appear to require it. ' METHOD OF CULTIVATION.—The following account of the method of Method. cultivation pursued is extracted from Messrs. Duthie and Fuller's Field 160 and Garden Crops :-SEASONS.—Cotton is a *kharif* crop, being the one first sown after the Seasons. commencement of the rains" (with the exception of a large portion of 161 the crop of the Meerut district, which is sown with the aid of artificial irrigation a month or so before the setting in of the monsoon), "and yielding its produce from October to January. This is with the ordinary variety, but narma and radya cotton do not bear a crop till the April and May following their sowing, and thus occupy the ground for at least eleven months. Cotton fills no place in any special rotation of crops, although it is reported generally to succeed sugar-cane in Meerut, and to intervene between two cereal crops in Bareilly, the deduction being merely that it is grown on good land which had at all events been manured in the preceding year. It is off the ground too late to admit of its being followed by a rabi crop in the same year, but an ingenious method of gaining a second crop off cotton fields is to sow the oil-seed dudn (Eruca sativa) broadcast amidst the crop just before it is finally weeded. The seeds are buried in the operation of weeding, and the *dudn* plants do not become tall enough to inteffere with the cotton until the latter has finished bearing. Mixtures. MIXTURES. Collottois is comparatively elelolong grown about, but is, as a The, as so so show with the but root five subcouling coops, amongst which the attem is trie chief.. The arhar is generally sown in parallel lines, not broad-cast, and it is said that the cotton plants find in its shelter some protection from cold winds and frost. The oil seddtill, ongoing dlly, occupies the fifst place amongst the remaining subordinate crops, which comprise the pulses

N. W. Provinces and Oudh. (Watt & Murray.) GOSSYPIUM.

urd or mung sown broadcast, and an edging of castor and of the fibre CULTIVATION plant known as patsan (Hibiscus cannabinus). in N.-W. P. & OUDH. TILLAGE AND SOWING.—The land is ploughed from four to six times on the first fall of rain, and the seed is sown broadcast at the rate of 4 to Sowing. 6 seers per acre and ploughed in. The seed is generally rubbed with cow-162 dung before sowing, which prevents its clinging together in masses as it would otherwise do, and is also said to stimulate its growth. Irrigation is applied to about one field in seven, and this much only in Canal Districts, where watering will not cost more than from one to two rupees. Narma cotton requires but little waler, although it has the whole of the cold and part of the hot weather to stand before it produces its fibre. The radya variety, however, is said to require copious irrigation. It is essential to the proper growth of the plants that they be kept free from weeds, and the ground is, as a rule, carefully weeded by hand at least twice in the season, and often four times. PICKING.—The cotton bolls begin to open in October^{*} and picking Picking. is in progress from then till the end of January, unless cut short sooner by **I63** frost,-the great enemy of the cotton plant. Good fields are picked every third or fourth day, but only between sunrise and mid-day, while the cotton remains damp with the night's dew and comes away easily. If force is necessary to separate it from the boll, bits of pod-shell come away with it, which are technically known as 'leaf' and greatly damage the commercial value of the prodfuce. Cotton picking is generally done by women, who are remunerated by receiving ith to T th of the pickings. CLEANING.—For 'ginning' or separating the cotton fibres from the Cleaning. seed, a simple but ingenious machine is used (called a charkhi), consisting I64 of two small rollers about a foot long (one of iron, the other of wood), each with one end turned into an endless screw, and so geared one into the other, that when one-the wooden one-is turned by a handle, the other also turns in the opposite direction. When cotton is applied to the rollers the fibres are drawn through, and are in this way parted from the seeds. With this instrument a woman can turn out from 4 to 5ft of clean cotton fibre a day. The proportion of fibre and seed varies considerably, being in great measure dependent on the quality of cultivation. Occasionally it rises as high as fths or falls as low as |th, but -Jrd is the general average. It is interesting to note that an instrument practically identical with the charkhi is used for cotton cleaning by the negroes of the Southern States of America. INJURIES AND DISEASES.—Stagnant water is most harmful to the cotton Diseases. 165

plant, especially at the commencement of its growth, and fields selected for cotton are, as a rule, those in which water does not lodge. Rain, when the pods have begun to open, is also most damaging, since the fibre becomes discoloured and rotten. Early frosts may altogether terminae the picking season a month or six weeks before it would otherwise have ended, and hence the eagerness shown to get the cotton seed into the ground as soon as possible. Caterpillars are often very destructive, sometimes stripping a field entirely of its leaves, and an immense deal of loss results from the ravages of a small white grub (called *súndi*) which lives within the pod."

YIELD PER ACRE.—The question of yield per acre in the North-West Provinces, has formed the subject of considerable discussion, and has given rise to many conflicting statements. Thus, Messrs. Duthie and Fuller write : "There is no crop the outturn of which has been so systematically under-rated as that of cotton, and if we are to believe the district reports of the last three years, the provincial average is only 5Q/8& per acre, in which case it may be demonstrated that it would not pay to grow it at all.

Yield. 166

115

.

GOSSYPIUM	Cotton Cultivation in the
CULTIVATION In NW. P. ft OUDH. Yield.	After consideration of the estimates arrived at by settlement officers, which exhibit, it must be said, the most astounding discrepancies, and utilising the experience of two years on the Cawnpore Farm, an all-round estimate of 170© of clean cotton per acre of irrigated, and 150ft per acre of un- irrigated land is the lowest which can be safely struck, except for Oudn and the Benares Division, where 100ft may be taken as sufficient, <i>ror</i> cotton mixed with <i>arhar</i> , these outturns should be reduced by about 25 per cent." On the other hand, the recent report by the Director of 1^nd Records and Agriculture, dated 1889, contains the following:— ^w Considering that the American average is only 160ft per acre, the estimate given in <i>Field and Garden Crops</i> appears high for India, and the enquiries prosecuted by this Department confirm this suspicion. After considerable correspond- ence with agriculturists of all classes, the following standards of yield have finally been adopted by this Department as the full average yield for the several portions of the North-West Provinces and Oudh :—
	DISTRICTS. . OUTTURN OF CLEANED COT- TON PER ACRE. Alone. Mixed.
	Gangetic Doab.IbRohilkhand and Terai.130Bundelkhand60Benares Division and Jaunpur.120Oudh55
Cost. 167	The latter figures being probably the more carefully and thoroughly estimated of the two, have been adopted by the authors in their statistics of total yield of the provinces. At the same time the argument based on the yield of American cotton does not appear to be altogether without flaw. Many Indian cottons, for example, the Sindi, produce a very much larger outturn than that laid down for the cotton of the North-West Provinces ' by Messrs Duthie and Fuller, and there seems no reason why the native cotton in this province should not produce equally largely. COST & PROFIT OF CULTIVATION.—The cost of cultivation is estima- ted by Messrs. Duthie and Fuller, as follows :—
	Ploughing (four times) $R a. p.$ Clod crushing (twice) $3 0 0$ Seed (nominal) $0 2 0$ Sowing $0 13 0$ Weeding (twice) $3 0 0$ Picking d\jth produce on 200ft) $4 0 0$ Cleaning (at it anna per iolbj $1 14 0$
	Manure (100 maunds) Total 13 1 0 Rent 6 6 0 6 8 0 GRAND TOTAL 22 9 0
	It appears probable that the above cost is considerably over-estimated.

the more so since comparison with similar statements regarding Bombay G. 167

N. W. Provinces and Oudh. (Watt & Murray.) GOSSYPIUM.

and other provinces, shows that in the latter the cost is returned at only CULTIVATION in N.-W. P. & OUDH. from one-fourth to half of the above grand total. If the above-quoted statistics as to outturn per acre be accepted as correct, R22-9, expended on the cultivation, is much too large to admit of the crop being grown at all. Cost. Thus, assuming the value of the total production to be proportionately equal to the value of the exports, we have, 825,734 cwt.: $7^{\circ}6,344^{\text{cwt}}$.» : R 1,99,43.447! Ri>70,59>73⁶» which last figure, when divided by the total area, gives an average value of R12 per acre. It may be noted that this figure very closely corresponds with the value obtained by a similar calculation for the acre crop of the Central Provinces. Provincial

ANALYSIS OF LAST YEAR'S TRADE.—Of the total exports, 825,734 cwt., the largest proportion, *vis.*, 397,825 cwt., went to Bombay, while 348,233 cwt, went to Calcutta. Smaller quantities were consigned to Bengal and Bombay Presidencies, Rajputana and Central India, the Central Pro-vinces, the Panjdb and Berar. The imports, which amounted to 122,006 cwt., were mainly derived from Rajputana and Central India, Berar, the Panjab and the Central Provinces, while small quantities were obtained from Calcutta Bombay port Bombay Bengal and Karachi from Calcutta, Bombay port, Bombay, Bengal, and Karachi.

A small trans-frontier trade exists with Tibet and Nepal, to the former of which 1 cwt. was exported, to the latter 649 cwt.

As already stated, the unregistered road traffic probably causes the imports to be considerably underestimated.

REVIEW OF THE AREA, &C—The total area under cotton in the Pan-jåb in 18S8-89^{was} returned as 759,465 acres. In the year under consideration, a marked decrease in area is noticeable, but this is owing to exceptional climatic causes. On the whole, the cultivation is yearly increasing. Thus, during the three quinquennial periods of the past fifteen years, 837,600 acres, and for the third 859,800 acres.

The total outturn in the year under review was returned as 931,824 cwt., an exceptionally high outturn in comparison with the figures of acreage. Deducting the net export from that sum the total amount available for local consumption during the year is seen to have been 637,737 cwt. This figure, however, is liable to several sources of error. The returns of outturn per acre vary inexplicably in neighbouring districts, and are probably, m some cases at least, erroneous. Here, as in the North-West Provinces, the absence of a regular system of registration of road traffic may have given rise to some considerable error. While, in the North-West Provinces, the imports are probably under-estimated, in this province on the other hand, the exports by road, if registered, would in all probability much augment the figure of net export. If, however, the amount available for local consumption be accepted at 637,737 cwt., the

Specimens, which the authors have had the privilege of examining, shew a much greater tendency towards G. neglectum or G. arboreum than do the Hinganghat and Berar cottons, which are nearly pure G. Wightianum.

Mr. Drummond, Deputy Commissioner, Karnal District, writes, "The standard name of the crop in the Panjab proper is karpas, pronounced in most of the local dialects karpa. But in the tract between the Sutlej and the Jumna, except in certain minor portions which conform to the PanjAb rather than to Hindustan, or where there are (?) Sikh settlers (as in parts of the Hissar, Karnal, and Umballa districts), the name of the crop is *bari*. The seeds are known apparently everywhere in the cis-Indus tract as *banaula* or *banauli*. The ordinary name for the actual cotton is generally *ru* or *tut*, but this word is primarily applicable to fluff of any sort, whether of animal or vegetable origin. The wild Gossypium of the Theorem. Thanesar country is known to the Brahmans and Hindu Rdjputs as nurma, 'n allusion possibly to its ritual use, or to the purity of the snowy bolls."

Several forms occurring locally are known by distinct vernacular names» Among these may be mentioned the *nurma*, above noticed by Mr. Drum-mond, and frequent in other districts. It is said to have a red flower, £nd a greenish seed, both of which characters distinguish it from the ordinary field crop, of which the flower is yellow, and the seed grey. This so-called wild cotton, occasionally cultivated, is probably a form of G. neglectum, Tod., though the Deputy Commissioner of the Ihang District believes it to be of Egyptian origin.

L he Pan jab-Himalayan forms appear to be hybrids between G. arboreum and G. Wightianum. AitchisoiVs 462, collected in the Kuram valley, is G. 172

Conf. with pp. 7,28.

Panjab

also of this nature, having a strong strain of the former. A specimen col- lected during the Gilgit expedition (No. 250) is, perhaps, the nearest ap- proach to G. herbaceum, which the authors have seen from any region within the Indian botanical area.	CULTIVATION in the PANJAB. Races.
Mr Drummond, in an interesting note on the cotton of his district kindly furnished (o the authors, writes : "The mass of the scrub of the Nardak is <i>Dhdk</i> (Butea frondosa), but species belonging both to the Siwalik and the Deccan type of flora respectively occur, and among these is a species of Gossypium, which I am satisfied is indigenous, or at least spontaneously produced from a remote antiquity. This wild cotton is well known to the modern inhabitants of the Nardak, by whom it appears to be called in their vernacular • <i>narma</i> * or ' <i>ban-narma</i> ,' and the* staple is used by preference for making up the sacred thread of the Kulchattar Brahmans. ³⁻ The plant referred to is, in all probability—like the" <i>narma</i> ⁹³ already mentioned—G. neglectum, <i>Tod</i> .	Wild Cotton in the Panjab. 173. Conf. with p. 28.
The same writer continues, "In the Karndl district the cultivators do not appear to distinguish with any precision special races or breeds of the cotton plant, but more than one race undoubtedly occurs. A red or pinkish flowered kind is not uncommon " (probably a cultivated form of G. neglectum) " in the Panipat Tahsil, and in parts of the Karnál sub-collectorate. The Nardak field cotton is barely distinguishable, ex- cept as regards its habit, from the wild Gossypium of the neighbouring thickets.	
"The spontaneous form has an almost zig-zag stem, and a rather flexuous habit, which obviously contrasts with the rigid and twiggy ap- pearance of the cultivated shrub. This habit is doubtless determined by the usual manner of growth of the wild cotton, which generally springs up inside a clump of <i>huin</i> (Capparis sepiara, <i>Linn.</i>) or some other of the prevalent shrubs."	
During the past twenty-five years experiments have been steadily con- ducted with exotic seed. It is unnecessary, in this place, to enter into an exhaustive consideration of these; for a full account the reader is referred to Baden Powell's <i>Panjab Products</i> , 488-496, also to the Panjab cotton reports. Suffice it to say, that Mexican and New Orleans seem to have promised well, while the Sea Island, Egyptian, and Nankin races did not succeed.	Exotic Cottons. 174
In 1875-76 attempts were made to introduce Hinganghat, but, appa- rently, with little success, for we find the Deputy Commissioner of Rawal- pindi reporting, "The people do not care for this variety, as they consider the cultivation costly and the yield scanty."	
SOILS AND METHOD OF CULTIVATION.—The soil of the Panjdb appears generally to be well suited for the cultivation of cotton, if irrigated or low- lying and subject to inundation. Thus, Mr. Berkely, in an interesting report on experimental cotton cultivation near Delhi, writes, "The selection of the soil is by no means a difficulty; all varieties of equally productive soils have appeared to me equally well adapted for cotton. Thus, for Instance, wherever sugar-cane, wheat, or gram grows luxuriantly, it may be expected that cotton will thrive equally well."	Soils. 175
In the report on the settlement of the Jhang district it is stated that the crop grows best on the <i>utdr</i> wells in a strong loam.and that it does not succeed on <i>saildb</i> lands. Perhaps one reason for this is that the mode of cultivation in the latter is more slovenly, but even on good wells in <i>saildb</i> lands the crop is said to be always lighter than in the uplands. Manure is frequently, but by no means always, applied. The extent G. 176	Methods. 170

to which irrigation was employed in cotton lands during the year 1888-89 may be most conveniently shown in the following table:—

IRRIGATED BY		 Flooded lands.	Dry lands.	
Canals.	Wells.	Flooded failus.	Diy failus.	
Acres. 231,900	Acres. 186,900	Acres. 21,600	Acres. 3»5,900	
			l	

The following extracts from Settlement Reports and Gazetteers may be quoted, as describing, with a fair amount of accuracy, the methods followed in the more important cotton-growing districts:— "

In the Gazetteer of Gurgaon it is stated that :—" Cotton is sown on wells or where there are other means of irrigation, and on rain lands as soon as the first rain falls. The land is generally ploughed three or four times, the seed is sown broadcast, having been first rolled in cow-dung, so as to separate the individual seeds: about eight seers go to the acre. Cotton sown on wells has to be watered every fifteen or twenty days until rain falls; weeding is required three or four times; ten labourers will weed half a bigah a day for one rupee."

In the report on the settlement of the Jhang district, a long account of the methods pursued in the district occur, from which the following may be quoted :--- "The cotton of Shorkot, grown on the utdr soil, irrigated during the hot weather months from *jhallars*, or by inundation from canals, is very good. Land intended for cotton ought to be ploughed up once beforehand, after the cold weather rains. It is then manured; all cotton land ought to be manured, but a good deal never is. The manure is spread and the first watering is given. If the *zamindar* is lazy, he sows the cotton seed smeared in cow-dung broadcast. The land is then ploughed twice and rolled. If the*zamindar is industrious, he will plough the land twice to cover in the The well beds and water channels are then made. In Chiniot seed. cotton is sown much earlier than in the two southern tahsils. Sowings are made from the end of *Chait* to the middle of *Jeth* (April and May). About 32ft of seed per acre are used. Early sown cotton is ready to pick in Bhadron (August-September) ; all Blwdron pickings belong to the tenant. The proprietor does not share in the pickings before the 1st Assin 1 September-November) and he takes nothing after the Lolnr festival, the 1st Magh (January/February). There is not much left after the 10th January, but what there is the tenant takes. Very little *mud hi* cotton is grown in this district. There is not enough rain. Cotton is hardly ever grown alone. Melons, *jowar*, *mandua*, *kangnia*, *swank* are almost in-variably found in the cotton fields. Melons are sown with the cotton. The other crops are sown later on and are used principally for fodder. Jowar is hardly ever allowed to ripen, and the writer cannot remember ever having seen an instance of the other three crops ripening, the reason being that they are sown where the soil is hard and saline and not well suited for cotton. Hence the cotton is light and the deficiency is made up. Jby the associated crop. In this district the crop is not usually ploughed after the bushes have reached some height. The fields are hoed and weeded and the jotnav or other seed is then scattered broadcast in between *e cotton bushes. A watering is at once given and the seed usually germinates. Less mandua, kangni, and swank are grown in Chiniot than in the other tahsils. During the hot months cotton is watered every sixth day. In the early stages cotton is liable to be injured by drought and hot winds. Too much rain is also injurious to cotton. In 1878 the

rains were very unfavourable and the cotton on well lands ran greatly

to wood. The bushes were very fine, but the outturn was nothing more

Daniah	(Watt P Marman)	COSSUDIUM
Panjab.	<i>{Watt & Murray.)</i>	GOSSYPIUM.

in the PANJAB. than average. The Uela' blight also attacks cotton. Early frosts do Methods. more damage than anything else. Two kinds of cotton are grown in this district, but the red-leaved plant is not often seen. The ordinary country plant is the most common." The following description of the methods employed in Shahpur is also of interest, and may be quoted: "Cotton has always been very largely grown in this district. Few wells are without their patch of two or three acres of the plant. More than this cannot ordinarily be set apart for its culture, as it is a crop that requires constant attention in weeding and watering. The seed is put into the ground in March at the rate of eight seers (16 fib) to the acre, and the pickings give an average of about one anCl a half maunds of cleaned cotton per acre. The same plants are often made to yield three crops, by cutting them down level with the ground each year after the cotton has been gathered; at the same time the soil is well ploughed up between the roots and manured." Mr. Drummond, Deputy Commissioner of Karnál, has kindly furnished the following account of cotton cultivation in the Eastern Districts of the Panjab :-" In the Nardak, country cotton seems to have been cultivated from an ancient period. It is usually sown on up lying patches (ordinarily clearings, or paddy reclaimed), on the edges of the water hollows, and watered by lift from natural hollows, or excavated reservoirs, or from aqueducts led out of these. In some cases these are fed from branches of the Sarsuti and Chautang, on which numerous wide dams and similar works have been made to Facilitate watering for different crops, but pri-

marily rice, none of these being probably of high antiquity. "Wells in the Nardak are rare, and confined for the most part to the environs of the village homestead. The cotton cultivation of the Nardak, in so far as it depends on these wells or on outlying wells, whiciV are almost all of very modern origin, is an innovation. In fact, it is not uncommon to find the husbandman irrigating his cotton plots from the village tank, though they may grow within a few yards of a well, which is reserved for the tillage of manured wheat or tobacco.

"This is a very different condition of affairs from that which prevails in other portions of the district, where cotton is now grown. In the Khadar of the Jumna the cotton crop is mainly dependent on wells worked usually with the Persian wheel. In the belt again between the Jumna valley and the Nardak (comprised in the Bangar of the Karnal and Panipat tahsils), the cotton is almost entirely dependent on the Western Jumna canal

•' Wells in the Nardak are, of course, restricted by the great depth of the water level, which slopes from 50 feet below the surface in the north of the Kaithal sub-collectorate, to over 150 feet in the south west corner of the same sub-division. The Nardak cotton is, perhaps; consumed almost entirely on the spot: but the canal-irrigated and Jumna valley outturn goes to swell the Khadar cotton supply of the Delhi market.

^{*u*} Khadar ovKhadir cotton is a commercial term for the produce of the districts (in the Panjáb and North-West Provinces) on the Jumna from Umballa to Delhi, both inclusive.

 $\bullet_{\rm B}$ "In the Eastern districts of the Panjáb, cotton is grown on all but the lightest soils, but it prefers the more tenacious loams. It requires copious watering and certain seasons, but unless the water be drained off naturally or by artificial means at the proper juncture, the flowers and, consequently, the pods, will suffer. Hence the Khadar is always more speculative than the result in the canal-irrigated uplands, or in the Nardak, notwithstanding

CULTIVATION

G, 176

GOSSYPIUM.

Cotton Cultivation in the

CULTIVATION in the PANJAB. Methods.

the fact that the cultivation in the last-named tract is so primitive in its character. On the other hand, too strong a sun when the buds are forming is most adverse to the field. The plants, if exposed at this stage to an excess of moisture, are drawn out and run to stalk. The blossom is then sparse and light, and of flowers produced, only a portion mature pods.

•' The usual time for sowing in the Jumna Khadar and the neighbouring uplands is just at the first heavy burst of the periodical rains, or from about the 20th of June to the 10th of July. But on land commanded by wells the seed is sometimes put in earlier. The practice of sowing in March or even earlier, which is reported from some districts of the Panjáb seems to be unheard of in the Eastern districts. In these the wells and labour are not set free for cotton before April.

