| either compare it to indigenous tubers, or allude to its sugary property—of<br>these names being ancient.<br>Medicine.—The ROOTS of this plant have a laxative property. Baden<br>Powell says that in the Panjáb the natives regard^ the sweet-potato, "as<br>hot, useful to strengthen the brain and in special diseases."<br>SPECIAL OPINIONS.—§ "The laxative properties of the roots must be<br>very slight, as they are eaten in large quantities as a vegetable without<br>any apparent effect" {Brigade Surgeon G. A. Watson, Allahabad).<br>"Sweet potato is indigestive" (V. Ummegudien, Mettapollium, Madras).<br>Food.—The sweet potato is eaten by all classes of the natives, either<br>in curry, or simply roasted, or after having been cut in half, lengthwise, and<br>fried. Another way of preparing the sweet-potato is to boil it, cut it in<br>slices and add rasped coconnut milk and sugar. In this way it becomes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | MEDICINE.<br>Roots.<br>350<br>FOOD.<br>351 |
| slices, and add rasped cocoanut milk and sugar. In this way it becomes<br>a faiily good dessert. It is also boiled, mashed, and made into pudding<br>in the usual European style with sugar, egg, and milk (L. Liotard).<br>Fodder.—The TOPS of the sweet-potato are used as cattle fodder, and<br>when young are eaten as a pot-herb. See Vol. III., p. 415.<br>Cultivation.—Bengal.—There are two varieties cultivated: one with<br>purple tubers and purple flowers which is known as Sakarkanda, and the<br>other with white tubers and flowers—the Chine dlu. Sweet potato requires<br>a sandy soil and is generally raised on lands that will scarcely grow any<br>other crop. Five to seven ploughings are given and the land then raised in<br>ridges often leaving a narrow belt between the trenches and ridges. It is<br>propagated by cuttings, to supply which creepers are grown near the home-<br>steads in a damp locality. Before planting, these creepers are pulled up<br>and cut into pieces, each containing two knots, the portions close to the<br>roots being rejected. The cuttings are planted in the ridges, one of the<br>knots being buried in the ground and the other left above. The planting<br>time is from August to September. When the cuttings have taken root,<br>the ridges are properly made, and later on the plants are earthed up. The<br>harvest time extends from October to November. The yield is from 20 to<br>30 maunds per bigha (=§rd acre.). Chine dlu sells from eight or ten annas<br>a maund and Sakarkand from twelve to fourteen. A kind of thread-like<br>worm sometimes grows inside the roots and does much injury to the plant<br>(Annual Report, Director of Land Records and Agriculture^ 1886. 4>. | TION.<br>Bengal.<br>353                    |
| In a special report furnished for this work the Director of Land<br>Records and Agriculture writes: "Sakarkand.r-In the Bhagulpore Division<br>the fields are ploughed and harrowed two or three times. The seeds are<br>then scattered in June-July, and dug out in January-February. It is<br>grown to a small extent in Chota Nagpur for home consumption. There<br>are two varieties: one is known as <i>desi</i> (country) or red, and the other<br><i>belati</i> (English) or white. The latter is fast driving the former out of cul-<br>tivation. The area under <i>aluas</i> and <i>sulknis</i> (species of sweet potatoes or<br>yams) is said to be considerable in the Mozufferpore districts, <i>viz.</i> , 6<br>per cent, of the whole cultivation. This article of diet is one of the chief<br>foods of the poorer classes in Mozufferpore, and lasts from October till<br>March, being dug up as required."<br><i>Assam.—In</i> a special report the Director of Land Records and Agricul-<br>ture states : "The sweet-potato is grown in the villages in or around the<br>homesteads. It is sown in September or October and taken up in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Assam.<br><b>35</b> 4                      |
| January."<br>North-West Provinces.—Mr. E. T. Atkinson {EconomicProducts,Part<br>V., 19) says the sweet potato or Shakrkand, rakt-alu, or pind-alu is cul-<br>tivated all over these provinces. There are two principal varieties, one<br>with white and the other with red tubers, both of which are highly                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | NW.<br>Provinces<br>355                    |

| CULTIVA-<br>TION.<br>NW.<br>Provinces. | esteemed as palatable and nutritious articles of food when boiled or<br>roasted. The young leaves and tender shoots are eaten in curries and<br>used as greens, and the leaves themselves are considered an excellent<br>fodder for cattle."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Central<br>Provinces.<br><b>356</b>    | <i>Central Provinces.</i> — <i>Mr.</i> J. B. Fuller reports : "This is commonly cultivated during the cold weather in the beds of streams and on the sloping banks of large rivers in company with <i>Brinjal</i> or <i>Bhata</i> (Solanum melongenum). Full details of area are not available. In the Saygor, Seoni, and Hoshangabad districts it is returned as covering over 500 acres, and                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Panjab.<br>357                         | it is grown on over 700 acres in Jubbulpur."<br><i>Panjdb</i> ,—Stewart wrote: " the sweet potato is commonly cultivated (in<br>the cold weather) in the eastern part of the Panjdb plains; the root is eaten<br>as a vegetable."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Bombay.<br>358                         | Bombay.—In a special report furnished for this work the DiPector of<br>Land Records and Agriculture writes :—"Sweet potato is grown every-<br>where in the Presidency. In 1887-88 it occupied 10,666 acres. It is irri-<br>gated and manured. There are two varieties, the white and the red. The 5<br>latter is smaller and sweeter. In Gujarat it is grown in the cold weather,<br>but in the Deccan and the Konkan any time in the rains or cold weather.<br>It takes about four to six months to mature. The land is ploughed,<br>harrowed, weeded, and dressed with manure and sown from a last year's<br>bed which has been watered and kept for the purpose. The potato rots<br>in the ground and sends out small shoots which consist of a knot or eye,<br>with a single leaf attached. The shoots are planted in the prepared beds<br>and irrigated. About 4,000 to 5,000 shoots go to an acre, and produce<br>from 1J to 5 tons. The price varies from Rf to R2 per Indian maund.<br>The young shoots and leaves are eaten as a pot-herb. The tubers are<br>eaten both boiled and roasted. They are largely used on fast days.<br>Dried and ground into flour they are also made into cakes which the higher                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Madras.<br>359                         | classes eat on fast days. During the rainy season, when the grain stock<br>of poorer cultivators runs short, sweet-potato not uncommonly forms part<br>of their bread stuff. The mature vine is an excellent cattle food. The<br>average yearly outturn may be estimated at 8,90,400 maunds."<br>In the report of the Crop Experiments mention is made of two kinds (i)<br><i>Deshi</i> or <i>Mulki</i> , with heart-shaped leaves only slightly indented and root<br>rather small but sweet, often red coloured: (2) <i>Vildyiti</i> introduced some<br>fifteen years ago, leaves deeply lobed, roots large and never red coloured.<br>The cultivation of the crop is regarded good for the land. Out of a field<br>of sweet-potatoes three rows were pulled and the produce weighed, <i>vis.</i> ,<br>947ft. Mr. Heaton, who reports on the experiment, remarks that if the<br>southern part of the field had given as good a return as the northern, the<br>outturn would have been 13,4891b per acre. The yield was by no means a<br>first-rate one. The roots were of medium size, not big. 1 estimate, he<br>adds, that a 16-anna crop would yield from 18,000 to 20,000& an acre.<br>Mr. Price, of the Southern Maratha Survey, experimented on sweet-pota-<br>toes many years ago and obtained as the result a yield of 6,200fb per acre.<br><i>Madras.</i> —»In the Coimbatore Manual it is stated "white and red<br>varieties are grown in gardens, the cuttings being planted from September<br>to December, and the roots dug out from January to March. The land<br>is well ploughed, manured, and ridged. The cuttings, which are from<br>«Me <sup>*</sup> e <sup>*</sup> ? | nominal half. A garden land of 1*35 acres has been known to let to a tenant for R70 per annum, one of the crops being sweet potatoes. The value of the outturn of sweet potatoes was perhaps R130. The Government assessment on 1*35 acres would be R2 and water rate R4-8."<br>The following special reports, contributed for this work, may be here given. Mr, H. Sewell, Collector of Cuddapah, wrote :" The creepers are first planted in June and July, and when multiplied are transplanted in October. The crop of potatoes is dug out in January and February. The soil required is red sand. The cost of cultivation is R15 and profit R25 a cawndy. The potatoes are sold at 2 annas a thk."<br>Mr. H. Willock, Collector of Trichinopoly, stated :"The area under sweet potato ( <i>valli kalangu</i> ) cultivation  in this district is only about 150 acres. The outturn is estimated at about Rio worth per acre per annum. The cost of cultivation is about R6. This tuber is cultivated to a very small extent in patches in <i>olapperi</i> lands under well and channel irrigation. It is generally grown on red loam or sandy soil." Mr. Goodrich, Collector of Bellary, reported :"The area devoted to sweet potato in three taluks is 112 acres, but the extent in other taluks cannot be estimated. The time of sowing varies according to locality from June to November, and that of reaping from December to March. The average cost of cultivation per acre is R29, the highest being R45, and the lowest R12. Red and mixed soils are those best suited to this crop. The ground should be ploughed and harrowed twice, and irrigated once, in eight days. It is eaten as a vegetable, and is also sometimes made into dishes. The annual yield of this crop is about 50,700 maunds, and the cost price varies from 8 annas a maund to 10 maunds for a rupee." | CULTIVA-<br>TION.<br>Madras. |
| Burma.—The following special reports have been received regarding<br>sweet-potato cultivation in Burma :—" In the Upper Chindwin district it is<br>grown on'soft soil. The ground is broken and small bits of stems planted.<br>No watering is required. It is planted in September and October, and<br>the potatoes are collected in February and March. It is grown largely,<br>afd sold at R3 per 100 viss. But the export is not much."<br>"In the Lower Chindwin district it is very plentiful. The grounds<br>selected are usually on the islands in the river. It is boiled, cooked, or fried                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Burma.<br>360                |
| and then eaten."<br>"In the Prome district, the area under cultivation is 21*50 acres. It is<br>sown in July and reaped in March. The cost of cultivation is R3-8 for a<br>quarter of an acre, yielding potatoes to the amount of 150 viss, which<br>being sold for R9 leaves a profit of R5-8. Slips are taken and planted in<br>sandy soil in a hole of a span's depth. It is cooked and eaten. The<br>annual production is estimated at 13,000 viss, and the cost at the place of<br>production is given as R5-8 or R6 per 100 viss "<br>"In the Pegu district it is cultivated in moderate quantities by Shan and<br>Chinese gardeners, The ground is divided into ridges about a foot high<br>and on them the tubers are planted. When ready for market the tubers<br>are dug out and sold at 10 to 12 annas per 10 viss. It is generally grown<br>on sandy loam near streams, as it does not form large tubers in the<br>shallow hard soil of the hills. It is planted at the beginning of the rains,<br>and the tubers are taken up in the cold weather."<br>"In the Akyab district, the area cultivated is about 50 acres. It is sown<br>about October or November and dug up in about three months. Cost<br>of cultivation about R30 per acre. The soil has to be ploughed, manured,<br>and made into ridges on which the cuttings are planted. It thrives better<br>when cowdung is used as manure. It is used as food, but only as a delicacy<br>and eaten in small quantities."                                                                                                                                                                                                                                                                                                                                                                                               | -                            |

| CULTIVA-<br>TION.<br>Burma. | "In the Kyoukpyu district it is grown all over, as both the leaves and<br>the tubers are eaten by the natives."<br>"In the Eastern Division, Upper Burma, it is cultivated to some extent<br>in two varieties—the yellow and white."<br>"In the Toungoo district it is largely sown by Shansin the river silt, at<br>the end of the rains, and at other times where loose, friable, and sandy soil<br>is obtainable."<br>Similar notices are given for the other districts of Burma, thus showing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ALCOHOL.<br>361             | a very extensive cultivation.<br>Alcohol prepared from Sweet Potatoes.—The utilisation of the sweet-<br>potato as a source of alcohol has recently been discussed in several news-<br>papers. M. Ralu, it would appear, has obtained patents for the distillation<br>of a specially prepared flour from these tubers. A Company has Mso been<br>formed at the Azores, and the alcohol it produces is said to be readily<br>purchased by Lisbon merchants to be used in the fortification of wines.<br>• The alcohol, M. Ralu reports, of which we have samples, is superior in<br>quality to that of the best marks of France. The distillery obtains 12 per<br>cent, ( <i>i.e.</i> , 12 litres per 100 kilogrammes of sweet-potato) of alcohol. We<br>have experimented with the sweet-potatoes of Algeria. They give 13*4<br>litres of alcohol per 100 kilog. The sweet-potato of Martinique and Brazil<br>has given 15 litres. There is here therefore a very rich material for dis-<br>tillation. Ordinary potatoes yield only 3 litres of alcohol per 100 kilog."<br>As compared with these figures it may here be added that with the excep-<br>tion of Indian-corn sweet-potatoes are cheaper than any of the substances<br>used in distillation, while they yield the highest recorded percentage of alco-<br>hol. Thus, for example, wheat yields from 28 to 30 litres per 100 kilog.;<br>barley from 22 to 23 ; oats from 20 to 21; buck-wheat from 24 to 25; In-<br>dian-corn from 28 to 30; rice from 32 to 33; and sweet-potato flour from<br>maize it has been stated there is a great saving of time and combus-<br>tibles when distilling from the flour of sweet-potato. Alcohol from maize<br>costs 10/. per hectolitre more to make, and when made, sells from Bf. to<br>ic/. less than the alcohol from sweet-potato. The writer of the article<br>in the <i>European Mail</i> , from which publication the statements given above<br>have been derived, very rightly remarks that it remains to be seen whether<br>it would pay to cultivate the sweet-potato on a large scale as a source of<br>alcohol. Doubtless the price of the tuber would rise considerably, and<br>oth |

| MEDICINE.<br>Roots.<br><b>380</b>          | In the rains.<br>Medicine.—The large tuberous ROOTS are very much used in native<br>medicine, being regarded as tonic, alterative, aphrodisiac, demulcent, and<br>lactagogue. The powdered root-stock is given with wine, for the purpose of<br>increasing secretion of milk, and for the emaciation of children with debility<br>and want of digestive power, the early Sanskrit physicians prescribed a<br>diet of equal parts of <i>viddri</i> , wheat-flour, and barley ( <i>Dutt, I.e.</i> ). Rheedd<br>refers to the use of the powdered sun-dried root, boiled in sugar and butte<br>to promote obesity and moderate the menstrual discharge. Dymock say<br>that the tuberous roots are in considerable demand, being extensively used<br>in Bombay, and that the young tapering roots, of a small variety, are known<br>in the herbalists' shops as <i>asgand</i> . The name <i>asgand</i> is also, however<br>given to Withania coagulans, <i>Dunal</i> (see Vol. VI.), the roots of which are<br>twisted, white, covered with a thick soft bark and contain a good deal o<br>red-colouring matter, which is visible through the greyish epidermis. The<br>roots of the Ipomaea <i>(asgand)</i> are only half the length of those of With<br>ania, or about 6 to 8 inches long ; they are light yellowish brown externally<br>white internally, brittle, with a short and starchy fracture. They are muci<br>laginous and bitter in taste. According to the <i>Mokhzan-el-Ad-wiya</i> the<br>are tonic and alterative, and by Chakradatta are recommended to be giver<br>to weakly children. The Rev. J. Long says the powdered root in<br>used in spleen disease; it is purgative in its action. In Davies' Trade and<br><b>I. 380</b> |

| IPOMiEA<br>hederacea.<br>MEDICINE.<br>385<br>Šogās.<br>386<br>Extract.<br>387<br>Tincture.<br>388<br>Powder,<br>389<br>Resin.<br>390 | The Kala-danah.<br>• himalaica: leaves and flowers large, seeds densely closely villous.<br>Found at altitudes of 4,000 to 5,000 feet.<br>Medicine.—This drug does not appear to have been known to the<br>early Sanskrit physicians, and is not described by Ainslie. The author<br>of the Makhzan-ul-Adwiya says that it is a drastic purgative, useful in<br>the treatment of billous and phlegmatic humours, and that it acts also as<br>an anthelmintic. Roxburgh was apparently the first to make these SEEDS<br>known to European physicians, and it may be said they nowliold an im-<br>portant position as a useful and cheap substitute for jalap. They were<br>made officinal in the Pharm. India in 1868, where directions will be found<br>to make the preparations in which the drug is now administered, namely,<br>in the form of a TINCTURE, an EXTRACT, a compound POWDER, or a resin,<br>consequently on the place of the corresponding preparations of Jalap. The<br>resin (introduced by Dr. Bidie) appears to be the most satisfactory forr.<br>of administering the medicine; it does is 4 to 8 grains. This substance<br>is known as Pharbitisin. It has a nauseous acrid taste and an unpleasant<br>odour, especially when heated.<br>The abumen and mucilage are given, consequently the result of the opera-<br>tion is an enormous bulk of almost inert extract, which in a short time<br>becomes putrid. Five to ten grains of this extract have no perceptible<br>effect as a purgative." O'Shaughnessy says that it proved an<br>diffective purgative in 94, occasioned vomiting in 5, but in 15 it produced<br>on an average five stools within 28 hours and the action generally com-<br>menced in an hour's time. O'Shaughnessy adds that in his time the<br>seds sold at 4 seers per rupee. Dr. Kirkpatrick regards <i>kdld danass</i><br>intermediate in strength between rubarb and jalap. According to Irvine<br>the ativer sroast the seeds before reducing them to a powder.<br>SFECIAL OPINIONS.—§ " A certain and efficacious purgative. Dose<br>51" 55 of 5° powdered seed mixed with powdered ginger" ( <i>Assistant</i><br><i>Surgeon Shib Chundra Bhat</i> |
| 1                                                                                                                                    | pensary practice. Its action resembles very much that of jalap, the dose<br>being usually £i » (Civil Surgeon R. Macleod, Sarun). "Several native<br>I. 390                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| practitioners have told me of the value of * Kdlddna seeds <sup>9</sup> as an active<br>purgative, causing copious liquid stools, and as being very safe and effi-<br>cacious, but inadmissible in inflammatory states of the alimentary canal "<br><i>[Surgeon J. Ffrench Mullen, M.D., I.M.S., Saidpore).</i> " Quite equal<br>to jalap and in many respects superior to it. Very largely used in charit-<br>able dispensaries. The powdered seeds given in drachm doses" ( <i>Civil</i><br><i>Surgeon S. M. Shircore, Murshtdabad).</i> " Much used as an ordinary<br>purgative in dispensary practice, the usual dose of the powdered seeds being<br>half a drachm " ( <i>Surgeon G. Price, Shahabad).</i> " A cheap and certain pur-<br>gative. I constantly use it in jails" ( <i>Surgeon R. D. Murray, M.B., Burdwan).</i><br>" An excellent and sure purgative, operating quickly. The seeds reduced<br>to a powder are used as a substitute for jalap. Dose Ji with 5 grains of<br><i>pulvia singiberis</i> and a little sugar " ( <i>Civil Surgeon C. M. Russell, Sarun).</i><br>"The seeds of Ipomaea hederacea or the <i>Kdld-zirki-kebinj</i> of Madras and<br><i>Kdlddna</i> of Calcutta. They are undoubtedly one of the few good and<br>cheap cathartics India possesses, and also one of those purgatives which<br>act very efficiently and satisfactorily when used alone. In this respect<br><i>Kdlddna</i> is preferable to jalap. The simple powder is prepared by drying<br>the seeds well and reducing them to fine powder in the ordinary way.<br>Dose, from 45 grains to one drachm. The compound powder should be<br>prepared with cream of tartar in equal proportions as follows :—Take of<br><i>Kdldddna</i> and cream of tartar, in powder, each seven ounces; ginger,<br>in powder, one ounce; rub them well together and pass the compound<br>powder through a fine sieve. Dose from one drachm to a drachm and a<br>half" (Honorary Surgeon Moodeen Sheriff, Khan Bahadur, G.M.M.C.,<br>Triplicane Madrae) |                                                                    |
| Triplicane, Madras).<br>Chemistry.—For an account of the chemical nature of these seeds see<br>Flückiger and Hanbury*s Pharmacographia (reproduced in Dymock's<br>Materia Medica, Western India, 560),                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                    |
| Trade.—In Bombay the seeds of I. muricata, <i>Jacq.</i> (imported from Persia), are sold much more commonly than those of the true <i>kdld ddna {Dymock)</i> . Their action appears to be identical (see the account of that species below). Irvine remarks that in Patna the <i>kdld ddna</i> seeds sold at 2 annas a pound during his time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 392                                                                |

In some of its forms it approaches so close as to be almost indistinguishable from certain conditions of I. hederacea, Jacq.; it is quite distinct from I bona-nox. It is said to occur on the Himalaya at altitudes of 1,000 to 5,000 feet, extending from Kangra to Sikkim.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | ,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>,<br>, |
| Medicine.—The SEEDS are used chiefly as a substitute for those of the preceding species, from which they can be distinguished by their large size, lighter colour, and thick testa. Dr. Dymock was the first to establish that the <i>Tukm-i-nil</i> imported from Persia was identical with this species. When exhausted, he writes, with rectified spirit, the Persian seeds jield brown resin and yellowish oil, having the same appearance as the resin and                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | r Seeds.<br>h <b>394</b><br>a d                                    |

| Lai- Dana.<br>414 | Habitat.—Although dried specimens of this plant do not appear to have<br>been submitted to any botanical authority for determination, Dr. De<br>affirms that it "grows abundantly in the Upper Provinces," and he adds<br>"When cultivated in Bengal, it grows equally well. The seeds are sola<br>in large quantities in Patna and other markets of the Upper $P^{rovm_Ae}T$<br>Each capsule contains three seeds of a brownish-red colour, and studaea<br>with minute hairs. When soaked in water, they swell and yield a muci-<br>iage. The seeds are to be dried in the sun previous to being $P^{ow}?^{ere}T$<br>The above passage practically contains all we know regarding the<br>identification of these seeds. Waring, in the <i>Pharmacopoeia</i> , $erre?$<br>them to Ipomaea, apparently on the assumption that they were $id_Antlgre$<br>with the <i>lal-dana</i> of Mr. T. O. Lahory, but he does not inform us whether<br>or not he personally examined either or both of these seeds. If the plan<br>that yields the so-called <i>shapussundo</i> be as plentiful as Dr. De wou<br>lead us to suppose, it is remarkable that it has never been botanicai<br>determined. Numerous writers refer to it, but perhaps repeat in $d??$<br>sentences only the statements originally published by De, so that during<br>the past twenty years nothing further has been made known than is con-<br>tained in De's <i>Indigenous Drugs of India</i> . |
| ~                 | The remark that the capsule contained only three seeds would (assume<br>ing that it is an Ipomaea, of which the writer has some doubts) a-sis-<br>it to the sub-genus Pharbitis, whereas Waring presumed shapussundo)<br>be the seeds of Ipomaea cymosa, R. fef S., and I. sepiaria, Kan., "wnich<br>have their seeds covered with short brown hairs," but these species do not<br>belong to Pharbitis. Turning to works on Economic Botany, however, to<br>discover references to shapussundo, Roxburgh {Fl. Ind., Ed. C.B-C, o <sup>•</sup> l><br>is found to assign the name shah-pusund to Amberboa (Centaurea) mos<br>chata, DC, Prod., VI., 560. and Voigt (Hort. Sub., Cal, 424) repeats this<br>as sapusuvd (the Sweet Sultan). Baden Powell (Panjdb Products, 355<br>& 386) adds to shahpasand the name of Idl ddna as the vernacular of<br>Centaurea moschata, and refers these to the same position with Centaurea<br>Benen, Linn {DC, Prod., VI., 567}, which he describes as a mild purga<br>tive root imported into India from Kabul. Stewart gives the name<br>*'''pia»p to Withania coagulans and asgand to W. somnifera. Dymock<br>while discussing the properties of Centaurea Behen, remarks "Ainslie<br>I. 414                                                                                                                                                                                                                            |

| confounds it with asqand,* and also with the root of Physalis (Withania)<br>somnifera'' (Cotif. with Mat. Ind, //., 14). The writer has read through<br>Ainslie's account, and is of opinion that he is there describing, as he<br>affirms, Withania somnifera, which Dymock himself admits is the true<br>asgand, though the tubers of an Ipomaea imported into Bombay from Persia<br>are also sold in the bazars as asgand. (See the information given under<br>I. digitate above.)<br>It will thus be observed that much confusion exists regarding shapus-<br>sundo, and were it not that the seeds of neither Amberboa nor Centaurea<br>would answer to De's description, the writer would be much more dis-<br>posed to transfer that drug to either of these genera than to leave it in<br>Ipomsea. It is curious, however, that shapussundo, asgand (Ipomaea),<br>asgand (Withania), and Centaurea Behen—mild aperient drugs—should be<br>so much confused one with the other, and that Amberboa moschata should<br>at the same time be the only plant of the lot that can be said to be met<br>with on the plains of India, though of course under cultivation only, still<br>further that Withania should be the only indigenous Indian plant of the<br>series. Irvine, in his Materia Medico, of Patna, does not allude to ska-<br>pus nun do, though De specially mentions that city as the market where it<br>is chiefly obtained                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |

| Turpethun<br>MEDICINE.     | m. The Further Root of mean shap. m. The Further Root of mean shap. and krishna or black. The white variety is preferred for medical use as a moderate or mild cathartic. The black variety is said to be a powerful drastic and to cause vomiting, faintness, and giddiness. <i>Trivit</i> has been used as a purgative from time immemorial and is still used as such by native practitioners, alone, as well as in various combinations. In fact this medicine is the ordinary cathartic in use amongst natives, just as Jalap is among Europeans. The usual mode of administering it is as follows. About two scruples of the root are rubbed into a pulp with water'and taken with the addition of rock salt and ginger or sugar and black pepper. Roxburgh wrote in his <i>Flora Indica</i> of this drug that "the bark of the root is by natives employed as a purgative, which they use it fresh, rubbed up with milk. About six inches in length of a root as thick as the little finger they reckon a common dose." In a separate and more recent note on this subject he says, quoting Dr. Gordon : "The drug which this plant yields is so excellent a substitute for jalap, and deserves so much the attention of practitioners, that I doubt not the following account will prove acceptable. It is a native of all parts of continental and probably of insular India.also, as it is said to be found in the Society and Friendly Isles and the New Hebrides. It thrives best in moist shady places on the sides of ditches, sending forth long, climbing, quadrangular stems, which in the rains are covered with abundance of large white, bell-shaped flowers. Both root and when fresh contain a milky juice which quickly hardens into a resinous substance, altogether soluble in spirits of wine. The milk has a taste at first sweetish, afterwards slightly acid; the dried root has accredy any perceptible taste or smell. It abounds in woody fibres, which, however, separate from the more resinous substance in pounding, and ought to be row the root that all the purgative matter exis |

<sup>•</sup> These Mr Colebroke mentions as amongst the best writings of the Hindus on Materia Medica.