"Cotton is also raised as an unirrigated crop in parts of the Karnái and other Eastern districts, but nearly always in such a situation" that the young plants can be watered, at a pinch, from a tank, or by catchwater drains leading from the waste. It is only in a specially favourable season that a cotton-patch can be left to the unaided rainfall. In the Eastern Panjáb the soil is not always manured for cotton. In the Khadar it is often sown on what is known as *sail aba* or spongy land, too far from the village site for the transfer of manure. In the Nardak the grey loam does not require more manuring than it receives indirectly from collections of flocks and herds at particular stations; possibly the soil contains particles of lime washed down from the Himálayan formations near which the hill streams originate.

^w The pods are picked from November to January. Near towns, and especially the large town of Panipat, the picking forms an occupation fur the women of the more industrious classes of the cultivating lower orders. The hire is sometimes paid in cash; more frequently as a proportionate share of the day's gathering.

•• The plan of sowing certain leguminous crops (chiefly species of Meli-*lofts and Trigonella) with the cotton, as an after-crop to be used as fodder for well bullocks when the natural grass begins to fail, which is pretty general in the Central Panjáb, seems to be unknown in the Eastern districts. This fact is probably due to the comparative richness of the pasture and the greater area of waste and fallow which still prevails, especially in the Karri'al and Hissar districts.

"Cotton mixed with other crops is commonest in the Khadar of the Jumna (til_9 melons, and certain autumn pulses are the crops most commonly sown with it), but throughout the Karnil district, and generally in the Eastern districts, san (Hibiscus cannabinus, Linn) is, as a rule, sown in strips along the edges of the cotton pastures, or in alternate ribbons with the main staple. The Karnái cultivators assign several explanations, more or less reasonable, for this practice, but cotton when so treated seems undoubtedly to have a better chance than when unprotected. Possibly the tall stems of the Hibiscus help to moderate extremes of sun-light and wind, but the primary object, as in the parallel case of gram being edged with kasumbha (Carthamus tinctorius), is likely enough to keep off antelopes and cattle, which the traditions of the Dharmdharti (home of *he law, or Aryavartta) do not permit to be kept of! by more vigorous measures.

"Jⁿ the eastern portions of the province cotton is one of those crops to 2215^{h} the system of agricultural association *{Una}* is almost universally applied. Indeed, in those tracts in which the wells are over 40 feet in depth (in such districts as Karnál and Hissar), the cultivation of cotton, except by the combination of ind*vidual resources in the way of oxen, implements, and labour, would scarcely be practicable."

I*. 176

Panjab.

{Watt & Murray) GOSSYPIUM.

CULTIVATION PICKING AND CLEANING.-The following is extracted from a monoin the PANJAB. graph on cotton manufactures in the Panjáb, 1883-84 :--- "Cotton is picked about November and December. The pods do not all ripen at the same time, and it is therefore necessary to go over the field several times. This work is chiefly performed by women. They are usually paid by a Picking. portion, generally one-tenth, of the cotton they pick. The pods are ex-177 posed to the sun and beaten to make the husks *{doda*} separate from the fibre. "The seed to which the fibre is attached is then extracted by a small hand machine which takes the place of the cotton gin. 1 his consists of two rollers, one of which is generally of iron and smaller than the other, which is of wood; but in some districts both rollers are stated to be of wood. By means of a spiral turn at the end of the iron roller, which engage's a projection of the wooden roller, the two are made to revolve in opposite directions when the handle attached to one of them is turned. The fibre (*rut*) is drawn through the rollers, while the seed {*binola* or *varema*), which cannot pass between them is left behind. This machine, which is called *belna*, is capable of ginning about 12 seers of cotton in a day. At Mult an a steam cotton gin has been established . • • which employs 70 persons. 'In the Hazara district there are at Pakhli some *belnas* worked by water power. The *belna-vrovVer* is commonly paid by receiving the cotton seed which he extracts, but sometimes receives cash. The operation is also very frequently performed by members of the household of the person to whom the cotton belongs. In the census tables 3.257 men and 1,345 women are recorded as cotton ginnes, but these figures do not represent the numbers really so employed. The cleaned fibre usually weighs one-third, the seed two-thirds, of the whole contents of the pod, but with, inferior cotton the fibre is sometimes only one-fourth of the whole.' SEASONS OF SOWING AND PICKING.—The period of sowing occurs at dif-Seasons. ferent times in different parts of the province, and is also largely regul_:texl< X78 by the rainfall. In Gurgaon it is sown on wells, or where there are other means of irrigation, from March to May, and on rain lands in June-July, as Foon as the first rain falls. The early-sown cotton begins to bear in August-September, the later in October-November, the plants continue to bear till they are killed off by frost. The early cotton has thus the great advantage of ripening a month earlier than the other, and of being generally able to bring out all its pods before the frost comes. If the rains or hot westerly winds are excessive, the pods are said not to ripen. In the Shahpur district the seed is sown in March, but the process of gathering does not commence till October and lasts till the end of December or even later. In other districts of the Panjdb, sowings, as a rule, go on from the middle of February to the end of March, and in well-watered lands to April and May; on all rain lands they are much later. Picking ought always to be completed before January, owing to the danger of loss from frost. The crop is sent to market from January onwards, and is available for export, according to the means of transit, from January to May or June. **DISEASES.**—Dr. Johnstone, in a valuable note on the blights of cotton Diseases. communicated to the Agri-Horticultural Society of the Panjáb, described 179 the crop as liable to four special pests, viz., (1) the larva of Helicopis cupido, which attacks the young plant; (2) the larva of Deprescaria gossipiella (weevil) which infests the seed in harvest and is known as the "toka" by the natives; (3) a large hairy caterpillar (bhungo) which attacks the leaves and stem on the approach of the rainy season; and (4) an Aphis which frequently attacks the crop in great quantities, and has, on several

{Watt & Murray.) GOSSYPIUM.

Mr. **Drummond** has kindly furnished the following note in explanation of the variation in the figures of yield per acre : ^M This varies, through-CULTIVATION out the province within wide limits, and even in the same district marked differences exist. A good Khadar plot, properly manured and steadily irrigated from a well, in a good season would probably produce as much as 4.00ft to the acre. On the other hand, a Nardak patch, on which the same crop has been raised for some autumns in succession, will yield so little, should the reservoirs, from which it is usually watered fail, that the cultivator will not even expend, in picking it, the menial labour for which there may be a demand in some other direction. But the average outturn per acre in the eastern districts \n an average season should probably not be placed below 2009>."

£OST OF CULTIVATION.—Details are given in the subjoined extracts from the Provincial Cotton Report for 1882-83, but, judging from the remarks thereon they do not appear to be very reliable. It is to be regretted that no more recent statistics are available*:-

"The following tables show the cost of the cultivation of cotton in those districts from which detailed estimates have been furnished, distinguished, according as irrigation and manure are, or are not, together or separately applied; also a detail of the cost of each agricultural operation on that class of land in which the cultivation is most complete, that is to say, land which is both manured and irrigated :-

Statement showing" the cost of cultivation of cotton in certain districts under the four heads A, B, C, and D, i.e., irrigated and manured, irrigated but not manured, unirrigated but manured, unirrigated and unmanured.

CULTIVATION In the PANJAB. Cost.	fit for the Delhi market (and excluding, therefore, cost of delivery to the broker) cannot exceed Rn or R12 at the utmost. The market value of the manure, if added, would hardly bring the total estimated cost to more than R13 or R13-8.
Panjab Trade. 182	ANALYSIS OF LAST YEAR'S TRADE.—The total exports in 1888-89 amounted to 295,976 cwt., of which 96,281 cwt. went to Bombay, 44,121 cwt. to Karachi, 42,123 to Calcutta, and 108,988 cwt. to other provinces and presidencies. Of the last mentioned quantity much the greatest propor- tion went to Sind, smaller quantities to the North-Western Provinces and Oudh, Bengal, Bombay, and Rajputana. As already stated, it is highly probable that a considerable unregistered export road trade exists between the Pan Jab and the North-West Provinces, more particularly Agra. In addition to the above, 1,304 cwt. were exported across the frontier to Kash- mir, and 3,159 cwt. to Sewestan, Tirah, Kabul, Bajour, and Ladak.' The total imports were very unimportant, amounting in all to only 1,889 cwt., to which the North-West Provinces and Oudh, Rajputana, and Central India, Sind, Karachi, Calcutta, and Bengal contributed small quantities, while the largest amount, <i>vis.</i> , 880 cwt., was imported across the frontier

Soc. of India, Transactions, V., Proc, 65; Journals (New Series), I., Proc., Ixt. REVIEW OF THE AREA, OUTTURN, AND CONSUMPTIONThe total area ueder cotton in these provinces during the year 1888-89, as will be seen from the table (p. 56) was 613,348 acres. As already stated in commenting on the facts regarding Hinganghdt cotton, the area has markedly fallen off within the past twenty years. Thus, about fourteen years ago, the cultiva- tion averaged 800,200 acres, five years ago it dropped to 688,400, while in the last five the average has only been 608,800 acres. The total outturn in the year under consideration was returned as 351,923 cwt. of cleaned cotton, giving an average yield to the acre of 64*2%. A comparison of the total imports from all sources, 8,756 cwt, with the total export, 170,130, shews the net export to have been 161,374 cwt., which, when deducted from the above given total production, leaves 190,549 cwt. in the provinces for local consumption. When distributed over the population of 9,838,791, this amount gives an average per head of nearly 2"2fc, or, taking Indian cotton cloth at 4\$ yards per ft, about 9*5 yards of cloth to each individual. In giving the above figures calculated from available information for one year, however, it would be urged that in these provinces, as elsewhere, they are only approximations, and are open to several sources of grave error. Thus, in a c
	 of area on which it is compiled are in most cases only estimates, and sometimes extremely rough ones. 2nd—That, granted the estimate of production is correct, the conclusions as to its consumption are justified only on the assumption that the exports and imports by road, of which no statistics are available, balance each other.
	G. 184

CULTIVATION in the CENTRAL PROVINCES. 3rd—That the years of production and of trade statistics do not correspond. An interesting calculation, subject, however, to the above errors, is made in the same report, from which it would appear that the total consumption Area. per head in these provinces, of local and imported cotton and cotton cloth, is approximately 3*18ft, while the production per head is 3*22fb per head. This shows that, on the whole, the provinces consume as much as they produce. A considerable portion of the amount above calculated as available for local consumption is annually consumed by the cotton mills of the province. of which there are three. Thus, in 1889, these mills are stated to have worker} up 91,021 cwt. of raw cotton, leaving approximately 100,000 cwt. for hand-loom manufactures, mattresses, wicks, &c. DISTRICTS WHERE GROWN.—The cotton country of the Central Pro-Districts. vinces lies on the left bank of the Ward ha river. In the north, where the **I84** river debouches from the Satpura Hills, the cotton cultivation covers a rich but narrow strip along the bank. This strip widens as it proceeds southwards until it ultimately attains a width of some 50 miles. The wellknown mart of Hinganghat may be said to be situated where the cotton field is widest; but the whole plain, though capable of producing cotton, is not entirely occupied by it, for wheat and joixari alternate with cotton fields. After reaching its greatest width, the cotton country again narrows, until at last, in the south of the Chanda district, it is lost in the encircling brushwood and jungle. The districts in which the cotton crop is of most commercial importance, are Nimar, Wardha, Chhindwara, and Nagpur. The rainfall in these provinces is very much lighter on their western border than elsewhere, and it is in the western districts that cotton is most profitably grown. In Chanda, which supplies the mart of Hinganghat with what is reported to be its finest cjuality of cotton, the kind known as *jari*, is also produced. The following figures represent the average area under cotton, during the three years 1885-1888, in the above-mentioned chief cotton-growing districts :----Unmixed. Mixed. Wardha (acres). .7,813 137.978 ²⁴>⁹⁵⁴ 881506 **JSMP**? ... Chhindwara " 23.041 26.508 Nimar 4SP97 1*278 Races. RACES OF COTTON.—As already stated the greater portion of cotton grown 1«5 in these provinces belongs to the growth known commercially as *Hinganghat*; indeed, this race is the only one of importance from a trade point of view. It occurs in two different forms, one of which is known as bant, the

ghat; indeed, this race is the only one of importance from a trade point of view. It occurs in two different forms, one of which is known as *bant*, the other as *jari*. The former is longer in staple and commands a price equal to that quoted for any other Indian cotton; the latter is whiter and freer from leaf but of poorer staple. Botanically, both races are forms of G. Wightianum, *Tod.*, the inferior form shewing degeneration through hybridisation with G. neglectum. in the remarks under G. arboreum a passage has Deen quoted regarding Seoni district, from which it will be found that G. neglectum is cultivated under the name *manua*, and G. arboreum as *deo* (p. 9). Here, as elsewhere, however, numerous experiments have been made with the object of attempting to introduce cottons of a higher class, In 1882-83, *Broach* cotton was planted at the Nagpur Experimental Farm, but the results appear to have been unsatisfactory. It suffered much from a drought which prevailed in that year, and afforded no remunerative yield. In 1883-84 experiments were commenced at the Government Farm with New Orleans (G. hirsutum), and Upper Georgian cottons (G. barba-19 G. 1885

Cotton with p. 9.

CULTIVATION in the	
CENTRAL PROVINCES.	
Races.	

dense), which have since been continued with fairly good results. Parallel experiments were made with the fibre obtained from these and with that of the *bant and jari* country or *Hingangh&t* cotton, by the Managers of the Cotton-Mills at Nagpur and Hinganghat, with the following results :—

tive va- lueof: I Hand- ginned. Saw- ginned. Saw- gin Saw- ginned. Saw- ginned. Saw- ginned. Saw- ginned. Saw	Compara-	NEW OR	LEANS.	UPLA GEOR	BA	NI.	JAR	I
KKKKKKNagpur Mills7555757873705556HinganghatII	tive va- <							•
	Hinganghat	75	55	75	73		55	56

The above-cited figures are of considerable interest, shewing, as they do, how markedly the New Orleans form of G. hirsutum deteriorated in value after being saw-ginned, while the Upland Georgian, on the other han-dj was, if anything, improved by the process, and the Indian cottons were only slightly damaged. The high value of the better class of country cotton is also worthy of notice. A recent communication from the Manager of the Khandesh Experimental Farm contains the information that the , short-stapled *jari* now fetches almost as good a price as the *bani** ^{ow*n}£ to its containing a higher percentage of fibre to seed, and to its purer white colour. A continuation of the cultivation of American cottons demonstrated that New Orleans was unsuited for the climate and soil of the provinces, but that Upland Georgian was capable of yielding very satisfactory results. It was proved to give a fair crop,— 173 b^{on} manured, ana from 71 to 11 lib on unmanured land,—and to produce a strong, £^{ovc1} " staple superior to the best Hinganghdt. In 1880, over 1,000% of seed ot the Upland Georgian cotton were distributed to the rayats in the Wardha district, and the resulting crop appears to have been highly esteemed both by the cultivators and cotton dealers.

Mention is made in several reports on the cotton of the Central Provinces of a *khaki* cotton which is grown in small quantities, and is consumed locally, none coming into the market. This is probably Nankin cotton (G. religiosum. Conf. with pp. 16-17).

CULTIVATION :—SOILS, SEASONS, &C.—The following description of the " cotton soil" of the Central Provinces, extracted from the *Central Provinces Gazetteer*, may be of interest, since the soil seems to be one of the best in India for cotton cultivation, and, at the same time, appears to lend itself readily to the growth of one of the best races of American cottons :—

"The black soil or *regar*, or, as it is not uncommonly called, the 'cotton soil,' forms one of the most marked varieties in these provinces. It is the common soil of the Deccan, Malwa, Narbada valley, &c. It varies greatly in colour, in consistence, and, with these, in fertility, but throughout is marked by the constant character of being a highly argillaceous, somewhat calcareous, clay, very adhesive when wetted, and from its very absorbent nature expanding and contracting to a very remarkable extent, under the successive influence of moisture and dryness. It, therefore, becomes fissured in every direction by huge cracks in the hot weather. It also retains a good deal o moisture and requires therefore less irrigation than more sandy ground The colour of this soil, often a deep and well-marked black, with ever variation, from this to a brownish black, would appear to be solely due t< an admixture of vegetable (organic) matter in a soil originally very clayey

.

Soils* **186**

13°

(fentral Provinces.

(Watt & Murray) GOSSYPIUM,

CULTIVATION Thus, deposits of precisely the same character as this regar are being formed now at the bottom of every *jhil* in the country, and throughout the very area where the regar is best marked, it is by no means an uncommon thing to find the slopes of the small hills or undulations formed of more sandy reddish soil, while the hollows below consist solely of the finest regar. This appears to be due to the more argillaceous and finer portions of the decomposed rocks below being washed away by ordinary pluvial action from the slopes and accumulated in the hollows, where this finer mud forms a soil much more retentive of moisture, and which therefore rapidly becomes more impregnated with organic matter, and is often marshy. Regar can thus be formed, wherever a truly argillaceous soil is found, and its general, but by no means universal, absence over the metamorphic and other rocks is easily accounted for by the fact that these rocks for the most part vield sandy, not clayey, soils. It is never of any very great depth, and excepting when re-arranged by rivers in their recent deposits, is therefore never met with at any great distance below the surface.

*'Obviously formed from the re-arranged wash of the older and more widely-extended soils we find large areas of very fertile soil, consisting of clays rather more sandy than the older alluvium, and not therefore so black or adhesive. Though rarely formed altogether of the true regar soil, it frequently contains a large proportion of this mixed with other clays and sands. Every intermediate form of soil occurs, and it would by no means be an easy task to distinguish them all. From an agricultural point of view, it is interesting to see how exactly the limits of certain kinds of cultivation coincide with the limits of these marked varieties of the alluvial deposits of the country." (Central Provinces Gazetteer, 1870, xlvL, xlvii.). An analysis of the soil shows its composition to be as follows: silica, 48*2; alumina, 20*3; carbonate of lime, 16; oxide of iron, 1; water and organic matter, 4*3 per cent.

METHODS.—The soil is prepared for sowing in May to June/the seed is sown in June, picking commences in November to December, and is completed from February to March.

The following account of the method followed is extracted from the Central Provinces Gazetteer | 1870: "Cotton is sown and reaped about the same time as jowar. As it does not early obtain any considerable height it requires more weeding and banking up with the kolfa (bullock hoe). The process of gathering the pods is a most negligent one, most of them being allowed to drop and get discoloured on the ground. It is the worst feature, perhaps, in the husbandry of Nimar, but the cultivators urge in excuse, that it would not pay to keep people running up and down the cotton fields every day for a month or so, when so little is grown and the return The process of cleaning is the same as in other parts of the so small. country."

It is encouraging to note, that though the total area under cotton in the Central Provinces has diminished of late years, improvements are being effected in the methods of cultivation and gathering. Weeding is more carefully attended to than it used to be, and many[^] cultivators are said tq, have adopted a system of light, but careful, manuring, which, as noted above, greatly increases the crop.

YIELD PER ACRE.—The following figures are given by the Government of the Central Provinces as the average outturn of cleaned cotton per acre during the three years ending 1887-88 :-

Jabalpur, 36'48ft;Narbada,43-5₉ft, Nagpur, 6i'33lb; Chhattisgarh, 32'iofc.

In 1870, Mr. J. Q. Fraserof Gopalpur, Jaunpur, reported the results of cultivating Hir.ganghat cotton by transplanting from a broadcast sowing 131

287

Yield. 188

GOSSYPIUM	I. Cotton Cultivation in the Nizam's Dominions.
CULTIVATION in the CENTRAL PROVINCES. Cost. 189	made in the rains. The yield was 376ft per acre of cleaned cotton. The reports on the samples published by the AgriHorticultural Society pronounced the staple to be very good, silky, of good length and strength, measuring a little over 1 inch, while the average Hingangh&t is 1*4 inch. COST AND PROFIT OP CULTIVATION.—It is difficult to arrive at anything like an exact estimate of the total cost of cultivation, and of the pront derived per acre. Assuming the value of the total production, however, to be proportionately equal to the value of the exports, we have 170,150 cwt. <i>i</i> 35*»9'3 cwt: 837,51*382 : 1*77,59,934: which last figure when divided py the total area gives an average value of Ri 1 per acre. The profit deriv-
Provincial Trade. 190	able from this sum would appear to be in most cases considerably les ^s than that from wheat, linseed, or <i>jowar</i> . ANALYSIS or LAST YEAR'S TRADE.—Of the total production of 1888-oQt w [*] »., 351,923 cwt., 170,130 cwt. is returned as having been exported. O [*] this, much the largest proportion went to the port of Bombay for export, 57,237 cwt. is shewn as having gone to the province of Bombay excluding the port, and smaller quantities to the North-West Provinces and Oudh, Berar, Rajputana and Central India, Bengal and Calcutta. The imports are unimportant, amounting to only 8,756 cwt. The chief amount was obtained from Berar, the North-West Provinces and Oudh, and Bombay
COTTON CULTIVATION in the NIZAM'S DOMINIONS. II Area. X92	Bombay. 9. NIZAM'S DOMINIONS. REVIEW OF THE AREA, OUTTURN, &c—The average area during the five years ending 1885-86 (the last period for which figures are available) was 1,016,565 acres, yielding 307,002 cwt. Statistics for road traffic not being available the net export can be approximately arrived at only from the statistics of rail-borne trade by accepting the road exports and imports as balancing each other. On this assumption the net export in 1888-89 was 81,84.2 cwt. of cleaned cotton. Taking for granted that the production in that year was approximately equal to the average of the five years a'uove stated, the amount left for local use would have been 225,160 cwt., a figure considerably in excess of the local consumption estimated from other sources of information, vis, 131,000 cwt. {Note on Cotton by ?*? venue and Agricultural Department}. It may be pointed out in passing however, that the exports representing, as they do, those by rail only are, necessarily, in a country such as Hyderabad, but a small propor tion of the total, and that, in all probability, the exports by road may more than double the above amount. Indeed, in the "Note on Cotton" the total exports are said to average 300,000 cwt. With such imperfect data therefore, any calculation as to the amount consumed per head would be
Races. 193	At present two cotton mills exist in the Dominions, which are stated to consume approximately 37,522 cwt. of cleaned cotton annually. RACES OP COTTON CULTIVATED.—In the northern division of the Niz am's Dominions the description of cotton known as <i>Barsee</i> and <i>Nugget</i> <i>{Oomras</i> } is produced, and, as previously stated (p. 83), finds its way into Bombay entirely by road, and is hence credited in the rail returns of the latter. In the rest of the Dominions the chief staple grown is ^w Westerns ^v (one of the forms of G. Wightianum, <i>Tod.</i>). A considerable portion of 'th produce of the Kunar Idldbad district finds its way to the Hinganghat' market, is greatly valued, and fetches high prices.
Provincial Trade. 194	ANALYSIS OP LAST YEAR'S TRADE.—Rail-borne imports during the yea under consideration were very insignificant. Of the 687 cwt. imported, 67 cwt. came from Bombay, 6 cwt. from Madras, and 4 cwt. from Bombay por The rail-borne exports amounted to 82,529 cwt., of which 38,609 cwt was despatched to Bombay port, and 7.429 cwt.to the seaports of Madra G. 194

Cotton Cultivation in Bengal. (Watt & Murray.) GOSSYPIUM*

for shipment; 30,226 cwt. went to the presidency of Madras, and 6,265 cwt. to Bombay. Besides these registered exports, however, a large amount is exported by road to the Central Provinces, Bombay, Berar, and probably also to Madras. **zo. BENGAL. REVIEW OF THE AREA, &C.—In the absence of agricultural statistics, the Lower Provinces, it is not known what is the exact area under cotton.