<sup>1. 416</sup> 

The Turpeth Root or Indian Jalap.

plant; in the last of these the root in question, *teori* (BENG.), is recommended as of use in removing worms and phlegm." •' Our present article," he continues, "had long a place in the British Matena Medica (Convolvulus indicus, Alatus maximus), but of late years it has fallen into disuse. I find it mentioned by Avicenna (264) under the name OJ y > turbad; but the first amongst the Arabs who prescribed it was Mesue, who gave the root, in powder, to the extent of from Ji <sup>to</sup> 5"» <sup>an(\*)</sup> of the decoction, from 5ii <sup>fo</sup> 5<sup>\*</sup>» Alston, in his *Materia Medica* (Vol. II, 530), speaks of *turbith* as a strong and resinous cathartic, and recommended in his days in gout, dropsy, and leprosy. The plant is known to the modern Greeks by the name of *TovpireQ.*" "Virey speaks of the root of the Convolvulus Turpethum as more drastic than the common Jalap." Muhammadan physicians recognise, like the Hindus, two forms of *turbad*, a white and a black, and recommend that the black should be avoided on account of its poisonous properties.

In India the usage of this drug, apparently, fell off after the appearance of O'Shaughnessy's Bengal Dispensatory, where he wrote, while commenting on the facts published in Roxburgh's Flora of India, "we have also subjected its properties to careful clinical experiment, and we feel warranted in asserting that the action of the medicine is so extremely uncertain that it does not deserve a place in our Pharmacopoeia." That verdict was reproduced in Waring's Pharmacopceia of India, and European interest in the drug, from the date of that work, may be said to have died out. It will, however, be found (from the selection of special opinions quoted below) that native practitioners continue strongly in favour of it, and that Dr. Moodeen Sheriff and others think that the adverse opinion held by European authorities is largely due to the whole root having been used instead of the root-bark. In this opinion Me rat and DeLens concur, recommending that the roots should be chosen in which the bark is intact, " as most of the activity of the root resides in that part."

Chemistry.-The bark is without odour and has little taste. " Examined by M. Bontron Char land, it was found to contain resin, a fatty substance, volatile oil, albumen, starch, a yellow colouring matter, lignin, salts, and oxide of iron. The root contains 10 per cent, of resin (*M.* Andouard). According to M. Spirgatis, this resin is a glucoside, turpethin, C<sub>36</sub> H<sub>6</sub>g O<sub>16</sub>, like that of other CONVOLVULACE^E, insoluble in ether, but soluble in alcohol, to which it imparts a brown colour not removable by animal charcoal. To obtain it pure the alcoholic solution is concentrated; the resin precipitated by water, boiled with this vehicle, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol, and thrown down by ether." "It is inflammable, burning with a smoky flame, and emitting irritant vapours" (United States Disfensatory, 15th Ed., 1770). Accordingly Spirgatis turpethin is only present in the root to the extent of 4 per cent. Under the action of alkaline bases it is transformed into turpethic acid ( $C_{34}$  H<sup>A</sup>  $O_{18}$ ), and by hydrochloric and other dilute acids it is decomposed into *turpetholic* acid ( $C_{16}$  H<sub>32</sub> O<sub>4</sub>) and glucose. (Watts, Chemistry, V., 925-Q26). According to Dr. Dymock the FLOWERS are in Western India applied to the head in hemicrania.

SPECIAL OPINIONS.—§" My experience of the root of Ipomaea Turpethum is much greater now than nineteen years ago, when I spoke ot it in the *Supplement to the Pharm. of India*, pages 346—348. There are two varieties of it which are well known in the bazar as *sufed-turbud*, and *kala-turbud*, or, the white and the black *turpeth* root, respectively. The drug consists of pieces of root and root-bark, and the latter being the best and not generally sold separately in the bazar, requires to be picked

| ODDER.<br>41Q | 2 to 4 inches, and in thickness from one quarter to one inch; quilled or<br>curved; smooth, but often wrinkled longitudinally; taste slightly acrid,<br>and odour agreeable if new. The colour of the white variety is grey or<br>reddish-grey; and of the black, brown. The cut ends of the piece, parti-<br>cularly in the white variety, are often covered with some resinous sub-<br>stance. The thickness of the bark itself is about a line or two, and the<br>bark of the white variety is generally thicker than that of the Wack.<br>The <i>turpeth</i> root, notably the white variety of it, is quite equal to jalap<br>and superior to <i>rhubarb</i> in its action, and preferable to both for having no<br>nauseous smell or taste, and for being a very efficient and satisfactory<br>purgative when used alone. Its dose is somewhat larger than that of<br>jalap, but this is no disadvantage, as long as it is safe and free from nauseous<br>taste and smell. The dose is larger only by 10 or 15 grains/ As a<br>cathartic and laxative, the <i>turpeth</i> root is useful in all the affections in<br>which either jalap or rhubarb is indicated. The best way of administer-<br>ing it is in simple powder; but it may also be employed in combination:<br>with cream of tartar in euqal proportion, and with or without a few<br>grains of ginger in each drachm of the compound powder. Dose "whe<br>simple powder is, from fifty to seventy grains, and of the compound powder<br>from a drachm to nintey grains" (Honorary Surgeon Moodeen Sheriff<br>Khan Bahadur, G. M. M. C, Triplicane, Madras). "What is sold as<br>black turband has the same structure as the white, but it is of smaller size<br>and darker colour "[Surgeon-Major Dymock, Bombay]. "Used as a pur-<br>gative by native practitioners" (Civil Surgeon, Ahmedabad). "" are jegs<br>powdered in doses of a drachm and a half is used as a purgative, but 1s<br>efficient than kaládána" (1st Class Hospital Asst. Lai Mahomed, $M < \frac{1}{10}$<br>Dispensary^ Hoshangabad, Central Provinces). |

Arjun, Bomb.<br/>Drugs, 142; Murray, PI. and Drugs, Sind, 19; Irvine, Mat. Med.,<br/>Patna, 10; Med. Top. Ajmir, 129; Year-Book, Pharnt., 1873, *'4&gt;<br/>Birdwood, Bomb. Pr., 89.</li> <li>Habitat.—This is the European plant so much used in the preparation<br/>of the sweetly-seen ted Otto of Orris. It is said to be sometimes met with<br/>in Indian gardens. In Kashmir this, as also several other species, are<br/>cultivated, and either wild or only acclimatised are frequently seen on<br/>the margins of fields near water. The writer collected what appears to be<br/>this species in Pangf. It is fairly plentiful in the Simla district and in<br/>Kullu, but always under circumstances that would lead to the suspicion<br/>of its being cultivated or at most only an escape from cultivation. This<br/>may probably be the Iris longifolia mentioned by Adams (Wanderings of<br/>a Naturalist, p. 196) as seen by him on the Northern P'injal, though it<br/>would seem that I. pallida is in many parts of the Himálaya also accli-<br/>matised and may possibly be the shrúl or skecho of Stewart's Panjdb<br/>Plants.</li> </ul> |                           |
| Perfumery.—It is not known whether the natives of India employ the tubers of any Iris in perfumery. But it is significant that while in the <i>Ain-i-Akban</i> a special chapter is devoted to Perfumes, no mention should be made of Orris. Presumably the perfume prepared from these rhizomes in Europe was not known to the Muhammadans of India 300 years ago. ( <i>Conf. with Piesse, Art of Perfumery, 172-174.</i> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | perfumery.<br>426         |
| Medicine.—There seems considerable doubt as to the identification of<br>the <i>irisa</i> root; in fact, it is not by any means proved to be obtained from<br>this species. Stewart says <i>irisa</i> is used externally in the treatment of<br>rheumatism. Irvine mentions that it comes to India from Kabul. But<br>I. germanica is cultivated in Kashmir and is more probably the source of<br>the drug mentioned by Stewart than is I. florentina*                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | MEDICINE.<br>427          |

| Iron exists in nature in three great classes of ores-<br>Iron P rites, with the chemical composition of $FeS_2$ ;<br>(3), as OXIDE. The FIRST class is not directly work<br>obtaining the metal; the second and third are consect<br>mercia importance as sources of iron. The SEC<br>which iron exists as the carbonate, Fe CO <sub>3</sub> , cons-<br>kinds, namely, those in which the salt is crystalline at<br>earthy matter, and those in which a larger or sma-<br>intimately intermixed with the ferrous carbonate.<br>termed spathic iron ore {siderite spat hose 9 sparry or<br>bears the name of argillaceous ore or clay-ironstone.<br>in large deposits in many coal measures, and in this<br>black-band. The THIRD class of ores in which iro<br>may be divided into three sub-classes, namely, (1) the<br>essentially occurs as anhydrous ferric oxide (1)<br>which it occurs as hydrated ferric oxide (Fe <sub>2</sub> ,O <sub>3</sub> . I)<br>which the iron is in the form of ferrous and ferric oxis<br>sub-class magnetic oxide of iron, Fe <sub>3</sub> O <sub>4</sub> is the type.<br>The ores of the first sub-class are chiefly known<br>specular ores. Red hcematite is generally soft and fri<br>as red ochre or puddler's ore, but it also occurs in h<br>called kidney ore. Specular ore is a hard well-crystall<br>or black colour, and brilliant lustre. | -(1), as SULPHIDE, or<br>(2), as CARBONATE;<br>(2), as CARBONATE;<br>(2), as CARBONATE;<br>(3), as CARBONATE;<br>(4), as CARBONATE;<br>(5), as CARBONATE;<br>(5), as CARBONATE;<br>(5), and (5), and<br>(5), and (6), and (7), and<br>(7), and (7), and (7), and<br>(7), and (7), and (7), and<br>(7), and (7), that in<br>(7), and (7), and (7), and<br>(7), and (7), and<br>(7), and (7), and<br>(7), and (7), and<br>(7), and<br>(7 |       |
| The ores of the second sub-class most frequently<br>large amount of earthy matter, together with cons<br>sulphur and phosphorus. They are known as <i>brow</i><br><i>ore</i> , or <i>limonite</i> . In texture these ores differ conside<br>tite, being cindry or earthy in character, and rare<br>definitely crystallized hydrate, called <i>göthite</i> , is, however                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | siderable quantities of<br><i>vn hcematite, bog-iron</i><br>rably from red haema-<br>ely massive. A pure,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |

The ores of the third sub-class are known as *magnetic iron ore*, or *magnetite*. The purest varieties are strongly magnetic, and often exhibit polarity, when they are known as *loadstone*. The magnetic iron ores may be easily distinguished from the other oxides by the fact that they give a black streak when drawn over a white surface.

Iron exists in great abundance in many parts of India, occurring in one or more of the forms briefly detailed above, and has long been known and worked by the Natives. The prevailing ore is the magnetic oxide, but members of the other classes are also met with abundantly. For the following remarks regarding the mode of occurrence and distribution of iron in this country, the writer is indebted to the admirable and exhaustive account of the metal published by Ball.in his *Economic Geology\_irom* which the facts here given have been mainly compiled.

GENERAL REMARKS.—In the peninsular area magnetite occurs in beds or veins, in most of the regions where metamorphic rocks prevail. In some places, as in the Salem District of the Madras Presidency, it

| IRON.               | Iron.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GENERAL<br>REMARKS. | is found in immense quantities, whole hills and ranges being formed of the purest oxide. Similarly, in the Chanda District, Central Provinces, enormous deposits of specular ore are found with which magnetite <sup>15*13</sup> ? present. The abundance and wide distribution of these ores in the ok*est rocks no doubt explains the frequent recurrence of deposits, and the general dissemination of ferruginous matter which more or less characterise the sedimentary rocks of all subsequent periods. In the submetamorphic or transition rocks, magnetite' <sup>1</sup> is known to occur in some localities. Also, along faults and fractures both $n$ the metamorphic and submetamorphic rocks, very considerable veins o* non-nite are to be found in many parts of the country, such as Cuddapah, *varnul, Manbhum, Jubbulpur, &c. The rich ores of Central India principally consist of haematites and occur in the Bijawar or lower transitios series trocks.                                                                                                                                                                                                    |
|                     | In the Vindhyan formation ferruginous matter is commonly dis-<br>seminated through immense thicknesses of beds, tinting the rocks it per-<br>vades; but in all localities in which the ores are sufficiently concentratea<br>to be workable, the deposits are found in veins, not in beds.<br>In certain of the conglomerates, sandstones, and shales of the Gond-<br>wana system, concretionary masses of limonite are abundant, wl?ile m<br>some of the coal-fields siderite, and clay ironstone, altered more or less<br>into limonite, occur imbedded in sufficient quantity to be of considerable<br>importance. It is believed that this limonite is used by Native smelters<br>in all the coal-fields, but the unaltered carbonates are rately if ever utilisea<br>in India, the Native furnaces being apparently unsuited for their <b>reduct</b> in<br>The next group, of so-called ironstone shale, is only represented in an<br>Damuda valley, and is largely utilised as a source of iron ore in the same<br>ganj coal-field, where there is an inexhaustible supply of readily a ??<br>ore. This ore, which originally existed in the form of black-band. <b>o</b> |
| }                   | In the next succeeding group, the Ranigani-Kamthi ferruginous matter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                     | absent, in others sufficient to tinge the whole rock, Segregated $\nabla^{nss}_{r}$ ,<br>and thin layers of ore also are found here and there, and are occasionally<br>utilised. Ore occurs in a similar way in the following groups or the<br>Gondwana series.<br>The cretaceous rocks of Southern India, in the Trichinopoly $Dk^{1}M^*$<br>contain nodules of iron ore in some abundance, which were formerly smeitea                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                     | to a considerable extent by the inhabitants. The Deccan trap includes a<br>large amount of iron ore, disseminated for the most part in minute crystals<br>of magnetite, but occasionally met with in nests of haematite, more rareiy<br>in layers which pass into ferruginous earth or bole. The beds of rivers<br>which traverse this trap not unfrequently contain magnetic iron-sand, w men<br>might be collected in sufficient quantity for the requirements of Native<br>furnaces, but rarely is so, owing to the brown haematite described below<br>being generally more readily obtainable in the same localities.<br>Segregated bands frequently occur towards the bases of beds of latente,                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                     | which are often prolific sources of an easily worked brown haematite, and<br>sometimes contain a high percentage of metal. These lateritic ores nave<br>been worked by native smelters in various localities, and at Bepur in Mala-<br>bar, and Muhammad Bazar in Birbhum, they have been utilised by British<br>Companies.<br>Lastly, detrital ores of sub-recent age occur in many localities, derived<br>trom the breaking up of the above deposits and from superficial accu-<br>mulations of ferruginous matter. These being in general easily obtained<br><b>I.</b> 439                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

OCCURRENCE, &C.—Mr. F. R. Mallet, Superintendent of the Geological Survey of India, has kindly furnished the following account of the regions in which Iron is found and of the manufacture of the metal in India:

Iron has not been found native except in meteorites, and, very rarely in volcanic rocks. It forms, however, an essential constituent of over a hundred minerals, although only a few of these are utilised for the extrac-tion of the metal. The most important ores are as follows, the percentage of iron they contain when pure being indicated by the figures :-

Magnetite, or magnetic iron, protosesquioxide; 72\*4. The black sand which is smelted in many parts of India consists of magnetite, with, very frequently, a varying proportion of titaniferous iron. *Hcematite*, or *red harmatite*, sesquioxide; 700. *Limonite*, or *brown hcematite*, hydrous sesquioxide; 59\*9. Ordinary laterite is an impure earthy variety of this ore. Siderite, or spathic iron, carbonate, 48'3 : clay-ironstone, or argillaceous *iron ore,* is an impure variety of the carbonate. *Black-band* is a carbon-

Magnetite. 442 Haematite. 443 Limonite. 444-Siderite. **445** Black-band. 446

| aceous clay-ironstone. <i>Ilmenite</i> , or <i>titaniferous iron</i> , an ore allied to haematite, but having a portion of the iron replaced by titanium, may also be mentioned, although it is of comparatively little importance.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| MANUFACTURE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| NATIVE METHODS—IRON.—In former times the manufacture of iron by<br>native methods was widely practised throughout the various provinces or<br>India, but within the last few decades, and more especially during the last<br>quarter of a century, since the opening of railway communications, the<br>competition of English iron has done much to curtail, and in many cases<br>has entirely extinguished, the native outturn. A long list of places might,<br>however, be given, in which the manufacture survives.<br>According to the method most usually adopted, the furnace,, which is<br>built of clay, is some three or four feet in height, more or less, although |
| the dimensions vary very considerably in different parts of the country.<br>Both the exterior and interior are more or less conical in form, the $ci[cU'']$ lar cross section at the bottom being greater than that at the top. Neak'                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| the better in funct is on original which is storned with alow while the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

try. ak' the bottom in front is an orifice which is stopped with clay while the furnace is in blast, and through which the bloom is removed at the end ot the operation. Clay tuyeres are inserted near the base which convey the blast from two skin bellows, worked alternately, so as to keep up a continuous stream of air. The fuel used is charcoal, and no flux is added with the ore. After the furnace has been brought to a sufficiently here. temperature, the ore, sometimes in the form of natural sand, but more commonly after having been pounded to small fragments or coarse powder, is sprinkled in at the top, in small quantities at frequent .mtervals, \_and alternately with a sufficiency of charcoal to keep the charge nearly level with the top off the furnance. Furn timeneo to memoduring inthe the form (which lasts several hours) the slag is removed through a hole which whi then stopped with clay. When such a quantity of ore has been added as will produce a bloom of iron of the size proper to the furnace used, the blast is stopped, the orifice opened, and the bloom removed. It is a pasty mass of *malleable* iron containing a good deal of intermixed slag, which is removed as far as practicable by immediate hammering. But before use the iron needs further refining by re-heating and hammering, a  $P^{roce}-f^{\bar{*}}$ which is sometimes carried out more than once, and which serves at the same time to bring the iron into more usable shapes.

In some cases the refining is done by the smelters, but very commonly they cut the bloom almost in two halves, to show the quality of the mass to the purchaser, and sell it in that state, the refining being Sone by others. The expenditure of charcoal is very great in proportion to the result oDtained (according to Mr. Ball, as much, sometimes, as 14 tons of fuel to i ton of finished iron), and a large quantity of metal remains in the sigg, so that the process is an extremely wasteful one (thus it is stated by iwr, Heath that in the Salem district magnetite, containing 72  $P^{er cent <}$  of metal, yields only 15 per cent, of its weight of bar iron). At the same time the iron obtained is generally of very good quality, and were it nor -on account of the convenient forms in which English iron can be obtained, the Indian product would have less difficulty in maintaining its position amongst the native smiths. On account of this competition, and also from increasing scarcity of fuel, "one finds" (as remarked by Mr. Ball) "the iron smelters in many regions the hardest worked, but poorest, amongst the population. The iron is sold at a high price, but the bulk of the  $\pounds \pounds i t ?^{\circ e}?^{to the}$  traders through whose hands the metal passes. The Sm\*11d "?" Prodl\*ced bears but a miserable proportion to the labour, time, and material expended."

not procurable, those of the Convolvulus laurifolia [Lettsomia elliptica, Wight],

It appears that in some cases the blooms produced in the ordinary iron furnace, after refining in the usual way, are sufficiently steely for em-ployment in the fabrication of edged tools, which are tempered by plunging them while hot into water. A steely iron thus made in the Jabalpur district 503

.