REVIEW OF THE AREA, &C.—In the absence of agricultural statistics, for the Lower Provinces, it is not known what is the exact area under cotton. It is, therefore, necessary to accept as approximations the following statistics for 1876-77, which nave been extracted from a report furnished by the Government of Bengal in 1878 :—" There are, as far as can be ascertained, 162,000 acres under cotton cultivation in Bengal, yielding 138,800 cwt. of cleaned cotton." Accepting the above figure of acreage as correct, and the total outturn as, approximately, 139,000 cwt., the average yield per acre would have been off.

٤.

acre would have been 0,6tb. In the year 1888-89 the net export amounted to 3,562 cwt., which would have left from the accepted average outturn 135,438 cwt. as available for local consumption, or "2lib per head of population. This small figure may either be due to an under-estimate of outturn, or to the fact that the increasing use of foreign twist and cloth is gradually but surely driving locally-grown cotton out of the bazaYs and is thus leaving a greater amount available for export.

DISTRICTS WHERE GROWN.—The largest area under cotton cultivation is in the district of Sarun, in which 31,000 acres were estimated to be under the plant during 1876-77. In the same year the Chktagong Hill Tracts came next in importance with 28,000, then Cuttack with 20,000, Lohardugga with 15,000, Durbhanga with 12,000, Midnapore with 10,000, and Manbhoom with 10,000 acres. But, although Sarun is shown to have had the largest area under cultivation, the outturn was not sufficient even for local requirements. The largest outturn was in the Chittagong Hill Tracts where it amounted to 50,000 cwt.; next in order came Midnapore, with an outturn of 12,800, Cuttack with 12,500, and Julpigori with 10,300 **cwt.**

In the General Administration Report for 1882-83 the following additional particulars are given :—

"The cultivation of cotton is not of very great importance in any of the districts of Bengal, with the exception of the Chittagong and Tipperah Hill Tracts, Cuttack, and Julpigorl. In the plains of Bengal, which are so fertile in other produce, the production of cotton is an inconsiderable industry, and nothing is exported, while much is imported from the North-West Provinces. The cotton grown in Bengal is in fact insufficient for the requirements of the people and has to be supplemented by cotton brought by land or river from the west, and by an increasing importation of English piece-goods.

"Generally speaking, then, it may be said that the production of cotton does not form an important industry of the cultivators in Bengal. It is cultivated, not as an article of commerce but, for the sake of variety and for domestic use, only the agricultural classes preferring strong Area.

196

Districts. 197

GOSSYPIUM	Cotton Cultivation in
CULTIVATION In BENGAL. Districts,	home-spun cloth to the less durable machine-made European piece-goods procurable in the bazar. There is no anxiety on the part of the cultiva- tors to extend or improve the cultivation of cotton." (General Administra- tion Report, 1882-83.)
	The last paragraph of the above extract appears to take a rather too gloomy view of cotton culture in Bengal, for both the exports and cultivation appear to have increased during the past few years. In his report for 1886-87 (page 8), the Director of Land Record* and Agriculture writes as follows:—"Cotton was formerly grown exatensively in the Dacca and Mymensingh districts, in a large tract o." land, the soil as well as the physical aspect of which are very well suited to the cultivation of the plai.t. The cotton raised here, $tnou$ £j rather short in staple, was the finest known in the world, and'formea the material out of which the very delicate and extremely beautiful Dacca muslin was manufactured. Since the decline of that celebrated fabric, the cultivation of cotton has almost entirely ceased in this tract. Constdering the high price that cotton fetches in most parts of Bengal and the improvement which has been effected in the yield by the introduction of some of the best American varieties, the cultivation of this im- portant crop may be revived in the locality with great advantage/*
Races. 198	RACES OF COTTON.—Though this province gives its name to the most extensively cultivated of all Indian cottons, "Bengals," it appears probable that much of the locally-grown cotton, most of which is used for home con- sumption, does not belong to G. herbaceum in any of its forms, as defined by the <i>Flora of British India</i> . It is needless in this place to again enter into a consideration of the plants which produce the finer staples of Mymen- singh and Dacca, a full account of which will be found in the descriptions of G. arboreum (pp. 7-13) and G. herbaceum (pp. 25-29). Sufficejt to sajr that, besides the ordinary hybrid forms of the G. herbaceum series, G.
Conf. with p. 24.	 "iieglectum. Tod., almost in its type form appears to be largely cultivated, especially in the eastern parts of the Lower Provinces. Numerous experiments have been made in Bengal, as elsewhere, with the object of introducing exotic seed. For a description of the earlier and more energetically carried out of these, the reader is referred to the article on G. barbadense, also to the exhaustive literature on the subject contained in the publications oi the AgriHorticultural Society of India* above cited, and to Mr. Medlfcott's Cotton Hand-book for Bengal* The following extracts from provincial reports, relating to the attempts made in later years, may, however, be quoted. It will be seen that recent experiments have been chiefly directed towards the introduction of Nankin cotton :—
Conf. with p. 17.	 '' It having been brought to notice that a species of indigenous khaki-coloured cotton is grown in Durbhanga, Chittagong, and Hill Tipperah, it was thought that the cultivation of Nankin cotton would be most likely to succeed in these or in the neighbouring districts. Arrangements have accordingly been made for the experimental cultivation of Nankin cotton in Mozufferpore and Hill Tipperah. It has been found that this cotton can be grown with success in the Government Estate of Kho'ordah in the Orissa Division. '' [Agricultural Report, Bengal, i88\$~86.) At the Burdwan Ráj experimental station ''eight different varieties of cotton were experimented upon. The plots were manured with bone-meal at the rate of I,080ft per acre, with the following results :
	G. 198

¢

Bengal.

CULTIVATION unlike experiments made in other districts, very good results were obtained with Nankin cotton this year in the Burdwan farm. The plants looked quite healthy, and proved more hardy than any ether varieties experimented upon. They have put forth new shoots and leaves, and a Experiments with exotic forms. second crop is expected. Experiments on the cultivation of Nankin cotton were also tried in Mozufferpore and Hill Tipperah, but without success. Mr. Sen at first tried Nankin cotton as a winter crop, and, as such, it did not germinate; but planted in the beginning of the rainy season, in drills 30 inches apart, and manured with bone-meal, Nankin cotton, as the figures quoted above show, gave very good results. I do not, however, think it will ever be extensively grown in Bengal. " {Agricultural Report, Bengal, 1886-87.)

h appears probable that the anticipation in the last paragraph will prove correct. The growth of Nankin cotton in several districts of Bengal is not unknown. Cotton of the natural khaki colour is grown extensively in some districts of the Patna Division. In 1883 khakicoloured cotton seed was obtained from the Government Experimental Farm at Cawnpore and distributed to the Commissioners of Burdwan, Chittagong, Bhagulpore, Orissa, and Chutia Nagpur for experiment in their respective divisions. The results of the trials reported by them were not very promising. Thus in the report on the trials in Manbhoom it is stated that "Dr. H. W. Hill sowed broadcast the pound of seed received by him. Only a small portion germinated, and the cotton produced was of small quantity and of a brownish red colour. Dr. Hill thinks that the *khaki* cotton is a hybrid between Gossypium herbaceum and G. barbadense.* He says that a species of this plant, if not indigenous, is cultivated to some extent in parts of Patkom and Burrabhoom, chiefly by the Sonthals, who call it *khuruah kapas*, in contradistinction to huraivah kapas, or white cotton. The colour of this khuruah kapas is of a much lighter shade than that of the *khaki* cotton experimented on, and the Sonthals spin and weave it into a sort of coarse cloth. TI 3 species found in the district is considered by Dr, Hill to be a hy jrid of Gossypium herbaceum. "t In the [report from the Commissioner of the Orissa Division, it is stated that the khaki-coloured cotton is liable to hybridise, which, to a great extent, destroys the uniformity of .the colour. In the agricultural report for 1887-88, Nankin is said to have yielded 594ft per acre, Lonacinu, 270ft, Upland 135, and New Orleans 162.

SOILS AND METHOD OF CULTIVATION.—The following information is chiefly extracted from the report on cotton published by the Bengal Government in 1876:-

I. RAJSHAHYE AND KUCH BEHAR DIVISION.—The cotton plant is found within the following four districts of this division—Rajshahve, Bogra, Julpigorf, and Darjeeling, but can be said to be cultivated only within the two last-named districts.

In the Darjeeling district, the cultivation is almost entirely confined to the Terai at the foot of the hills, where the cultivators are the Mechis and Dhimals, who inhabit the jungle tracts near Nuksurbari, Adulpore, 'Kyna-noka, and Champasari, and also the country west of the Teesta and north of the Julpigorf district. Virgin soil, or, at the least, land for the most part with jungle growth, is selected, of sufficient elevation to secure natural drainage. The land is prepared from February to April,

(Watt & Murray.) GOSSYPIUM.

The chief cottons of Sarun are known locally as— I, Bhagtha; 2, Bho- [CULTIVATION] *chri*; 3, *Jathua*; and 4, *Kockti*. The first three forms are called collectively *Bysakhi*, being harvested in *Bysakh* (April), the fourth is called *Bhadoi*, being harvested in *Bhado* (August). The latter is sown in January In BENGAL. *Bhadoi*, being harvested in *Bhado* (August). The latter is sown in January and February, the first three in June and July. It seems probable that the crops reaped in the hot weather are approximately typical forms of G. **neg-lectum**, *Tod.*, the others conditions of the hybrid which yields the com-mercial "*Bengals.*" In Gya three kinds are distinguished, *viz, braisa* or *bung a, rerhia*, and *bhochri*, of which the first is the most valuable, but the second most grown, since it yields a greater outturn. Two forms chiefly are grown in Mozufferpore known as *bhogla* and *bhochri*, the former of which is the better. An exotic called *belati* (possibly Peruvian cotton) is also grown, to some extent, round houses. In Durbhanga very little is grown. The cro^Trecorded is of three kinds, *kockti, bhoera*, and *bhogla*. Of these, the first is very much prized as the cloth prepared from its floss is very lasting. Conf. with pp. 10-12. first is very much prized, as the cloth prepared from its floss is very lasting. It is sown twice a year, first in October to November, second in February and March. The first crop is uncertain, the second seldom fails.

The authors find it impossible to relegate all the forms distinguished by the above vernacular names to their respective species, varieties or hybrids; they have, however, mentioned them in the hope that some or all may be collected and botanically identified.

V. BHAGULPORE DIVISION.—In this division cotton is generally grown either with other crops, or on the boundaries of fields, as a hedge. It is never irrigated. In the Sonthal Pergunnahs it is grown on second class upland soil in company with *serguja* or *til*. The samples from this division seen by us are G. neglectum, Tod.

VI. ORISSA DIVISION -In the Cuitack district two sorts of cotton are grown, locally distinguished as achua and haldia. The former is preferred to the latter, as it contains a greater amount of fibre in proportion to the seeds, and the staple is finer, softer, and more glossy achua is growp c? lower lying ground, a small part of the area being irrigated. *Haldia* is cultivated on higher lands near dwellings. The latter is probably G. aeg-Iectum,7W., the former a condition of G. herbaceum. Small quantities are annually raised in Pufi* and Balasore, but neither of these districts is of sufficient importance to call for description.

VII. CHUTIA NAGPUR DIVISION.—Cotton cultivation is not carried on on an extensive scale in any part of this division. The people generally grow it in small patches in their baree or homestead lands, or in the jungles on variable areas only partially cleared. Many villages and tracts lying on the borders of rivers possess very fine alluvial soil which probably (with irrigation) would yield very fine crops. But the people do not care to grow cotton as a staple of trade, preferring those crops, such as cereals, which give them least trouble.

The principal cotton-growing district of the division is Palamow. In Chutia Nagpur proper, the most important cotton cultivating locality is Biru, where the staple forms one of the main sources of income to the people. In the Sili and Tamar pergunnahs to the south-east of the district, a large quantity of the better class of irrigated cotton is produced.

In Hazaribagh, Singhboom, and Manbhoom the outturn of cotton is small, and is entirely used for home consumption. Specimens seen by the authors from the last-mentioned district belong to G. neglectum, *Tod.* (see p. 8).

SEASONS OF SOWING AND REAPING.—The-information given below of the time when cotton is sown and pickeS is taken from the report by

|                                           | <ul> <li>YIELD PER ACRB.—According to agricultural returns the average yield all over the presidency is Gift per acre. The returns for various districts, however, show great differences. Thus, in Mymensingh, the outturn is put as high as 476<sup>o</sup> per acre; in theChittagong Hill Tracts it is said to be 200lb; in Midnapore, 144ft; <sup>m</sup> Manbhoom, 90ft; in Cuttack, 70S); in Lohardugga, 56ft; in Durbhunga, 30ft; and in Sarun, only 20 to 24ft per acre.</li> <li>It is difficult to explain why such great variation in yield should exist in neighbouring districts, in which the method of cultivation and soil do not necessarily greatly differ. At the best, however, the figures are only approximations, and must at present be accepted for want of better.</li> <li>For the yield of various races experimentally grown in the Burdwan Raj Experimental Station in 1886-87, see p. 134.</li> <li>COST AND PROFIT OF CULTIVATION.—In the Bengal Government Report already referred to, the cost of cultivation, and selling price of cleaned cotton per cwt., is given for three districts as follows :—</li> </ul> |                                                                                                                                                                                                                            |                                                                                                        |                                                                                                                                                                                                                  |                                                                                                               |  |  |  |  |

#### (Watt & Murray) GOSSYPIUM.

from Madras; 4,029 cwt. were also imported by trans-frontier routes from CULTIVATION Nepal and Sikkim.

The total exports from the province were 123,317 cwt., of which 120,219 cwt. went to Calcutta, 152 cwt. to the North-West Provinces and Oudh, 80 cwt. to Assam, 7 cwt. to the Panjab, I cwt. to the Central Provinces, 7 cwt. to British Burma, and 2,842 cwt. by frontier routes to Nepal and Sikkim.

The above figures have been derived from the rail and river statistics published by the Revenue and Agricultural Department, and from the Bengat statement of Sea-borne Trade and Navigation, and, consequently, do not include road traffic. The exports from Bengal to Calcutta are mostly from Dacca and the other parts of Eastern Bengal. Details of the propor^ons contributed by the principal districts for the past three years are given below :—

The above figures to some extent include road returns which have not been embraced by the foregoing statement. From the table it will be se<sup>n</sup> that exports from Bengal to its chief town are gradually increasing, the increase being most marked in the case of Dacca and Chittagong. It is difficult to determine how much of the increase in the case of the former is dependent on re-exports of cotton imported from other provinces, and railed to Calcutta. In the case of Chittagong the increase is probably due to an extension of cultivation and increase of outturn in the Chittagong Hill Tracts.

REVIEW OF THE AREA, &C.—Owing to the absence of an establishment for registering agricultural statistics over the greater part of the province, it is almost impossible to frame an accurate estimate of the area under a particular crop. This difficulty is said by Mr. Darrah, the Director of Land Records and Agriculture in Assam, to be particularly intricate in the jcase of cotton, a crop which is almost unknown in the plains of the Assam Valley where alone the rudiments of a registering system are to be found. In the hill districts, on the other hand, where no such system of any kind exists, the crop is a very important one. The figures given below are, therefore, at the best only fair approximations to the actual state of affairs. The total area under cotton in Assam during the year 1888-89 <sup>w a s</sup> returned as 40,588 acres. The total outturn in the same year was 54,359 <sup>c</sup>wt<sub>></sub> giving the high average yield of 150ft per acre. Deducting the net export from the total outturn the amount available for local consumption is seen to have

| CULTIVATION<br>ASSAM.<br>Area. | been 28,593 cwt. This, divided by the population, gives the consumption of<br>home-grown cleaned cotton at o*67ft per head. The Director of Land<br>Records and Agriculture, commenting on this figure, remarks, "At first<br>sight the figures, thus obtained, appear ludicrously wrong. But, though I<br>do not contend that they can be trusted, or even that they possess any<br>value, I would submit that they are not so absurd as thev seem at first<br>sight to be. A very large proportion of the population in Assam wears no<br>indigenous cotton whatever—traders, officials or all ranks, tea planters, es-<br>tablishments, garden coolies, pleaders, priests and their disciples, well-to-do<br>Assamese, and, in fact, all but the very poorest classes, probably nevSr use<br>indigenous cotton at all. Silk is largely worn by all respectable Assamese,<br>and, if cotton cloths are required, they are usually of English make. Indi-<br>genous (Assam grown) cotton is probably in little demand, except ar'ongst<br>the hill tribes who mainly grow it." In the same report the average con-<br>sumption per head in the Giro Hills is stated to be 3* 17ft, in Cachar<br>2*64, while in Nowgong it is returned as only 0*2lib.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |  |  |  |
| Districts.<br>207              | Districts of the province may be learned as only 0°210.<br>Districts of the province may be learned by the following extract from the Monograph on Cotton in Assam, written, in 1885, by the Director of Land Records and Agriculture:—<br>I. Assam Valley.—'' In the plains patches of cotton are met with here and there. The Miris of Lakhimpur and Sibsagar grow a little for their own domestic consumption. In some mauzas of the northern frontier the cultivation of cotton on the lower slopes of the Bhutfn hills, and in the light soil at their foot, used once to be carried on extensively. It was known as gari cultivation, and the Chaqaguri mauza in Kamrup was once famous for it. In the Godlpara district some cotton is grown in the hilly portions of the Sidli and Bijni parganas. In Kamrup <i>jliuming</i> (removing jungle for purposes of cultivation) is carried on for cotton to a limited exten on that portion of the Khasia hills which is included within the district th'^only district in the Assam valley which grows cotton largely is Now grong. The exception is due to the fact that the range of the Mikir hill is included within its boundary. The Mikirs grow cotton, not only fo domestic consumption, but also for export, and boat-loads of it may b seen going down the Kopili and Kollong towards the close of the cole weather."<br>II. Surmą Volley.—"Similarly, in the Surma valley, cotton is only occa sionally cultivated in the plains districts. The Mikirs andTipperas grow some by <i>jhtiming</i> in pergunnah Mulagul in Sylhet. About 50 acres ar supposed to be under cotton in Cachar is high, but that is because the district in Cultivation in the Plains,—" Altogether, however, the cultivation of the Cathar Asism range. Here cotton is largely grown for export as well as for local consumption, by hill Cacharis, Nag-as, an Kukis. The Sadr sub-division grows but little cotton."<br>III. Cultivation in the Plains,—" Altogether, however, the cultivation of cotton in the plains districts of Assam is, with the exception of that i Nowgong and the North Cachar Hi |  |  |  |  |  |  |

climate is too cold. The Giros grow it in very large quantities. The CULTIVATION inhabitants of the Khasia and Jaintia Hills carry down hundreds of maunds every year to Kámrup and Nowgong. The Ndgás (Lhotas and Rengmas) export partly to Nowgong, but principally to Sibsagar."

As already stated the figures of outturn and area in the hill districts of Assam are based on calculations which are open to grave error. They have been arrived at as follows:-"The usual system has been to ascertain, by enquiries at the various submontane fairs, the quantity that has been exported in a given year. An addition is made for the amount taken out of the country by traders who do not visit the fairs, and also for the amount believed to be locally consumed. The result gives the probable quantity produced. This is divided by the assumed outturn per acre, and an estimate of the area is thus found."

BV calculations carried out on this plan in the case of the hill districts, and by the imperfect system of registration in the case of the plains, the following figures have been arrived at for the year I888-89 :--

| DISTRICT.                                                                                                                         |                   |   |   |   |   |     |  |                 | Area under<br>Cotton.                                                                                        | Total outturn<br>of cleaned<br>Cotton.                                                                                    |  |

RACES OF CoTTON.—Mr. Darrah, in the report above quoted, writes as follows :---'' The varieties of cotton are not numerous, but the names by which the crop is known differ from district to district, and peculiarities of soil, climate, and method of cultivation, have no doubt produced divergences from the original type. It is not easy, therefore, to say exactly how many really different kinds there are. Roughly speaking, there are two well-marked forms :---

"(1) The large-boiled high growing cotton, known as dhal (white flowers) in Lakhimpur, as bogakapdh in the Majuli, as khungi deva in Cachar, as kil in the Garo hills, and as borkapdh (lit. % large cotton) in Nowgong. This is probably also the same as the bhugai of Sylhet. In Nowgong, this species is grown on level ground, has a smaller number of seeds than the second variety (mentioned below), can be ginned more easily, can be plucked twice a year instead of once, and bears for three seasons. The kil of the Garo hills is very nearly the same, except that the crop is annual, that it is grown everywhere on the hill-sides, and not confined to level ground, and that it can only be plucked once a year. The pods are very large, sometimes as much as eight inches in length, and when they burst the contents come out in a cataract of cotton which gives a field the appearance of being covered with snow. This variety is, however, not as much in request for ordinary purposes as the smaller kind. The fibre is Races. 208

in ASSAM. Districts.

| GOSSYPIUM                                              | 1. Cotton Cultivation in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CULTIVATION<br>in<br>ASSAM.<br>Races.<br>Soils.<br>209 | said by the trade to be harsh and to twist badly. It is better adapted for mixing with wool than for any other purpose.<br>"(2) The small, round-boiled species, known as <i>shet</i> (reddish flowers) in Lakhimpur, as <i>thumsa</i> in Cachar, as <i>ukynphdd</i> in the Jaintia hills, and as <i>horu kapdh</i> ( <i>ii.</i> , small cotton) in Nowgong possibly identical also with the chotsd of the Angdmi Nagas. This species is sown annually, and can only be plucked once a year. The Lakhimpur variety has pale reddish flowers. That grown in the Jaintia hills is said to be the best cotton produced in the province. Its thread can be more closely woven than that of other kinds. The N£ga hills variety is rated lowest of all, being very short in the staple and coming into the market in a very dirty condition, " There is a pale <i>khaki</i> variety in Cachar and Manipur known as <i>khungdjas</i> in the former and as <i>tissing anguangba</i> in the latter district, The pods are not a uniform <i>khaki</i> , but contain a few white threads here and there." It is difficult to determine to what species all the above mentioned kinde belong. The large boiled, high grown cotton, however, is in most cases probably G. neglectum, <i>Tod</i> .; in the case of the Garo hill cotton it certainly is so. Specimens which have been seen by the authors are perfect types of that species, and have the very large ovoid bolls referred to by Mr. Darrah. The statement that the cotton of Lakhimpur ( <i>dhdl</i> ) has white flowers is curious, and would suggest its being a form of G. neglectum <i>var</i> . Otusifolium; the small cottons of Cachar, and Nowgong are probably also forms of G. herbaceum or G. Wightianum, <i>Tod</i> .*" Weile the <i>shet</i> of Lakhimpur would appear, from its reddish flowers, to be: small round-boiled form of G. arborum or G. Augent, the anture or soil, methods of cultivation, cleaning, &c., to Mr. Darrah the difficulty is greater. The <i>chotsd</i> of the Angámi Nágas is undoubtedly G. herbaceum for a distribution of G. arborum or G. Wightianum, <i>Tod</i> .*" Weile the <i>shet</i> of Lakhimpur would appear, from its |
| Methods.<br>210                                        | when they can. The soil should be calcareous, and the situation sunny. I<br>the Garo hills a species of small bamboo grows with great luxuriance, an<br>the soil on which it is found is invariably selected, if the other condition<br>for cultivation are favourable. No manure is ever used, except the ashe<br>of the burnt jungle. One reason why the bamboo is so appreciated by the<br>Garos is that it burns with much more completeness than tree jungle <sup>^</sup> an<br>therefore affords better manure."<br>METHOD OF CULTIVATION.—HOEING.—"Land is never ploughed for<br>cotton, except in the few places where it is grown in the plains. In they<br>the ground is ploughed three or four times, and then hoed once, the latter<br>process being considered indispensable in Mangaldai. A trench for drain<br>age is usually dug round the plot. The hill-men always use the hoe, as the<br>slopes on which cotton is grown are too steep for cattle to be employee<br>Moreover, between the stumps of trees and the half-burned logs whic<br>G. 210                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| • · · · · · · · · · · · · · · · · · · ·                                                                                                                         |             |

| Assam, (Watt & Murray.) GC                                                                                                                                      | <u> </u>    |
| often litter the ground, a plough could not be worked. The Nagas generally                                                                                      | CULTIVATION |
| give two hoeings, the Tipperahs and Garos none at all. The other tribes                                                                                         | ASSAM.      |
| generally hoe once. The jungle is usually cut in the cold weather and al-<br>lowed to dry on the ground. It is burnt in March or April, and then, as a          | Methods*    |
| rule, hoed. As soon as possible afterwards the cotton is sown. It is scattered                                                                                  | }           |
| broadcast generally, not put down in drills. The Tipperahs and Garos                                                                                            |             |
| have a different custom. After the burning is finished, they go over the land with a pointed stick, and making small holes in the ashes drop a seed             |             |
| into each. In Cachar a similar process is employed, the seed being dibbled                                                                                      |             |
| in with a pointed stick called <i>kuar</i> . In the first year only one kind of                                                                                 |             |
| seed is placed in each hole. The soil is not further disturbed. It is ferti-                                                                                    |             |
| lised by the ashes on the first shower of rain. If the rain is delayed, the valiy? of the ashes, as a fertiliser, diminishes considerably."                     |             |
| ASSOCIATED CROPS.—" The associated crops are usually broadcast rice                                                                                             | Associated  |
| and <i>til</i> . But some forms, <i>e.g.</i> , <i>thumsd</i> of Cachar, are always sown                                                                         | Crops.      |
| alone. The other varieties are also sometimes sown alone; but, as a general                                                                                     | 211         |
| rule, other crops are mixed with cotton,—mustard, Indian-corn, chillies, brinjals, linseed, jute, water-melons, are all used according to the wishes or         | •           |
| convenience of the cultivator. But <i>dhu dhdn</i> (unirrigated, broadcast rice)                                                                                |             |
| is the most commonly associated crop. In the Giro hills, the usual practice                                                                                     | 1           |
| is for <i>dhu dhdn</i> to be sown broadcast the day after the fire. When the shoots show themselves above ground, the vacant spaces become apparent,            | •           |
| and these are sown with cotton in the manner already described. The                                                                                             |             |
| Rengma Nagas sow the cotton broadcast, with <i>dhu dhdn</i> , the cotton seeds                                                                                  | l'          |
| and the <i>dhdn</i> being mixed up in the same basket. The reason for asso-                                                                                     |             |
| ciating a second crop with cotton is said to be that the latter always grows best if shaded in the beginning."                                                  | 1           |
| OCCUPANCY.—"A jungle-clearing is rarely cropped for more than one                                                                                               | Occupancy.  |
| season with cotton. In the second year upland rice is often sown alone,                                                                                         | 212         |
| and when the crop has been gathered the <i>jhum</i> is usually abandoned. If                                                                                    |             |
| there is suitable land available in reasonable quantities, the clearing !s not<br>resumed for ten years. In no case is it re-occupied until at least five years | ļ '         |
| have elapsed. No rotation of crops is ever observed. In Cachar in the                                                                                           |             |
| second year the paddy straw of the previous year is burnt off, and the                                                                                          | l.          |
| land having been cleaned and turned over with the <i>kuar</i> , rice and <b>seea</b> -<br>mum mixed are sown broadcast. A few days later Indian-corn and cotton | -           |
| mixed with earth are sown, and the ground is kept weeded till August.                                                                                           |             |
| The Indian-corn ripens in July, the rice in August, the sesamum in Nov-                                                                                         | 1           |
| ember, but the cotton not till December. A similar course is followed in                                                                                        |             |
| the third year, and in the fourth the land is abandoned. The Angami                                                                                             |             |
| Nagas, however, frequently crop a clearing with cotton for two or three years, according to the richness of the soil. The variety of <i>dhu dhdn</i>            |             |
| known as <i>tidi</i> is generally sown by them the first year, while in the second                                                                              |             |
| year the kind called <i>teke</i> is usually planted. The Rengma and Lhota                                                                                       | 1           |
| Nagas, who are the principal cultivators of cotton in the Naga hills, never crop a clearing with cotton for two successive years."                              |             |
| IRRIGATION AND WEEDING.—" Irrigation is hardly ever practised,                                                                                                  | Irrigation. |
| ^though occasionally required. The land is usually weeded once or twice,                                                                                        | 213         |

Plucking. 214

<sup>^</sup>Though occasionally required. The land is usually weeded once or twice, rarely oftener. When the crop germinates, sacrifices of eggs are offered by the Mikirs to the god Longlo Ahi. Similar ceremonies take place when the plucking begins."
 PLUCKING.—" Plucking generally begins about November. It is usually over in January. *Kunghideva* is plucked from time to time as the pods open and burst. With *thumsa* the plucking is usually made once for all. The *borkapdh* of Nowgong is plucked twice—once in December and January, when the crop is called *bataria kapdh*, and once in May, when the land is usually made once for all.

the ordinary native cotton gin, repeated experiments have given the out-turn as 17,174, and 18 seers to the maund, whereas the proportion assumed above is only 16 seers to the maund. The Deputy Commissioner of the Garo hills, experimenting with an English ginning machine, gives 20 seers to the maund as the correct proportion. On the other hand, experiments

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | • Assam.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | (Watt & Murray)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | GOSSYPIUM                                                                                                                                                                                                             |

"After being cleaned, the cotton is subjected to a process of beating (*dhuna*) by means of a bow-string, in order that the fibres may separate and become loose enough to be spun into thread. The bow (*dhanu*) is usually a piece of bamboo, about three feet long; the string *{jar*} consisting of a twisted strip of the outside of the midrib of a plantain leaf. The bow is usually held so that the string may touch the cotton. The string is pulled and let go, and the vibration separates the fibres. The principle is precisely the same as that used in most parts of India."

is precisely the same as that used in most parts of India." "There is no special caste in the province, like the *Dhunta* of the Worth-Western Provinces and the *Pinja* of the Panjab, whose occupation it is to pifepare cotton for spinning in the manner described. Each household scutches, if the process may be so called, as much cotton as it requires for its own purposes."

Nearly all the cotton exported from Assam is uncleaned, probably owing to two reasons :—(1) that local labour is too dear; (2) that the seed is of much more value in Calcutta than it is in Assam. In any case the fact is certain that cleaning cotton for export with the native hand-gin does not pay. With the European machine gin, however, the case is differ-

| GOSSYPIUN                                | A. Cotton Cultivation in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| CULTIVATION<br>in<br>ASSAM.<br>Gleaning. | ent. Mr. Darrah states that in 1885-86 there were two working European gins in the province—one at Tura in the Garo hills, the other at Doboka in Nowgong, each admirably placed for working the cotton of the Garo and Mikir hills, respectively. The machines have been found capable of turning out one maund of cleaned cotton a day, each realising a daily profit of $\mathbf{R5}$ -                                                                                                                                                                             |
| Packing                                  | Reports from Calcutta, however, tend to shew that, though the Emery<br>gin may be worked profitably, the fibre is considerably diminished in value<br>by its action. Thus, in one case a bale of hand-ginned cotton was found<br>to be worth R21 per maund, while the same fibre, saw-ginned, was valued<br>at only R16.                                                                                                                                                                                                                                               |
| Packing.<br>218                          | PACKING.—Assam cotton is not, as a rule, made up into the heavy half-<br>compressed bales commonly met with in other parts of India, but is pack-<br>ed either in conical baskets or in small bales for transportation by^coolies.<br>The former are packed as follows:—" The basket having been lined with<br>leaves of the <i>tar a</i> plant is placed upright in a hole in the ground. One man<br>fills it with cotton, while another treads down the fibre. When filled, some<br>leaves of the <i>targ</i> are placed on the top, and the whole firmly bound down |
| Trade.<br>219                            | leaves of the <i>tara</i> are placed on the top, and the whole firmly bound down<br>with strips of bark or cane. A basket thus packed is called <i>dang</i> , by the<br>Mikirs, and usually weighs half a maund." In the plains instead of these,<br><i>dangs</i> the small bales above alluded to are generally made. They are sus-<br>pended to the ends of a stout bamboo which is borne on the shoulder.<br>ANALYSIS OF THE TRADE.—I. INTER-DISTRICT TRADE.—"The trade in<br>cottop is partly inter district and partly provincial. The registration of the        |
|                                          | cotton is partly inter-district and partly provincial. The registration of the former is carried on at a few police-stations, but no attempts nave as yet been made to summarise or elucidate the figures. The registration is really too partial to throw much light on the character of the trade. It is known, however, that the plains districts purchase largely for local consumption at the marts at the foot of the hills. The Garo hills supply God)para and parts of                                                                                         |
|                                          | Sylhet. The Jaintia and Lower Khasia hills meet the wants of South Kdm-<br>st.rup and North Sylhet. Jaintia Hills cotton also goes down to Nowgong and<br>parts of Sylhet. Darrang is supplied, like the greater part of Nowgong<br>itself, by the Mikirs. North Cachar cotton goes into Nowgong by the<br>Doyang and Kopili, and also into the plains of Cachar. The Naga hills<br>export to Sibsagar and parts of Lakhimpur. In all these transactions-                                                                                                              |
|                                          | human beings are the beasts of burden, except when boats are used. Pack-<br>bullocks are unknown, and ponies are not used for the purpose. The hill-<br>men carry down the fibre, nearly always uncleaned, in conical bamboo<br>baskets, which they support by a plaited cane strap across the forehead,<br>partly on their heads and partly on their shoulders." "The plains people                                                                                                                                                                                   |
|                                          | carry cotton in small bales suspended to the ends of a stout bamboo<br>which is borne on the shoulder. Boats are used when the trade route<br>coincides with a river, and considerable quantities are floated down to<br>the more important riverine marts. Wheeled carriage is absolutely un-<br>known, and long strings of camels, laden with heavy, half-compressed<br>bales, such as are so Frequently met with in the cotton districts of Upper                                                                                                                   |
|                                          | India, are never seen in Assam."<br>II. EXTERNAL TRADE.—"The export trade by boat is registered at<br>Dhubri for the Brahmaputra, and at Bhairab Bazar for the Surma vqiley.<br>The steamer traffic, which is inconsiderable, is known from the returns fur-<br>nished by the steamer companies."<br>In the year under consideration the total exports amounted to 20,4 <sup>^</sup>                                                                                                                                                                                   |

REVIEW OP AREA, &c.-The average area, for the five years ending 1886-87 was 29,814 acres; and the outturn during the same period 11,459 cwt.; the average yield would.*too*, have  $taff| \ll IPJ \land e^{-c}$ . The total outturn is insufficient for local  $\land h \ll H$  and  $J \land J \land L \land \land$  by rail, the latter to I,120 cwt.; considerably greater quantities, however,

are probably imported by road. n/u,ertrp arp nmba-

RACES OF CoxTON.-The ordinary native cottons of M y w « p r oatrad bly similar to those of Madras, «\*., forms of G. W «  $^{\circ}$  « \*\*  $^{\circ}$  t on s of G. herbaccum, J, obtusifolium, and G.  $MZ^{I**TM}$ .  $^{U^{\circ}}$ ?TM $^{0^{\circ}}$ 

Numerous experiments have been made at Bangalore to test: the suitability of the soil and climate of that district for exotic cottons, with the result that Upland Georgian, Sea Island, New Orleans, and Egyptian were all found to do well. None of these have gained, however, any hold on the cultivation of the State, \* Ј гтмгм

SOILS AND METHOD OF CULTIVATION.—The following IS extract^ Irom the Gazetteer of Mysore and Coorg, Vol. /..-"The soil on which cotton is sown at Sira is a black clay containing nodules of limestone, in me two months following the vernal equinox, plough three times: At any convenient time, ia the next two months, mix the seed with dung, ana drop it in the furrows after the plough, forming lines about nine inches apart. A month afterwards plough again between the lines1; and in oraer to destroy the superfluous plants and weeds, use the hot drawn by oxen three times, crossing these furrows at right angles. The second and third times that this hoe is used it must follow the same track as at first; otherwise too many of the plants would be destroyed. Between each hoeing three or four days should intervene. In six months the coffice begins to produce ripe capsules, and continues in crop four more. Tn plants are then cut close to the ground, and after the next rainy season the field is ploughed twice in contrary directions. A month afterwards it is hoed once or twice with the same implement, and it produces a crop twice as great as it did the first year. In the third year a crop of *same* or *navane* (Panicum frumentaceum and Setaria italica) must be taken, and in the fourth year cotton is again sown as at first. The principal crop in the fine country towards Narsipur and Talkad is cotton, which iL this locality is never raised in soil that contains calcareous nodules. The black soil that is free from lime is divided into three qualities. The first gives annually two crops, one *oijola* " (Sorghum vulgare, a name also used for Zea Mays) «' and one of cotton ; the two inferior qualities produce cotton only. Cotton is raised towards Harihar entirely on black soil, and is either sown as a crop by itself, or drilled in the rows of a *navane* field. In the former case two crops of cotton cannot follow each other, but one crop *oiiola* at least must intervene. In the second month after the vernal equinox, the field is ploughed once, then manured, then hoed with the *heg kunte*, until the sowing season in the month preceding the autumnal equinox. 1 he seed is sown by a drill having only two bills, behind each of which is fixed a sharp-pointed bamboo, through which a man drops the seed; so that each drill requires the attendance of three men and two oxen. The seed, in order to allow it to run through the bamboo, is first dipt in cow-dung and water, and then mixed with some earth. Twenty days after sowing, and also on the thirty-fifth and fiftieth days, the field is hoed with the edde kunte. The crop season is during the month before and that after the vernal equinox.

**CLEANING.**—The floss is cleaned by means of a rude native gin or *charka* G. 224 10 A

| Trade.<br>225            | ANALYSIS OF THE TRADE.—The railway-borne trade in cotton is very insignificant, and probably represents, but very imperfectly, the total traffic, most of which must be by road. In the year under consideration (1888-89) the exports by rail amounted to 1,120 cwt., of which 1,024 cwt. went to Madras seaports, 60 cwt. to the presidency, 35 cwt. to Bombay, and 1 cwt. to Bengal. The imports were larger, amounting to 3,159 cwt., of which 3,043 cwt. came from Madras, 104. cwt. from the sea-ports of that presidency, 9 cwt. from Bombay, and 3 cwt. from Bombay town.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                          | 13. <b>BURMA.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| LOWER<br>BURMA.<br>226   | <b>I. LOWER BURMA</b> —It is necessary in this article to consider Lower and Upper Burma separately, since no accurate statistics are available for                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Area.                    | area, outturn, or trade in the case of the latter.<br>REVIEW OF AREA, &c—Cotton cultivation has greatly fallen off in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 227                      | Lower Burma, notwithstanding the fact that the more inland districts<br>possess soil and climate apparently well suited to the plant. In fact, in<br>former times, cotton was largely cultivated in these districts. A consider-<br>able quantity was at one time exported from the Tharawaddy and Prome<br>districts by Arakan to Dacca, where it was used in the manufacture of the<br><b>fine muslins of that place.</b> In the Journal of the Agri-Horticultural<br>Society of India, Vol. XL, 584, it is stated that, " The species of cotton is still                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                          | <sup>^</sup> Jthe green seed variety and requiring from seven to nine months from the<br>sowing of the seed until the crop arrives at maturity. The staple is of a<br>peculiarly soft and rich appearance, and even now nearly the whole pro-<br>duce is exported to Tinian for the Chinese market." Now-a-days, however,<br>the crop is an extremely unimportant one, and the produce is used almost<br>exclusively for home consumption. During the five years ending 1885-86                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Methods.<br>228          | the average area under the crop was 11,500 acres, while in 1888-89 it was<br>only 10,191 acres. The total outturn is said to have been 9,494 cwt. The<br>total imports were 55,295 cwt., the total exports 48,897 cwt, leaving a net<br>import of 6,398 cwt. This, when added to the outturn, gives a total of<br>15,892 cwt. as available for local consumption. Dividing this amount by<br>the population, 3,736,771, we obtain '47© per head of population as the<br>average annual consumption. This figure, however, is probably an un<br>der-estimate, since it appears likely that considerably more cotton may be<br>imported from Upper Burma than is shewn by the trade returns.<br>METHODS OF CULTIVATION.—Cotton is not grown to any extent as<br>field crop except in parts of the Sandoway and Amherst districts; else<br>where, as in the hilly tracts of Thayetmyo and Northern Arakan, it i<br>almost invariably grown mixed with other crops. Referring to the diminution in area, the Chief Commissioner in 1882-83 wrote as follows:—<br><sup>11</sup> The shrinkage of the area is most conspicuous in the Thayetmy |
|                          | district and appears to be due, in some measure at least, to the prefe<br>ence which the Burmese cultivator has for other crops, requiring less la<br>bour and trouble to produce, and to the cheapness of imported twist, which<br>in some parts of the country, is forcing the home produce out of the marker<br>altogether. In Kyaukpyu, for instance, no cotton whatever is now grown<br><b>G. 228</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

and in Arakan generally the home product is rarely brought to market or even disposed of locally in a cleaned state." Further particulars regarding cotton in Burma are given in the sub-

Further particulars regarding cotton in Burma are given in the subjoined extract from the *Lower Burma Gazetteer* published in 1880 {Vol. *L.*, 427):-

"Cótton is grown principally in hill-gardens, and in Thayet. In former years the Thayet produce was carried up-country and exported to Yunan, but the outbreak of the Panthay rebellion checked, if it did not altogether stop, trade by this route, and the price of rice in the husk rose so rapidly anid has continued so high, and the importation of cotton goods and of twist has been so large that there was little or no demand for the homegrown article, and the cultivation of rice has become far more profitable, ifor many years persevering efforts have teen made to introduce foreign cotton, especially Egyptian, Upland, Brazilian, and Carolina, which would give a longer staple, but these have been unsuccessful, not only for the reasons given above—of which undoubtedly the greater returns from rice, together with the large areas of rice land available on the easy terms on which land is granted are the most important—but also because the native plant is hardier and requires little care.