| 1012 101 J. P. N. Bose, 1012., XXI., 83). But in the district of Darjeening C. S. iron is smelted from magnetic containing no manganese (Mem. G. S. XL, 67).<br>ENGLISH METHODS.—Numerous attempts have been made to a ve bee ture iron on the English system in India, but nearly all of $t_{*}$ iese v insuccessful and have been long since abandoned ; one of the . <sup>CTMWE c</sup> ause of failure being the difficulty in keeping large furnaces supplied with char in the Salem district; and at Beypur, in Malabar. Pig-iron was smelg from the Salem ore, part of which was sent to England, and comma pogood price for conversion into steel; a large quantity of it was used · w construction of the Britannia and Menai bridges. Excellent s eei also produced at the Indian works, and iron was smelted at Beypur 'col company, however, appears never to have paid a dividend, and the cern was a steadily losing one. About 1855, the Birbhum Iron ^ real But from various causes the works were financially a failure. I ne 1 maun Iron-works were started in 1857, and after many vicissitudes f/J like the preceding ventures. About 1861 works were commenced at is wai, in the State of Indore; but, when the preparations for smelting wai, in the State of Indore; but, when the project. In $1 \wedge c^{1/2}$ (Cennary complete, it was decided to abandon the project. In $1 \wedge c^{1/2}$ (Cennary converse), however, has not hitherto proved a financial success, or chiefly, to the long distance and bad roads over which the ore has conveyed from the mines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | IRON.             | Manufacture of Iron.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2. English Method of-<br>450 ENGLISH METHODS.—Numerous attempts have been made to ture iron on the English system in India, but nearly all of $t_{s}^{tese}$ is a vector of failure being the difficulty in keeping large furnaces supplied with charged of failure being the difficulty in keeping large furnaces supplied with charged of failure being district; and at Beypur, in Malabar. Pig-iron was smear from the Salem ore, part of which was sent to England, and command good price for conversion into steel; a large quantity of it was used to construction of the Britannia and Menai bridges. Excellent s eei also produced at the Indian works, and iron was smelted at Beypur 'collection' company, however, appears never to have paid a dividend, and the retrieve was a steadily losing one. About 1855, the Birbhum Iron 'recompany commenced operations, and produced pig-iron of goodLauge But from various causes the works were financially a failure. I ne is maun Iron-works were started in 1857, and after many vicissitudes f/l like the preceding ventures. About 1861 works were commenced at is wai, in the State of Indore; but, when the preparations for smelting is nearly complete, it was decided to abandon the project. In 1^AO'/Q'n, abouts, works were established at Naliun, in the Punjab State of Simmathing the enterprise, however, has not hitherto proved a financial success, ow chiefly, to the long distance and bad roads over which the ore has conveyed from the mines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | MANUFAC-<br>TURE. | is produced from a highly manganiferous hæmatite (Rec. G. S I., XVI.,<br>101; P. N. Bose, Ibid., XXI., 88). But in the district of Darjeeling similar<br>iron is smelted from magnetite containing no manganese (Mem. G. S. I.,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| posed for use. In 1875, however, an experimental trial was method determine whether the rich iron ores of Chanda could be smet! Let a commercial scale with the coal raised in the same district. Investigation of the same time (1874) the coal raised in the same district of the fuel, and its unsuitability to the purpose in it. About the same time (1874) the Bengal Iron Company commenced on tions at Barakz.r, in the Raniganj coal-field. The ore employed, the same standard from the surface in the neighbourhood of the works, of abundantly in the ironstone shale group of the Damuda (coal-Dear series. In these rocks the ore forms bands and nodules of clay, it on the surface this has been altered into an earthy peroxide, pa hydrated and partly hematitic. It was this altered form which was structure and in the Karharbari collieries. For flux, limestone obtained at, i-an hill, and at Hansapathar, a few miles further off, was employed, agether the company produced 12,700 tons of pig-iron, but it was concern was taken over by Government, and placed under the man ment of Ritter von Schwartz. One blast furnace, on an improving the end of 1888 being 30,616 tons. A second blast furnace, on an improving type, has lately been erected to meet the increasing demand for pig-iron up the end of 1889-90, and 20,000 in the year following. The annual of sumption of pig-iron in the foundry is at present about 2,000 tons, the cings being chiefly pipes, sleepers, bridge-piles, ornamental work, railing a stale-boxes, and agricultural implements. To Ritter von Schwartz below is sumption of pig-iron in the foundry is at present about 2,000 tons, the cings being chiefly pipes, sleepers, bridge-piles, ornamental work, railing a stale-boxes, and agricultural implements. | RON ORES.<br>Madras. | Excellent iron is produced in the Salem district, but, as in so many other parts of India, the outturn is decreasing, partly from the g^^n gracticy of charcoal, and partly from the influx of English iron. The manufacture of steel has been described on p. 503. The ore smelted at the Porto Novo Iron-works was brought from balem.<br>South Arcot.—Ore is abundant, and has been smelted in a very <sup>3</sup> a <sup>[1]</sup> 'E number of villages, more especially in the taluks of Trinomalai and Kallakurchi. The manufacture of steel has also been carried on. <i>#</i><br>North Arcot.—About the year 1855 there were 86 villages where smeltaing was conducted. The ore principally used was "black sand," but solid ore (magnetite?) was raised in many places. It is said that ore was mined "in every taluk."<br>Chingalpat.— Magnetite is stated to exist in considerable quantity in the hills near the town of Chingalpat.<br>Nellow.—Numerous beds of magnetite occur in the schistose gneiss near the town of Ongole, and in the lower part of the Gundlakamma valley. Haematite schist has been noticed in the Chundi hills. Iron used to be smelted in the district, but the industry appears to be now extinct. Kadapah and Karnul.—Iron ore is pretty generally distributed in the rocks of the two formations named after these districts, but that which is seamed with great veins of very pure specular iron. Rich deposits also occur south-east of Ramulkota; but there are numerous other localities in both districts where mining is carried on, the ore being generally haematite.<br>Mantipur.—Iron is said to be abundant, the ore being, in part, at least, of the same character as that in Bellary.<br>Bellary.—In the Sandur and Copper hills to the west of the chief town of the district "the supply of splendid haematite ore is absolutely unlimited." It occurs in a series of bands interstratified with schiat and contemporaneous trap belonging to the Dharwar series. The old iron in dustry is, however, nearly extinct, owing mainly to the scarcity of fuel.<br>Similar ore also occurs in profusion in the "Penn |
| Mysore.<br>452       | MYSORE.<br>Ashtagram division.—Ores, which are in large part magnetite, are<br>abundant in many places, but the number of mines is not very great.<br>Bangalore division. —Both iron and steel are produced, the ore princi-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Haematite occurs in profusion in the "Pennar-Haggari band" of Dhárwar rocks, which traverses the <i>Lingsugur district</i> , as noticed under Bellary. Fairly rich beds of magnetic iron have been found nine miles to the south-east of the town of Khamamet, and a very large and important band of the same ore occurs close to the Singareni coal-Reid, in the same district ( <i>Khamamet</i> ). haematite is obtainable about four miles north of the field. The co-existence of such rich ores, coal, and limestone in the same neighbourhood naturally suggests Singareni as one of the localities in India most favourably circumstanced for the manufacture of iron on European principles. Smelting has been carried on extensively, in native furnaces, in the parganas of Kallur and Anantagiri. Haematite, titaniferous ironsand, and yellow and red ochre are stated to occur in <i>Warungul</i> . Steel-making has been carried on at several villages in <i>Yelgandal</i> , but one of the most celebrated places for its manufacture is Konasamundram in <i>Indor</i> , 12 miles south of the Godávari and 25 from the town of Nirmal. Accounts written some fifty years ago state that most of the outturn was bought by dealers from Persia who travelled to Konasamundram for the purpose, and that the steel was used in making the celebrated Damascus sword blades. Two kinds of iron were used in its production—one from Mitpalli smelted from "ironsand," or from Dimdurti, reduced from magnetic occurring disseminate through gneiss and mica schist, and the other from Kondapur smelted from an ore "found amongst the iron clay" (laterite?): three parts of the former were employed to two of the latter. A boundless supply of the above ores is said to be obtainable. | 453                   |
| CENTRAL PROVINCES.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Central               |
| Bastar.—Iron ore is said to occur, in immense quantities, on the Bela<br>Dila, and in the valley of the Jorivág river; also less plentifully towards<br>the North-Western boundary. The quality is good, but it is little worked,<br>as the demand is insignificant.<br>Sambalpur.—'* Iron ore is found in nearly all the zamindáris and Garh-<br>jdt States. It is most plentiful and of the best description in Rairakhol.''<br>The metal has been smelted in some quantity at Kudderbuga, 20 miles<br>north-east of Sambalpur, from altered magnetite. Ores obtained from<br>the Barákar group, and, less frequently, from the Upper (Hingir) sand-<br>stone are used in other places.<br>Bildspur.—Ores are to be found in many places, although they are                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 454                   |

| IRON.<br>RON ORES.<br>Central<br>Provinces. | <ul> <li>Chanda.—This is one of the most remarkable districts in India, containing "enormous and splendid accumulations of ore" which occur principally in the metamorphic rocks. Haemattie is the most abundant, and furnishes all the supplies for the native furnaces; but magnetite and limonite also occur. The most noted localities are: Lohara, where haematite of extreme purity forms an entire hill fths of a mile long, 200 yards broad, and 120 feet high; Pipalgaon, near which there is an enormous amount of similar ore; Dewalgaon, in the vicinity of which there is a hill 250 feet high, composed in large part of haematite; Ratnapur, where a very rich lode of brown iron ore, 40 and 50 feet thick in places, has been found; and Dissi, the lode near which is of haematite and magnetite. Immense deposits also exist at Gunjwdhi, Ogalpet, Metapur, Bhdnapur, and Mendki. The unsuccessful attempt to smelt the Chanda ores with the coal of the same district has been already noticed.</li> <li>BdInghd.—The iron industry is very near extinction, although a few furnaces still struggle for existence in the Baila, Kini, and Bhánpur zamindáxis. Ore from the lateritic rocks is that chiefly used. ", Bhanddra.—The ore commonly smelted in this district is lateritic, and the metal produced from the mines at Agri and Ambighari in <sup>116</sup>. P?r' gana of Chandpur is said to be of excellent quality. About the middle of the century 160 furnaces were at work.</li> <li>Magnur.—Ore of good quality is reported to exist near Mansar. <i>Mandla</i>.—Lateritic ore is known to exist.</li> <li>Mindr.—Some ores of poor quality have been noticed to the southeast of Barwai and near Pundsa.</li> <li>Marsinghpur.—Tendukhera has long attracted notice owing to tne excellent quality of the iron manufactured there, which is said to command a higher price than any other iron made in the Narbada <sup>2728</sup>% in 1830 a suspension bridge over the Bias river, in Sagar, was opened, the iron for which had all been smelted in native furnaces at Tendukhera. The ore</li></ul> |
|                                             | the transition rocks and in the laterite. The ore in the older series is<br>mainly haematite, in part manganiferous, while that in the lateritic form-<br>ation is limonite. The transition ores are worked in several places, and<br>iron is still smelted on a somewhat considerable scale in the district. Gan-<br>gai is perhaps the only spot where magnetite is raised. At Agaria and<br>Partabpur there are whole hills of schistose and micaceous haematite, con-<br>taining only traces of phosphorus and sulphur. The micaceous variety is<br>mined in preference to the other from being softer. The Janli mine, how-<br>ever, is the most extensively worked in the district, the ore, being an<br>ochreous haematite, is easily extracted, and probably has been found by ex-<br>perience to be easy of reduction. <sup>TM</sup> Olpherts <sup>1</sup> metallic paint" is made from                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <u></u> | Iron Ores of India.                             | (F. 1    | R. Mallet) | IRON.      |
|---------|-------------------------------------------------|----------|------------|------------|
|         | At Mangeli, Mogala, Gogra, and Danwai in the Lo | ra ridge | a manga-   | IRON ORES. |

At Mangeli, Mogála, Gogra, and Danwai in the Lora ridge, a manganiferous haematite is worked, the iron produced therefrom being a hard steely kind used for edged tools. The iron smelted from the Agaria, Partabpur, and Janli ore is much softer. Manganiferous haematite also occurs in large quantity at Gosalpur, where limonite is also found.

The laterite ores occur in beds near the base of the formation, and consist of rich pisolitic limonite. They are obtainable over a wide area to the east, ncrth, and south-west of Marw&ra, the KanhwaYa hills being especially rich in such. The laterite ore used to be smelted on a considerable scale, but of late years the mines have been abandoned.

The opening out of the Umaria Colliery has recently directed attention to the advantages north-eastern Jubalpur possesses for the manufacture of iron on European principles. M agnificent ores, pure limestone, and coal are all comprised within a comparatively small area.

## CENTRAL INDIA.

*Rewah.*—The broad band of transition rocks which traverses this State parallel to, and south of, the river Son, is known to contain iron ore, which is also believed to exist in the coal-measure strata.

*Bandelkand.*—The transition rocks, which occupy a large area in the State of Bijawar, in some places contain abundance of rich haematite. It is worked on a considerable scale, Herapur being one of the chief centres of production.

*Gwalior*.—Iron ores occur most profusely in the transition rocks which extend over a wide tract to the southward of Gwalior Fort. The mines at San tan, Maesora, Gokalpur, Dharoli, and Banwari are described as extremely rich, the ore being schistose and more or less ochreous haematite, which is manganiferous at Santan. Haematite is also worked at Raypur, Par hill, and Mangor, while magnetite is obtained at Gokalpur and Girwai. All the above mines are within 10 miles of Gwalior, except those at PaY hill and Mangor which are at a somewhat greater distance. The ores are said to contain only traces of sulphur, and no phosphorus. Limonite occurs at Binaori, Baroda, Imilia, Gunjari, and Baron, villages between 45 and 80 miles from Gwalior. But the ore is inferior to the anhydrous kinds.

About 50 miles to the north-west of Gwalior there is a forest, which it is estimated would, without replanting, supply fuel for an outturn of 12 tons of bar iron a day for a period of 900 years.

The mines of Bágh (about 60 miles west-south-west of Indore) have long been celebrated. They are in the transition rocks, the ore being haematite.

*Indore, Dhdr,* and *Ch&ndgarh.*—The same rocks are exposed near Barwai, and cover large areas in the *Dhdr* forest and north of Chdndgarh. Rich deposits of haematite occur in connection with them, some of which are found along fault lines, while others are surface accumulations derived from the older rocks.

AH Rajpur.—Some ore has been observed in the metamorphic rocks.

BOMBAY.

North Kanara.—Ore (apparently lateritic) occurs in the Sahya'dri range. Dhdfwar. - Formerly, when fuel was plentiful, much iron was smelted in the Kappatgudd hills.

*Kaladgi.--The* haematite, occurring in the *Dhdr war* series, has already been noticed in connection with the Bellary district.

*Belgaum.—Iron* was formerly smelted in several places, but the manufacture is now extinct.

| RON ORES.<br>Bombay. | Goa<— Iron ore is found at Bdga, Satdra, Pernem, and especially in th<br>District of Zambaulin.<br>Sawantwdri and Kholapur— Iron is (or used to be) produced from<br>(apparently lateritic) ore.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                      | Ratnagiri.—The metamorphic rocks are said to contain magnetite o<br>haematite near Mdlwdn. Lateritic ore is also found in the district, and<br>formerly was largely smelted.<br>Sdtdra.—Lateritic ore has been utilised here also, but, apparently, or                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                      | only a small scale.<br>: Surat—Iron ore is said to be found in the Balsar and Pardi Subdivisions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| •                    | <i>Rewa Kdntha.—Iron</i> seems to have been once worked on anr<br>scale along the western limits of the district. Near Ja''mbughoda, "TM**<br>and Ladkesar large heaps of slag still remain. Near Mohan, in onno<br>Odaipur, a bed of haematite, of limited extent, occurs in the Nimar sand<br>stone.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                      | Panch MahalsAt Palanpur, in Godhra, ore of considerable richnes<br>is found.<br><i>Kaira and Ahmadabad.</i> —Heaps of slag, in certain places, show that                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                      | iron was formerly produced.<br><i>Kdthifitvdr.</i> —Even fifty years ago the manufacture of iron was in provide the moribund condition, and to-day there is not a single furnace in blast, the west, the laterite yielded very rich ore, while the ironstone bands, near the top of the Omia (Jurassic) beds, were utilised in the northern part the peninsula.<br><i>Cutch.</i> —Here also the industry is extinct. Much of the ore former used was derived from the haematitic laterite of the sub-nummuhtic gro Y                                                                                                                                                                                                                                     |
| Rajputana.           | RAJPUTANA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 457                  | Sind.—Almost the only ore hitherto discovered, in sufficient $QJf_{a}^{8/r*11}$ ?<br>iron-making, is in the passage beds between the Kirthar and Kan<br>groups, north-west of Kotri, Masses of magnetite, and bands of. <sup>red</sup> an<br>brown haematite, more or less pure, occur, however, in considerable q.<br>tity, in many places. The scarcity of fuel in Sind renders the ranty<br>iron ore bi little importance. Large deposits of iron ore occur, in seve<br>places, in the Arvali (transition) rocks. Some of these are situated<br>Marwar, Ajmere, Bundi, Kota, and Bhartpur.<br>Meyivdr.~A promising bed of limonite exists near Gangar, wnicn<br>worked to some extent.<br>Jaipur.—Large quantities of ore have been raised at Karwar, |
|                      | Hindaun, but the workings are now abandoned $_{fl}r \sim AlwarThe$ mines at Bhdngarh still produce large quantities 01 of and are now the only source of supply for the numerous furnaces <sup>m</sup> Alwar territory. The ore is a mixture of limonite, magnetite, and <sup>ma T 1</sup> here source of and extensive mines near Rajgarh are no lon 5~ worked, but the deposit extends in a regular belt for a distance of over it miles, and has an average width (it is said) of 500 feet; the ore consisting chiefly of rich haematite and limonite.                                                                                                                                                                                                |
| Panjab.              | PANJAB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 458                  | Bannu.—The hills 25 or 30 miles south-east of Bannu are reported to<br>contain haematite in abundance. The iron produced from it is in great<br>demand at Kålabågh.<br>Peshdwar.—It is said that iron is smelted in Peshawar, and other neigh<br>bouring places, from ore (magnetic ironsand?) obtained from Bajaur.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Iron Ores of India. (F. R. Mallet.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | IRON.                 |

| Kumaun.— $ n $ several parts of Kumaun deposits of iron ore occur<br>some of which are rich and abundant. Amongst the localities which have<br>attracted most notice is Rámgarh, near which several mines (Pahli, Losh-<br>giáni, Natna Khán, Parwára, &c.) have been worked in micaceous haema-<br>tite and limonite. Haematite and micaceous iron also exist near Khairna,<br>but the deposits are not of much importance. Very large quantities of<br>ore, which is earthy haematite and limonite, occur in beds in the Siválik<br>strata, in the neighbourhood of Káladhungi and Dechauri. The Dechauri<br>ore is of better average quality than the other.                                                                                                                                                                                                                                               | 460                   |
| <i>Lalitpur.</i> — At Salda, in the Maraura pargana, a considerable amount of iron is smelted from haematite, while a hard steely kind is made at                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                       |

| <i>Bdnda.</i> —In pargana Kalyángarh iron is rather extensively worked at several points, especially at Gobarhái. There are also mines at Deori and Khiráni.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                       |
| <i>Mirzapur.</i> —The metamorphic rocks in the southern part of the dis-<br>trict contain some small bands of magnetite, which have been worked on<br>a trivial scale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                       |
| BENGAL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Bengal.               |
| Orissa.—Iron of excellent quality has been produced in Lálcher, the<br>ores used being chiefly derived from the sandstones of the coal-measure<br>and upper groups. Smelting is (or used to be) also carried on in Dhen-<br>kanal, and probably other tributary states as well as in Katták.<br><i>Burdw&amp;n.</i> —In the Ranigdnj coal-field throughout the ironstone shale<br>group, but more especially in the upper part of the group, bands and<br>nodules of clay ironstone are common, and constitute an inexhaustible<br>supply of ore. When unaltered, the ore is either clay-ironstone or black<br>band (a carbonaceous variety of the same), but near the surface it has been<br>converted into earthy haematite or limonite, or a mixture of both. It is<br>this altered form that is used at the Barákar Iron-works, which have been<br>briefly noticed in the preceding part of this article. |                       |

| IRON ORES.<br>Bengal. | Birbhum.—Iron used to be made on rather a large scale, the kacha,<br>or crude, metal unlike that produced in other parts of India, resembling<br>pig-iron, from which pakka, or refined, iron was produced by a sort of<br>puddling process. The ore used in the Birbhum Iron-works Company's<br>furnaces was obtained from beds near the base of the laterite.<br>Bhdgalpur and Monghyr.—Some smelting has been carried on in<br>both districts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                       | <i>Gyd.</i> —A raiher large deposit of magnetite has been found HI the Bara-<br>kar hills, which has not been worked, although iron has been made from<br>other ores.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                       | Hazdribdgh.—-Furnaces are numerous in the vicinity of the BokArs ami<br>Karanpura coal-fields, where ore from the ironstone shale group is used.<br>Magnetite from the metamorphic rocks is also smelted in places<br>Mánbhum.—A portion of the Rániganj coal-field, noticed under Bard-<br>wán, is situated in Mánbhum. Magnetite exists in both the metamorphic<br>and transition rocks, but not in very great quantity. Ilmenite occurs also,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                       | and the excellent quality of some of the native-made iron has been attri-<br>buted to the presence of this mineral in the magnetic iron-sand used in<br>the furnaces. In places along the line of disturbed junction between the<br>rocks just mentioned, there are veins or lodes of red and brown haematite,<br>the latter sometimes in great abundance. Other deposits, again, are in<br>close relationship to the Dalma trap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                       | Singhbhum.—As in Mánbhum, nests of very pure haematite occur in the Dalma trap dyke. The ores smelted are chiefly from ferruginous schists, and from the laterite. The most promising ores, however, are to be found in a number of lodes or veins in the transition rocks near, and west or>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | Chaibasa. Some of these are manganiferous.<br>Loh&rdaga.—There is a remarkable abundance of ores in the Palaman<br>subdivision, which includes magnetite in the metamorphic rocks; klac <sup>8</sup> -<br>band, limonite and haematite in a well-defined zone of ferruginous shales<br>in the Barakar group of the Aurunga coal-field, and to the north, ot<br>Balunagar; and, thirdly, red and brown haematite in the laterite. I ne<br>magnetic ores are not very important, and the lateritic ores, although plen-<br>tiful and of excellent quality, are found on the tops of lofty plateaux, where<br>they are practically almost inaccessible. The Barakar ores, however, are<br>both favourably placed and abundant, and excellent crystalline limestone<br>occurs in the immediate vicinity of the coal-field. There is some doubt<br>about the quality of the coal, but should railway communication with the<br>district be established the position will probably attract attention as a site<br>for iron-works.<br><i>Tributary StatesIn</i> the Tributary States of Chutia Nagpur iron<br>smelting is carried on to some extent.<br><i>Ddrjiling.—K</i> valuable bed of extremely pure magnetite, with some<br>micaceous haematite, occurs in the metamorphic rocks near Sikbhar, about<br>5 miles south-east of Kalingpung. The magnetite has been smelted on a tri-<br>fling scale, and is said to yield a steely iron suitable for making <i>kukris</i> and<br><i>bans</i> . There is a strong ferruginous band in the tertiary sandstones ot<br>Lohargarh hill, from which an immense supply of ore might be obtained;<br>but it is of very indifferent quality. |
| Assam.<br>462         | ASSAM.<br>$w \mid y^{Kl} \& i \sim 7^{aintia} $ #»H*Inm used to be made in the Khási-Jaintia<br>nins, but the manufacture has completely died out. The ore employed was<br>$\ll .F^{t \wedge n} \cdot I^{erous}$ , "I <sup>a</sup> gnetite, occurring in the form of minute grains dissemi-<br>nated through decomposed granite. The soft friable rock was raked into<br><b>1.</b> 462                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|---------|------|----------|---------|-----|------|---------|-----|------------|----------|-------|
|         |      | <br>     |         |     |      |         |     |            |          |       |

a narrow channel with a rapid current of water running down it, and the **IRON** ORES. heavy ironsand caught by a small dam, while the lighter particles were washed away. After further purification by re-washing, the ore was smelted, and vielded an iron which, after refining more than once by reheating and hammering, was of excellent quality.

*Ndga Hills.*—In former times nodules of clay-ironstone, occurring in the tertiary coal-measures of the Naga hills, were smelted for iron, and during the most flourishing period the outturn must have been very considerable. As long ago as 1841 the manufacture was all but extinct, and has, for many years, been wholly so. In some localities impure limonite is very plentiful in the Siválik strata, but the ore is of poor quality.

Manipur.—In more than one locality in the valley of Manipur, a layer in the alluvium, occurring a few feet below the surface, is utilised as a somce'cf iron. The clay, which contains small pisolitic nodules of limonite, is washed to separate the latter, which are afterwards pounded and smelted. Titaniferous iron ore is said to be obtained in some of the The peculiar furnace used in Manipur has been alluded to streams. previously.

## BURMA.

Upper Burtna.—A very large proportion of the iron used is smelted in the country around Puppadoung, an extinct volcano about 30 miles southeast of Pagan, ferruginous concretions, occurring in the tertiary strata, are employed as ore, and the iron produced is of excellent quality. The furnaces are peculiar in being worked by a natural draught only, no bellows being used. Iron is also smelted at Maldu, a good distance north of Shue-bo-myo. To the west of Sagain, for miles of the Irawadi, rich haematite is said to abound.

Iron ore is reported to be very plntiful in the Shan States, and within the last year, the occurrence of an enormous deposit of haematite near Sengaung in the vicinity of Myit-nge, in the Shan hills, has been brought to notice.

*Pegu*,—Limonitic concretions in the newer tertiary strata in eastern Prome furnish excellent ore, which was smelted on a considerable scale prior to the British occupation of the province.

Tenasserim.—East of the Sittaung the ore usually met with is magnetite, which often occurs in thick beds or lodes; but specular iron is also found. The lower ranges of hills to the east of Shue-gvin station are said to contain abundance of ore.

Between Maulmain and Tavoy seventeen localities have been noted where iron ore occurs in the hiJls of tertiary strata. The best locality, however, with respect to quantity, quality, and position, is one near Tavoy. On the right bank of the river, opposite the town, runs a range of low hills at a distance from the river varying from 1 | to 3 miles, and extending to a distance of 5 or 6. These are said to be formed almost entirely of magnetite, the supply of ore being inexhaustible.

Some 10 miles south-west of the town of Mergui, there is an island, comprising a hill about 200 feet high which is said to be formed of iron ore. A similar island is reported to exist 4 miles to the southward of the first mentioned. Magnetite and haematite have been noticed on an islet between King and Tawlang islands. Limonite is stated to occur in some abundance at Podan-or.

## ANDAMAN ISLANDS.

Within the last few years haematite has been discovered at Rang-u-Chang, a place some miles south of Port Blair; but it is not very abundant, and is mixed with too much quartz and pyrites to be of any value. 33 .

| PROSPECTS<br>of the<br>IRON | GENERAL SUMMARY OF PROSPECTS OF IRON MANU-<br>FACTURE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| INDUSTRY.<br>465            | The following summary by Sir G. M ofesworth, written in 1882, way be here quoted in entirety, giving, as it does, the unbiassed opinions of a careful and competent expert :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                             | "It appears to me to be doubtful whether iron manufactured from<br>charcoal will be produced at rates sufficiently low to compete with English<br>manufacture; but if practicable, it must be combined with a Very perfect<br>and well-organised system of forest conservancy in a <i>district capable of</i> .<br><i>producing timber of a quality eminently suited</i> for the manufacture 01<br>charcoal fit for smelting operations, at a low price; and the timber must<br>be in a position near the iron works, as charcoal is bulky and consequently<br>expensive in carriage, and the expense of carrying ore and flur "?. <sup>a</sup> PX<br>great distance would be very great." Abstracting the information which i<br>have given above as bearing on the economic manufacture of iron, I arrive<br>at the following conclusions :—<br>In the Panjab and Sind the scarcity of fuel is an insuperable obstacle.<br>In the North-West, after a patient trial, iron manufacture has not been<br>successful, and Mr. Bauer man reports against the probability of success.<br>In the Central Provinces, Jubbulpore and Chanda afford very fair<br>promise of success.<br>In Central India the Gwalior iron-field may possibly be successful:<br>but the absence of coal and the distance of the forests militate <sup>a</sup> £ <sup>a</sup> ! <sup>n</sup> ?!<br>success. At Berwai the failure has been without a fair trial, but the late |
| -                           | success. At berwal the failure has been without a fair that, but the fate<br>enhancement of the price of fuel renders its success doubtful.<br>At Rewah there appear to exist elements for success; but works in thi<br>district would naturally be combined with the Jubbulpore works.<br>In Rajputana and Bombay Presidency the scarcity of fuel and com-<br>petition with England appear to preclude the establishment of iron-work <sup>6</sup><br>on a large scale.<br>In Bengal the Bengal Iron Works appear to hold out promise of suc-<br>cess, but other localities in that district, so far as they have been examinea,<br>do not appear to hold out any such promise.<br>In Orissa the coal is too poor to hope for success.<br>In Assam the ore where abundant is not sufficiently rich, and in the<br>coal measures where it is rich, it is not in sufficient abundance.<br>In the Nizam's Dominions the ore and fuel are not in juxta-position<br>so far as is known at present.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                             | In Madras the scarcity of fuel prevents the utilisation of most valuable<br>ore.<br>In Burma there appear to be elements for the production of iron, but<br>the market will doubtless be limited.<br>Taking all these circumstances into consideration, we can only, in the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IRON<br>WORKS.<br>466       | present state of our knowledge, assume three centres as the <i>probable</i> fields<br>for iron industry on a large scale by the agency of English capital, w.«—"<br><i>1st</i> —The Bengal Iron Works,<br>2wrf—The Jubbulpore District,<br>jrrf—The Chanda coal and iron fields."<br>IRON WORKS AND FOUNDRIES.—Mr. <b>O'Conor,</b> in his Statistical<br>Tables for British India, 1888-89, gives a list of forty-seven iron and brass<br>foundries, of which eight are in Bombay, three in Sind, five in Madras,<br>seventeen in Bengal, one in Lower Burma, two in the North-West Pro-<br>vinces and Oudh, and eleven in the Panjab. Of these the most important<br>are the Barrakar Iron Works, and Burn and Co.'s Iron Works in Bengal,<br>the Byculla Iron Works, Bombay, and the Iron Foundry and Ship-build-<br><b>1. 466</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| The trade in iron and steel may be considered under<br>Internal, II, External,.<br>I. INTERNAL.—The total rail and river transactions<br>past year amounted to 49,37,135 maunds, valued at H<br>arge&w exporters were Bombay with 17,65,925 maund<br>13,57,136 maunds; Madras seaports with 5,67,774. mau<br>with 5,02,873 maunds; Bengal with 1,64,779 maunds;<br>sidency with 1,47,551 maunds. The largest importing<br>bay Presidency with 10,42,159 maunds ; the Pan jab with<br>Bengal with 6,90,450 maunds; the North-West Pro<br>with 6,16,118 maunds; Madras with 4,47,911 ma<br>and Central India with 2,61,185 maunds; and the<br>with 2,38,117 maunds. %<br>The coasting trade returns for the same year differ<br>Foreign iron. The imports of the former amounted to<br>at R99,561. The largest importer was Bombay with<br>R44,718; followed by Madras with 3,744 cwt., Bengs<br>Burma with 921 cwt., and Sind with 891 cwt. Of the<br>6,553 cwt. was received from British Ports within the Pre<br>from Goa, and about 1,000 cwt. from Kathiawar, Kach, a<br>Territory. Madras received its supply almost entirely<br>Bombay; Bengal was supplied altogether by other Br<br>the Presidency; Sind received nearly the whole of its sup<br>and Burma from Bengal. The exports coastwise for t<br>returned as 32,634 cwt., or nearly double the imports,<br>be assumed that the period of most active trade nearly<br>time of returning the trade figures. Of these, Bombay<br>exported 30,915 cwt., 11,879 °* which was destined for<br>have been on its way at the time of compilation of the i<br>94,270 cwt. Bombay followed with 74,414 cwt., then Sind v<br>with 31,641, and Bengal with 22,275 cwt. Of the Mad<br>cwt. was derived from Bombay, 21,729 cwt. from British<br>Presidency, and smaller quantities from Bengal and Bu<br>whole of the Bombay imports were derived from other F<br>the Presidency. Those of Sind with the exception o<br>from Bombay, those of Burma from Bengal, Bombay,<br>Ports within the Presidency, and those of Bengal from | in iron during the<br>2,22,60,226. The<br>ls; Calcutta with<br>nds; and Karachi<br>and Bombay Pre-<br>centres were Bom-<br>17,08,147maunds;<br>vinces and Oudh<br>unds; Rajputana<br>Central Provinces<br>entiate Indian and<br>6,400 cwt., valued<br>8,701 cwt., valued<br>8,701 cwt., valued<br>8,701 cwt., valued<br>1 with 2,143 cwt.,<br>9 Bombay imports,<br>sidency, 1,115 cwt.<br>und the Gaekwar's<br>from Bengal and<br>itish Ports within<br>ply from Bombay,<br>he same year were<br>from which it may<br>corresponds to the<br>is shewn as having<br>or Sind, and must<br>mport figures.<br>the same year was<br>2,455 cwt., value<br>nport into Madras<br>vith 39,855, Burma<br>as imports 60,128<br>1 Ports within the<br>rma. Nearly the<br>critish Ports within<br>f a few cwt. came<br>and other British |                            |

The export table for the same year again, probably for the same reason, shews a considerably larger trade, amounting to 332,094 cwt., valued at R19,20,168. Of this a very large proportion, *viz.*, 244,114 cwt. was shipped from Bombay, chiefly to British Ports within the Presidency, Madras, Kathiawar, and Sind.

The coasting trade in steel is unimportant, the imports in 1888-89

To the above figures must be added the raw and manufactured metal imported by Government, which represents a considerable sum and has largely increased during the same period. In the year under consideration these imports were as follows:—

|                                     |   |   |   |   |   | Cwt.        | ft                    |

A review of the above figures reveals the fact that during the past eighteen years the imports of iron have doubled, both in quantity and value, while those of steel have increased more than fifteen times in quantity, though only four times in value. The imports of Hardware and Cutlery have increased in value more than twice in the same period, while those of Railway plant and rolling stock have increased five times. The development of the imports of machinery from about 5 lakhs in 1850-51 to nearly 2} crores in 1888-89 is a startling testimony to the enormous advance made by steam power in India during a period of less than forty years. Though the above facts point to increased mercantile and industrial activity and prosperity, they at the same time accentuate the fact that no practical development in iron-making has as yet been made in India. As already shown, in the Barakar works and elsewhere, an important industry might be created, but up to this time the production of Indian metal is limited to trifling quantities of cast iron,-and that, notwithstanding the fact the Government and the public require and import close on a quarter of a million tons of iron and steel yearly, without including the enormous amount imported as machinery, railway plant, &c. In connection with this subject it may be noted that the increase in cost of all machinery, railway plant, and other manufactured iron from freight is very large. This is well shewn in a series of tables recently compiled by Mr. E. H. Stone, Assistant Secretary, Railway Branch, Public Works Department, shewing the cost of the material for one mile of single track, of the several

| Trade in Irôn.       (J. Murray.)         haps the greatest increase has taken place in galvanised iron, and piping and tubing. The former is now largely utilised for roofing sheds and workshops in the plains, and residences in the hills. The increase in the latter has been brought about by the constant progress of waterworks and drainage schemes in municipal areas.         Of the total imports of steel, 137,108 cwt. consisted of "hoop" which is now largely replacing iron hoops for all purposes, markedly so for binding bales of rotton, &c. Of the remainder 32,201 cwt. consisted of "cast steel," and 373*070 was returned under the miscellaneous heading of "other sorts."         Here, again, as in iron, the United Kingdom was the chief source of supply, contributing 456,550 cwt. out of the total. Belgium came next with 7,976 cwt., followed by Germany with 7,063, and the United States, Franca, and other countries with small and unimportant quantities.         The chief importer of steel was Sind, with 212,595, followed by Bombay with 165,476 cwt. Bengal with 136,160 cwt., Madras with 22,065, and Burma with 6,092 cwt.         The hardware and cutlery came almost entirely from the United Kingdom, which furnished an amount valued at 899,23,931, out of the total on lakhs. Austria, Belgium, Germany, and the Straits Settlements contributed to the value of {^3,26,873, R2,45,318, R 1,55,408, and R 1,1,2,404, respectively. Bombay imported to the value of 65,297,815; Bengal, R31,59,ni; Burma, R 12,05,248; Madras, Rq.,03,773; and Sind, R4,56(209).         The machinery and millwork came almost entirely from the United King, dom. Bombay imported Ri,12,05,1630f steam machinery and R8,222 of other sorts; Bengal, 810,89,867 of the former and 875,41*341 of other sorts: 680(23,427; materials for construction, cc, ex or 37,66,78. |                            | The above figures have been enumerated, not so much for the value o<br>the trade, which, indeed, is almost unworthy of anything but a passing men<br>tion, as for the sake of comparison with the large figures of the impor<br>trade. It is unnecessary to go into a detailed account of the ports export<br>ing and receiving these small quantities, but it may be mentioned tha<br>Bombay is the largest exporter, and that the trade is almost entirely with<br>small Eastern ports. In the case of hardware and cutlery, however, the<br>United Kingdom in 1888-89 imported goods to the value of R3 <sup>6</sup> * <sup>01</sup> *-                                                                                                                                                                                                                                                                                                                                                                                 |  |  |  |  |  |  |  |

| Dye and Pigment.—The ochres, both yellow and<br>employed in many localities for the adornment of the v<br>houses, by Hindus for painting caste-marks on the fore<br>the clothes of certain castes, and for other similar purposes<br>writes in his Dyes and Tans of the North-Western Provin<br>stance (geru) is found in some parts of these Provinces, a<br>ported from Gwalior. It is much used by fakirs and as<br>their clc+hes of a dull orange colour, but plays a more of<br>part in the hands of the dyers in the production of sex<br>colours. The earth is simply pounded and mixed with v<br>the cloth is dipped. Red ochre of a lighter colour than,<br>hirmji, while yellow ochre is occasionally used as a dye<br>of ratnraj." He then gives the following examples of dy<br>geru:—In Allahabad a buff colour known as Geru, is<br>ochre and alum; in Cawnpore a dove grey called Faktd<br>the same oxide with myrobalan, sulphate of iron and a<br>lahabad a purple called Nafarmani, is produced by red<br>and indigo. Geru is also used in calico-printing.<br>At Jauti or Jauli in Jabalpur large mines of massive<br>been leased by Mr. W. Q. Olpherts for the purpose of<br>mineral paint, prepared by grinding the ores to an im<br>between stones worked by water-power. Ball states tha<br>#rote, the value per ton in London was $\pounds g-10$ —retail £13<br>paint has proved to be the cheapest in the Indian marked<br>on wood or iron, and has been successfully used against<br>tiles, bricks, and plaster. It is now used by the principal<br>ship Companies, and has stood a practical test on the n<br>principal bridges in India; it has been found most useful<br>boilers. In the preparation of one cwt. of paint, ready fo<br>ing components are required: Dry oxide of iron, 65 jib, H<br>Ions. The addition to the oil of one-fourth of its weight or<br>resin renders the colour more brilliant and lasting. Three<br>coat and two pounds for a second are sufficient to cove<br>feet on an average" (Ball) | valls of huts and<br>ehead, for dyeing<br>. Sir E. C. Buck<br><i>nces</i> , "This sub-<br>and is largely im-<br>cetics for dyeing<br>or less important<br>veral well known<br>water, into which<br><i>geru</i> is known as<br>under the name<br>yes produced by<br>roduced by red<br><i>i</i> , is produced by<br>lum; and in Al-<br>ochre, safflower,<br>e haematite have<br>manufacturing a<br>palpable powder<br><i>t</i> , at the time he<br>b. "This mineral<br><i>t</i> , it lies smoothly<br>damp on porous<br>Rail and Steam-<br>netal work of the<br>on the inside of<br>r use, the follow-<br>inseed oil 5^ gal-<br>of common bazar<br>pounds for a first | DYE ft<br>PIGMENT,<br>474                                                                                           |
| feet on an average" (Ball).<br>Medicine.—A yellow impure OCHRE is believed in Sik<br>for goitre.<br>The MAGNETIC OXIDE is used in doses of from five to<br>tonic and hsematinic. It is highly esteemed as a medicine<br>lities, e.g., Mysore, where a drinking cup of magnetic o<br>mended to the late Raja by his native physicians. They he<br>ing out of it he would prolong his life. In the same distr<br>that milk, if boiled in such a cup, cannot flow over.<br>HYDRATED PEROXIDE of iron is employed in doses of fiv<br>or more as tonic, emmenagogne and anthelmintic, and r<br>is a valuable antidote in cases of arsenical poisoning. In<br>a mixture of the proto- and per- oxides is largely administ<br>from six to twelve grains in many diseases, under the<br>reality powdered and refined iron. The following accound<br>U. C. Dutt:—"Three varieties of iron are used in H<br>namely, kanta lauha or cast iron, mandura or iron rust, a<br>salts of iron, produced by iron being kept in contact with<br>The form of cast-iron used in the manufacture of pans<br>is considered superior to all others for medicinal use. Th<br>of iron which are scattered around when hot iron is bea<br>are called man dura. They are allowed to remain in<br>earth till they become very rusty and brittle, when they are                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | ten grains as a<br>in various loca-<br>xide was recom-<br>eld that by drink-<br>ict it is believed<br>ve to thirty grains<br>nixed with water<br>Hindu medicine<br>tered in doses of<br>idea that it is in<br>unt is given by<br>Hindu medicine,<br>and <i>lauhasara</i> or<br>vegetable acids.<br>for boiling milk<br>te small particles<br>ten on the anvil,<br>contact with the                                                                                                                                                                                                                                                                                  | MEDICINE.<br>Yellow Ochre.<br><b>475</b><br>Magnetic<br>Oxide.<br><b>476</b><br>Hydrated<br>peroxide.<br><b>477</b> |

| MEDICINE.                 | use. The properties of <i>mandura</i> are said to be analogous to those of cast <sup>**</sup><br>iron. "^ " Cast-iron is purified by beating it into thin plates, heating the<br>plates in fire, and sprinkling them with cow's urine, sour congi oil, and a<br>decoction of the pulse Dolichoa biflorns (kulattha) seven times in success<br>sion. The plates are reduced to powder by pounding them in an iron ""~<br>tar, rubbing them with cow's urine, and roasting the mixture in a covered<br>crucible repeatedly till it is reduced to a fine impalpable powder, that will<br>float on water and will not irritate the eyes when applied to them, It is usual<br>to rub the iron with cow's urine and roast it about a hundred times in suc-<br>cession. In some cases it is recommended that iron should be thus roasted<br>separately for a thousand times. Mandura is purified and prepared for <sup>*</sup><br>use in the same way. Prepared iron is a fine impalpable powder of a<br>reddish-grey or brick-dust colour." This preparation of iron oxicjes was<br>believed by the practitioners of Sanskrit medicine to increase strength,<br>vigour, and longevity, to cure all sorts of diseases, and to be the best or<br>tonics. Dutt writes, "When gold and silver are not available, iron, is<br>substituted for them. It is used in painful dyspepsia, chronic fever, phthi-<br>sis, anasarca, piles, enlarged spleen and liver, ansemia, obesity, urinary<br>diseases, diseases of the nervous system, skin-diseases, &c. When iron is-<br>^ administered, the following articles of diet should be avoided, namely,<br>* kushmanda (fruit of Benincasa cerifera, Savi), sesamum oil, kulattfra<br>(pulse of Dolichos biflorus, Linn.), mustard, wines, and acids."<br>The above described preparation of iron oxides enters into many com-<br>plex preparations, in which it is combined with the other metals, spice*,<br>aromatics, and other vegetable drugs* Each preparation is supposed to<br>have specific virtues, and is specially employed for certain diseases. It,<br>needless in such an article as the present to enter into a detailed description<br>of these, for which the reader may be referre |

| localities.<br><b>479</b> | Reference.— $\pounds/.$ C. Dutt, Mat. Med. Hind., 56.<br>Occurrences.—This ore is widely distributed through formations of vari-<br>ous ages. Thus it occurs in quartz reefs associated with the ores of other<br>metals, and often with metallic gold, and is also to be found in slates,<br>limestones, coal, and in the extra-peninsular tertiary rocks, e.g., the<br>nummulitic formations of Sind. Though it is possible that this ore may<br>occur in considerable abundance, and, indeed, it is stated that it does so-<br>in the Rhima limestones of the Deccan, still it appears probable that the<br>supplies of Indian pyrites are not easily accessible, and are unlikely to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MEDICINE.<br>480          | become of commercial importance. At the present time the chief supply is<br>imported into Calcutta from Arabia, where it is obtained on the surface<br>and in the beds of rivers.<br>In the Calcutta market, the wholesale value is said to be R6 to Rio a<br>maund. It is used almost entirely as a drug ( <i>Ball</i> ).<br>Medicine.—Dutt writes, <sup>M</sup> Iron pyrites has been used in medicine from<br>a very remote period. It occurs in two forms, namely, in dark yellow<br>nodules with a golden lustre, and in silvery 'radiating crystals. The<br>former is called <i>Svarnamdkshika</i> , and the latter <i>Tdramdkshika</i> . The<br>ancients supposed that they contained gold and silver respectively, in<br>combination with other ingredients, and possessed in part the properties<br>of those precious metals. Iron pyrites is purified by being boiled in<br><b>I.</b> 480                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| come to be viewed as a source of isinglass for Europe, the trade having been<br>previously with China in the edible substances known as FISH MAWS and<br>SHARKS' FINS. Many writers, however, affirm that all that is necessary to<br>expand an Indian trade in Isinglass is to instruct the fishermen to bestow<br>greater care in selection and preparation of the substance.<br>The uses of Isinglass are in the preparation of jellies and confections<br>and as a clarifying or filtering medium for wine, beer, coffee, and other<br>liquids. 'It is also employed along with gum as a dressing to give lustre<br>to ribbons and other silk articles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ISINGLASS. |
| The reader is referred to the article under Sharks' Fins and also to that on Fish.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | •          |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 492        |
| (5) Gelatine (or Gelatin) and (c) Glue.<br>TJiese substances are prepared from animal flesh, bones, skins, hoofs,<br>and horns. The former is a purer article than the latter, all the stages in its<br>manufacture being carried out with scrupulous care and cleanliness. Glue<br>may be defined as a glutine manufactured from the tan-yard.refuse.<br>But there is no chemical difference between gelatine, glue, and isinglass.<br>The purer forms of transparent gelatine are used for culinary purposes<br>(calves'-feet jelly, milk-white blance-mange, usually containing gelatine<br>instead of isinglass), but for certain purposes gelatine like glue is used as<br>an adhesive medium and hence glues of every quality passing into gela-<br>tine are met with in commerce.<br>The Edible Swallows' Nest may be described as an Indian edible gela-<br>tine (see Vol. II., pp. 505-509). In some parts of India a glue is said to<br>be prepared from fish bones, but ordinary glue is also made as, for exam pie,<br>in Lucknow. The article chiefly used is apparently, however, entirely im-<br>ported (see <i>Hoey, Trade and Manuf. N. Ind</i> %i 176).                                                                                                                                                                                                                                                                                                                                                                                                                                |            |
| (d) Gelose (a name given by Payen).<br>This is a gelatinous substance prepared from the various Algae designated in India as Agar-Agar, and in European commerce as CHINA MOSS.<br>The best known substances of this nature are the so-called Ceylon Moss (see Gracilaria) and the Japanese Isinglass. The last mentioned is derived from one or two species of sea weed (according to Mr. D. Hanbury), but more especially from Gelidium corneum.<br>Gelose differs from gelatine in not being precipitated by tannic acid : from the starch jellies in not being rendered blue by iodine, and from gum, by its insolubility in cold water, and its greater gelatinising power. In this last respect it forms ten times as much jelly as an equal weight of isinglass, and may, therefore, be economically substituted. It contains no nitrogen, and is therefore not nutritious; but as isinglass and gelatine are most frequently used in culinary purposes as vehicles for other nutritious materials, this need not be a serious objection to the employment of gelose. Gelose contains 42770 per cent, of carbon, 5775 hydrogen, and 51*455 oxygen. It, therefore, belongs to the class of proximate principles which possess a larger proportion of oxygen than is required to form water with the hydrogen. It swells up in cold water and dissolves almost wholly in boiling water and on cooling forms a jelly of 500 times the weight of water to the quantity of gelose employed. It differs, however, from jelly with isinglass in the important character that it requires a high tempera- |            |

with this substance do not dissolve in the mouth, and in consequence the jellies known as seaweed are exported from China without deteriora-tion. One of the chief forms of gelose appears to have been shown at the Paris Exhibition of 1878 under the name of Thao or Ta-o, If the hot solu-tion of that substance be stirred until cool, it forms a liquid instead of a jelly; and that preparation gives body and gloss to fabrics without stiffenings

| GELOSE.         | them—the defect of dextrine and starch. The properties of Ta-o in this respect are further heightened by combination with glycerine. It may be mixed also with talc, and even while hot it will intermix with gum, starch, dextrine, gelatine, or gum tragacanth, thus forming <i>size</i> or <i>dressing</i> that may be employed with great advantage to silk goods. Since this dressing is only again softened at high temperatures, the fabrics are not deprived of it by rain or when exposed to damp atmospheres. Gelose may also be employed in double-dyeing by being combined with sulphate of copper and the chlorides of aniline and potassium. For sizing paper it is of great value; indeed, its chief obstacle to an extended application in the arts is its high price. It is somewhat surprising that so valuable a substance should not have been made better known and more carefully examined. Watt, for example, remarks that since no definite compound has been formed with it, its atomic weight and rational rormula has not been determined. Its chief properties seem, however, to ally it with the gums (n. Morin) and according to M. Porumbaru the formula for pure gelose is $C_6H_{10}O_5$ thus analogous to lichenin, inulin, and tunisin. Dr. Dymock remarks of China Moss: "There is, however, no reason why a similar substance should not be made from our common native seaweeds, of which Gelideum corneum and Gracilaria confervoidea approach most nearly in character the Algae from which Thao is made." This statement would justify the recommendation made by Royle nearly half a century ago that the indigenous Algae and other sources of singlass on the seashores of India should be carefully examined with the view to discovering whether any of them might find a place in European commerce. At present the <i>Agar-agar</i> used in India is entirely imported. |

silky hairs. This species is plentiful in the Sub-Himdlayan tract as well as in the hilly parts of Bundelkhand and Central India. It is frequently found associated with Eriophorum comosum (which see, *Volume III., 266)*, and hence from Waliich and Royle proceeded ap error, only recently corrected, of viewing both as one and the same. Eriophorum is a sedge and Ischsemum a grass, but both are no doubt employed for the same purposes.