"The cotton grown in Upper Burma is still shorter-stapled than that grown here, and much of that imported uncleaned is taken to Prome, Allan-myo, and Kwa-toung, where are the principal cotton-ginning mills, and cleaned and mixed with Thayet and Prome cotton for export. The plants in British Burma are of two kinds—known to Burmans as the \* large ' and the 'early,' respectively, 'The early kind is a plant which does not grow more than three or four feet high and its bolls are ripe in December and January. The large kind reaches a height of from six to ten feet and its seed does not ripen till a month or two later. The produce of the two kinds is hardly distinguishable.' "

DISTRICTS — The following special report, communicated by the Government of Burma, shows the extent of cultivation in certain districts :\*-

<sup>"</sup> In the *Prome District* it is grown to a small extent.

In the *Sandoway District* there were 282 acres of ground under cotton cultivation during the past year, and the cotton produced is believed to be of the indigenous Asiatic kind. The cultivating season commences about October. The quality of cotton hitherto grown has been very poor.

In the Akyab District the area of ground under cotton cultivation is about 940 acres. The seeds are planted with other miscellaneous growths on the hill-side, about May. The cotton can be used about February. The cost is about R15 per acre, and the profit about R30. The hill-sides are cleared of jungle and the soil turned up with rude ploughs. The floss is employed in the manufacture of cloths, and wearing apparel, thread, &c, and the productton is worth about R30 per acre.

In the *Skwegyin District* it is grown in small quantities on the Karen hills, especially up Dondami Choung.

In the *Toungoo District* it is cultivated by Burmans and Shans to a moderate extent. There are two kinds, one with white and the other with yellow flowers. It is planted in May.

In the Amherst District it is grown on the banks of the Sal ween river from indigenous seed. The area under cultivation in 1887-88 was 556 acres. It is sown in September and October, and reaped in January and February. The seed is planted upon alluvial soil collected on the river banks during inundation. The produce is consumed locally in the native looms, and none is exported. The estimated outturn of clean cotton is about 1,430 cwt., and the retail price Ri-8 to R2 per viss."

| CULTIVATION<br>in<br>LOWER<br>BURMA.<br>Races. | from Lower Burma correspond with G. Wightianum, Tod. In 1882;83<br>experiments were made in the Arakan Hill Tracts and Sandoway with<br>seed of the Bamia and other Egyptian varieties of cotton (G. $\pounds V_{15}^{st}$ util $\pounds^{st}$ .<br>They were not, however, successful. In a report for 1868-69, published ov<br>the Cotton Commissioner for the Central Provinces and the Berars, it is<br>stated that a variety of Persian cotton closely allied to the Egyptian grows<br>exceedingly well about Rangoon at all seasons and yields a fine wnile<br>cotton of strong staple. A more recent allusion to this exotic cotton can-<br>not be discovered, though the subject is interesting. Mason, however,<br>states in his •• Burma and Its People," that Peruvian and Sea "Iana<br>cotton were at one time introduced experimentally, but that in Burrna, as<br>in most other parts of India, they appear to have taken little hold, But<br>it may be added that in 1831, Major Burney contributed to <i>tintAggi</i> .<br><i>Horticultural Society of India</i> , samples of Pernambuco cotton, called in<br>Burmese Shembanwa, or ship-cotton, which had been grown near Ava.<br>The plant he described as growing into a lofty tree as thick as the thigh,<br>yielding its cotton in February, March, and April (Trans., IL, 124).<br>Mr. Edward Riley, in a Paper on the Agricultural Capabilities of the<br>Province of Amherst (1838), refers to the same cotton as occurring in<br>the lower jungles in a state of acclimatisation. Commenting on this plant,<br>however, he admits that the attempt to introduce it as an agricultural<br>crop had failed, though he expresses the opinion that the failure was due<br>to a misjudgment of the kind of soil best suited to the crop. This is pro-<br>bably the cotton referred to, in the Note on Upper Burma, as having<br>been introduced by King Min Doon Min. In 1841 Dr <sub>6</sub> Wallich brought to<br>England samples of Martaban cotton collected from the Pernambuco stock.<br>The floss was pronounced inferior to none, either in the quality of its staple<br>or the ease with which it could be separated from the seed. | Trade.<br><b>Z'31</b>                          | ,,f. ANALYSIS OF THE TRADE.—In the <i>Provincial Cotton Report for 1882-83</i> , if-is stated that none of the cotton grown in Lower Burma is exported from the Province, an assertion that would appear to be confirmed by the relation between the imports and exports. The land trade in cotton is wholly confined to imports by river and overland from Upper Burma. The greater part of the exports by sea is shipped to China, either direct                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| UPPER<br>BURMA.<br><b>232</b>                  | or through the Straits Settlements.<br>II. UPPER BURMA—Trustworthy cotton statistics are not available re-<br>garding the area, outturn, and trade of Upper Burma, as a whole. The<br>following valuable reports by the Deputy Commissioner of Meiktila, and<br>from other districts, however, are sufficient to shew that cotton cultivation<br>exists, to a considerable extent, at least in certain tracts, and is probably<br>capable of extension:—<br>"Cotton is grown to a considerable extent in the Mahlaing sub-divi-<br>sion—in fact it may be said to be the staple product. In other parts of the<br>district it is grown to a small extent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Raees.<br>233<br>Area.                         | RACES.—There are three forms of cotton grown here, $viz$ :—(1), $v/a$ -gyt <sup>*</sup><br>(2), wa-galé, and (3),/>*'««*'. The flowers of 1 and 2 are white, whilst that of<br>3 is red; 1 and 2 produce the pure white cotton, whilst 3 produces *>nly<br>cotton of a light brown tint, which eventually develops into a colour similar<br>to <sup>the</sup> ordinary dark <i>khaki</i> . American cotton seed was introduced by<br>King Min Doon Min, but in this part it has turned out a failure. The ori-<br>SI!fi <sup>See</sup> f 1 <sup>1</sup> d well> but xt, failed to acclimatise. Subsequent seed deterio-<br>rated and the cultivators ceased to plant it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 234                                            | AREA UNDER CROP.—It is a difficult matter to estimate the area at<br>nt unaer cultivation, but in Mahlaing it is stated at 30,000 pes (1 pte=<br>77 acres), and mthe other parts of the district at 5,000. Taking ape<br>G, 234                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Trade.                            | " In the <i>Bhamo District</i> the plant grown has 3 to 5-lobed leaves (small), with a flower usually whitish, often yellow, and sometimes pale pink, it is grown pretty extensively."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 242                               | ANALYSIS OP THE TRADE.—NO statistics of the cotton trade of ${}^{II}PP \oplus^{r}$<br>Burma are available. A large proportion of the exported produce of the<br>lower districts is imported into Lower Burma, either for use there, or tor<br>transmission to Rangoon. It is believed that a great part of the produce<br>of the upper districts are exported trans-frontier to China. In the $A^{ru^{m}}$<br><i>Horticultural Society of India Journal (Old Series), XL, 584, it IS</i><br>stated that, " according to the records of the old Burmese customs, the ex-<br>ports at one time reached the large amount of 30,000,0001b annually^ and,<br>in after years, the Resident at the Court of Ava, Colonel Burney, reported<br>that Burma exported to China fully 4,000,000a, and a like quantity <i>via</i> the<br>Arakan mountains, Chittagong, and Bengal."                         |

|                                   | that the soil and climate appeared to be well adapted for the growth of Sea<br>Island cotton, and that it would be well to try the experiment. Seed was<br>accordingly obtained and sown, together with that of what Colonel Man<br>calls the indigenous cotton. Both did well, but the American plants<br>were largely attacked by beetles and other insects. Samples of the "indi-<br>genous cotton " were subsequently forwarded to the Bombay Chamber of<br>Commerce and pronounced much superior to any grown in India, superior,<br>indeed, to any American race except the finest Sea Island. Its cotton                                                                                                                                                                                                                                                                               |
| a.                                | was found to greatly resemble Brazilian, having adherent seeds, and an excellent long, strong staple. Specimens of the plant were examined by Mr. C. B. Clarke, who pronounced them to be Gossypium acuminatum.<br>'Conf. with p. 23).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                   | Samples of both were afterwards sent to England, where they were<br>submitted for valuation to the Liverpool Cotton Brokers' Association, with<br>the result that the "wild " cotton was valued at <i>ud</i> . to <i>i2d</i> . per ft, the Sea<br>Island at <i>2od</i> . to 24 <sup>^</sup> . per ft. The latter was said to be very irregular in<br>staple; part of the sample was long and fine, worth from 33d. to 36c <sup>*</sup> . per ft<br>but other portions so much inferior that the whole would not fetch more<br>than $\langle 6d$ . to 19//. per ft.<br>In 1872 experiments were made with Hinganghat,Sea Island, Egyptian<br><i>Jari</i> , New Orleans, and Dharwar, but none of these, except perhaps the<br>form of G. barbadense found by Dr. Prain in the Andaman Islands ( <i>Conj</i><br><i>with p. 20</i> ) proved equal to the reputed native cotton above alluded to. |
| GINS ft<br>GINNING.<br><b>244</b> | GINS AND GINNING.<br>References.—Watson, Report on Cotton Gins, i87g; Agri-Hort. Soc. of<br>India, Transactions, V., 187 / VIII., 301; Journals (Old Series): If<br>Sel., 203; V., 83-100; VI., 222, proc, xx., xc; VII., 35, 189; VIII., 161<br>*74* '75f XIII., proc., xfoi. / XIV., proc, xv., hit.'<br>The methods of cleaning cotton in India, as will have been seen from<br>the above provincial reports, are primitive in the extreme. Indeed up to<br>twenty years ago mention is frequently made of cotton being picked by<br>hand, in which manner one woman could clean one to one-and-a-hal<br>pounds of fibre per day. In all the chief cotton-growing districts, how<br>ever, there have been in existence from time immemorial two simple form<br>of machine for the purpose, viz., the foot-roller and the churka. Of these<br>G <sub>1</sub> 244                            |

# **Gins and Ginning:**.

(Watt & Murray.) GOSSYPIUM?

the foot-roller is used only locally in a few places, and is alone adapted to the hard-seeded Indian cottons. By it the fibre is cleaned as follows :the cotton is spread over a smooth flat stone of from one to two feet square, sometimes square, sometimes round; an iron rod 18 inches long, thick in the centre, tapering towards the extremities, is placed on the stone, and rolled forwards and backwards by the feet of the worker. Sometimes the rod is shorter and slightly conical, in which case the motion is circular, round and round the stone. Under the combined influence of the rolling motion and the pressure of the feet, the seed is squeezed out and pushed <sup>a</sup>way in front of the roller, leaving the cleaned fibre behind. One worker can in this way turn out from four to six pounds of cleaned cotton in a day.

The usual implement employed, however, is a simple double roller machine called the *churka*. This has been already described (see pp. 94, 106, 123) and need not be further discussed. Suffice it to say, that the essential parts of the machine are two rollers, either both of wood, or one of wood and one of iron. To these a revolving motion towards each other is communicated by means of a crank or wheel at one or both ends. The effect is, that the cotton is presented at one side of the revolving<sup>1</sup> cylinders, and the fibre is drawn through and pulled off the seed, which is too large and hard to pass through. On an average the *churka* produces from six to eight pounds of clean cotton per day for each man or woman engaged in the work.

The common *churka* is evidently liable to many imperfections. The feeding being done by hand it is necessarily impossible to keep the whole length of the rollers constantly supplied, so that the machine is never worked up to its actual ginning power, though, at the same time, there is now and then in places such an excess of seed-cotton that the rollers become clogged. As a consequence of this clogging, the surface of the wooden roller or rollers is liable to become worn in lines or narrow grooves, which tend to diminish the girip of the rollers on the cotton and eventually allow seed to pass through into the heap of cleaned fibre. In the case c2 the Guzerat *churka*, which has one small iron and one large wooden roller, the surface velocities of the two are unequal, consequently the tuft of cotton is exposed to an injurious grinding action.

exposed to an injurious grinding action. The smooth and gentle working of the *churka* has suggested many mechanical adaptations of its principle, and numbers of roller gins have been constructed with the idea of preserving this gentle action, whilst increasing the outturn and diminishing the rapid wear of the rollers. "Im-proved mechanical feeding, arrangements for preventing the coiling of clean cotton round the roller, and contrivances for regulating the grip and the motion of the two rollers have been added to the simple native machine without, however, achieving any definite practical success." (*Watson.*) This being the case, attention was directed to American gins, which have now been largely introduced into the country. In the year 1792, Eli Whitney, an American, invented the saw-gin, a machine which, under various modifications, is still employed for cleaning the greater propor-tion of the cotton grown in the Southern States. It consists of a series of " saws " (in reality discs with hooked blunt teeth), revolving between the interstices of an iron bed which forms the base of a large box or hopper. The fibre is caught up by the hooks and pulled through the interstices, leaving the seeds behind. Since the fibre of certain of the long-stapled. cottons was found to be more or less cut, crushed, or broken by the action of the saw, a more recent American invention, the Macarthy gin, came largely into use for cleaning Sea Island, Egyptian, and Brazilian came largely into use for cleaning Sea Island, Egyptian, and Brazilian cotton. In this gin the fibre is drawn by a leather roller between a metal plate called the  $\leq$  doctor," fixed tangentially to the roller, and a blade

| <ul> <li>in 1829, when the Court of Directors stated that they had at several times sent different machines to India, with the hope of bettering the condition in which their cotton reached England, and amongst these "two of a Jiev instrument called Whitney's saw-gin." Other American gins had 10 merly been sent to India, and on one occasion under the charge of an American mechanic; two gins had also been made by Mr. Maudsley for the Company, but all alike had failed. Writing in 1839, the Court of Directors again state that the American machinery, which up to that time had been sent out to India, had not succeeded.</li> <li>Attention was consequently again directed towards improvements in the native churka, and in 1848 a Mr. Mather was employed by the Government of the North-West Provinces to improve that machine. He shortly afterwards exhibited a working model of an improved churka which obtained the approval of a committee. This body recommended that twelve similar instruments should be constructed. These were, ac cordingly, made in Calcutta, and in 1849 eleven were sent to Agra for trial In 1848, the Apri-Horicultural Society awarded a prize of KS00 to Mr Mather for this machine, and in 1849 orders were issued by Government to construct ninety-six such churkas, being eight sets of twelve each. If 1880, these were procured at a total cost olover R20,000, and twenty-nine were distributed. After this large expense had been incurred the machine "-xyere found to be inferior in every way to the native churka and turned ou less cotton for the power employed, and that too in a dirtier and less satis factory state. Finally, all were advertised for sale in Calcutta, and the 65 which had not been distributed, were sold by manual labour in Manchester and reported very highly on them, with the consequence that 48 wer ordered to be sent to India in 1849. These were found to answer we when fitted with small gratings suice to India not the recommendation of the <i>Agri</i>. <i>Horicultural Society of India</i>, offered a prize</li></ul> | GOSSYPIUM | Gins and Ginning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

As the cotton is drawn througn by the roller the seeds are forced out by the action of the moveable bl". <sup>3,5</sup> which, in some machines, is made to work horizontally instead of vertically. Many improvements have been made on the original and simple forms of both machines, for a description of which the reader is referred to Dr. Forbes Watson's valuable Report on Cotton Gins. The first notice of the introduction of foreign gins into India occurs in 1829, when the Court of Directors stated that they had at several times sent different machines to India, with the hope of bettering the condition in which their cotton reached England, and amongst these " two of a Jievy instrument called Whitney's saw-gin." Other American gins had for merly been sent to India, and on one occasion under the charge of an American mechanic; two gins had also been made by Mr. Maudsley for the Company, but all alike had failed. Writing in 1839, the Court of Directors again state that the American machinery, which up to that time had been sent out to India, and not succeeded. Attention was consequently again directed towards improvements in the native churka, and in 1848 a Mr. Mather was employed by the Government of the North-West Provinces to improve that machine. He shortly afterwards exhibited a working model of an improved churka which obtained the approval of a committee. This body recommended that twelve similar instruments should be construct. These were, accordingly, made in Calcutta, and in 1849 orders were issued by Government to construct minety-six such churkas, being eight sets of twelve each. In 1850, these were parcured at a total cost tover R2(000, and thenty-nine were distributed. After this large expense had been incurred the machines "-were found to be inferior in every way to the native churka and the effectory state. Finally, all were advertised for sale in Calcutta, and the 65. which had not bece meths the functi |

Gins and Ginning.

*{Watt & Murray.)* 

monly entertained upon the subject are far from being correct. The great advantage of saw-gins has been supposed to consist in the rapidity of their work and their economy in the consumption of power. This opinion was well founded in the days when a 40-inch Macarthy gin was not expected to turn out more than from 8 to 128) of clean cotton per hour. At the present time the construction of Macarthy gins of all kinds is greatly improved; in fact, the improvements effected in the knife-roller gin during the progress of the trials, and which may fairly be regarded as having resulted from the experience gained at the trials, have rendered it possible to obtain a rate of outturn of as much as 120 or even 200ft of clean cotton per hour, and this with a smaller consumption of power than that required for saw-gins, thus surpassing the latter both in outturn and in economy of power. Even the common double action Macarthy gin, when compared with saw-gins of a similar price, and worked at the moderate rate of speed at which alone it is safe to employ them, will probably have the advantage as regards rate of outturn though not as regards consumption of power. On the other hand, it was usually supposed that cotton was more liable to be cut by the saw-gins than by the roller gins, and a good deal of ingenuity has been devoted to the discovery of a form of tooth which would reduce the cutting action of the saw to a minimum. Without denying that the shape and size of the teeth may have some influence, and are, therefore, worthy of attention, it has been proved that, errors of adjustment excepted, the cutting and tearing action in all systems of gins is mainly determined by the striking speed, and that with a similar striking speed no great difference in this respect has been observed between the different systems of gins. In fact, the greatest amount of cutting action observed at the trials was exhibited, not by saw-gins, but by roller-gins running at an excessive speed. The great diameter of the striking part in the case of saw-gins, however, renders it particularly necessary to avoid any high rates of speed, as otherwise the permissible limits of striking speed may soon be exceeded. It may be observed that, in the Uilited States, where the saw-gins are usually worked at a moderate speed and where the fibre of the cotton does not adhere very strongly to the seed, comblaints as to the cutting action of the seed are always less frequent than in India, where the gins are frequently drawn at an excessive rate, and where the strong attachment of the fibre to the seed renders the staple specially liable to injury.

"But the one real drawback to the use of saw-gins is their tendency to 'nep<sup>5</sup> the cotton, although even this defect is greatly diminished by employing a moderate speed. A certain amount of nepping is produced even in the case of Macarthy gins, but the defects to which the Macarthy-ginned cotton is peculiarly exposed are curling and twisting, faults which may give rise to 'neps' during the subsequent carding of the cotton. It is thus only at the carding engine that the different samples of cotton can be compared in this respect." • • • • "The observations gave a clear result in favour of the Macarthy gins, their average 'neppiness' amounting to 2\*2 (out of a possible 3) against 3\*4 degrees in the case of saw-gins. The increased 'neppiness/ moreover, appears to be usually accompanied by a certain diminution in the strength of the yarn.

"But, on the other hand, the use of saw-gins offers one undoubted advantage over the Macarthy gins in the greater cleanness of the cotton which, under certain conditions, it is possible to attain by their use. Most sawgins possess mote-boards, fixed in such a position under the saws and brushes that a certain proportion of the leaf, crushed seed, and other coarse impurities, thrown off by the centrifugal force imparted by the rapidly revolving brushes is retained by them. As regards the quality

of the cotton, if a saw-gin be driven at such a moderate speed as not to cut the cotton, the opinions for or against its use will depend in each particular instance on whether more importance is attached by the valuer or spinner to the cleanness of the cotton, or to its 'neppiness.'" . . , ""<sup>The</sup>  $2^{\Lambda n}$ !ftt conclusions just arrived at are of some importance in considering the tutur" of cotton cultivation in the Southern Mahratta country. At the present time the whole of the acclimatised American cotton, produced in the unarwar and adjoining districts, is cleaned by the saw-gins which were originally supplied by the Dharwar Government Factory, and it may be esu mated that there are at the present time (1879) about 3,000 of these in the hands of the rayats.

<sup>if</sup> The cotton cleaned by these gins, however, even when they are in perfect condition, is proved by thelresults both of the valuations <sup>ai</sup>V?.<sup>o</sup> I the spinning experiments to be inferior in quality to that prepared by the <code>htest</code> American gins." . . • "Not only does the cotton prepared by the <code>htest</code> marries a sw-gin present the unavoidable defects of saw-ginning (that is, neppmg and cutting if the gin has been driven at too high a speed), but it does not possess, to any extent, the compensating advantage of cleanness. In tact it is one of the gins which produce the largest quantity of broken seed,. considerably more indeed than a well-adjusted Macarthy gin. This is particularly the case with the Dharwar-American cotton; in fact, the unexpected result was brought to light that the native varieties of cotton appeared to be, on the whole, less injured by the Dharwar saw-gin than the American cotton for which it was specially intended." (off. P'/^'-l . . . <sup>u</sup> As the Dharwar'gin, even in the perfect condition in whicn it was tested at the trials, has been shown to be inferior to the American gins now in use, it follows that, in the neglected condition in which these gins are frequently found in the Dharwar district, many of them not having been set or repaired for years, this inferiority must be immensely increased.

Dr. Forbes Watson then goes on to discuss the best means of re,medyifsg the then existing state of matters, which was year by year contributing so largely to lower the position of the Dhárwár-American cotton. After comparing the relative merits of the Macarthy and saw-gins, he arrives at the conclusion that " until the introduction of steam power on a large scale, gins of the type of saw-gins must be mainly relied on for cleaning the Dhárwar crop." He recommends a modification of the Emery gin as likely to prove most useful, and continues, " But in the meantime it appears possible to utilise, to some extent, the existing saw-gins. A certain advantage would be obtained by simply reducing the speed, which could be easily done by merely increasing the diameter of their driving pulleys. A speed of 200 revolutions per minute would very nearly correspond to the striking speed of 100 inches per second, which has been fixed as the approximate limit, every increase above which is injurious to the staple of the cotton.<sup>5</sup><sup>^</sup> . , "A more material improvement would be obtained by the substitution of the Emery saws and grids, or even by the replacement of the saws above, which could be effected at a moderate cost."