Fibre.—[This grass is used in paper-making and in the construction of strings, ropes, and mats. It seems doubtful whether the natives of India separately distinguished it from the sedge above alluded to, and these two plants accordingly appear to bear the same vernacular names. The passages that would appear more especially to allude to the sedge allude to it as employed in the construction of rope-bridges, but as a source of paper there is probably no doubt that the bulk of the material so employed is the grass here dealt with. It is perhaps unnecessary to repeat the facts published in the Kew Bulletin (/. c.) showing what led to the confusion regarding these two plants, nor those which ultimately cleared the matter up. It would seem that had Dr. Stewart's remarks republished below (made in 1863) received more careful consideration, the ambiguity that for long existed would never have existed. The following passages regarding the grass as a source of paper, &c, are, however, of practical interest and may be said to convey all that is known on this subject:-

Mr. R. W. Bingham, writing of the Sasseram District of Bengal in 1862, remarked :—

"Buggaie is a wild grass which is ready for cutting in October and November. Several hundred thousand maunds are cut annually in the forest of the Kymore range, and it is sold for roofing and other purposes; when made into a coarse twine it answers for tying thatch and bamboos, as well as for bottoming the cots, or charpoys of the lower orders, as well as a more expensive article. Much of it finds its way to the river ports, but I fancy it is all consumed in this country, and would be but of little use in the manufactures of Europe" (Agri.-Hort. Soc. Journ., Vol. XII., p. 332).

Dr. J. L. Stewart wrote of this grass in Bijnor (September, 1863) as follows: —" This grass, which is abundant in this part of the Himalaya and occasional on the skirts of the Siwaliks, appears to furnish almost all the material called *bhabar* so largely used for string in these parts. Botanists, from Waliich and Royle downwards, have stated this to be the produce of Eriophorum comosum, of which, however, apparently a very small proportion of that brought to the plains consists. Dr. Brand is first drew my attention to the probability of the ordinary belief being erroneous, and subsequent enquiry has shown that the case is as above stated.

"The string is very coarse but strong, and although there is great waste in the manufacture, exceedingly cheap. It is well adapted for boat ropes, the rope-work of bedsteads, and other ordinary purposes. Possibly the *bhabar* may come into play as a paper-material, at least it is worth the trial, and probably larger quantities of the raw article could be got than of any other fibre that I know of in this part of the Himalaya." Dr. Stewart says, the price of the raw material is annas 8 per maund and of the string R2 per maund (*Agri.-Hort. Soc. Journ., Vol. XIII., 293*).

Dr. King, in his report of the Royal Botanic Gardens, Calcutta, for 1882-83, re-established the independence of the two forms of the *bhabar*.

"In several former reports I have referred to the leaves known by the vernacular name *bhabur* as the produce of Eriophorum comosum. I have now satisfied myself that the bulk of the *bhabur* used by natives for rope-making is not derived from Eriophorum, as I had supposed, but from Andropogon involutus. This grass, I find from enquiry locally made,

| <u>Angustifo</u><br>FIBRE. | <ul> <li>abounds in the hill parts of Behar and Chutia Nagpore, where it is known as Sabai. From these regions it can be obtained in quite considerable enough quantity to make its utilization as a paper material a feasible project, and the people who actually collect it, sell it at a reasonable enough rate. But in order to get it brought to Calcutta in sufficient quantity for local manufacture, or for shipment to Europe, middlemen have to be employed, whose ideas of profit are pitched so high that, until they become modified, the utilisation of bhabur must remain in abeyance. This is only in accord with the common experience in the mofussil, that competition in trade is not sufficiently keen to have much effect in keeping down prices, but that, on the contrary, traders still form guilds banded together to entrary, traders still form guilds banded together to entrary traders still form guilds banded together to entrary traders the price being too high ; besides the outturn is not so great as with jute. I found it not to yield more than about 35 per cent, of paper. This is to a great extent owing to the tops being more exposed to the atmosphere, as this part appears to get ripe much earlier than the bottom.</li> <li>The process of boiling the perished or top part gets destroyed before the bottom part of the stems gets sufficiently reduced to a pulp. This accounts for the great loss in the manufacture, but this could be obviated by having the top parts cut off before despatching it to the paper mills, fact reguing bhabur as a source of paper :— 'I believe it will make a fair sheet of paper, much the same as fine esparto, but does not suffact the same proces.'. The some suffact reguing bhabur as a source of paper is suffact reguing parts is in collection, carriage to port of shipment, and, igterly, bautons and erroyses. Freight to England, &amp;c. Whether from India, with long and probably costly inland carriage, with heavy freight added, it can cons as esparto is. Like esparto, in <i>situ</i> it is worth very littl</li></ul> |

An Indian Paper-makiag Material. (G. Watt) ISCHGEMUM angustifolium.

it gives a *good* crop. The plot on which it is planted must be kept free from other grass. When it is seven or eight years old, the roots should be beaten down with wooden mallets, or a plough should be run through them in every direction, and fresh earth thrown over the whole; this will increase the yield. If not treated in this way, it will cease yielding any crop. When grown too old, it must be taken up entirely, re-divided in small bunches of roots, and transplanted to a fresh locality.

"(4). We bought the grass always in local *hats* for roofing purposes (as rope) befoVe we grew our own, and nowhere in OUT neighbourhood am I aware of its being cultivated in any but very small patches by a solitary man here or there. It is not cultivated as a source of income or trade, so that I am unable to say where the roots may be bought, or at what price. We got a small quantity of the roots originally from a Hindu village, but by fostering and spreading their cultivation we have now a considerable quantity. It should be planted in a dry spot where no water lodges, as experience has shown in one of our stations, where the water oozed up from below and rotted the roots, that it would not grow there. A sloping site is probably the best."

"When we first started the Mission here we had to pay R4 a maund in the *hdts* for the grass, in order to twist it into rope or string, and it was the having to pay so much that led me to try and cultivate it ourselves. The grass runs to seed in the hot months, shortly before the rainy season, but these must be cut off and removed, or the crop will deteriorate."

It is understood that the Bally Paper Mills, Calcutta, still continues to use a considerable amount of the grass, drawing its supplies from Chutia Nagpur and the Nepál Tarai. In the *Colonial and Indian Exhibition Catalogue* the writer stated regarding this paper material :—

" In a country teeming with fibres, it is a surprising fact that the question of a paper-fibre should still be under consideration. European authors seem always to forget, however, the immense size of the continent of India, and that a few hundred miles are of little consideration in most Indian questions; but, when this assumes the form of railway freight upon a bulky article, it becomes prohibitive even to industries that can afford to pay more than paper-making. To cultivate fibre, especially for paper, has many drawbacks, and one only need be mentioned-the cost of land near commercial centres is so high as to almost preclude the idea of the cultivation of paperfibres. But the paper fibre must, like esparto, be fit almost for immediate immersion in the vats, for paper-making can never pay for cultivation and separation of fibre, even where land can be got at a merely nominal rent. No fibre known to commerce can compete with jute in point of cheapness, yet the paper-maker can afford to purchase jute waste and jute cuttings only, so that but for the demand to meet an altogether different purpose, the paper-maker could never procure jute. The two most important indigenous paper grass-fibres in India are munj grass and *bhabar* grass. These are now being used by our Indian paper mills; the supply at a remunerative price is the chief obstacle to an extend-ed employment. The roots and lower stems of rice have been suggested as a paper material, and if it be shown that these are worth the trouble of collecting, the supply might be practically unlimited; but it is doubtful whether the paper-maker could pay sufficient to cover freight and expense of collection. It has been demonstrated that bamboo affords excellent paper, but practical difficulties exist which have, for the present at least, dispelled the hopes once entertained of the immense tracts of bamboo forest becoming of commercial value as supplies of paper material.

The most valuable pr.per materials in India are, after all, old rags, waste gunny bags, and old *sunn* ropes."

FIBRE.

|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FIBRE.                | The results of the Exhibition abundantly justified the above opinions<br>and the gentlemen who were present at the conference on INDIAN PAPUI<br>MATERIALS agreed that "while the <i>bhabar</i> and <i>muni</i> grasses were ver-<br>good for paper, it would never pay to import them into fiurope in that condi-<br>tion, the more so since esparto was obtainable at a price far below what would<br>be charged in freight alone from India. Unless these grasses scold pro-<br>fitably be shipped in the form of half stuff they were out of the question."<br>Thus, so far as a foreign trade in these grasses is concerned, it would seen<br>that no hope need be entertained as against esparto, and it is probable<br>that next to the want of a uniform and large supply, the question of railway<br>freight within India itself is likely to operate unfavourably against the<br>development of a large Indian paper trade in <i>bhabar</i> grass. The Agduc<br>tion, prices, and uses of <i>bhabar</i> grass, and at the instance of the '^mmiPif<br>of Commerce issued to its members in 1886-87 a series of questions. //?<br>maunds might be obtained in a season from the Kharrackpore hills at<br>about Ri-14 a maund. Dr. Hill, Parulia, stated that it was cultivated if<br>some parts jpf Manbhoom, but to a larger extent in Singhbhoom (Chutta<br>Nagpur). The people miake 'strings and ropes' of it which are exported<br><b>RI per maund. Mr. T. M. Gibbon, O.I.E.,</b> replied that "the <i>abov</i><br>grass is grown largely in the northern portion of the district, but I believe<br>only in the north, in the jungle lands of Ramnuggur and Rajeporp<br>Solureah. It is also grown in the Nepal Tarai from Apri-<br>"Egreve the exports of the grass was sent direct to the Bally Mills at, 1<br>believe, R2-8 per maund.'' Syed Ali, Nawab, of Jainugger, D <sup>athot, mag<br/>grows on the first range of hills in Nepal: that growing at the bottom<br/>Peppe of Gorakhpore reported that " This grass is called here <i>bunkas</i>, ang<br/>grows on the first range of hills in Nepal: that growing at the bottom<br/>Banjaras and others at Bahadurgunj, about 3 miles south of the hills and<br/>about 25 miles north-</sup> |

According to Roxburgh it is a native of China and the Moluccas, but Kurz regards it as a native of Lower Burma also. Medicine.—" In dysentery 2 tolks of the flowers, fried in gli, are rubbed down with 4 gunjać sech of "cummin and ndgkessar, and made into a bolus with butter and sugarcandy and administered twice a day "(Dymock). SPECIAL OPINIONS.—§ "The root of the plant is used in the treatment of acute dysentery by Assistant Surgeon U. Lai Deb attached to the Howrah General Hospital who first introduced the remedy. The mode of preparing the drug is given as follows:—The root is ground to a pulp with a little water on a stone with a small proportion of long pepper, and about 30 to 40 grains of the fresh root should be taken in this way every three or four hours. A tincture made with 40 z, of the dried root to one pint of proof spirit has been largely used in the form of tincture in the Howrah General Hospital in both the European and Native Departments. It is a valuable remedy, but not as certain and effective as Ipecacunaha. The remedy is not disagreeable to the taste, nor emetic or poisonous" [Civil Surgeon J. G. Pikher, Howrah).</li> <li>Sher, Yora, KaBOR</li></ul>                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                       | 515   |

| <ul> <li>JACK-FRUIT.</li> <li>Jack-fruit, see Artocarpus integrifolia, Linn.,- Vol. I., 330.</li> <li>JADE.</li> <li>Jade, Ball, in Man. GeoU of India, III., 5/6.</li> <li>Under the name Jade several different minerals are included, which are not always easily ditsinguishable. Scientifically, however, the name is restricted to a definite substance called NEPHRITE. This term, derived from ve<f>pos, the kidney, refers to the reputed value of the mineral in renal diseases, whence also it was formerly known as Lapis nephriticus by the Romans. The word Jade is probably a corruption of the Spanish "hijada," from the old name "piedra de hijada " applied by the Spaniards in Mexico and Peru to the mineral.</f></li> <li>True jade or Nephrite is a native silicate of calcium and magnesium, and may be regarded as a crypto-crystalline variety of horneblende. It has a specific gravity of from 2'91 to 3*06. Most specimens can be scratched by flint or quartz, but the mineral is said to become harder after exposure of its broken surfaces. It is compact, non-crystalline, and extremely tough, and varies in colour, from every shade of green to yellowish grey or white.</li> <li>JADEITE is one of the substances most commonly confused with true jade, from which it differs in its more complicated structure, containing as it does a number of bases combined with silica. Much of the Chineses so-called jade is in reality Jadeite. This substance was employed for making axes, and for ornamental purposes, by the inhabitants of the ancient Swiss Lake-dwellings, by the Egyptians, and by the Mexicans, &amp;c. A considerable proportion of the Chinese " Jade *' also consists of another mineral, Prehnite (a silicate of lime and alumina). Amongst other substances passed off as Jade are serpentine, and Cever imitations in glass, which may be seen even in the bazars of Burma and Central Asia.</li> <li>Vein.—Yashnt, HIND.; Sang-iyaskab, changtaw, sang-i-kas, P.B.; Yashm, sang-i-yaskm, PERS.J Suttashi, kashtaski, TURKI.</li> <li>References.—Mallet, Geol. of In</li></ul> |                          |
| SOURCES.<br>Begnal.—The horneblende rock west of Dumrahur and Urjhut, in<br>South Mirzapur, passes into a finely granular to nearly compact tremolite<br>forming a coarse Jade. In this state it is met with, more especially between<br>Kotamowa and bhamni, and at the top of Kurea Ghát. An olive-green<br>Jade occurs north-west of Kisari, and the mineral is also found associ-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | SOURCES.<br>Bengal.<br>3 |
| ated with the Corundum at Pipra ( <i>Ball; Mallet</i> ).<br><i>Turkistnn.</i> —For many centuries Jade mines have been worked by the<br>Chinese at Karakash on the Kuenlun range. These mines were visited<br>and described by Dr. Stoliczka in 1874, from whose account it appears<br>that the rocks in which the Jade-bearing veins occur are syenitic gneisses<br>with micaceous and horneblendic schists. The mineral varies from pale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 4                        |

"Hitherto the collection of the duty had been in the hands of an official who had paid a very high price at Ava for his appointment and who was in the habit of remitting to the capital only as much as he thought fitusually about one-fifth—of the actual receipts. In 1866 the tax was farmed out for the first time. The price obtained was R 60,000 for a three years' lease. At the expiration of this term the King, dissatisfied with the amount of the Jade revenue, determined to buy all the stone from the Kachins himself, and appointed a high official to act as his agent at the mints. For a whole season Chinese and other dealers in Jade were excluded from the mines. The stone, as it was dug up, was purchased by

| SOURCES.<br>Upper<br>Burma. | the King's agent, carried to Mogaung, and there retailed to the traders.<br>This arrangement was of course highly unsatisfactory to the Kachins, who<br>first protested against the exclusion of other purchasers, and then, finding<br>their protest of no avail, resorted to the much more effectual method or<br>curtailing the supply of stone and producing only pieces of indifferent<br>quality. For this reason the King's experiment was a failure, and the<br>total revenue he secured did not equal the proceeds derived from the sale<br>of the monopoly in the preceding year. The Chinese explain the failure<br>on other grounds. The experiment, they say, was doomed from the out-<br>set 'owing to the inherent impropriety of a sovereign descending into<br>the arena of trade and taking the bread out of the mouths of his own<br>subjects.'<br>" During the years 1870, 1871, and 1872 the King obtained an a <sup>#11</sup> "# <sup>1</sup><br>remittance of R 12,000 from the Collector at Mogaung on account of the<br>Jade duty. In the following year new deposits of fine Jade were discover-<br>ed at Mantiemmo, and the King again determined to become the sole<br>purchaser from the Kachins. On this occasion, too, the revenue he realised<br>fell far below the average of former years.<br>"In 1874 the old system was reverted to and the collection amounted to<br>R6,000. Once more, in 1875, <sup>Ine</sup> King undertook to buy the stone himselt<br>from the Kachins, and again the experiment failed, though not so badly<br>as on the two previous attempts. About this time the Iku quarry was<br>discovered, and the output being very good the right of collecting the 9SJY<br>was sold in 1876 for three years for the sum of R60,000. In 1880 Wu<br>Chi, the son of a Canton Chinaman by a Burmese mother, "bial" here Jieg<br>three-years' lease of the monopoly at the rate of R50,000 a year. In the<br>second year of his term* the Tomo quarries were opened and he made a <sup>11</sup><br>immense fortune. j<br>" In the autumn of 1883 Mogaung was sacked by the Kachins, and<br>during the ensuing winter and spring there was no trade in J <sup>ade</sup> / 1 <sup>11</sup><br>June 1884, |
| fethod of<br>Mining.<br>6   | with the traders, were permitted to collect duty at Bhamo instead or, as<br>h t f t Mogaung. During the first two years of their term, "Will'S<br>to the disturbances connected with the adventure of Hsiao Chin and the<br>British occupation of Upper Burma, they collected little or no duty 5 out<br>the proceeds of the third year left them with a margin of R2O,oooover ana<br>above their total expenses for the three years." frmej<br>The tax (at the same rate of 33 per cent, ad valorem) was then a rmmed<br>out by the British Government to a Cantonese lessee for about "50" and<br>who appears to have been very strict in exacting his rights, levied new^athe<br>unauthorised taxes* and made every endeavour not only to *J <sup>ollec</sup> J<br>duty, but to get the management of the mines into his own hands. 'As a<br>result he became extremely unpopular, and in 1887 was assaulted ana<br>outraged at Mogaung.<br><b>quarter Holestribely No follo Web protocole for stone</b> they are guided by indica-<br>tions furnished by burning bamboos; when it is discovered, favourable<br>omens are anxiously awaited before the discovery is announced to the Iva-<br>chin community. A meeting is then convened by the Chief Sawbwa,<br>and again sacrifice and other methods of divination are resorted to in<br><b>I</b> 6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| JADE.                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SOURCES.<br>Upper Burma.                        | which the Jade stone has at one time or another been discovered, the im-<br>practicable nature of the country, covered for the most part with thick<br>jungle, and the rough character of the prospecting, which consists merely<br>in examining large and obvious outcropping stones, it is probable that the<br>jade hitherto discovered bears a very small proportion to that still con-<br>cealed. It is likely, therefore, that in the Jade country our Government<br>possess a source of revenue capable of considerable development. Put-<br>ting out of sight the probability of future discoveries of jade, there is no<br>doubt that the revenue derived from the present mines might be much im-<br>proved if free access could be obtained to the country. The introduction<br>of European appliances, which should supersede the present injurious<br>method of working the quarries, would add considerable value to the<br>output, a good part of which is now calcined by the action of heat. *^!? <sup>d</sup><br>the smuggling of stone overland to China would at the same time be<br>effectually prevented."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| TRADE.<br>7<br>MEDICINE.<br>8<br>DOMESTIC.<br>9 | <ul> <li>The or inclusion and the include of revying it is in present under the consideration of Government.</li> <li>Trade.—For a statement of the exports from Burma during the years from 1880 to 1386 the reader is referred to the articles Cornelain, Voh 1*** 168. In continuation of the table there given, it may be stated that the exports in the last year for which statistics are available (1888-89) were 4,898 cwt., value R6,54,040.</li> <li>It would thus appear that the lade trade from Burma which had seemingly fallen off from 1881-82 onwards has again begun to revive, and hopes may be entertained that it will continue to increase as the country becomes more settled.</li> <li>A considerable amount of a false Jade, in reality serpentine, is JTYP<sup>4</sup></li> <li>ed into the Panjab from Afghanistan. It is said to be found near Kandahar, and to be brought down the Indus on rafts floated with inflated skins to Attock, whence it is earned to Bhera in the Shahpur district to be used in the manufacture of knife-handles.</li> <li>Medicine.—Liquor drunk from a Jade or Agate cup is supposed to allay palpitation of the heart, and the cup itself is believed to act as a protection against poisoning.</li> <li>Domestic—Cups, vessels, and ornaments of Jade are highly valued oy the Chinese, and also by certain classes in India. Not only are its hardness, weight, sonoriety and peculiar sombre tint admired, but wearing the stone is supposed to impart to the warer many good qualities and -virtues, Easy to work when first extracted, Jade acquires a considerable degree of hardness after exposure, a property which together with its toughness readers it very useful as a material for ornaments. In Burma, it is principally employed in the manufacture of these ornaments is at Momein, where the stone, according to Dr. Anderson, is cut by means of circular disco 91 copper and rotating conical tipped cylinders, 'charged with siliceous mua and what appears to be ruby dust. At Momein a pair of bracelets of the finest Jade cost about Rioo. The mo</li></ul> |

| as the true article. Perhaps the most commonly employed of these, in<br>India, is the Afghan Jade-like serpentine, which is largely used in Bher<br>(Shahpur district) for making hilts of <i>peshquabz</i> (or Afghan knives), and<br>of the hunting or dinner knife. Baden Powell describes the method of<br>cutting this stone as follows:—" The pale green plasma called * <i>sang-%</i><br><i>yesham'</i> is cut by means of an iron saw, and water mixed with red san<br>and pounded * <i>kurand'''</i> (corundum). "It is polished by application to<br>the ' <i>sin</i> ''' (polishing wheel), " wetted with water only, then by bein<br>kept wet with water, and rubbed with a piece of • <i>wdtt</i> * (a smooth fragmen<br>of stoneware, pottery or potshera), and lastly by rubbing very finely pound<br>ed burnt <i>santr-i-yesham</i> on it. This last process must be dc;ne ver<br>thoroughly. The other stones used for handles come from the Salt Rang<br>an£ the hills near Attock."                                                         | a j<br>d !<br>of [<br>d<br>a<br>g<br>ht<br>d-<br>y |

| ma, and Ceylon, at altitudes up to 2,000 feet; extensively cultivated in the tropics of both hemispheres.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                         |
| Oil.—This species, together with J. officinale and J. grandiflorum, is ex-<br>tensively cultivated for its fragrant FLOWERS, fiom which a considerable<br>proportion of the oil of Jasmine used in India is derived (see J. grandi-<br>florum). The method of <i>enfleurage</i> is resorted to in India, as in Europe, for<br>extracting the odorous principle, but instead of fat or oil, crushed sesamum<br>seeds.are employed. Dr. Dymock states that in Persia almonds are simi-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | OIL,<br>Flowers.<br>36                  |
| larly used.<br>Medicine.—The FLOWERS are, in Madras, generally believed to possess<br>considerable powers as a lactifuge. For this purpose about two to three<br>handfuls of the flowers are bruised, and unmoistened are applied to each<br>breast, and renewed once or twice a day. The secretion is sometimes<br>arrested in 24 hours, though the period is more frequently two to three<br>days. Dr. W G. King states in a special opinion quoted below that the<br>action of the fresh flowers is quicker than that of belladonna. The dried                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | MEDICINE.<br>Flowers.<br><b>37</b>      |
| LEAVES soaked in water and made into a poultice are used in indolent<br>ulcers. "The ROOT of the wild variety is used as an emmenagogue in<br>Goa" (Dymock). Baden Powell states that this plant is used in the Pan-<br>jdb as a remedy in cases of insanity, in weakness of sight, and affections<br>of the mouth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Leaves.<br>38<br>Root.<br>39            |
| SPKCIAI. OrixiO2*Sm'^—§ "Largely nsotf hy the ri-iffvos an a lactifugc,<br>the flowers being applied externally to the mammae" (Surgeon W. F.<br>Thomas, 33rd Madras Infantry, Mangalore). "The flowers applied over<br>the mammae suppress secretion of milk" (Surgeon-Major A. F. Dobson,<br>M.B., Bangalore). "Stomachic—useful in heart-burn" (Surgeon-Major<br>y. M. Houston, Travancore). "The flowers used as a poultice or wash<br>next to the breast, suppress the secretion of milk" (Surgeon-Major L.<br>Beech, Cocanada). "The fresh flowers when applied to the mammary<br>gland direct, act more quickly as a lactifuge than belladonna" (Surgeon<br>W.G. King, M.B., Madras). "The flowers applied to the breast act as<br>a very efficient lactifuge" (Surgeon-Major J. North, Bangalore).<br>Domestic and Sacred.—The FLOWERS are highly esteemed in the East<br>on account of their fragrance, and are frequently referred to by Arabian,<br>Persian, and Sanskrit poets. Those of one of the double varieties are<br>held sacred to Vishnu, and are used as votive offerings in certain Hindu<br>religious ceremonies. They are also supposed to form one of the darts of<br>Kama Deva, the Hindu God of Love. | DOMESTIC &<br>SACRED.<br>Flowers.<br>40 |
| JATROPHA, <i>Linn.</i> ; <i>Gen. PL, III.</i> , <i>290.</i><br>A genus of woody plants belonging to the Natural Order EUPHORBIACE^E,<br>and comprising <sup>1</sup> about 70 species, chiefly natives of America. Of these, four are<br>indigenous to India, and three others are naturalised or cultivated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                         |