Up to the present day nearly all the indigenous cottons of India are hand-ginned by the ordinary *churka*; indeed, it appears doubtful if the American saw-gin will ever obtain a hold for this purpose. Notwithstanding the proof to the contrary, brought forward by Dr. Forbes Watson, reports are still frequent that the native cotton is much damaged by the saw-gin. It is possible that this may be due to imperfections in adjustment, excess of speed, and general carelessness, but it appears doubtful if it is entirely so, since by the same machines American cotton is improved in ginning. Moreover, the *churka* being, as already stated, almost entirely worked by women of the cultivator's household, whose labour

(Jinning and Pressing. {Watt & Mutt ay) GOSSYPIUM.

and time cost practically nothing, can never be replaced by an expensive niachine, unless the increase of value of the product should prove sufficient to more than cover the outturn involved by its use. The only case in which the saw-gin is said to produce a higher quality fibre from indigenous "*kapds*" than the *churka*, is that of Sind, where the machine is reported to be consequently "much appreciated by the people." This fact is confirmed by the experimental trials, and Dr. **Forbes** Watson re-Pprts that " the percentage of cleaned cotton yielded by this variety is higher than in the case of any other of the native cottons."

Dr. Forbes Watson divides the Indian cottons into two classes: (1) those easily ginned, and (2) those ginned with difficulty. To the first belong the introduced American and certain Indian races, *via.*\* Broach, Dholleras, the *jari* form of Oomras, Westerns, Coomptas, Khandesh (Vila^tip), and Tinnevellies; to the second Madras *Uppam<sub>t</sub>* Hing-anghât, Khandesh, and the *bani* form of Oomras. Of all these, the Broach and Dhdrwar growths are the only forms entirely cleaned by steam or hand saw-gins at the present time, but the quantity of Umras *{jari*} and Dholleras thus treated is yearly increasing. With the exception of *jari* and Dhollera, these are soft-seeded American races, which cannot be satisfactorily cleaned by the native *churka*. All other descriptions of Indian cotton are still entirely hand-cleaned by the *churka*, or by the foot-roller. It appears possible, however, that the Sind cotton also may soon be extensively cleaned by the saw-gin, and that the Westerns and Coomptas, classed by Dr. Forbes Watson as "easily ginned," may also be found to be more satisfactorily cleaned by the same means.

### COTTON PRESSING.

A good deal of the cotton produced in India is still sent to the seaports in bundles or *dokrahs* of about 200fe each, but the greater portion of the crop is pressed up-country ready for shipment. The method of packing these rough bundles is generally similar to that already described Utsee p. 106) and need not be further discussed.

The number of steam presses in India is increasing year by year. Mr. Beaufort, in his Indian Cotton Statistics, gives a list of 190 Cotton Steam-pressing Companies as existing in all parts of the country in 1889. Mr. O'Conor in his statistical tables, however, returns 949, of which 116 are in Bombay, 5 in Sind, 41 in Madras, 17 in the Pan jåb, 1 in Burma, 36 in Berar, 13 in the North-West Provinces, 4 in the Central Provinces, 3 in Central India, 11 in Rajputana, and 2 in the Nizam's territories. The total capital employed (so far as known) is R1,87,07,125, and the value of the outturn Ri 1,10,26,240. The head offices of the larger companies are in Bombay, but they possess steam presses in various important centres of the cotton districts such as Bombay Sind, Berar, and the North-West Provinces. Besides these, numerous smaller companies have their presses and head offices in the inland towns of Madras, Bengal, the Panjåb, the North-West Provinces, Central India, Rajputana, the Central Provinces, Berar, the Nizam's territory, Sind, Bombay, and Burma.

\* According to Mr. Beaufort, cotton is generally exported from Bombay and Karachi in bales of 3<sup>^</sup> cwt. each, or 392th net. "As the staple is bought and sold by the *candy* of 784th, two bales equal one *candy*. Formerly, at all other ports cotton was shipped in bales of 300ft net, but within the past fifteen years the trade has gradually, in Calcutta and Madras, changed the weight to 400lb net. From Coconada shipments are made in bales of both 300tb and 400ft, while at Tuticorin, of the steam presses at work, several have been converted so as to admit of

GINS.

# GOSSYPIUM.

PRESSING.

Manufactures of Cotton.

pressing 500& bales, the others confining themselvos to 400tb bales\* Since nearly the whole of the Tinnevelly crop is sent to Bombay by coasting steamers for transhipment to European ports, and many bales burst *en route* to Bombay, thus requiring to be re-pressed before re-shipment, it may be as well to point out to those interested that there is not in Bombay a single press capable of pressing a 500ft bale. A Bombay bale is, therefore, 2-04 per cent, smaller than a Calcutta or Madras one ana 27\*55 per cent, smaller than a Tuticorin bale.

On an average, at Bombay four bales (1,568ft net) go to the shipping ton of 40 cubic feet, but some of the more modern presses turn out bales 100 of which equal 21 tons measurement. Many of the older presses have now finishers attached which, after the bales have been pressed to a certain point in the larger presses, extract the cotton and complete the process. At Karachi a space of 40 cubic feet also constitutes a sterner ton of freight, while at both ports 50 cubic feet is the sailing ship scale. On the other hand, both at Calcutta and the ports in the Madras Presidency, Coconada, Masulipatam, Madras, Pondicherry, and Tuticorin, a ton of freight, both by sailers and steamers, is on the single basis of 50 cubic feet.

The bales are covered with jute,' gunny,' cloth of Calcutta manufacture, and lashed with iron or steel bands, the latter of late years generally superseding the former owing to their lightness and greater strength. In the Government Railway returns, railway freight being payable on the gross weight of the bales, five per cent, is deducted for tare, a correct percentage fifteen or twenty years ago, but obsolete now that iron and steel bands have taken the place of jute ones. The Bombay Chamber of Commerce in their daily returns of receipts from up-country deduct but two per cent., which is approximately correct.''

#### COTTON MANUFACTURES.

1. HAND-LOOM.—Important and interesting as are the native cotton manufactures of India, it is impossible to enter into a discussion on the subject in an article such as the present which is designed to deal more especially with the raw product. The total number of hand-looms in the country, and the amount of raw material which they consume, can only be guessed at. With the increase in the number and outturn of Indian mills, and the gradual growth of the Manchester trade the manufacture of the finer textiles by the hand-loom, such as the Dacca muslins, once so famous all over the world, has almost, if not entirely, ceased. The local manufacture of the coarser kinds, however, for consumption in rural localities, and of ornamental varieties, such as the *do-pattas* of Benares, is likely to continue to a much greater extent. Sir George Birdwood (*Indian Arts, pp. 244—260*) gives an interesting and detailed account of Indian cotton goods arranged provincially. The reader is referred to that article for information regarding the technicalities of these Indian manufactures.

2. POWER-LOOM.—Mr. Beaufort has written an excellent *resume*\* of the available information on this subject, in his Cotton Statistics, from which the following may be quoted:—

"The first mill built in India was the Bombay Spinning and Weaving' Company's, which was formed about 1851, but does not appear to I.ave been in working order till 1854. The earliest return we have met with of the Indian mills, is one dated 1875, which gives the later date against the name of this concern, followed by the • Oriental,' September 19, 1855, and <sup>1M</sup>\* Throstle/ January 10, 1857. By 1861 the number in the country had increased to a dozen, containing 338,000 spindles, with an estimated annual consumption of 65,000 bales iof *zh* cwts. each) of cotton. By 1879 or just five and twenty years after the starting of the first mill, the number

**Review of the Indian Trade in Cotton.** (Watt & Murray.) GOSSYPIUM. MILLS. there were 75 in the Bombay Presidency, including 52 in the town and island of Bombay. There were 7 in Bengal, all in the vicinity of Calcutta; 8 in Madras, of which 4 were in the town; 6 in the North-West Provinces, all but one at Cawnpore; one at Indore; 3 in the Central Provinces; 3 in the Nizam's Territory; 2 in Mysore; 2 in Pondicherry, and one in Travancore. Of the 108, 50 are returned as both spinning and weaving: 53 as purely spinning mills; and 5 as entirely weaving mills. Two of the Bombay mills are stated to have manufactured hosiery in addition to yarn, piece-goods, &c. According to Mr. O'Oonor's tables, the mills contain-"They consumed about 347 miled 22,156 looms and 2,669,922 spindles. lion pounds of cotton in the year, and employed a daily average number of 92,126 persons, of whom, as far as details have been obtained, there were<sup>^</sup>3,317 men, 18,031 women, 15,309 young persons, and 3,469 children. The nominal capital of the mills worked by joint stock proprietary is returned at 95J million rupees; but there is no return of the capital of eight mills worked by private proprietary, and probably the whole capital invested in this industry is quite one hundred million rupees, or (in conventional exchange of ten rupees to the pound) 10 millions sterling. TRADE. •REVIEW OF THE INDIAN TRADE IN COTTON AND COT-262 TON MANUFACTURES. In the table (p. 56) summarising the statistics regarding the production of, and trade in, raw cotton (for the year ending March 1889), India is shewn to have produced 9,219,493 cwt. of cotton. Of that amount 7,755,741 cwt. appear to have been exported from the provinces, the bulk of which naturally went to the ports, and constituted the supply from which the exports to foreign countries were derived, vis., 5,33<sup>I</sup> »9°4 <sup>c</sup> wt., which, deducted from the above outturn, would leave 3,887,589 cwt. as the amount available for local consumption in all India, plus 64,627 cwt. obtained from foreign countries. A critical examination, however, of the returns on every aspect of the cotton industry confirms the suspicion that either the area, 13,998,639 acres, is under the mark, or that the yield per acre is under-estimated. Mr. Beaufort gives the outturn for the year in question as having been 9,625,000 cwt., but it is probable that even that amount would not meet the total transactions shown in the trade statistics. It has  $S^n$  tffi^2<sup>OT</sup>i'u<sup>thatt!</sup> e<sup>reareat</sup> kasl two errors in all the returns outturn ans  $A''**''^{the}$  T<sup>rIa</sup>?<sup>P</sup><sup>n</sup>\* of the official y« with the year of State?' To thpi <sup>thereareat</sup> kasl two errors in all the returns outturn ans  $A''**''^{thereareat}$  kasl two errors in all the returns outturn ans  $A''**''^{thereareat}$  kasl two errors in all the returns outturn ans  $A''**''^{thereareat}$  kasl two errors in all the returns outturn ans  $A''**''^{thereareat}$  so  $A''**''^{thereareat}$  with the year of State?' To thpi <sup>thereareat</sup> S'' a down the state of second the tableto the trade of Cors is down the state shown as having been less than the importsinto .... p. to attrade of India, to accept the total outturn, the imports, eports, &c, there given as correct. xas having been 9,625,000 cwt., but it is probable that even that amount Conf. with pp, 54-55, 61. ports, &c, there given as correct. In the annual statement of the trade and navigation of British India, tor 1888-89, Mr. J. E- O'Conor gives the value of the exports to foreign countries as R 15,04,56,476. Assuming that the amount retained in India was of equal proportionate value to the people as that which they sold for

tneforeign markets, the outturn may be valued at R26,0i,75,009. It is, perhaps, not, strictly speaking, correct to add together the value of a raw with that of a manufactured material in estimating trade, but this may be allowed, since these items represent actual financial transactions. The total valuation of Indian-grown cotton, plus the value of the imports of raw and manufactured cotton, last year amounted to R 57,66,93,851. The more

Value of the raw cotton exported, R 15,04,56,476; estimated value of

important branches of the cotton trade were as follows :

Rx.=lakhs of rupees (1,00,000.)

#### Cotton and Cotton Manufactures. (Watt & Murray.) **GOSSYPIUM.**

TRADE— INTEENAL. " It must not be supposed," continues the author of the *Review*, "that the figures in the third column represent the whole consumption *oi* twist and varn of Indian manufacture. No estimate can be given of the produce of Twist and native spindles, which is still considerable; but putting the value of the annual outturn of Indian mills at 515 lakhs of rupees, and deducting 356 lakhs as the export to foreign countries, the home consumption of Indian mill produce alone comes to 159 lakhs against a foreign import valued at 343 lakhs."

The coastwise trade in Indian twists and yarns has been remarkably steady during the past five years. In 1884-85 the imports amounted to 20,231,819ft, valued at R93.67.197, in 1888-89 to 20,505,130ft, value £85,20,195. The largest importer in the year under consideration was Bengal, with 9,691,143ft, followed by Madras with 4\*308,051, Burma with 3>8<sup>o</sup>,i<sub>9</sub>3, Bombay with 2,153,209, and Sind with 492,534<sup>-</sup>largest exporter was Bombay, with 18,897,068ft, followed by Bengal with 2,428,851, Madras with 1,030,575%, Burma and Sind with very unimportant amounts.

The coastwise imports of foreign twist and varn have also remained steady, but are much less important than those of Indian. In the year under consideration they amounted to 10,637,127ft, valued 3^63,13,272, of which Bengal imported 4,035,666ft, Madras, 3,972,109, Sind, 934,718, Burma, 891,520, and Bombay, 803,144ft. The largest exporter was Bengal with 6,723,474ft, followed by Bombay with 3,044,486, and Madras, Burma, and Sind with smaller amounts.

Owing to its short staple the bulk of Indian cotton is unfit for the production of the finer descriptions of yarn, and local manufactures are therefore, as a whole, considerably inferior in value to that of the European article. For the same reason European yarns are largely used by native looms throughout the country in the manufacture of the finer classes of cloth.

PIECE-GOODS.—-Mr. Tucker (Review of the Inland Trade) writes: ' 'Α correct representation of this important item in the inland trade return" is attended with special difficulties. In the case of goods passing thiough the Custom House the value if declared, and the nature and volume of consignments in pieces, yards, bales or other approximate ascertained. Railway invoices, however, shew only weights in the gross without distinction of kinds, and the fixation depends upon local enquiries of a tedious and difficult nature, and upon estimates which must be largely conjectural," "To study, however, the correlation between imports by sea and the distribution of English piece-goods over the interior of the country, the inland values with all their imperfections must be accepted, for no comparison is possible between a trade represented on the one hand by pieces, yards, &c, and on the other, by maunds.'

The total value of English piece-goods, &c, conveyed by rail and river in India in 1888-89 was RŽo,26,99,428, of Indian piece-goods, 1\*1,88,64,912. The proportion received by each province may be shortly represented bj the following table:

Net hnports of Cotton piece-goods.

ie statistics of internal trade are substantially accurate. they indicate very forcibly what is evident from the returns of foreign trade, vis,, the pre-eminence of Bengal as a consumer and distributor of English piece-goods. Mr. Tucker writes of the rail-borne trade: "Calcutta, which is one of the largest emporiums for piece-goods in the world, supplies the requirements of the vast population of Bengal, the North-West Provinces and Oudh, the Panjab, and Assam. It exports 13,78 lakhs of rupees against 6,87 lakhs from the other provinces combined; but the disproportion between these figures is, in some measure, caused by the higher value rates applied in Bengal to the traffic in European piece-goods. Bombay town supplies its presidency, the Central Provinces, Berar, Rajputana and Central India, and Hyderabad, and to a less extent, the North-West Provinces and Oudh, and the Panjab; while the Madras Presidency and Mysore have their demands met through the Madras seaports."

As far as can be gathered, the demand for European grey goods is much keener on the Calcutta than on the Bombay side; in bleached cloths and coloured prints it is about equal; while in handkerchiefs, shawls, &c, Bombay does the largest trade. Judging by the returns, the competition of Indian with European manufacture is much less pronounced in the case of piece-goods than in that of twist and yarn. The inland trade in country piece-goods is but one-tenth that of imported stuffs. But it must be remembered that, while the latter must necessarily all enter into the trade returns, a large local cloth manufacture exists in many parts of the country,

Ir s<br>eed, cotton operatives have refused to work with Indian cott<br>troublesome to manage. This is not the case on the Conti<br>is exist possessing machinery energiably adapted to the treatm<br>pled cotton, and in these quarters there seems to be a growi<br>our staple."<br>The falling off in raw cotton exports to China within the pas<br>very marked. In the thirteen years 1834 to 1846, the ex-<br>ombay alone averaged 4759 cwt., in comparison with 533                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

#### Cotton aAd Cotton Manufactures. (Watt & Murray.) GOSSYPIUM.

the same port to China. During the American War of 1863-64, how\* ever, not only was Surat cotton exported to America, but Bombay imported cotton from China. The erection of spinning and weaving mills after Raw Cotton-this date has gradually lessened the exports to China, and in the year under consideration they have fallen to only 139,000 cwts.

The shares taken by the seaports of India in the exports of the last two years have been as follows s-

|                                               |       |    |    |             | Cwt. (000'                       | s omitted).                      |
|-----------------------------------------------|-------|----|----|-------------|----------------------------------|----------------------------------|

The principal ports to which the exports from Bombay were consigned in 1888-89!, named in order of importance, were:-Liverpool, Antwerp, Trieste, Genoa, Havre, London, Venice, Hamburg, and Odessa. From Coconada and Masulipatam nearly all went to Havre and London; from Madras town nearly the whole used to be taken by London which still secures about four-fifths, but the trade with Italy and Austria is steadily growing; from Tuticorin about four-eighths of the whole has recently annually gone to Liverpool, while smaller quantities are exported to London, Venice, Barcelona, and Antwerp, named in order of importance. The most important receiving port of cotton from Calcutta is London, though, in the past two years, Hamburg has been rapidly pushing to the front. Genoa, Venice, Antwerp, and Trieste foljow in the order named. A litt/e of the cotton exported from Calcutta still goes via the Cape, while from al! other ports it goes entirely by the Suez Canal. About equal quantities of the exports from Karachi go to Great Britain and the Continent. London is the principal importing port, Antwerp being next, followed by Marseilles. A small and, apparently, decreasing quantity is imported by China. Most of the exports from Burma are shipped to China either direct or through the Straits Settlements.

II. TWIST AND YARN.—IMPORTS.—The total imports of twist and yarn, in the year under consideration, was 52,587,181ft, valued at 374/68 lakhs of "upees. The trade is a steadily increasing one, notwithstanding the competition of Indian yarns, as wilf be seen from the table below :--

**Ouinquennial averages of Imports of Twist and Yarn**,

| 1876-77 to 1880-81<br>1881-82 to 1885-86<br>1886-87<br>1887-88<br>1888-89 |  |  | · · · · · · · · · · · · · · · · · · · | • | 31,934,495<br>36,339,902<br>44,542,928<br>49.° 13,979<br>51,542,549<br>52,587,181 | R<br>2,72,68,650<br>2.96,16,344<br>3,31,97,40i<br>3,31,83,769<br>3,58,19,061<br>3,74,67,969 |
|---------------------------------------------------------------------------|--|--|---------------------------------------|---|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
|---------------------------------------------------------------------------|--|--|---------------------------------------|---|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|

The above figures shew that, while the quantity imported has largely increased during the past twenty years, the value has been augmented in a smaller proportion, indicating a considerable reduction in prices.

| TRADE-<br>FOREIGN.<br>Other Cotton<br>Manufac-<br>tures-<br>imports. | It will be seen that nearly every article shows a steady and fairly proportional increase, with the exception of canvas, the imports of which have markedly diminished in value.<br>The United Kingdom virtually possesses the monopoly of this exten, sive trade. Thus, in the year under consideration, imports to the value or $^{27*34,92,942}$ came from that source, leaving only 1*41,52,140 to be accounted for by other countries. Of this small amount, Italy supplied goods to the value of 1*9,44,910; Austria, R8,37,33i; the Straits Settlements, 1*7,25,928; the United States, £5,87,745; France, R5,33»^7; and uermany, R 1,83,561. Other countries supplied small amounts valuing less than one lakh.<br>In 1887-88, the amount derived from other countries than the Unitea Kingdom, showed a marked correspondence in value with that of 1888-89, amounting to R40,05,262. In that year, however, Austria suppli&l niucn the largest quantity, while the value of the imports from the United States valued R 1,41,134 only.<br>The shares taken in the imports, by each of the seaboard provinces, during the past two years were as follows:— |                                                                                                                                                                             |                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                           |                                                                                                                                                           |                                                                                                                                                                               |                                                                                                                                                                          |                                                                                                                                                                                                     |                                                                                                                                          |                                                                                                                                                                                                                                                                                                                       |                                                                                                |

Cotton and Cotton Manufactures. (Watt & Murray.) GOSSYPIUM.

EXPORTS.—The exports of all Indian cotton manufactures, exclusive of twist and yarns, in the year under consideration, valued 81,16,74,640. This amount was made up as follows :—

| NATURE OF GOODS.                                                                                                                                                                                                                                        | ft                          | Yards.                                                                            | R                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| I.—Piece-goods—<br>1. Grey (unbleached)<br>2. White (bleached)<br>3. Coloured, printed, or dyed .<br>4. Handkerchiefs and shawls in the<br>piece.<br>5. Other sorts of piece-goods .<br>)»—Hosiery, pure and mixed<br>{11.—Thread, sewing<br>Ij.—Canvas | <br><br>50,739<br>1,851,855 | 54,938,813<br>n6,355<br>15*189,059<br>1,073,077<br>21,122<br><br><b>1,856</b><br> | 64,66,979<br>46,504<br>43^8,741<br>5*23,515<br>15,888<br>19,036<br>39-732<br>833<br>2,43,412<br>1,16,74,640 |

The trade has been rapidly progressive within the last twenty years, as might naturally be expected from the increase in the number of mills. Thus, in the quinquennial period ending 1875-76, the value amounted to R34,99J927; in that ending 1880-81 to R51,12,644; in the five years ending 1885-86 to 882,14,879; in 1886-87 to  $894,56,437^*$  <sup>in</sup> 1887-88 to R 1,15,05,419 £and in 1888-89 to 81,116,74,640. Substantial as the progress has been, it is far short of the advance made in the export of yarns. Mr. O'Conor remarks on this point: "As long as the Chinese and Japanese maintain their preference for weaving their cloths themselves from imported yarn, instead of importing it ready-made, the export of our yarns must necessarily augment much faster than that of piece-goods."