| <u>glandulife</u>    | A Populad Croop Dyo                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DOMESTIC.<br>Si      | Domestic Uses.—This plant is readily propagated by cuttings and is<br>much employed in making hedges. The young twigs are used as deter-<br>gent tooth-cleaners and are supposed to strengthen the gums. They are<br>also said to be employed in making pipe stems. Lisboa states that the<br>young leaves and branches are used in Damaun as a manure for cocoanut<br>trees. Captain Jenkins writes that if castor oil leaves are not procur-<br>able, the leaves of this plant, with others, are used in Assam to feed silk-<br>worms ( <i>Trans. Agri -Hort. Soc. of Ind.</i> , $H_{36\%}$ 168).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                      | Habitat.—A shrub or (?) small evergreen tree, common near villages in<br>Bengal, Burma, the Northern Circars, and the Deccan, rare in Oudh and<br>the Panjáb. One of the most abundant of hedge plants in the lower pro-<br>vinces but also prevalent on village waste lands. Distributed to tropical<br>Africa.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| RESIN.<br>53<br>dye. | Resin.—Kurz states that this species yields a resin, which appears to<br>have been unnoticed by other writers, and is probably not used.<br>Dye.—One of the most interesting economic features of this plant is the<br>fact .that it is one of those reputed to yield a green dye. The first person to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Leaves.<br>54        | bring this to notice was Dr. Thompson, Civil Surgeon of Malwa, who in<br>1862 submitted to the AgriHort. Soc. of India, specimens of cotton, silk,<br>and wool, which were said to have been dyed green by the. juice of the LEAVBS*<br>From recent investigations, however, it would seem extremely improbable<br>that the beautiful green colour then shown, was obtained without the aid of<br>indigo or some other blue dye. In 1877 samples of the dye were forwarded<br>by the Government of India, to Mr. Wardle. Careful''experiments were<br>made by many processes with silk and cotton, but the colours obtained<br>were all yellow, arab, fawn or brown, with, by one or two of the processes,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Seeds.<br>55         | a faint greenish tint. Mr. Wardle reported as follows :—" In the report<br>of Surgeon-Major G. Bidie, M.B., it is stated that these leaves yield a<br>green dye of great beauty; but none of the methods which the limited<br>quantity of dye-stuff at my disposal has enabled me to apply, have pro-<br>duced any such result, nor do I think it likely that they will produce a<br>green without the aid of indigo or other bluish dye,"<br>Oil.—The SEEDS yield a light straw-coloured fluid oil, similar to castor<br>oil in appearance. According to Lepine it has a sp gr. of 0*963, and solidi-<br>fies at s°C. "For preparing this oil, the seeds should be collected as the<br>capsule begins to split or change colour from green to brown; the latter<br>should then be thrown down on a mat, and covered with another mat, and<br>on a few hours exposure to a bright sun the seeds will have separated from<br>the shell; for if allowed to remain on the shrub till qufte ripe, the c&psule<br>bursts and the seeds are scattered and lost" ( <i>Thompson</i> ). The oil is<br>then obtained in the ordinary way by expression, or <sup>M</sup> by roasting the seeds in<br><b>J-55</b> |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | JUGLANS                                                        |

| The Walnut Tree.(9 Murray)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <u>regia</u>                                                   |
| a perforated earthen vessel, fitted upon another vessel, into which when<br>the whole apparatus is heated in a pit filled with burning cow-dung the oil<br>drops" <i>{Dymock}</i> . It is chiefly used medicinally as an external application.<br>Medicine.—The OIL has long been used as an external stimulating ap-<br>plication in cases of chronic rheumatism and paralytic affections. Like<br>that obtained from J. Curcas it is purgative, but is little employed inter-<br>nally. It is also used as an application to sinuses, ulcers, foul wounds,<br>and ririgworm. Dymock states that the ROOT brayed with water is given<br>to children suffering from abdominal enlargements. It purges, and is said<br>to reduce glandular swellings. The JUICE of the plant is used in various<br>parts of the country as an escharotic to remove films from the eyes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | OIL.<br>MEDICINE.<br>Oil.<br>56<br>Rort.<br>57<br>Juice.<br>58 |

| The typical genus of the Natural Order JUGLANDE^E, comprising <sup>1</sup> three or four species, natives of Asia and North America. Of these one is Indian. AH the species are large, handsome, deciduous, and monoecious trees. The generic name is derived from the old Latin appellation of the walnut <i>Jovisglans</i> or the nut of Jupiter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                |

II., 27.</li> <li>Habitat.—A large deciduous tree found wild and cultivated in the Temperate Himálaya and Western Tibet, from Kashmir and Nubra eastwards at altitudes from 3,000 to 10,000 feet, also in the Manipur and Ava UIISS; distributed to Northern Persia, the Caucasus and Armenia (Fl. Br. Ind.). Aitchison states that it also occurs wild in the ravines of She*ndtoj and Darban in Afghánistán, and DeCandolle considers that it has a wider range of distribution than that described above. According to the latter learned author it has been proved that this tree also occurs wild in Japan, in the nountains of Greece, and in the mountains of Banat, giving a range extending from Eastern Temperate Europe to Japan. This opinion is confirmed by the existence of palaeontological evidence of its having at one time extended as far as Provence.</li> <li>Cultivation.—The use of the walnut and its consequent cultivation late from very remote times; so remote, indeed, that it is impossible to ay at what period the tree was first cultivated in India. For <sup>m*n</sup>, y enturies the nuts have formed an important article of export from the hills o the plains. In the Ain-i-Akban' mention is made of Kashmir wal-</li> </ul> |

| in<br>of<br>B<br>y<br>w                                                                                                                             | the plants. In the All-t-Akbah mention is made of Kasmin wat-<br>nuts, which, even in the sixteenth century, had a wide reputation, and the<br>nferior "Tartarian'* nuts are also alluded to. At the present day, the<br>ree is extensively cultivated all over the Temperate Himálaya, especially<br>a Afghánistán and Kashmir. It requires a climate with neither extremes<br>f heat nor cold, good soil, and, in the young state, careful weeding-<br>tranch's mentions three varieties:— a tenera, (thin shelled) /3 beluchistanat<br>kamaonia. At Chumba and Kashmir a superior quality is grown,<br>which is characterised by having a soft shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DYE.<br>Bark. ta<br>63<br>Bind. of<br>64<br>OIL. n<br>Kernel. ti<br>95<br>tv<br>ro<br>10<br>p<br>ti<br>ai<br>a<br>a<br>a<br>k<br>w<br>w<br>is<br>th | Dye.—The BARK and RIND of the fruit are used in dyeing and anning.<br>Oil.—The albuminous KERNEL affords, by expression, about 50 per cent, f a clear sweet oil, largely used in the hills for culinary purposes and illumi-<br>tation, but rarely seen in the plains. Stewart states that a large propor-<br>tion of the hill walnut oil is prepared by simply bruising the kernel be-<br>ween stones. It is one of the most important vegetable fixed oils of Eu-<br>ope, and is said to form one-third of the total oil manufactured in France.<br>In Spain and Italy also, outside the olive-growing regions, it is largely ex-<br>ressed. The following description of the mode of preparation, composi-<br>ion, and qualities of the oil may be quoted from $S_{>ons}$ Encyclopaedia:—<br>'The oil should not be extracted from the nuts until two to three months<br>fter they have been gathered* This delay is absolutely necessary to secure<br>n abundant yield, as the fresh kernel contains only a sort of emulsive milk,<br>nd the oil continues to form after the harvest has taken place; if too long<br>period elapse, the oil will be less sweet, and perhaps even rancid. The<br>extends are carefully freed from shell and skin, and crushed into a paste,<br>which is put into bags and submitted to a press; the first oil which escapes<br>termed 'virgin* and is reserved for feeding purposes. The cake is<br>hen rubbed down in boiling water, and pressed anew; the second oil called<br>fire-drawn * is applied to industrial uses. The exhausted cake forms good<br>attle food.<br>"The virgin oil, recently extracted, is fluid, almost colourless, with a                                                                                                                                                                |

| The Walnut Tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | (J. the tree often reaches a height of 100 to 120 feet with a girth of 12 feet or more. Walnut is at present being grown entirely for the sake of its timber in large plantations at Rangbul and other localities near Darjfling. It is largely used throughout the Himalaya for making furniture, for ornamental, carved, and inlaid work, and as a timber for indoor house-work in European buildings. The wood takes a long time to season, but when thoroughly dry does not shrink nor warp by heat or moisture. This property, together with the fact that it does not corrode iron, renders it most valuable for gun-stocks, in the manufacture of which a large amount of walnut is yearly employed. It is occasionally used for shingles by the Bhutias but is not so good for this purpose as chestnut. At one time a European Company is said to have been formed with the object of purchasing the right to remove the knots from the stems of the walnut trees in Kashmir It is believed this concession was, however, cancelled owing to the reckless injury done to the trees.

Domestic Uses.—" The BARK is largely exported to the plains to be sold under the name of *dinddsa* for women's tooth-sticks, or for chewing to give a red colour to the lips; it is said to prevent the formation of tartar" (*Stewart*). Honigberger states that a twig is recommended to be kept in

| fruit, a sp. gr. of $0*847$ <sup>to</sup> $0*870$ , and is slightly soluble in alcohol.<br>Chemically it consists of a mixture of levogyre oils, one of which has the<br>composition of C <sub>10</sub> H <sub>16</sub> and boils at $155^{\circ}$ C, the other and prevailing portion<br>of the oil consists of hydrocarbons, polymeric with terpene, C <sub>10</sub> H <sub>16</sub> and<br>boils at 200 <sup>o</sup> C. ( <i>Fliickiger and Hanbury</i> ). Juniper-oil is considerably<br>used in medicine. The WOOD and YOUNG TWIGS also yield a volatile oil<br>which is frequently distilled abroad. It is sometimes substituted for the<br>officina <sup>1</sup> oil in Europe and America, but though cheaper, ii more close-<br>ly resembles Turpentine in its composition and properties ( <i>Bentley and<br/>Trimen</i> ). Piesse states that it is much employed on the continent in<br>the manufacture of Juniper Tar Soap, made by dissolving the oil in a<br>fixed vegetable oil, such as almond or olive oil, or in fine tallow, and<br>adding a weak soda ley. The result is a moderately frm and clear soap, | OIL.<br>Wood.<br>82<br>Young Twigs.<br>83 |
| which possesses the advantage of ready mixibility with water.<br>Medicine.—The FRUIT and the OIL above described are officinal in<br>the Pharmacopoeia of India and Great Britain. The former, commonly<br>called a berry, is in reality a galbulus, and is round, about the size of a<br>pea, and of a deep purplish black colour, covered by a glaucous bloom.<br>In addition to the oil it contains a large quantity of glucose, 33 per cent.<br>(Trommsdorff), 41*9 percent. (Donath), 16 per cent, in the dried fruit<br>(Rielhausen), 1877—also small quantities of albumenoids, formic, acetic,<br>and malic acids, resin, and inorganic substances. In addition to these<br>Donath in 1873 eliminated '37 per cent, of a bitter principle which he                                                                                                                                                                                                                                                                                                                                                                     | MEDICINE.<br>Fruit.<br>84<br>Oil.<br>85   |
| termed Juniperine.<br>When bruised the fruit has an agreeable, aromatic odour, and a warm,<br>somewhat spicy, sweetish, slightly terebinthinate taste. The medicinal<br>properties of the fruit and oil are similar, both possessing carminative,<br>stimulant, and diuretic qualities, their physiological action closely resem-<br>bling that of turpentine. The remote local stimulant action of Juniper on<br>the kidney, however, is more marked, and it further possesses the advan-<br>tage of being neither disagreeable nor dangerously powerful. But it also<br>must be administered with caution, as in large doses it causes strangury<br>and renal inflammation.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                           |
| In European practice the oil is employed in doses of 1 to 4 minims,<br>as a diuretic in dropsy not dependent on acute renal disease, <i>i.e.</i> <sub>9</sub> in<br>hepatic and cardiac anasarca, and in some cases of chronic Bright's<br>disease. It has also been employed in mucous discharges, such as<br>gonorrhoea, gleet, and leucorrhoea, and in some cutaneous diseases.<br>The Juniper Tar Soap above described has been considerably used<br>on the continent of Europe as a remedy for skin diseases, its ready                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                           |
| mixibility i» ith water, and the cleanly nature of the application, giving<br>it considerable advantages over terebinthinous ointments.<br>The NUTS are'sold in the bazaVs of Northern India for medicine, and<br>are similarly prescribed as diuretic and stimulant. Irvine mentions that<br>they are imported into Patna from Nepdl, and are used in the treatment<br>of generic process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Nuts.<br><b>86</b>                        |

| MEDICINE.<br>Root.<br>112    | These terms are applied not only to the root of this plant but also to many otner<br>fragrant products used as incense. (See species of <b>Juniper</b> above.)<br><b>References.</b> — Stewart, Pb. PI., 125; Baden Powell, Pb. Pr., Vern. Index,<br>xlix.; Atkinson, Him. Dist., 312; Christy, Com. PI. and Drugs, VI., 93.<br>Habitat.—A herb, with perennial root, common in the Western Hima-<br>laya, from Kashmir to Kumaon, at altitudes from 11,000 to 24,000 feet.<br>Medicine.—"The bruised ROOT is applied to eruptions, and a decoc-<br>tion of it is taken in colic, &c. Aitchison also remarks that some part of<br>the plant is used medicinally. The root is from many places exported to<br>the plains, sometimes after being pounded and made up into cakes with<br>its own juice, as I was informed in Khagan. And it appears to be officinal<br>in the Panjab bazdrs under both of the above names. It is considered cor-<br>dial, and is given in puerperal fever, &c. This is probably <i>the jan</i> (root)<br><i>dhup</i> , of which nearly seven maunds from Bissahir were exposed for sale<br>at the Rampur fair in 1867, according to the Official Report " (Stewart).<br>In confirmation of the above statement of Stewart's it may be men-<br>tioned that Dr. G. Watt saw the preparation <i>dhup</i> being made from the |
| DOMESTIC<br>& SACRED.<br>113 | roots of this plant in Rampur, and also higher up on the neighbouring hills<br>bordering on Kulu witnessed the plant being collected for export to Ram-<br>pur.<br>Domestic and Sacred Uses.—Madden states that the odorous root is<br>used as incense offered at shrines and to rajds. The flowers also are placed<br>in temples on the Sutlej. ( <i>Cf. dhup</i> under Juniperus.) A considerable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                              | quantity of the root is believed to be exported from Kashmir to Tibet for<br>use as incense.<br>JUSSLdEA, Linn.; Gen. | <ul> <li>Habitat.—An evergreen, dense shrub, 2 to 4 feet high ; found in tropical forests throughout India, from Bengal to Ceylon and Malacca, often an escape from cultivation. C. B. Clarke writes in the <i>Flora of British India</i>, "Distribution, Malaya and China to the Phillipines (?wild). This commonly cultivated plant is considered by Nees and T. Anderson to be wild in various parts of India, but the rarity of the seed renders this doubtful. Colonel Beddome says 'Wild on Mooleyit in Tenasserim.''' Medicine.—The LEAVES and TENDER SHOOTS when rubbed emit a strong but not unpleasant odour; used in decoction in chronic rheumatism (<i>Ainslie</i>). The Malays employ the PLANT as a febrifuge. In Java it is considered to have emetic properties (<i>Pharm Ind.</i>). Dr. Dymock, in his <i>Materia Medica</i>, says that the medicinal properties attributed to this plant by Ainslie and in the <i>Indian Pharmacopoeia</i> do not correspond with those which it actually possesses, and conjectures that it has been confounded with some species of Vitex.</li> </ul> | MEDICINE.<br>Leaves*<br>H7<br>Tender<br>Shoots.<br>US<br>Plants. |
| locally is said to be useful in eczema and an infusion of the leaves is<br>given internally in cephalalgia, hemiplegia, and facial paralysis" (Sur-<br>geon-Major J. M. Houston, Trarancore). "The juice of the fresh leaves<br>is dropped into the ear for earache, and into the corresponding nostril on<br>the side of the head aftected with hemicrania" (Honorary Surgeon P.<br>Kinsley, Chicacole, G an jam, Madras),                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                  |

| CHEMISTRY.<br>124                          | The reader should consult the article Corchorus, Vol. IL> $$34'5^{\Lambda^2'}$<br>Since the date on which that article was written certain new and interest'<br>ing facts have been brought to light, the most important of which is<br>perhaps, the exhaustive chemical study to which the fibre has been sub-<br>jected by Messrs. Cross and Bevan. These chemists published, an the<br><i>Journal of the Chemical Society (1889)</i> , the results of their detailed anap-<br>lysis both of the formation of the fibre and its chemical nature. $^{\Lambda_{nel}}$<br>paper is too elaborate and technical for the present work, but doubless,<br>as their discoveries become better known, practical developments of an<br>industrial nature will be brought to light that may extend the uses 01<br>the fibre. The following brief risumi may, however, be here given :<br>ChemistryJute, the best representative of the group of lignified cel-<br>luloses, in the chemical investigations contained in the paper, is <sup>176</sup> HP ? f <sup>5</sup><br>the type. Although from its nature jute fibre is an aggregate, it $^{\circ}J^{1611''}$ ,<br>notwithstanding, a constancy in composition and properties which denote<br>a chemical individual. The simplest expression of its elementary compo-<br>sition is the empirical formula, C <sub>12</sub> H <sub>18</sub> O <sub>3</sub> (C=47*0, H=6-0, O=47° <sup>5</sup> )<br>whilst its proximate resolution into <i>cellulose</i> (78-80 per cent.) and <i>nen-<br/>cellulose</i> (20-22 per cent.) may be represented by the formula 3 C <sub>6</sub> ''w V?'<br>C <sub>6</sub> H <sub>6</sub> O <sub>3</sub> . This is for the time advanced more as a statistical than a map-<br>lecular expression. The authors, however, proceed to show that the mog<br>a oxidisable constituents of the jute-fibre (non-cellulose) are compounds, op<br>compound, characterised by an atomic ratio approximating to C <sub>6</sub> : «6 ··-<br>. Isot-—the fact that in those reactions of the fibre substance wmen-<br>depend on its alcoholic characteristics (OH groups), i «<br>molecular homogeneity is equally manifest.<br>This second proposition is proved by a series of very elaborate «J « <del>groups</del> , <del>fron</del><br><i>i</i> authors further state that, fron the earliest appearance ot the . |

| JUTE.<br>TRADE | Trade in Jute.<br>mumber of operatives employed has been estimated at 62,000 hands.<br><i>[Coni, with Vol. II., 558]</i> . In the article Corchorus the probable con-<br>sumption of Jute by the Bengal mills was assumed to be about 8,571428<br>cwt. The commercial returns, which the writer has now been able to con-<br>sult, give the Bengal consumption at 5,000,000 maunds and the probable<br>value of their productions at R300 lakhs. Mr. J. E. O'Conor ( <i>Statistical</i><br><i>Tables of British India</i> ) shows 24 mills at work in Bengal, one in Madras,<br>and one at Cawnpore, and he gives the amount of Jute worked up by these<br>mills during 1888-89 as 3,769.494 cwt. But in comparing commercial with<br>official returns, it has to be borne in mind that the years do not correspond.<br>It, however, seems probable that the estimate of total production of jute<br>( <i>P</i> -535 <i>P</i> <sup>1+se</sup> article Corchorus of 15,000,000 cwt, per annum is not far<br>from correct, being an under, rather than over, estimate. |

A Medicinal Herb.

Vern.—J{etn3agar, HIND., BENG.; Zakhmkydt, parna-bij, BOMB.; Mala" kulli, TAM.; Hétnasdgara (=sea of gold), SANS.

*Kuui*, 1AM.; *Hetnasagara* (=sea of gold), SANS. **References.**—*Roxb.*, *Fl. Ind., Ed. C.B.C.*,388; Voigt, Hort. Sub. Cal., 268; Kurz in Jour. As. Soc, 1876, Pt. II., 30g; Thwaites, En. Ceylon *PL*, 129,417; Dais. & Gibs., Bomb. FL, 105; Grah., Cat. Bomb. PL, 8J / W. & A.<sub>9</sub> Prod., 360; Mason, Burma and Its People, 773; Dymock, Mat. Med. W. Ind., 2nd Ed., 360; Pharm. Ind., I., Sgo-Spr; Gazetteer, Mysore & Coorg, /., 61; Honigherger, Thirty-five years in the East, II., 263.

Habitat.-An erect, stout, perennial herb, common throughout the tropical regions of India, especially the Deccan Peninsula, and from Bengal (Behar-Dacca) to Burma, Yunan, Malacca, Java, and Tropical Africa.