The chief importers in the past year were:—Aden, with a total amounting in value to 820,61,942; China with 819,93,595; the Straits Settlements with Ri7>37»944; Ceylon with 816,99,511; Zanzibar with 811,79,446; Mozambique with 88,37,220; the United Kingdom with 86,19,520; Arabia with R5><sup>2</sup>7»<sup>2</sup>o2; Persia with 83,19,792; Turkey in Asia with 82,49,714; Mekran and Sonmiani with 81,35,9715 and Abyssinia with 81,13,104. Several other countries imported smaller quantities valuing less than one lakh of rupees.

The exports were distributed as follows, among the seaboard presidencies and provinces, during the last two years:—

| <u> </u>                                       |   | <u> </u> |                     |             |             |   | 1887-88.                                                   | 1888-89.                                                   |
|------------------------------------------------|---|----------|---------------------|-------------|-------------|---|------------------------------------------------------------|------------------------------------------------------------|
| Bombay<br>Madras<br>Bengal<br>Siyd.<br>Burma • | • | •        | <br><br>•<br>•<br>• | •<br>•<br>• | •<br>•<br>• | • | 8<br>69,68,896<br>42,22,203<br>1,69,443<br>i,44>334<br>543 | R<br>75.47»780<br>38»54,49i<br>1,41*403<br>1,30,562<br>404 |

Bombay thus possesses more than 64 per cent, of the trade in woven goods. It should be mentioned, however, that a considerable proportion of the exports from Madras consists of cloths dyed in that presidency, the pieces having been woven in Madras, in Bombay, or in England—that, in fact, Bombay is the centre of cotton-spinning and weaving 'industry in India.

| TRADE-<br>FOREIGN.<br>Other Cotton<br>Manufac-<br>tures-<br>Exports, | (See <i>Trade Review for 1888-89.)</i> The following remarks from Mr. Beaufort's <i>Indian Cotton Statistics</i> regarding the progress made by, and the distribution of, the chief cotton manufactures of Bombay may, therefore, or of interest :- "The demand for T. cloths and Sheetings, especially in the past three years, has increased considerably. Longcloths, too, have been in more favour in the past two years, but Domestics show no expansion, "Drills' and * Jeans * have fallen off largely. * Dhoties' and 'Shudders' find but few buyers out of the country, but the total trade in the last three years has been growing. The increase in T. cloth is purely to China, the largest consumer of this description of cloth, Mozambique and Zanzibar oping the next largest buyers. Of • Sheetings' Zanzibar takes nearly halt the exports, Mozambique being the next important outlet. * Longcloths '.go* ** a rule, principally to Aden, for re-export; but last year China tookjjie leaa* whereas but two years ago her takings were so small as to be included, under ' other ports.' Aden takes nearly all the • Domestics.'"                                                                                                                                                                         |

| length and varying in thickness from the size of a crowquill to that <sup>o</sup> f ordinary thread. It has a feebly saline taste, a flavour of sea-weed, and <sup>a</sup> cartilagenous consistence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | MEDICINE.                             |
| CHEMICAL CHARACTER.—Ceylon moss as examined by O'Shaugh-<br>nessy yielded :—vegetable jelly 54'5 P? <sup>r</sup> c <sup>ent</sup> ? starch 15 per cent., cellu-<br>lose 18 per cent., gum 4. per cent., and inorganic salts 7'5 per cent. The<br>authors of the <i>Pharmacographia</i> write: '* Some chemists have regarded<br>the jelly extracted by boiling water as identical with pectin, but this state-<br>ment requires proof. Payne called it <i>gelose</i> , and found it composed of<br>carbon 4277, hydrozen 5*77, and oxygen 51*45 per cent," The salts<br>according to O'Shaughnessy consist of sulphates, phosphates, and chlo-<br>rides, with neither bromide nor iodide.                         | Chemistry.<br>276                     |
| M«DICAL PROPERTIES AND USES.—In its properties it resembles Carra-<br>gern moss, being emollient, demulcent, and nutritive. It may be used in<br>the form of a decoction or jelly, as a light and readily digestible food for<br>invalids and children, as an emollient in intestinal catarrh and irritation,<br>and as a demulcent in pulmonary complaints and irritation of the throat.<br>The jell or decoction may be made more palatable by the addition of<br>milk, w" e or aromatics.                                                                                                                                                                                                                      | Properties<br>and Uses.<br><b>277</b> |
| Foot —In the Indian Archipelago and China large quantities are<br>employed in place of isinglass for the preparation of jellies, and, as already<br>stated, considerable quantities are exported from India to China.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | FOOD. <b>278</b>                      |
| Industrial Uses. —Occasionally employed in England as a jelly for dressing silk.<br>Grains, see Cereals, Vol. II., 257,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | INDUSTRIAL:<br>USES.<br><b>279</b>    |

|       | Madras.)<br>GRANITE, Ball, in Man. Geology of India, III., S34-<br>The following note has been kindly furnished by Mr. H. B. Medlicott,<br>late Director of the Geological Survey.<br>ranite, Eng.; GRANITE,/V.; GRANIT, Ger.; GRANITO, ItaU<br>Granite has as yet, economically considered, been only specialised as<br>such in European countries and their off-shoots, and even there in many<br>cases, the rock is not in reality a granite but some form of massive<br>crystalline igneous or metamorphic rock. In India the term is evpn more<br>general, and all crystalline rocks, as long as they are tolerably compact,<br>granular, crystalline igneous rock might be set down as of universal occur-<br>rence in India; except in the Bombay Presidency and the Deccan, or in<br>the flat alluvial districts. Keeping, however, to the proper idea of<br>granite, that is, a crystalline igneous rock principally composed of quartz,<br>felspar, and mica, either as a ternary compound of these minerals or as a<br>binary compound of two of them, the occurrence of the rock becomes,<br>for industrial purposes, very restricted. Without running the distinc-<br>tion too close, it may be well, on the economic view, to notice localifies-<br>for stone which, for all practical purposes, and without infringing very<br>much on the geological definition of the term, may be considered granite.<br>With this proviso, the rock can be expected to occur only in the areas of<br>crystalline rocks, which are, <i>par excellence</i> , the Himalayan region, in and<br>the southern and eastern tracts of Peninsular India. In the Himatayan<br>district the distinction of granite from gnesis is still a vexed question, but<br>t'ere seems to be no doubt that the rock occurs in the Central Hima-<br>laya in what is called the granitic axis of these mountains. To the<br>east in Sikkim, and in the north-west, from the frontier of Nepal to KuUt<br>wherever examined, coarse white granite has been found in profusion<br>along the line of peaks, near the present edge of the sedimentary basin<br>of Tibet. It occurs in veins and dykes of every size, s |

The leaves possess tannin, shown by the infusion blackening with a salt of iron." The sample examined by Mr. Wardle having been sent from the Panjab, the inference may be accepted that it is employed as a dye by the natives of that province, but the writer can find no mention of the fact in available literature.</li> </ul>                                                                                                                                                                                                                                                                                        |
| FIBRE.<br>Bark.<br>3IO                                    | Fibre,—A strong coarse fibre is obtained from the BARK by retting,<br>and is much employed by the Natives of the North-West Himálaya for<br>making ropes and nets. Captain Huddleston appears to have been the<br>first to bring this fibre to the notice of Europeans, in his Report on Hemp<br>cultivation, &c, in British Garhwal, published in the <i>Transactions of the</i><br><i>AgriHort. Soc. Ind., vol. viii., 260</i> , he wrote: "The branches of the tree<br>are cut from July till March, or at all seasons save the spring. The<br>sticks are soaked for a month or forty days in water, and when dry are<br>beaten on stones, and the bark stripped oft. One tree will give about<br>five seers of the inner fibre fit for making ropes and string, which is used<br>for tying up cattle and stringing cots. It is neither very strong not<br>durable, and is not to be had in any quantity." In another passage he<br>remarked: "The <i>Bhimal</i> ropes get stronger from wet for the time, but de<br>not last above eighteen months if kept constantly exposed to the weather."<br>Eighteen years later (in 1858) Lieutenant Pogson submitted samples of<br>the same fibre and rope from Simla, to the AgriHorticultural Society<br>of India. These were examined by the Fibre Committee,one of the mem-<br>bers of which reported as follows: "Weak and brittle; like all fibres from<br>the bark of trees it will not bear dressing. Very probably, if worked by<br>hand, a common sort of rope might be made of it for local use, but I de<br>not think it would ever become an article of commerce." Later the fibre<br>was employed for paper-making in the Kangra valley under European<br>supervision, with a fair amount of success, but, as in the case of the fibre<br>of G. tdiaefolia there would be little chance of its exportation for that<br>G'. 310 |

| Bhfmal Fibre.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <u>,£?££</u> .                                                                                                                  |

| Habitat.—A shrub or small tree of North-West India, extending along<br>the Himalaya from the Salt-Range to Nepal, ascending to 4,000 feet; also<br>met with in Chutia Nagpur, the Central Provinces, Konkan, Pegu, and<br>Ceylon.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                 |
| Medicine.—The Rev. A. Campbell reports that the FRUIT is employ-<br>ed as a medicine by the Santals, in cases of diarrhoea and dysentery.<br>The ROOT pounded is also prescribed for the same diseases, and powdered<br>in water is applied externally to hasten suppuration, and as a dressing for<br>wounds. The paste dries and forms a hard coating, thus effectually<br>excluding air from the raw surface. The knowledge of the medicinal<br>virtues of this plant in Chutia Nagpur is interesting, since an antidy-<br>senteric property is also attributed to it by the aborigines of North-West                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | MEDICINE.<br>Fruit.<br>317<br>Root.<br>318                                                                                      |
| Australia. Mr. Christy commenting on its virtues writes : "Dr. W. E.<br>Arm it states that on one occasion having had to treat dysentery follow-<br>ing on fever and ague, this plant was pointed out to him by a native as a<br>sure remedy. He collected a quantity of LEAVES, and having made a pale<br>sherry-coloured decoction, administered about two table-spoonfuls for a<br>dose. Repeating this every four hours throughout the night, the sixth dose<br>made a complete cure. 'Since then,' says Dr. Armit, 'I have tried the<br>remedy in scores of cases, and I have never known it to fail, however seri-<br>ous.' <sup>97</sup> As already stated, the leaves contain tannin, which, together with<br>the mucilaginous properties peculiar to the whole genus, probably explains                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Leaves.<br>319<br>FOOD                                                                                                          |
| its special action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Fruit.                                                                                                                          |

Food.—The FRUIT is eaten in Chutia Nagpur.

| used as a substitute for althea." It is doubtful to what part of the plant<br>the first sentence refers, but it may probably be to the scabrid LEAVES.<br>Food.—The FRUIT is of the size of a large cherry, nearly round, brown-<br>ish-grey when ripe, with a glutinous, pale yellow, pulp. II is eaten by<br>Natives.<br>Structure of the Wood.—In the Kandra Gazetteer, it is stated that<br>G. obliqua, Roxb., referred by the Flora, British India, to this species, is a<br>small tree, the wood of which is used for field tools and posts. Some<br>other species, however, is probably meant, since G. scabrophylla, Roxb., is                                                                                                                                                                                                                                                                                 | Leaves.331FOOD.Fruit332TIMBER.333                  |

| Habitat.—A moderate-sized tree met with in the hot dry forests through-<br>out the Sub-Himálayan tract, from the Jumna to Nepál, ascending to 4,000<br>feet; also in Central and South India, Burma, and Ceylon. It flowers in<br>April and May, and its fruit ripens from June to October.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                    |
| Fibre.—The BARK yields a fibre employed in many parts of India for<br>cordage. It, like the fibres of other Grewias, has been recommended for<br>paper-making, but is apparently little worthy of consideration. Speci-<br>mens were sent to Kew in 1878, and were, amongst other fibre-yielding<br>barks, examined by the late Mr. Rout ledge of the Ford Works, Sunder-<br>land. He described the fibre as "strong, harsh, wiry, hard," and stated<br>that the green-yield of the bark was 50 per cent., the bleached-yield 437.                                                                                                                                                                                                                                                                                                                                                                                     | FIBRE.<br>Bark.<br>335                             |
| As in the case of other Grewia fibres, it would not pay to export it to<br>Europe for paper-making purposes.<br>Medicine.— Dr. Dymock writes that, "In the Konkan the BARK, after<br>removal of the suber, is rubbed down with water, and the thick mucilage<br>strained from it and given in five-tola doses with two tolds of the flour of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | MEDICINE<br>Bark.<br><b>336</b><br>Wood.           |
| Ptnicum miliaceum, as a remedy for dysentery." Colonel Cox in his<br>•' Remarks on Certain Specimens of Wood from Central India" says that<br>the WOOD reduced to a powder acts as an emetic, and is employed by the<br>Natives as an antidote to opium poisoning. <i>{Journ. AgriHort. Soc. Ind.</i><br><i>loc. cit.</i> ). The BARK is also employed externally to remove the irritation<br>in cow-itch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Bark.<br>338<br>FOOD.<br>Drupes.<br>339<br>FODDER. |
| Food and Fodder.—The small DRUPES are of an agreeable acid flavour,<br>and are eaten by Natives. The LEAVES and TWIGS are lopped for cattle<br>fodder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Leaves                                             |
| G. 341                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                    |

Murray.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | speciosa.                                                                         |
| siderable strength, breaking at 100ft. when dry and 1401b when wet.<br>Messrs. Cross, Bevan, and King have recently examined it, and state as<br>the result of their observations that the ultimate fibre is 1 to 2 mm. in<br>length, and that if the plant were cultivated for the purpose, it would<br>probably yield a fibre which would prove useful for rope-making.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | FIBRE.                                                                            |
| Medicine.—The medicinal properties of this tree appear to have been<br>first brought to notice by Lindley who wrote: "In Martinique the infusion<br>of the old BARK is esteemed as a sudorific, and as useful in cutaneous dis-<br>eases, and diseases of the chest." Moodeen Sheriff in his forthcoming<br><i>Materia Medica of Madras</i> , proofs of which have been obligingly furnished<br>to the editor, describes the bark as tonic and useful in some of those cases<br>for which calumba and gentian are generally prescribed. The preparation<br>recommended by him is a decoction prepared as follows : "Take of the<br>inner bark, cut into small pieces or in coarse powder, four ounces; water<br>one pint and a half; boil till the liquid is reduced to one pint, and strain                                                                    | MEDICINE.<br>Bark.<br><b>348</b>                                                  |
| when cool; dose from two to three fluid ounces." The inner bark is esteemed as a remedy for Elephantiasis in the West Indies.<br>Food and Fodder.—The FRUIT, which contains a sweet'and agreeable mucilage, is edible. The LEAVES are valued as fodder in the Bombay Presidency.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | FOOD.<br>Fruit.<br><b>349</b>                                                     |
| Structure of the Wood.—Loose-grained, light-brown or brown, streak-<br>ed, coarsely fibrous, takes a good polish; weight, according to Skinner,<br>32ft per cubic foot. It is employed in Southern India for furniture, the<br>panels of carriages, and packing-cases.<br>Industrial Uses, &c.—The glutinous decoction of the inner bark is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | FODDER.<br>Leaves.<br><b>35</b> 0<br><b>TIBB</b> ER.<br><b>351</b><br>INDUSTRIAL. |
| employed in the West Indies for clarifying sugar. The tree is admirably<br>adapted for avenues, and has been largely planted in Southern India for<br>this purpose, as well as for fodder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 352                                                                               |

| Domestic and Sacred Uses.—Drury quoting Persoon writes: "The<br>flowers of this tree are exquisitely fragrant. They come out in the even-<br>ing, and have all dropped on the ground by the morning. The natives in<br>Travancore distil an odoriferous water from the corollas, which is very<br>Ske rose-water. In order to procure it they spread a very thin muslin<br>cloth over the tree in the evening, taking care that it comes well in contact<br>with the flowers as much as possible. During the heavy dew at night the<br>cloth becomes saturated, and imbibes the extract of the flowers. It is<br>then wrung out in the morning. This extract is sold in the bazars." The<br>writer can find no other reference to this interesting product in available<br>literature. The tree is considered by the Hindus to be sacred to Siva<br>and Vishnu. | Berfumery.<br>354                                                                 |

| MADRAS.—The Collector of Cuddapah writes : "A three months' crop<br>sown both in January and July, in drylands (generally red loam), in Cud-<br>dapah (200 acres) and in Pulivendula. The seed is sold at from 14 to 15<br>seers a rupee; the cost of cultivation is R7 and the profit R15 an acre." The<br>following note has also been furnished by the Madras Government:" Grown<br>in many parts of the Presidency to a small extent. In South Arcot it is<br>sown on red loam in both January and July and is a three months' crop.<br>Cost of growth R7; profit R15. Seed sells at 18 measures per rupee; oil<br>is extracted and mixed with gingelly oil." No further particulars regard-<br>ing the total area under the crop in Madras are available, but the follow-<br>ing account by Drury of the method of cultivation pursued in Mysore<br>may be quoted: "The seed is sown in July or August after the fir,, 'heavy<br>rains, the fields being simply ploughed, neither weeding nor manure being<br>required. In three months from the sowing, the crop is cut, and after be-<br>ng placed in the sun for a few days, the seeds are thrashed out with a<br>tick. The produce is about two bushels an acre. In Mysore the price is<br>about R3-8 a maund." |                                                          | 359                                                           |                         |

Oil.—The shining, black, ACHENE yields a clear, limpid, pale, sweet oil largely employed for culinary and lighting purposes throughout India. From a chemical analysis of the achene, given in Watts, Dictionary of *Chemistry*, it would appear that the actual percentage of oil which it contains is 43\*22, but 35 per cent, is the maximum yield recorded, or 10 per cent, less than the vield from the *til* seed (Sesamum indicum). In the Deccan it is the chief substitute for *ghi* amongst the poorer classes, and the achenes after extraction of the oil are used to make oil-cake which is considered a valuable food for milch-cows. From its inferior quality and low price it is also extensively used to adulterate gingelly and castor oils. In 1851 the seed was reported on by brokers in London as follows: "It has been imported from Africa as Niger seed, and from Bombay as kersani seed, and the present value (1857) of the quality represented by the sample is 37s. per quarter, taking the value of rape seed at 485. The oil is good, but the yield is only about 16 gallons against an average of about 20 from rape seed per quarter. The cake is unfit for feeding, and could only be used for manure, owing to the horny excrescence (sic) and dry, heating property of it. The average weight of this seed is also deficient of that of rape seed by 8tb per bushel, which is of great moment in making calculations for shipment. There is no doubt it would meet with a ready sale at its relative OIL. Achene. **360**

| r                                                                                                                       | plants are described in this work. These products will also (as mentioned<br>in the short note under the heading Domestic and Sacred, Ill.» 19))<br>form the subject of a collective article in the Appendix, in which they will<br>be classified, and an enumeration of the plants yielding them will be<br>given. It may, however, be useful in this place tto mention those of<br>chief commercial value, and to refer to the views of experts in England<br>as to the prospects of the Indian gum trade. For this purpose the follow-<br>ing list may be given, which was selected by Mr. O. Christy (of Messrs.<br>Ha, <sup>10</sup> and Sons) at the Colonial and Indian Exhibition, as most likely to<br>meeffhe demands of the European market :<br>Acacia arabica.<br>A. Sundra.<br>A. Sundra.<br>A. Sundra.<br>BalsamodendroD Mukul.<br>Butea frondosa.<br>The same expert remarked at a conference on the gums shown at the<br>Exhibition that owing to the troubles in the Soudan, and the consequent                                                                                                                                                                                                                                                 |
|                                                                                                                         | Exhibition that, owing to the troubles in the Soudan, and the consequent<br>impairment of Egyptian trade, the supply of gums from India had greatly<br>increased, and that if it could be possible to induce the Natives to collect<br>any one of the gums above referred to, pure, and free from dirt, a large and<br>important trade would immediately open out. The great disadvantage of<br>Indian gums imported at that time consisted in the mixture of different<br>kinds, resulting from the consignments having to be opened out, reasserted,<br>and sold as broken packages which never realised anything like their pro-<br>per value. Mr. Christy strongly advocated attention being paid to this<br>fact, and urged that, if possible, the natives should, through the agency of<br>Government, be taught to prepare honest consignments. It may be of<br>interest to note that the subsequent trade statistics of Indian Gums and<br>Resins fully substantiate Mr. Christy's statements. The exports from<br>India excluding Cutch in 1883-84 immediately before the Exhibition were<br>only 2,180 cwt., valued at 824,538, in 1885-86 they had increased to<br>55,407 cwt., valued at Ri5»97»997, while in 1887.88 they had again<br><b>G. 366</b> |

| Gun-stocks and Gun-carriages. (J. Murray,)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | GYMNEMA<br>.sylvestre. |  |

| MEDICINE.<br>Root.<br>369<br>Leaves.<br>370 | Medicine.—The ROOT has long been esteemed amongst the Hindús as<br>a remedy for snake-bite, the powdered root being applied to the part bitten,<br>and a decoction administered internally. But the most curious property of<br>the plant was first noticed and described by Mr. Edgeworth, who dis-<br>covered that on chewing some of the LEAVES the power of taste for sac-<br>charine materials was completely destroyed for 24 hours; powdered sugar<br>tasting like so much sand. Dr. Dymock, criticising this statement says,<br>that in his experience sugar taken into the mouth after chewing the fresh<br>plant, had a saltish taste, but was still easily recognisable. Mr. Hooper,<br>however, repeated the experiment and in his paper above cited, states that<br>"after chewing one or two leaves it was proved undoubtedly that sugar had<br>no taste immediately afterwards, the saltish taste experienced by others<br>was due to an insufficiency of the leaf being used." He also further dis-<br>covered that the leaf had the valuable property of completely removing the<br>taste of bitters, sulphate of quinine after a good dose of the leaf tasting<br>like "so much chalk." He, and several friends who also tried the experi-<br>ment, found however that the effect did not last for 24 hours as stated by<br>Edgeworth, but for only one or two. Mr. Hooper also found that Gym-<br>nema had no effect on the appreciation of the taste of pungent or saline<br>articles, nor of astringents and acids. Though of opinion that this property<br>might prove of value in pharmacy for the purpose of destroying the taste<br>of quinine, he writes," I am not going to propose its use in the adminis-<br>tration of nauseous drugs, until the properties of the Gymnema have been<br>more studied, otherwise the quantity of the vehicle taken may be proved<br>to counteract the effect of the medicines." The leaves have been subjected<br>to a careful and thorough analysis by Mr. Hooper, the results of which<br>have been published in the above cited paper, to which the reader is referred |  |  |
| 771                                         | for further information regarding their chemical composition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |  |

| • <i>Mai., IX., t. 34.</i><br>Habitat.—A small, annual herb, abundant throughout the warnter parts of India, and all tropical countries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                           |
| Oil.—When crushed in the fresh state, the HERB yields an acrid volatile<br>oil having the properties of garlic or mustard oil. ( <i>Pharmacog. Indica.</i> )<br>Medicine.—Ainslie noticed the medicinal properties of the plant, thus :—<br>"The small numerous, warmish, kidney-formed black SEEDS, as well as the<br>LEAVES of the plant, are administered in decoction in convulsive affections<br>and typhus (?) fever, to the quantity of half a tea-cupful twice daily."<br>"The Cyngalese physicians use our article for nearly the same purposes<br>that the Vytiansdo." Sir W. Jones ( <i>Vol. V.g138</i> ) observed that the sensible<br>qualities of Cdravilla promise great antispasmodic virtues, since it had a scent<br>much resembling asafcetida, but comparatively delicate. Later Dr. Wight<br>and several other English writers, following his opinion, have written of the<br>bruised leaves as rubefacient and vesicant, producing a very copious exuda-<br>tion, and affording in many cases the relief obtained from a blister, without<br>the inconveniences of the latter. Moodeen Sheriff, however, in his fbrth-<br>coming <i>Materia Medica of Madras</i> , states that the leaves of G. pent^hylla<br>are neither distinctly rubefacient, nor do they possess a scent resembling asa-<br>foetida ; he maintains that these properties have been assigned to them<br>owing to confusion of the plant under consideration with Oleome viscosa.<br>His observations seem, however, at variance with the chemical nature of the<br>fresh leaves above described under On. The following properties and uses<br>appear to be unquestioned. The seeds are anthelmintic and rubefacient and | OIL.<br>Herb.<br><b>374</b><br>MEDICINE.<br>Seeds.<br><b>375</b><br>Leaves.<br><b>376</b> |
| are employed internally for the expulsion of round-worms, and externally<br>as a counter-irritant. The JUICE OF THE LEAVES is used in many parts of<br>the country as an anodyne instillation for the relief of otalgia and catarrhal<br>inflammation of the middle ear. In certain localities the leaves are applied<br>externally to boils to prevent the formation of pus. A decoction of the ROOT<br>is said to be mildly febrifuge. The following note kindly furnished by<br>Moodeen Sheriff indicates the best methods of exhibition of the various<br>medicinal parts of the plant.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Juice.<br>377<br>Root.<br>378                                                             |
| SPECIAL OPINIONS.—§"The seeds are anthelmintic' and the leaves a remedy for a few diseases of the ear. They are employed internally for the oipulsion of round-worms; and externally their application to the skin is attended with relief in all cases in which mustard is indicated. The                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | -                                                                                         |

remedy for a few diseases of the ear. They are employed internally for the oipulsion of round-worms; and externally their application to the skin is attended with relief in all cases in which mustard is indicated. The juice of the leaves is often used by natives for the relief of otalgia and otorrhcea and occasionally with success; but the burning sensation it produces in the ear, particularly in the cases of the latter disease, is a drawback to its employment. The seeds are prescribed internally in powder, which should always be used with sugar; and externally in the form of a poultice or paste, by bruising them with vinegar, lime-juice, or hot water.

| MEDICINE.                                             | For the use of the ear, the juice of the leaves is to be pressed out by bruising them without water. The dose of the powder is from 30 grains to one drachm, with sugar, morning and evening for two days, and followed on the third morning by a dose of castor oil. For children the dose is from five to twenty grains according to their age." (Honorary Surgeon Moodeen Sheriff, Khan Bahadur, G.M.M.C., Trlipicane, Madras). "The expressed juice of this plant, a lttile warmed, is a useful remedy for ear-ache. It is also used internally in cases of bronchitis. It is purgative, but rarely used for that purpose." {Civil Surgeon J. H. Thornton, B.A.,M.B*> Monghyr).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| FOOD.<br>Leaves.<br><b>379</b><br>DOMESTIC.<br>Seeds. | Food.—The LEAVES are eaten by natives in curries, and as a pot-herb.<br>( <i>Roxb.</i> )<br>Domestic Uses.—The SEEDS are used, rubbed up with oil, as,? vermi-<br>cide in dressing the hair. They are also said to be employed for poison-<br>ing fish.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Hist., China (1871), F. P. Smith, 140.</li> <li>Habitat.—A moderate* sized evergreen glabrous tree, readily known by the hard, round, fruits, which grow on the stem and main branches. It is found from Sikkim and the Khasia mountains eastward to Chittagong, Rangoon, and Tenasserim.</li> <li>Oil.—The sEEDS yield under the hydraulic press from 25 to 30 per cent. of OIL, to ether 51*5 per cent.; the latter oil turns green with the sulphuric acid test. (Dymock.) Chaulmugra oil has long been known and used in India as a remedy for cutaneous diseases, and has lately become a drug of some importance in European practice. As obtained in the bazars, the oil is commonly very impure, and fhe means of detecting these impurities, has foi med the subject of careful investigation by Dr. Dymock. When pure, the expressed oil is clear, of a pale sherry colour, with the odour of chaulmigra, and a sp. gr. of</li></ul> |

| OQOTATA<br>MEDICINE, | an ointment prepared from the oil. The remedy is generally employed both externally and internally, and it has been recommended that patients taking the medicine should live generously, as a weakly and under-nour-<br>ished person is said to be specially liable to the bad effects of the drug, <i>vis.1</i> loss of appetite, nausea, and intestinal irritation. The oil is best ad-<br>ministered in capsules and should be taken immediately after meals, gra-<br>dually increasing the dose from 4 grains to 30, 40, or even 1 drachm, as<br>recommended in the <i>Pharmacopoeia of India</i> ; the best form of ointment<br>is one prepared with vaseline. Perhaps the most satisfactory and trust;<br>worthy results have been those obtained in the treatment of chronic ana<br>acute eczema, and other forms of skin disease.<br>A selection of the more interesting reports from the experience of Euro-<br>pean practitioners in India may be here quoted :— **<br>SFECIAL OPINIONS—S '' The oil is alterative and long-standing, no<br>improvement takes place under its use until it is persisted in for months or<br>years. It is useful in all the forms of leprosy (tubercular, anaesthetic and<br>mixed), but the first-named variety is the one which is most benefited by<br>it. The internal use of the oil should always be assisted by its external<br>application to the affected parts. If used alone externally, if proves itself<br>to strong in some cases and excoriates the tender and diseased parts, or<br>renders the ulcers irritable and painful, and I have, therefore, generally<br>if produces nausea, vomiting or looseness of bweys, it should be stopped for<br>one or two or three of the latter. It is also very useful in lepra vulga-<br>ris, soriasis, and tertiary syphilis. During the use of this oil the patient<br>may be kept on a good and nourishing diet, but prohibited from taking the<br>following articles—fish, prawn, beef, brinjal, greens, curdled milk, lime-<br>givce, and ardent spirits.<br>The oil is best taken floating on water or milk. Its dose is from 5 <sup>to 3</sup> 5<br>drops or more (gradually increased) three or four times in the 24 |
|                      | G. 385                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>GYPSUM,</b> Ball, Man. Geol. of India, III* 450.<br>The hydrous calcium sulphate has numerous varieties of form; when occurring in an amorphous mass it is known as Gypsum, when in a more massive form it constitutes alabaster, and when in transparent crystals it is called selenite. Gypsum on being calcined loses its water of combination and is easily powdered, forming the important industrial substance, Plaster of Paris. As is well known, the addition of water to this powder causes it to become hard and compact, and at the same time slightly to expand in volume, a property which renders it invaluable for making casts or moulds.                                                                                                                                                               |                                                        |

| small that as a commercial source of gypsum it is practically useless. At<br>Kyauk Tyan and on Amherst island sparsely dessiminated crystals of<br>selenite occur, and a granular variety is said to be found on the banks of<br>the Tenasserim river.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | LOCALITIES.                        |
| Medicine.—Gypsum is considered by the Hindu's to have cooling pro-<br>perties, a gruel made from it being frequently administered in cases of<br>fever. It is kept in small quantities as a drug in most Indian bazaYs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | medicine.<br><b>397</b>            |
| Domestic and Industrial Uses.—It is occasionally burnt and used for<br>chewing with betel instead of Carbonate of Lime. It is also employed for<br>whitewashjand as a plaster; but only in one locality, <i>viz.</i> , Sind, do the natives<br>appear to understand its value for making mouldings, hard cements, &c,<br>when in the condition of Plaster of Paris. Of late years, however, the<br>knowledge of its properties and decorative uses has spread to some extent;<br>it is employed in all art schools, and there is every probability that its utili-<br>sation will increase. Should this be the case, it would seem that the<br>fypsum obtained from the Salt Range would be most likely to supply the<br>emand. As already stated, small ornamental articles are carved in a<br>few localities from certain of the harder forms of the mineral.<br>Gypsum is a valuable manure especially for leguminous crops, in the<br>ash of which it is an important constituent, <i>see</i> Manures, Vol. V. | DOMESTIC.<br>398<br>Manure.<br>399 |

|                                      | Habitat.—A small spreading tree, native of Central America and the West Indies; wood imported into India. The tree is mentioned by <b>Mason</b> as cultivated in a few gardens in Burma, where it is said to flourish as if an indigenous plant.                                                                                                                                                                                                                                                                                                                                                                        |
| DTE.<br>Heart-Wood.<br><b>2</b>      | <b>Dye.</b> —A decoction of the chips of the HEART-WOOD is used for Eyeing violet and blue, certain shades of grey, and more especially blacks, to which latter it gives a lustre and velvety cast.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| MEDICINE.<br>Heart-wood.<br><b>3</b> | Medicine.—For use in medicine the hard HEART-WOOD is cut up into<br>small chips by the aid of powerful machinery. These have a feeble, sea-weed-<br>like odour, and a slightly sweet, astringent, taste. Prescribed as a decoction<br>and extract, it is a mild astringent and tonic, and is useful in chronic<br>diarrhoea, atonic dyspepsia, and infantile diarrhoea. The decoction has                                                                                                                                                                                                                               |
|                                      | been found a valuable injection in leucorrhosa. It is also said to be use-<br>ful as an ointment in cancer and hospital gangrene, in which cases it pro-<br>bably acts as a feeble antiseptic, diminishing foetor and purulent dis-<br>charges. Long-continued use has sometimes been followed by phlebitis,<br>hence caution is necessary in its employment.                                                                                                                                                                                                                                                           |
|                                      | SPECIAL OPINIONS.—§" In cases of menorrhagia, women are often treated with a decoction of log-wood; which is also used as an injection" ( <i>Surgeon-Major C. W. Caltkrop, M.D., Morar</i> ). "In cases of chronic atonic diarrhoea, I have found the decoction of log-wood a valuable addition to astringent mixtures. Its powers as a tonic are undoubted." ( <i>Sur-</i>                                                                                                                                                                                                                                             |
| chemistry.<br>4                      | <i>geon S<sub>n</sub>H. Browne, M.D., Hoshangabad, Central Provinces).</i><br>Chemical Composition.—The important part of the plant is the red<br>HEART-WOOD, which contains <i>Hcematoxylin</i> , also a volatile oil and tannic<br>acid.                                                                                                                                                                                                                                                                                                                                                                              |
| 5                                    | Haematoxylin, when pure, is nearly colourless, very soluble in hot water<br>and alcohol, but only sparingly so in cold water and ether. It is some-<br>times found crystallised in clefts of the wood. WJhen exposed to the air<br>under the influence of alkalies, it becomes red, <i>hcematein</i> being formed.                                                                                                                                                                                                                                                                                                      |
| 5                                    | Hair dyeing or staining as practised in India.<br>Ist Process*—Mix equal parts of chalk and soap and half the quantity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                      | of lime; rub in a leaden pestle and mortar until the mixture acquires a bluish colour; apply this to the hair, rubbing in; tie up the hair within a cloth for about an hour; wash; thereafter apply a paste, which has been allowed to ferment to some extent, made of wheat flour, pulverised iron filings, and yeast; tie again for another hour; wash in a strong infusion of galls or of <i>amid</i> (Phyllanthus Emblica), the latter being cheaper; there * after apply an oil to give a gloss. The colour thus obtained is very biack and perfectly fixed being readered weakers only by the growth of the hair. |
|                                      | and perfectly fixed, being rendered useless only by the growth of the hair<br>below which reveals the original colour.<br>2nd Process.—Rub henna leaves on the hair and tie for an hour<br>Wall's fi <sup>Pply</sup> thereafter a P <sup>aste</sup> of indigo or indigo leaves; wash and fix<br>t*? Sans or <i>dmld</i> . This gives a bluish black, but as the indigo becomes<br>rubbed off the henna gives the bein time a rad times                                                                                                                                                                                  |
|                                      | rubbed off, the <i>henna</i> gives the hair tips a red tinge.<br>Halicore dugong, <i>Cuv.</i> , THE INDIAN DUGONG, see Whales. ; V)1 VI                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| HALOXYLON, Bunge; Gen. Pl. <sub>9</sub> III., 70.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                    |
| A genus of shrubs or small trees, having, according to the <i>Flora of British</i><br><i>India</i> , from 8 to 10 species, of which 4 are Indian; namely, H. recurvum,<br>H. Thomsoni, H. salicornicum, and H. multiflorum. Mr. Lace has,<br>however, in his collection of the CHENOPODIACE^: of Baluchistan (Quetta, Sibi,<br>&c.) added H. Griffithii, <i>Bunge</i> , and also what appears to be a new species<br>to which the name of H. Laceii may be assigned. This somewhat resembles<br>H. multiflorum, but is more slender, more profusely branched, and has large<br>pink or yellow flowers. It is known in Sibi as <i>Shordi</i> and is recognised by the<br>natives as quite distinct from H. multiflonim (the <i>land</i> ). Like the other species<br>it is eaten by camels, but in this respect H. Griffithii, <i>Bunge</i> , is much pre-<br>ferred, even <i>to pilt</i> (Salvadora olioides). (Compare with correction under<br>Cąroxylon Griffithii, <b>Vol.</b> II., 176.) |                                    |
| DIACEA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 6                                  |

| Habitat.—A low shrub, from 4 to 6 inches high, of the north-western<br>Panish plains: distributed to Afghénistan and Balýchistan                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | }                                  |
| Panjáb plains; distributed to Afghánistan and Balúchistan.<br>Medicine.—This species is mentioned in <i>Badtn Powell's List of Drug-</i><br><i>yielding Plants</i> , but no account is given of its properties or uses.<br>Fodder.—Camels are fond of the PLANT.<br>Domestic.—In the settlement report of the Montgomery district gora                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | MEDICINE.<br>7<br>FODDER.<br>Plant |
| <i>lana</i> , or <i>metra lana</i> (both, according to Stewart, vernacular names for H. multiflorum) are mentioned as being used in the manufacture of BARILLA or <i>Snjji-khar</i> ; but the plant referred to is probably Salsola Kali, <i>Willd</i> . (See article on BARILLA, <i>Vol. /., 3Q6.</i> ) Stewart writes, "It is used in some parts for washing clothes, and it is probably this whcJn Bel lew states to be used by women in the Peshawar valley for washing the head."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 8<br>DOMESTIC.<br>9                |

| Fibre.—The fibre obtained from the inner layers of the BARK is slightly<br>woolly and of a brownish colour. Chemically it ought to be a valuable<br>fibre, as it contains 63*4 per cent, of cellulose to 13*3 of water. It is strong,<br>and used in the manufacture of ropes by the natives of the forests in<br>which it abounds. Elliot, in his <i>Flora Andhrica</i> , writes, "I saw the people<br>extracting the fibre in considerable quantities and employing it as cordage,<br>without further preparation, in the island of Sivasamudram." It is also<br>a very useful paper-making material, but it would not, at the present rates<br>of freight, pay to send it to England for that purpose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | FIBRE.<br>Bark.<br>19         |
| Fodder.—The LEAVES are given as fodder to cattle, and, owing to this,<br>fine trees are often so much lopped as to be destroyed. Beddome re-<br>ferring to this subject, in his <i>Flora Sylvatica of Southern India</i> , writes,<br>"It is naturally of straight growth, but, cattle being very fond of its<br>leaves, it is pollarded to a frightful extent wherever it grows. It is heart-<br>rending to see the damage done in the Cauvery Forests."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Leaves. <b>20</b>             |
| Structure of the Wood.—Sapwood small, white; heartwood extremely<br>hard, dark red, often with a purplish tinge, and very close-grained; weight<br>about 82ft per cubic foot. This wood, perhaps the hardest and heaviest<br>in India, is extremely durable and does not warp, though it has a tend-<br>ency to split. It is used for bridge and house posts and for ornamental<br>work. It has been recommended for sleepers but is probably too hard,<br>heavy, and difficult to work to be much in favour. <i>{Gamble.)</i> At the<br>Dehri workshops it has been used instead of brass for bearings of machi-<br>nery, and has been found to wear well. In the Sone River piles of <i>anjan</i><br>have been found after twenty years as sound as when first put in. It is<br>much used for building purposes, also for making carts and agricultural<br>implements in the districts where it occurs; but, owing to its hardness and<br>weight, it is difficulty bring to market. The shoots grow very straight,<br>and are hence valuable as rafters.                                                                                                                                                                                                            |                               |

| the Karnatic.<br>Balsamic Oleo-Resin.—An oleoresin of a dark red colour is obtained by<br>deep incision into the heart of the tree. In properties and chemical composi-<br>tion it much resembles the wood oil obtained from species of Dipterocarpus,<br>and the balsam of Copaiva (see articleson D. turbinatus, Vol. III., 161).<br>In Beddome's Flora Sylvatica, the following report on the analysis of<br>the balsam by Mr. Broughton is given:—"The substance appears on<br>examination to consist of a solution of certain chemically different resins<br>in an essential oil, and is in fact an oleo-resin. Like the wood-oils<br>from the different species of Dipterocarpus, it greatly resembles both in<br>composition and properties the Copaiva balsam, though it lacks the<br>transparency and light yellow colour of the latter. It is nearly entirely<br>soluble in ammonia, but does not produce a clear solution. The essential<br>oil has the same composition as that from Copaiva balsam. It boils (on<br>the Nilghiris) at a temperature of 225°C. It rotates the plane of polari-<br>zation to the left, but to a different degree from that found with the oil of<br>Copaiva. This essential oil occurs in different amounts in the balsam, | BALSAMIC<br>OLEO-RESIN.<br>23 |
| Н. 23                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                               |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                               |

| HARES.<br>BALSAM.<br>MEDICINE.<br>Oleo-resin.<br>2+ | Indian Hares.<br>and more abundantly in the fresher collected specimens \$ these are quite<br>fluid, but other specimens are almost semi-solid, doubtless owing to the<br>evaporation and oxidation of the oil. The oil is best obtained by pro-<br>longed distillation of the balsam with water. By this means I have<br>obtained, from an apparently old specimen of balsam, 25 per cent, of oil,<br>and in the most recently collected specimens, I have found over 40<br>per cent. I have made many attempts but have not obtained any crys-<br>tals of copaivic acid from the balsam. The solid resins are of an acid<br>character, but the balsam does not solidify so strongly as that of copaiva<br>after being heated with magnesia. The oil can be separated from the<br>balsam by Ader's process, but it is obtained in a very impure and<br>coloured state." The authors of the <i>Pkarmacographia</i> describe this oleo-<br>resin as a thick viscid fluid, which, owing to its intense tint, looks black<br>when seen in bulk by reflected light, though it is perfectly transparent.<br>It is dichromic by transmitted light, in a thin layer appearing yellowish<br>green, in a thick layer vinous red.<br>Medicine.—The OLEO-RESIN forms an efficient substitute for copaiva,<br>being useful in gonorrhoea and catarrhal conditions of the genito-urinary<br>and respiratory tracts.<br>Dr. Dymock, in his <i>Materia Medico, of Western India</i> , probably in-<br>advertently quotes the <i>Pharmacographia</i> account of the oleo-resin in <i>Bed-<br/>dome's Flora Sylvatica</i> , writes, "There appears little doubt that this<br>balsam could effectually substitute copaiva balsam in medicine. But the<br>appearance of the specimens that 1 have received is greatly inferior to the<br>latter, and they could not, certainly under present circumstances, com-<br>pete with the Brazilian balsam in the European market." It appears,<br>however, that this balsam has by no means attracted the attention that it<br>deserves; indeed, mention of it seems to have been made only in two out of |
| •                                                   | the numerous list of works which treat of Indian Materia Medica. It is<br>doubtfUV, however, whether the oleo-resin or the essential oil obtained from<br>it could be manufactured and exported with profit; still there is no doubt<br>of its valuable properties, and it is probable that, in India at least, it might<br>become an efficient and economical substitute for copaiva balsam.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TIMBER,                                             | Structure of the Wood.—Sapwood large; heartwood brown; weight 4.7ft per cubic foot; used, in the neighbourhoods in which it abounds, for building purposes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