Medicine.—Bail Ion (Natural History of Plants, III., 317) remarks of the CRASSu LACEJE that the succulent species owe their cooling properties as topical applications to the quantity of water contained in their fleshy organs. It\*seems probable that most of the large-leaved species might be so used, as, for example, the house-leeks of Europe, but at the same time it is probable that certain of the genera and even species possess special peculiarities. It is on this account that the writer does not follow the example, recently given, by the authors of the *Pharmacofrraphia Indica*, in treating Kalanchoe laciniata, K. spathulata, and Bryophyllum calycinum conjointly. Dr. Dymock, in his Materia Medica of Western India, gave a detailed account of Bryophyllum, and quoted under Kalanchoe a brief sentence said to be derived from Ainslie. It would thus seem that no very good object has been served by assigning the properties of Bryophyllum to the species of Kalanchoe. There is a historic interest, however, in this subject which it seems desirable to point out When Roxburgh wrote his Flora Indica (1820), Bryophyllum was a garden curiosity, which he states had been procured from the Moluccas. At the present day, thousands of square miles of Bengal possess that plant as their most prevalent weed. Every lane around the Botanic Gardens, Calcutta, possesses a rampant growth of Bryophyllum, and throughout the greater part of Bengal this is the case, the plant becoming less abundant as the drier areas are reached, though it is also met with as far north as the Sutlej valley in the Panjdb (20 miles from Simla), also in Bombay, Madras, and Burma. We are told it was brought to India by Lady Clive in 1799 (see Rev. J. Long, Journal Agri.-Hort. Soc. Ind. (Old Series), X., 7), but whether that date is absolutely correct or not, botanists agree in viewing it as an introduced plant. Even supposing it existed in Bengal prior to a foreign introduction, such as that attributed to Lady Clive, it must have been an extremely rare plant indeed, to have escaped Roxburgh's scrutiny of the Flora of the Lower Provinces, and even so recent a writer as Stewart apparently did not know of its existence in the Panjdb. This rapidity of distribution within the past sixty years practically proves, therefore, its exotic nature. U. C Dutt, in his *Hindu Materia Medica*, does not allude to either Bryophyllum or Kalanchoe, and, indeed, everything points to an opinion adverse to the belief that Bryophyllum could have been known to even the most modern of Sanskrit writers. In the Pharmacographia Indica, however, we are told of Kalanchoe and Bryophyllum that they ••are called in Sanskrit Asthibhaksha and Parna-vija or 'leaf-seed,' because their leaves, when placed upon moist ground, take root and produce young plants." Now this application of these Sanskrit names could only be made of Bryophyllum, since none of the Kalanchoes possess the remarkable property exhibited by Bryophyllum of producing budules in the crenatures of the leaves. Dr Moodeen Sheriff gives a series of vernacular pames under Kalanchoe laciniata which, in the present work (Vol. I., 543)i <sup>have</sup> been transferred almost entirely to Bryophyllum. It seemed to

| MEDICINE.                                         | the writer at that time, that these names, together with the others given<br>in the passage cited, were, by modern usage, assigned to <b>Bryophylum</b> <sup>*</sup><br>but it may be added that <b>Kalanchoe laciniata</b> being not only the most<br>abundant and best known species, but the one with the strongest claims<br>to the possession of medicinal properties, is in all probability the plant<br>alluded to by all Muhammadan ana Hindu writers on the Materia M edica<br>of India. On the Himalaya <b>K. spathulata</b> is a fairly plentiful species,<br><b>but</b> it has the reputation of being poisonous, and is, therefore, said to be<br>rarely used as a cooling external application, though special preparations<br>from it are so employed.<br>The medicinal properties given in the <i>Pharmacographia Indica</i> will be<br>found in the first volume of this work under Bryophyllum (/. c), but the<br>sentence said to be derived from Ainslie regarding the leaves of K. laciniata<br>may be here given :—• I can myself speak of their good effects in cleaning<br>ulcers and allayirg inflammation." The authors of the <i>Pharmacographia</i><br>add :—"We have seen decidedly beneficial effects follow their application to<br>contused wounds; swelling and discoloration were prevented, and union of<br>the cut parts took place more rapidly than it does under ordinary treatment.<br>The juice of the leaves is administered in doses of \ to 1 tola (45 to 180<br>grains) with double the quantity of melted butter in diarrhoea, dysentery,<br>and cholera; it is also considered beneficial in lithiasis." The above<br>passage has been quoted as it seems of very considerable interest, but the |
| Juice.<br>16                                      | writer is not quite certain whether or not it applies to <b>K. laciniata</b> or to <b>Bryophyllum calycinum.</b><br>SPECIAL OPINION.—§ "The JUICE is used externally in bruises, sprains, and burns; also to cure superficial ulcers. As a styptic it is used on fre-h <b>cuts and abrasions,</b> " ( <i>Civil Surgeon J</i> <sup><math>\%</math></sup> <i>H. Thornion* B.A., M.B., Monghyr</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| MEDICINE,<br>Root.<br><b>39</b> | Habitat.—A native of Peru and Bolivia.<br>Medicine.—Rhatany ROOT is powerfully astringent and tonic. It has<br>been successfully employed in chronic diarrhoea, in passive or atonic<br>haemorrhages, and locally in leucorrhoea, ophthalmia, &c. ( <i>Pharm. Ind.</i> )»<br>The powder may be used as a dentifrice when mixed with prepared chalk<br>or myrrh. The drug is entirely obtained from foreign sources.                                                                                                                                                                                                                                                                                                                                                                   |
| 40<br>fibre.<br>41              | Kulu.—In the Report on Madras fibres (published in the Selections of the Records of the Madras Government, 1856) mention is made of a strong and useful fibre known as <i>Kulu</i> which is said to be prepared by retting. This may be the fibre of Sterculia ureas, <i>Roxb.</i> , which see, Vol. VI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

It ascends<br>the Himalaya to altitudes of about 2,000 feet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FIBRE.<br>Bark.<br>43           | Fibre.—The inner BARK yields a bast fibre used for coarse ropes, &c.<br>It was chemically analysed by Cross, Bevan and King, and found to pos-<br>sess moisture 10*9; ash 2*5. The decomposition (hydrolysis), by alkalis, gave<br>the following results : loss after boiling for five minutes in solution of 1 per<br>cent. N^O, 13*2, after boiling for one hour, 25*2. Amount of cellulose<br>70*2. Effect of mercerising <i>[i.e.,</i> subjection to action of strong caustic soda<br>(33 per cent. Na <sub>2</sub> O) in cold for one hour] loss 7*2. It will thus be seen<br>that in point of cellulose, and in power of resistance to hydrolysis, Kydis,<br>fibre is fairly useful, being about twentieth in order of merit of a list of<br>some 300 fibres met with in India. |

E. O'Conor in the note above cited : "In India lad occurs in Bengal and Assam (abundantly), the North-West Provinces and Oudh (sparingly), the Central Provinces (abundantly), the Panjab, Bom bay, Sind, and Madras (more or less sparingly), ana Burma (abundantly in some places). Lac is also found in some other countries of Southerr Asia, viz., Siam, Ceylon, some of the islands of the Eastern Archipelago and China, Siamese lac being held in high estimation. In India the best Uu is obtained from Assam and Burma." Lac from the last mentionee locality would appear to have been long known and esteemed. Thus in the sisteenth century it was noticed and described by the traveller Linschot</li></ul> |
| ngal and<br>ssam.<br>3 | above enumerated, is chiefly consumed in local manufactures.<br>The following more detailed account of the distribution of lac in the<br>various Provinces is condensed from Mr. O'Conor's valuable report:—<br><i>Bengal and Assam.</i> —In Bengal, lac is produced abundantly in the jungle<br>tracts of Birbhum, Chutia Nagpur, and Orissa. In various places in the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Distribution of Lac in India. {J. Murray.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | LAC.                                       |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| forests of Assam, it is also found in large quantities and forms a regular<br>article of trade, a portion of the production being manufactured at Dacca,<br>and the rest sent to Calcutta. In 1867 the Deputy Commissioner of Púrúlia<br>in C'hútia Nagpur reported that the smallest average yearly supply from the<br>district was 15,000 maunds, though the actual yield was, he believed, consi-<br>derably more, while it was capable of great extension. From Singhbhúm,<br>at the same period, about 1,250 maunds of lac were exported annually. In<br>the Gya district the supply was estimated at 12,000 maunds; in Kamrup<br>(Assam) about 5,000 maunds. Mr. O'Conor, however, remarks that these<br>figures probably do not by any means approximate to the actual yield of<br>the districts named.<br>In Bengal, lac is gathered twice a year, <i>viz.</i> , from about the middle of<br>October to the end of January, and from the middle of May to the middle<br>of July. | DISTRI-<br>BUTION.<br>Bengal and<br>Assam* |
| <i>The North-West Provinces</i> ,—Lac is obtained in some quantities from<br>the Garhwal forests, and is said to have been largely exported to the plains<br>some years ago. Mr. O'Conor, however, considers it probable that most<br>of the substance thus brought down from Garhwal is consumed in the<br>Province, very little, if any, being sent to Calcutta.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | NW. Prov<br>inces.<br>4                    |
| Oudh.~La.c is gathered in the more wooded parts of the south-eastern districts, and is exported to the Mirzapore factories and elsewhere.<br>The Punjdb.—Baden Powell states that the production of lac is universal in this Province. According to Mr. O'Conor, however, Panjab lac is inferior in quality, and is probably not exported, the whole production being consumed locally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Oudh*<br>5<br>Panjab*<br>6                 |
| Sindm—Lac is, in Sind, found only in the forests about Hyderabad, 12 miles north and south of the town. It occurs on Acacia arabica, a tree which, in moister regions, appears to be exempt from the attacks of the insect. The substance thus obtained is largely used in the manufacture of the well known lacquered ware of Hyderabad.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | SInd.<br>7                                 |
| <i>Central Provinces.</i> —Large quantities of lac are found in all the districts<br>of these Provinces, but particularly in the more Eastern parts. It has been<br>stated that the Central Provinces could readily supply some 25,000 tons of<br>stick-lac annually, A considerable amount is consumed locally for the<br>manufacture of bracelets and other articles, but most districts also export to<br>a greater or less extent. The incrustation is collected by jungle-tribes,—<br>Bahelyas, Rajhors, Bhirijas, Kurkus, Dhanuks, Nahils, Bhois, and some<br>classes of Muhammadans—who sell the produce in small quantities to<br>Patwas, who again retail it in larger quantities to the regular dealers.                                                                                                                                                                                                                                                                       | Central<br>Provinces.<br>8                 |
| <i>Mysore.</i> —In this Province lac is produced in all three districts, but chiefly in Nundidrug. It is, however, not known how much might be pro-<br>curable annually, the produce being collected in many places by several petty contractors, but the supply is certainly large, and probably capable of increase. At present nearly the whole production appears to be con-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                            |
| sumed locally, since the exports from Madras and Mysore are very small.<br>Burma.—hs already stated the vast forests of Burma are capable of<br>producing an almost unlimited quantity of lac. The chief sources of com-<br>mercial Burmese, lac are the Shan States and Upper Burma, "stick-lac"<br>from these places being imported in considerable quantity into Calcutta,<br>where it is remanufactured into "shell-lac," for export.<br>Endeavours have been made in various parts of India to increase the<br>quantity and improve the quality of lac by artificially rearing the insect on<br>& e most suitable trees. For a complete resumé of the information re-<br>garding these experiments the reader is referred to Mr. O'Conor's exhaus-<br>tive note on the subject.                                                                                                                                                                                                     |                                            |
| L. 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | -                                          |

| LAC.                             | Chemical Composition of Lac.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PESTS.<br>ZZ<br>CHEMISTRY.<br>12 | Pests.—Besides the damage brought about by fire, drought, and frost,<br>the lac-insect is subject to the attacks of various enemies, which frequently<br>cause great havoc and materially decrease the lac crop. These are fully<br>dealt with in the <i>Indian Forester</i> , <i>Vol. /, 281</i> , by Mr. McKee, who writes :—<br>'  The ant, both large and small, attends the female cells for the purpose of<br>licking up the sweet excrement; they do not appear to hurt the insect be-<br>yond biting off the ends of the white filaments, and thus bringing many an<br>occupant of the cells to a premature end by cutting off the supply of<br>breathing air, which the filaments serve to convey through the holes in the<br>lac. Where ants are seen about the lac, it never appears healthy, and many<br>cells are found with the insect dead inside them. The lac whilst on the tree<br>is also attacked by the larva of a moth, which appears to be a species of<br>Galleria, belonging to the ninth section of the Nocturnae, named Tinetes by<br>Latreille, oneof which is famous for eating the honeycomb of bees, living<br>on their larvae, and destroying their wax. A second species was also de-<br>tected, which appeared to belong to the Genus Tinea. The ravages of<br>these insects destroy the colouring matter contained in the females, and a<br>brood of young is never obtained from the cells visited by them.<br><sup>11</sup> At present there seems to be no way of protecting the lac from the<br>depredations of these larvae. The ants, however, may be circumvented in<br>* two ways—either by surrounding the trees with wooa-ashes, or by some-<br>thing sufficiently attractive to draw their attention away from the encrust-<br>ations.''<br>Chemical Composition.—The following analyses are given by Mr.<br>Hatchett:— |
|                                  | <ul> <li>thing sufficiently attractive to draw their attention away from the encrustations."</li> <li>Chemical Composition.—The following analyses are given by Mr. Hatchett:—</li> <li>Stick-lac' Resin, 68; colouring extract, 10; wax, 6; gluten, 5*5; extraneous substances, 6*5; loss, 4. per cent.</li> <li>Seed-lac.—Resin, 88*5; colouring extract, 2*5; wax, 4/5; gluten, 2 per cent,</li> <li>Shell-lac.—Resin, 90*9; colouring extract, 0*5; wax, 4; nitrogenous matter, 2*8 per cent.</li> <li>Ir (Ire's Dictionary of Arts, Manufactures, &amp;c, the following more elaborate analysis by Dr. John is given :—</li> <li>Stick-lac in 120 parts contains—An odorous common resin, 80; a resin insoluble in ether, 20; colouring matter analogous to that of cochineal, 4*5; bitter balsamic matter, 3; dun-yellow extract, 0*5; acid {laccic acid}, 075; fatty matter like wax, 3; skins of insects and colouring matter, 2*5; salts, 1-25; earths, 0-75; loss, 375. The writer of the same article continues,—</li> <li>'' The resin may be obtained pure by treating shell-lac with cold alcohol, and filtering the solution in order to separate a yellow-grey pulverulent matter. When the alcohol is again distilled off, a brown, translucent, hard and brittle resin of specific gravity 1-139 remains. It melts into a</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                  | viscid mass with heat, and diffuses an aromatic odour. Anhydrous alcohol<br>dissolves it in all proportions. According to John it consists of two resins,<br>one of which dissolves readily in alcohol, ether, the volatile and fatty oils,<br>while the other is little soluble in cold alcohol and is insoluble in ether and<br>the volatile oils. Unverdorben, however, has detected no less than four<br>different resins and some other substances in shell-lac. Shell-lac dissolves<br>with ease in dilute muriatic and acetic acids, but not in concentrated sul-<br>phuric acid. The resin of shell-lac has a great tendency to combine with<br>salifiable bases, as with caustic potash, which it deprives of its alkaline<br>taste.<br>This solution, which is of a dark-red colour, dries'into a brilliant, trans-<br>parent, reddish-brown mass, which may be re-dissolved in both water and<br>"FOP" 1. ^ P <sup>assin</sup> g chlorine in excess through the dark coloured alkaline<br>solution, the lac-resin is precipitated in a colourless state. When this pre-<br>L. 12                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Manufacture of Lac. ( <b><i>J</i></b> . Murray.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | LAC.                                  |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| cipitate is washed and dried, it forms, with alcohol, an excellent pale-yellow varnish, especially with the addition of a little turpentine and mastic. With the acid of heat, shell-lac dissolves readily in a solution of borax. The substances which Unverdorben found in shell-lac are the following:—I, a resin soluble in alcohol and ether; 2, a resin soluble in alcohol, insoluble in ether; 3, a resinous body, little soluble in cold alcohol; 4, acrystallisable; resin; 5, a resin soluble in alcohol and ether, but insoluble in petroleum, and uncrystallisable; 6, the unsaponified fat of the coccus insect, as well as oleic^and margaric acids; 7, wax; 8, the <i>laccine</i> of Dr. John; 9, an extractive colouring matter" <i>{p. 786</i> }. White shell-lac changes rapidly on exposure to the air, becoming, within a fortnight of its preparation, incapable of solution, and is generally kept in water for this reason. Manufacture.—The method ordinarily employed has been already described ( <i>Vol. II.</i> , <i>411</i> ), but the following interesting account by Mr. O'Conor fcf the improved process adopted at Cossipore may be quoted as likely to be of value : — | CHEMISTRY.<br>MANUFAC-<br>TURE.<br>13 |
| a platform on the other side. These are afterwards again examined by<br>women, and all the remaining lac separated by hand, and, as far as it may<br>be worth while, used in manufacture. The refuse is bought by natives for<br>the manufacture of <i>choories</i> and other articles made of lac. The sticks are                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                       |
| used for fuel in the furnace of the steam-engine.<br>"The lac is now placed in a horizontal cylinder furnished internally with<br>arms, arranged on a bar passing through the cylinder from end to end.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                       |
| These arms are worked by steam power, and their action, combined with<br>water with which the cylinder is filled, breaks up the lac into very small<br>pieces, and separates the colouring matter which forms lac-dye. Lime is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                       |
| frequently employed to assist in the precipitation of the dye when the water<br>is not naturally impregnated with lime. In the liquid thus obtained the lac<br>is left to soak for twenty-four hours in a large vat, the liquid being then<br>drawn off by the removal of plugs into a vat on a lower level and there                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                       |

is not naturally impregnated with lime. In the liquid thus obtained the lac is left to soak for twenty-four hours in a large vat, the liquid being then drawn off, by the removal of plugs, into a vat on a lower level, and there left to settle in the same way as indigo, the colouring matter being precipitated to the bottom. The clear water at top is drawn off, and the sediment, after having been passed through a strainer, much of the same nature as that used by paper-makers for the straining of pulp, is finally allowed to settle and consolidate, when it is pressed in frames into cakes, which are afterwards dried in the sun. These cakes are the lac-dye of commerce.

"The lac, now called 'seed-lac,' after maceration, is thoroughly melted in a close vessel heated by steam, and thence conducted into open shallow troughs, also heated by steam, where the melting continues. Some resin is here mixed with the lac, to act as a flux and to prevent the lac from burning and adhering to the vessel. The resin, which is probably useful for this purpose, flies off, at least in great part, during the process of ebullition. But I may remark here that great complaints have been made in Calcutta of the adulteration of shell-lac with resin by some unscrupulous

| 574                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| LAC.                | Lac-dye as a Cosmetic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| MANUFAC-<br>TURE.   | native manufacturers. Undoubtedly the high prices offered in 1874 en-<br>couraged adulteration. It is said that what was then offered as lac often<br>consisted of resin to the extent of 50 and even 60 per cent., and it may be<br>that the practice still exists. Lac thus adulterated may be detected by<br>its smell when broken.<br>"Ranged round the troughs are a series of zinc columns, inclined out-<br>wards at an angle of 45°. These columns are hollow, and being supplied<br>by pipes with tepid water, are maintained at a certain temperature. They<br>must never become too hot, or the fluid lac would not consolidate; nor<br>must they become too cool, for then the lac would harden at once, and<br>break up into small fragments which would adhere to the surface of the<br>column. A quantity of the melted lac is now taken up by a workman in<br>the concavity of a piece of plantain-bark, this being the material best<br>adapted to the purpose, and dexterously flung on to one of the columns.<br>Here the liquid mass is spread evenly and thinly over the surface by a man<br>who makes use, for the purpose, of a leaf of the pine-apple plant or some<br>other tough fibrous material. The leaf being held in both hands, its edge<br>is drawn over the liquid until the mass is properly spread over the surface<br>of the column to the required degree of fineness. It begins to consolidate<br>at once, and becomes of a pliable, leathery texture. As soon as the lac is<br>thoroughly consolidated it is taken off by .a workman, while still so hot that<br>it would burn the fingers of any person not accustomed to the work, a<br>considerable section of the upper portion of the sheet of lac being torn off,<br>because it is thicker there than in the rest of the sheet, and thrown back<br>into the trough to be melted again. The sheet is placed on a rod held in<br>readiness by a woman, each extremity of the sheet hanging down like a<br>towel on a" rack, and the whole is hung up to dry in a large drying-shed,<br>the rods supporting the lac being ranged on supports running across the<br>shed from side to side, just like a tobacco drying-h |
| USES.<br>Dye.<br>14 | <sup>M</sup> The points in which Messrs. Angelo's machinery differs from the ordinary processes are— (1) the triple system of rollers and sieves, and the endless chain of receivers; (2) the strainer for lac-dye, which is made of metal; (3) the system of melting the seed-lac by the action of steam; and (4) the hollow zinc columns with the arrangement for keeping them at an equable temperature. The natives use stems of plantain-trees, which do not last of course for more than a day, and the European improvement of porcelain and stone columns is inferior to Mr. Angelo's invention. This factory turns out on an average 100 maunds of shell-lac a day, from 200 maunds of stick-lac, for six months in the year, working from October to April; and with a sufficiency of raw material it could turn out 150 maunds a day during the whole year."<br>USES.<br>Dye.—For a description of lac-dye, the reader is referred to Volume II., 412. In addition to the information there detailed the following account of its utilisation as a cosmetic in India may be quoted from McCann:—" Lac-dye seems to be employed in various parts of Bengal by native women as a cosmetic for dyeing the soles of the feet and the palms of the hands or tips of the fingers, taking the place of <i>mehndi</i> or <i>henna</i> (Lawsonia alba) which is almost universally employed for that purpose. To prepare this cosmetic pieces of stick-lac are bruised in water, and cakes made either of cotton (Murshiddbacl) or of the similar floss covering the seeds of the <i>mudar</i> (Calotropis gigantea) are steeped in the water so that the fibres may attract the dye. These are the cakes used as cosmetics, either by wetting them on the hands and feet, or else by soaking them in water, and applying the water to the skin. The cakes are called <i>alia.</i> "                                                                                                                                                                                                                                                                                                                             |

| Medicine.—A decoction of shell-lac is much used in Hindu medicine for<br>preparing several medicinal oils, such as <i>Ldkshddi tał la</i> , <i>Chandanddi taila</i> ,<br><i>Angdraka taila</i> , &c. (U. C. Dutt). Honigberger states that the substance<br>was officinal at Lahore during the Sikh rule, being used in enlargement<br>of the liver, dropsy, ulcers, &c, and also, in the form of a varnish, as an                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | MEDICINE.<br>15 |
| by the first, they are seen as a set of the form of a variation as an application to wounds.<br>Domestic, &c.—Lac is largely used in India for the manufacture of bracelets (c <i>Huits</i> ), rings, beads, and other trinkets worn as ornaments by women of the poorer classes, and also in the production of turned wood-lacquer work. It appears to have been employed from very remote times for the latter purpose, perhaps the earliest description of the process being that of Linschoten in the sixteenth century, who, in describing the lac of Pegu, wrote as follows:—" Being refined and cleansed they make it" (the lac) " of all the colairs of India. Then they dresse their bedsteds withall, that is to say, in turning of the woode, they take a peece of lac of what colour they will, and as they turne it, when it commeth to his fashion, they spread the lac upon the whole peece of woode which presently, with the heat of the turning (melteth the waxe, so that it entereth into the crestes, &c.), cleaveth unto it about the thickness of a man's naile: they then burnish it (over) with a broad straw or dry rushes so (cunningly) that all the woode is covered withall, and it shinch like glasse, most pleasant to behold, and continueth as long as the woode being well looked unto. In this sorte they cover all kinds of household stuffe in India, as bedsteddes, chaires, stooles, &c., and, all their turned wood-work, which is wonderful common and much used throughout all India." This description agrees almost exactly with the process now commonly employed, excepting that, instead of the grass and rushes referred to as used for polishing, a dry palm leaf stalk, cut chisel-wise, and an oiled piece of rough muslin, are generally substituted. Lac-turnery of this description reaches a high development in certain parts of the Panjab and Sind, perhaps the most esteemed being that of Pak Pattan in the Montgomery district. The following description of the method employed may be quoted from a note by Mr. Kipling:—"The most notable industry of the Montgomery d |                 |

| LAC.                 | Domestic Uses of Lac.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DOMESTIC.            | Coats of different colours are super-imposed on the surface, and the pattern<br>is produced by scratching through these with a sharp stylus. Thus a ree<br>flower is made by scratching through the black and green films; for th<br>leaves the black only is cut away exposing the green; and for a white lin<br>all these are cut through to the white wood. This is obviously work requir<br>ing great delicacy of hand and long practice. The articles made at Pal<br>Pattán, besides objects for native use, are tea-poys, toys, flower-stands<br>plateaux, chessmen, work-boxes, &c. The workmen are Muhammadans.'<br>Work of a similar nature but less pleasing, owing to the brilliancy of the<br>aniline colours which of late years have been largely employed to colour th<br>lac, is made in the Hoshiarpur district. In the work of the same dis<br>trict transparent lac colour is also used, being applied over a ground of the<br>foil. Lines are then scratched in the layer, and filled in with lac of another<br>colour. Various coloured lac is also considerably employed for coiburing<br>metal work.<br>The lac-ware of India is thus entirely different from the true lacquer<br>of Japan, which is made by applying a varnish made of the sap of Rhur<br>vernicifera, to the article on which, the reader is referred for a description<br>of true lacquer-ware, and the possibility of its manufacture in India.<br>Lac is also used as a varnish in India, for which purpose the dye is<br>generally left in the resin to secure a deep colour. In Burma it is employed<br>to fix the blades of knives and similar instruments in their handles. In<br>Bombay and elsewhere it is employed in manufacturing grindstones, for<br>which purpose it is mixed, after being ground, with fine river sand in the<br>proportion of one of the former to three of the latter, and moulded to the<br>desired form.<br>In Europe lac is chiefly used in the preparation of varnishes, and by<br>hatters, who stiffen the silk hats in common use by an application of a<br>mixture of shell-lac, sandarach, mastic, and other resins, dissolved in alco-<br>hol or naphtha. It is also largely emplo |
| TRADE.<br>Lae.<br>17 | Mr. O'Conor recommends to the pignent lake, which last unisation<br>Mr. O'Conor recommends to the consideration of manufacturers of lac-<br>dye in India. Lacquer, prepared for giving a golden colour to brass and<br>other metals, at the same time preserving their lustre, is made by add-<br>ing gamboge, saffron, or some other transparent yellow, to an alcoholic<br>solution of shell-lac.<br>Trade.—LAC.—A consideration of the foreign trade in lac—shell, button,<br>stick, and other kinds, not including lac-dye—shews that while the quantity<br>exported during the last ten years has on the whole increased, the price of<br>the article, and the consequent relative value of the total exports has con-<br>siderably decreased. During the ten years ending 1875-76 the quantity in-<br>creased more than 120 per cent. The last year of that decade shewed a spe-<br>cial increase, the total exported being 92,915 cwt, value 872,91,751. In the<br>five years ending 1883-84 the average total export was 99,723 cwt., value<br>^57*48,415, while during the five years ending 1838-89 " amounted to<br>139*263 cwt., value 1*52,08,973. The average value of 1 cwt. of lac has thus<br>fallen from R78 in 1875-76 to R37 in 1888-89. F <sup>or</sup> many years shell and<br>button-lac were subject to an export duty, which, however, was remitted,<br>together with that on most other articles of merchandise, in February 1880.<br>Lac is exported chiefly in the form of shell-lac, and, to a smaller extent, as<br>button-lac. The unmanufactured form, stick-lac, is exported only to a very<br>small extent.<br>IT -Ti <sup>6</sup> 15 <sup>out</sup> j <sup>ries which</sup> constate the principal markets for lac are the                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Nearly the whole quantity goes<br>from Bengal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | TRADE.<br>Lac. |
| During the five years ending 1883-84 an average of 11641 cwt. of lac,<br>valued 847,573, is shewn as imported from foreign countries; in the four<br>years ending 1888-89 the amount increased to 2,194 cwt., value R49,808.<br>Nearly the whole of this consists of stick lac, imported into Calcutta from<br>the Straits Settlements to be manufactured into shell-lac and re-exported.<br>The inland trade in lac for the year is valued at 101 lakhs of rupees. Cal-<br>cutta received 17 lakhs from Bengal, 32 lakhs from the North-West Pro-<br>vinces and Oudh, and 11 lakhs from Assam. The North-Western Provinces<br>collect the produce of the Central Provinces, the Panjáb, and Rewah for<br>exportation, and a portion of the consignments from Bengal to Calcutta<br>consists of re-exports of arrivals from Assam.<br>LAC-DYE. —The export trade in this substance was once a very import-<br>ant and profitable one, but of late years it has dwindled away to almost no-<br>thing. As early as 1875 Mr. O'Conor wrote:—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Lao-dye.<br>18 |
| " Commencing in 1865 with a valuation twice as high as that of shell-<br>lac, we see lac-dye fall gradually from 1872, until during the last two years<br>the market value has been for the better sorts barely half the price of shell-<br>lac, while the inferior kinds are hardly saleable at any price. Lac-dye in<br>fact is now of very minor importance, both in the eyes of manufacturers and<br>shippers, as compared with shell-lac. It has always had competitors in<br>cochineal and other dyes, but lately the competition of mineral dyes has be-<br>come very formidable. These aniline dyes are produced so cheaply and<br>are worked so easily, that they threaten to supersede the use of most vege-<br>table dyes, and it is probable that the prospects of Indian dyes will before<br>long require much consideration from the State and all interested in them.<br>"When in 1871 a tariff value of R45 per cwt. was placed on lac-dye, the<br>article occupied a place relatively to shell-lac which it no longer occupies,<br>and to which it will probably never again attain. The tariff valuation was<br>far above the real value of the inferior kinds, and the duty therefore pressed<br>heavily on them, representing indeed a real levy of six times 4 percent and<br>more. Taking these facts into consideration, and having regard to the<br>small importance of the revenue derived from the duty (about R28,000 a<br>year on the average) the Government of India, by Notification dated 27th<br>November 1874, removed lac-dye altogether from the list of dutiable exports.<br>The remission of duty has no doubt so far been a relief to manufacturers,<br>but it has not had any substantial affect in reviving the trade " |                |
| but it has not had any substantial effect in reviving the trade."<br>At the present time lac-dye is manufactured only because it is a neces-<br>sary by-product in the preparation of shell-lac, but being almost unsaleable<br>in Europe, it is an export of very little value. During the five years ending<br>1883-84, the average export was 6,010 cwt., value RI,OI,803J while in the<br>past five years ending 1888-89, the average export was only 684 cwt., value<br>863,3^5. In 1887-88 the total quantity was only 279 cwt., in 1888-89, 334<br>cwt. The average price per cwt. has fallen from approximately R57 in<br>1865 to R24 in 1888-89, and while the former average includes the inferior<br>kinds once saleable, the latter represents the price obtained for the very<br>best quality, which is the only form now saleable at any price. The foreign<br>market is the United Kingdom.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |
| LACTUCA, Linn. ; Gen. PL, VII., 524.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |
| A summer of the Nicksond Onder COMPACTER which as 1 (0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1              |

A genus of the Natural Order COMPOSITE, which comprises some 60 species, of which 22 are known to be natives of India. The name is derived from the milky juice contained in the stems and leaves, &c.

Mir Muhammad <i>Hussain</i> , in<br>his <i>Makhzan</i> , mentions several kinds of lettuce, and also lettuce opium,<br>but he acknowledges the superiority of the lettuces raised from English<br>seed in India over that of Persia, and enlarges upon the cooling and puri-<br>fying action of the herb upon the blood." ( <i>Dymock</i> ). The plant appears,<br>however, to be unknown to Hindu medicine. To the ancient Greeks and<br>other European nations, the soporific action of the plant ( $d^{/S} \ll f$ of the<br>Greeks) was well known. LACTUCARIUM, the concrete juice obtained by<br>incision and spontaneous evaporation of the juice, is officinal in the United<br>Mates Dispensatory, but though formerly recognised in the London, Edin-<br>burgh, and Dublin Pharmacopoeias, it is no longer officinal in the Pharma-<br>copceia of the United Kingdom, nor in that of India. In these publications<br>its place is supplied by the inspissated juice of Lactuca virbsa, <i>Linn</i> . In<br>L. 24 |

| Action and Uses of Lactucarium 19, 19, Marray.) virosa.<br>addition to these two sources, Lactucarium may also be obtained from L.<br>altissima, Bieh., a native of the Caucasus, now cultivated in Auvergne for<br>that purpose.<br>CHEMICAL COMPOSITION.—Lactucarium is a mixture of various<br>torganic substances, together with 8 to 10 per cent, of inorganic matter.<br>It is not completely taken up by any solvent, and when heated softens,<br>but does not melt. The principal constituents are <i>lactucon or lactucerin</i> ,<br><i>lactucin</i> , and <i>lactucic acid*</i> Lactucon when pure occurs in the form of<br>colourless needles, which are without odour or taste, neutral, and insoluble<br>in water, though readily soluble in alcohol or ether. It resembles mannite,<br>a peculiar variety of sugar contained in manna (see Vol. III., 442), and<br>is also analogous to euphorbon, echicerin, taraxacerin, and cynanchol.<br>Latucin forms white pearly scales, readily soluble in acetic acid, insolu-<br>ble in ether, and with a strongly bitter taste. Lactucic acid when first<br>obtained is a light yellow, annorphous mass, but after standing for some<br>time, it assumes a crystalline appearance.<br>ACTION AND USES.—Lactucarium appears to be a mild hypnotic,<br>which, however, owing to its extreme uncertainty, is now very rarely pre-<br>scribed. It may be administered in doses of from two to ten grains, as<br>a mild soporific in cases not suited for the exhibition of opium. It has<br>the reputation of being-sedative, anodyne, purgative, diuretic, diaphoretic,<br>and antispasmodic, and useful in the treatment of phthisis, bronchitis,<br>asthma, and pertussis. Most of these properties, however, are probably<br>imaginary, since numerous experiments have failed to show that lactu-<br>carium possesses more than very slight sedative properties, if, indeed, it is<br>not absolutely inert. The anodyne property probably exists more largely<br>in the wild than in the cultivated letture.<br>SFECIAL OFINIONS.—§ "The seeds are given boiled, or made into a<br>conflection, in cases of bronchitis, especially chronic ones                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |

Its properties<br>are similar to those already detailed under Lactucarium, in the description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | which, however, owing to its extreme uncertainty, is now very rarely pre-<br>scribed. It may be administered in doses of from two to ten grains, as<br>a mild soporific in cases not suited for the exhibition of opium. It has<br>the reputation of being-sedative, anodyne, purgative, diuretic, diaphoretic,<br>and antispasmodic, and useful in the treatment of phthisis, bronchitis,,<br>asthma, and pertussis. Most of these properties, however, are probably<br>imaginary, since numerous experiments have failed to show that lactu-<br>carium possesses more than very slight sedative properties, if, indeed, it is<br>not absolutely inert. The anodyne property probably exists more largely<br>in the wild than in the cultivated lettuce.<br>SPECIAL OPINIONS.—§ "The seeds are given boiled, or made into a<br>confection, in cases of bronchitis, especially chronic ones" (Surgeon-Major<br>C. W. Calthrop <sub>9</sub> M.D., Morar). "Lettuce poultice acts as a soothing<br>application to painful and irritable ulcers " (S. M. Shir core, Civil Surgeon, |                    |

At the present time<br>it is largely grown all over the country, from October to February as a<br>cold season crop, but is rarely if ever eaten by the Natives, being culti-<br>vated almost entirely for the European population.                                                                                                                                                                                                                                                                                                                                                                                                          | 27                 |

| CULTIVA-             | Abyssinia; extensively cultivated in America, Australia, and China, ana<br>many parts of India. The fruit assumes many different forms, the re-<br>sult of cultivation. Perhaps the most remarkable of these are the pil-<br>grim's gourd (in the form of a bottle), the long-necked gourd, the trumpet<br>gourd (shapes which are indicated by their names), and the calabash, which<br>is generally large, rounded, and devoid of a neck. The bottle gourd some-<br>times reaches as much as 6 feet in length. The flesh of the cultivated<br>forms differs from that of the wild, the former being sweet and edible, the<br>latter bitter, unpalatable, and sometimes even purgative. The species may,<br>notwithstanding the number of its forms, be popularly recognised by its<br>white flowers, and of the hardness the outer rind of the fruit.<br>Cultivation.—As already stated, this gourd is largely cultivated through- |
| 31                   | out India. The following information regarding the best methods, given<br>by Mr. Qollan in the <i>Indian Forester, IX., 202</i> , may, however, be quoted<br>as generally applicable :—<br>," It can be sown as early as February and as late as July. However/for<br>rainy season use, two sowings should be made, the first in April and the<br>second m June. The first sowing will be ready for use in the beginning<br>of the rains. The second will come in about the middle, and keep up the<br>supply until the cold season. It can be sown in nurseries and transplanted,<br>or sown at once where intended to be grown. The latter mode is prefer-<br>able, but if an empty plot be not available when the sowing season arrives,<br>it is better to ad The first named than let the sowing season slip past. It<br>succeeds tild the availy manured sandy soil, but will thrive ordinarily ^ell<br>L. 31                  |

## The Bottle Gourd. (J. Murray.)

CULTIVAin any. When sown or transplanted, the seeds or plants should be inserted in patches 6 feet apart. No supports are required, as it prefers to trail along the ground. It should be weeded when necessary, until the patches interlace and cover the ground. Afterwards it will not require to be touched, as the dense network of branches will keep down the weeds.

As an example of the extent to which this gourd is Cultivated all over India, the following figures relating to the area under *kaddu* in certain districts of the North-West Provinces, during the rainy season of 1880, may be given on the authority of Messrs. Duthie & Fuller:- ' Allahabad, 202 acres; Meerut, 140; Mainpuri, 765 Shajahanpur, 61; Bulandshahr, 54; Bijnor, 37; Jalaun, 28; giving a total in these districts of 598 acres.

Oil.—The SEEDS yield a clear limpid oil, similar to that derived from thefcseeds of the cucumber. Beyond the fact that it is employed medicinally in certain localities, nothing is known of its properties.

**32** MEDICINE. Medicine.—The SEEDS were originally one of the four cold cucurbitaceous seeds of the ancients, but pumpkin seeds are now generally substituted for them (Dymock). They are, however, still considered cooling and are given internally as a remedy for headache. The OIL above described is also employed for headache, being applied externally. The PULP of the Wild form *tumri* is purgative, sometimes excessively so. Thus Lindley states that certain sailors were poisoned by beer which had been standing in a hollowed bottle gourd, the symptoms produced being similar to those attending cholera. It is said to be largely used, by native farriers in the Panjab, as a purgative for horses. The pulp of the Cultivated forms is occasionally employed as an adjunct to purgatives, and is also considered cool, diuretic, antibilious, useful in coughs, and an antidote to certain poisons. It is applied externally as a poultice, and as a cooling application to the shaved head in delirium. The LEAVES are purgative, and are recommended by Hindu physicians to be taken in the form of decoction for jaundice.

diarrhoea" (V. Ummegudien, Mettapolliam, Madras).

Food.—The cultivated forms are eaten both by Europeans and Natives, By the former the FRUIT is boiled when young and used as vegetable marrow. Firminger says that " cut up into slices in the manner of French Beans, it affords a palatable, but rather insipid dish about the beginning of the cold season." By the latter it is sliced and cooked in curry, or the pulp is eaten with vinegar, or mixed with rice. If hung in a free current of air it will keep well for three or four months, a property which ought to render it of value as a vegetable for sea-voyages. The YOUNG SHOOTS and LEAVES are in India also eaten by all classes.

Domestic and Sacred.-The dried shell of the fruit of the bottle-shaped gourd is used as a bottle for water, and by the Nagas for holding their  $su_{9}$ or beer. The small wild form *tumri* is used for making the stringed instrument, si  $tar_9$  and the wind instrument called bin. The latter, an instrument principally used by snake-charmers, consists of a double flageolet, fitted to a hollow and narrow-necked gourd.

In the Deccan and other localities the hollowed-out gourd is used as a float for crossing rivers, four or five being considered sufficient to support a man with a burden on his head.

## LAGERSTRCEMIA, Linn.; Gen. PL, /., 783.

A genus of trees or shrubs which belongs to the Naturl Order LYTHRACE^, and comprises 18 species, natives of South-east Asia, extending- to Australia. Burma is the centre of the genus. All the species are highly ornamental, and may be either propagated by seed, or by cuttings in garden soil. Leaves\* 36 Juice\*

| correct scientific name of the <i>kakronda</i> (HIND.) or <i>kamaf&amp;Hs</i> (ARAB.). He describes the flowers as white and about the size of a largje pea. This precludes it from being Blumea aurita, <i>DC</i> , which has pink flowers. The colour of the capitula of this great natural order is a character of much more importance than almost in any other family, and we are therefore almost justified in saying that the white-flowered plant alluded to cannot be either a Blumea or a Laggera."                                                                                        | MEDICINE.                                                   |

|                        | A genus of rambling shrubs belonging to the Natural Order V.E * <sup>£</sup><br>NACEJE, and comprising 40 species, chiefly natives of Tropical ana <sup></sup> of<br>tropical America. Of these three are natives of India, but none arc<br>economic importance. One species, however, Lantana Camara, <sup>Un'''</sup> e<br>native of America, has run wild from cultivation in many parts or en-<br>country, especially along the Western Coast and in Ceylon, and is or on a<br>siderable interest, owing to the damage, which it has already done, anu<br>which is likely to increase with its extension. <sup>K1p</sup><br>This prickly plant grows so densely as to become perfectly impenetrapic<br>to men and cattle, and consequently may completely prevent the utilisation<br>of large areas. Owing to its extraordinary vitality it is extremely difficult<br>to exterminate. The only method of getting rid of the growth is said to De<br>by digging it up and burning it, root and branch, reappearing twigs being<br>similarly destroyed as soon as they are seen. A few writers, however,<br>have held that under certain conditions the Lantana growth is by no means<br>an unmixed evil, since, owing to its shade-giving properties and density, it<br>exercises a markedly renovating effect on the soil. Thus Mr. R. Thompson,<br>""Iff" <sup>m</sup> J <sup>h</sup> efirfuin <i>Forester</i> (Volume VI.), states that in his opinion it is<br>mgnly useful in tracts which have been deforested. The plant, according to<br>sol??' <sup>Pi<sup>a</sup></sup> r <sup>P1C</sup> !L <sup>yover</sup> S <sup>r</sup> owing such land, serves to retain the humus in the<br>forest th <sup>*</sup> KUTT <sup>s</sup> V * <sup>es</sup> that in the eve * t of the land again coming under<br>invest the light-loymg Lantana quickly dies out.<br><b>T</b> . <b>*</b> . <b>*</b> . |

| In cultivated and pasture lands, on the other hand, there is no doubt<br>that the shrub is a serious evil, and one against which it is difficult to<br>combat. Thus in the <i>Gazetteer of Mysore Sf Coorg</i> it is stated that it<br>has spread over the whole of Coorg and, covering as it does, many tracts<br>which might be much more profitably occupied, has rendered its extermina-<br>tion a matter of imperative necessity.                                                                                                                                                                                      |                        |
| Lapidary. For an account of the stones principally used in India in the lapidary's art, see the articles op Carnelian, &c, Volume II., 167 3 also Jade, p. 535; and Precious Stones, Vol. VI.                                                                                                                                                                                                                                                                                                                                                                                                                               |                        |

| 0 A mineral of somewhat complex composition, containing silica, alumina, soda, lime, iron, sulphuric acid, sulphur, and chlorine. Its value has considerably decreased in modern times, owing to the discovery, by a French chemist, in 1828, of an efficient artificial substitute, the composition of which is identical or nearly so with that of the natural stone. The colour of both, which varies from a rich Berlin to an azure blue, is supposed to be due to sodium sulphide.                                                                                                                                     |                        |

| Occurrence.—This mineral is found in Persia, Bucharia, China, Siberia,<br>and Chili, and is also said to occur in Afghánistán and Biluchistdn.<br>Though not known with certainty to occur in India, it is imported into the                                                                                                                                                                                                                                                                                                                                                                                                | locality.<br>76        |
| country, where it is employed for several purposes.<br>Pigment.—True ultra-marine, composed of finely powdered Lapis Lazuli,<br>was at one time largely used in India for house-decoration and book-illumin-<br>ating. It is said to have cost, when purified, from R80 to Rioo a seer, but<br>now, as in Europe, its place has been taken by the artificially-made sub-<br>stitute, which is sold in the bazars under the same name of <i>lajward</i> for<br>some R4 a seer. In Europe, the refuse in the manufacture <i>is</i> calcined and<br>affords delicate gray pigments, known as ultra-marine ash ( <i>Ball</i> ). | pigment.<br>77         |
| Medicine.—It is employed as an astringent and refrigerant by native<br>practitioners <i>[Irvine</i> ); it is also said to be mixed with jalap and other<br>purgatives, and to be used as an external application to ulcers.                                                                                                                                                                                                                                                                                                                                                                                                 | medicine.<br><b>78</b> |

|                           | Habitat.—An evergreen arborescent shrub, met with in the Tropical Himd-<br>laya from Sikkim eastwards, also in Assam, the Khásia mountains, and<br>Perak, distributed to Ceylon and Java. It has powerfully stinging hairs,<br>contact with which causes excessive burning pains which last for several<br>days and are greatly intensified by the application of water. Beddome<br>remarks that with natives the sting often brings on fever, hence the name<br>by which the plant is known to coffee planters and other English residents.<br>Hooker states that the plant possesses this property of stinging only in the<br>autumn, a fact which appears not to have been noticed by most Indian<br>writers.                                                                                                                                                                                                                                |
| fibre.<br>80              | Fibre.—This plant yields a strong useful fibre, used by the hill tribes<br>of Assam for cordage, and in the manufacture of a coarse cloth. Major                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 80                        | Hannay, who was one of the first to bring the fibre to the notice of Europeans, stated that it was fine, white, apparently of no great strength, and by report, not very lasting. Messrs. Cross, Bevan, and King, 'however, in their recent report on Indian fibres, appear to hold a more favourable opinion, stating that the fibre " is good, is more or less allied to rhea, and, like that fibre, is very strong " On comparing the results of the chemical analyses of these two fibres, however, by the same observers, it will be found that while rhea fibre contains 803 per cent, of cellulose, that of Laportea has only 53'4 and is also very largely acted on by hydrolysis. The small percentage of cellulose would appear to indicate a very great inferiority in the latter, and this fact, together with the heavy loss it sustains lay hydrolysis, stamps the fibre as unlikely ever to become of commercial importance.     |
| Medicine.<br>Seeds.<br>81 | Medicine.— Irvine states that the SEEDS, in doses of J drachm to J oz.i are used in Patna in the same way as coriander, also that they are imported from Nepal, and are sold for 8 annas per tb.<br>Lard, see Hog, p 253.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

HabitatAn annual herb, indigenous, according to DeCandolfe, in the region extending from the south of the Caucasus, to the north of India It has spread as a weed of cultivation from its original home. It is cultivated all over India from the northern indigenous area, through the North-West Provinces lo the plains of Bengal, and the Southern and Westerr Dravidonzias.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                     |
| Presidencies.<br>Cultivation.—It is grown as a cold weather crop on land which will<br>raise no other kind of pulse. Regarding the method pursued in the North<br>West Provinces, Messrs. Duthie & Fuller write : "Its cultivation is<br>commonest on very heavy clay soils, and it is frequently sown on land sub-<br>merged in the rainy season, which hardens during the cold weather almoss<br>to the consistency of* a stone, splitting up into long deep fissures. After<br>prolonged floods it occasionally offers a means of raising a cold weather<br>crop from land which would otherwise be unculturable, since it can be sown<br>broadcast on wiry ground, and is not so injuriously affected by the subse<br>quent hardening of the surface as would be the case with any other <i>rab</i><br>crop. For similar reasons it is occasionally sown in rice fields even before<br>the rice is cut, springing up between the rice stalks, and yielding a crop in<br>the spring while the rice stubble is still standing.<br>• <sup>4</sup> Its cultivation is commonest in the Eastern Districts, and is of considerable extent in that part of the Allahabad District which lies south of the<br>Jumna. It is also much grown under the name of <i>latri</i> in the Azamgarh | 10N.<br>101         |
| Districts."<br>The method employed in the Panj£b is very similar to that above detailed. New alluvial lands or the beds of <i>nallahs</i> are generally chosen, and the seed is scattered broadcast, and left to take its chance. The crop is sown in September-October, and reaped in March. Occasionally the land receives one or two ploughings, and the seed is in that case sowed by drill. When other food-grains are obtainable the crop is valued as fodder only; it is rarely threshed except for seed, though the young pods are occasionally used as a green vegetable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                     |
| The writer of the Settlement Report of the Jhang District states tha<br>nearly 8,000 acres were under this crop at the time at which he wrote; tha<br>the best crop he had seen was one raised on silt only a year old in Shorkot<br>and that the plant occasionally suffered severely from the ravages of cater<br>pillars which attacked the pods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | ,                   |
| AREA UNDER THE CROP.—No trustworthy statistics are available of the area under Lathyrus in the Panjab, Bengal, Oudh, Madras, Assam Burma, Ajmere, or Coorg. The figures quoted below regarding the North West Provinces are unavoidably incomplete, but those regarding Bombay Sind, the Central Provinces, and Berar may be received as accurate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 102                 |
| <i>The North-West Provinces.</i> —The only available statistics (which, as above stated, are incomplete) give the area under this crop in 1887-88 as having been 56,100 acres, or more than double the average of the same statistics for the three years immediately preceding, which amounted to only 24,820 acres.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | vinces.<br>103      |

*Bombay*.<sup>^</sup>-The returns of the Director of Land Records and Agricul-ture shew the crop to be an unimportant one, and to have varied during the past few years between 32,783 acres in 1888-89 and a maximum of 57,661 acres in 1886-87. The only locality in which it is cultivated to any extent is Broach, which in 1886-87 had 48,000 out of the total of 57,661 acres.

| CULTIVA-<br>TION.<br>Sind.<br>105<br>Central<br>Provinces.<br>106 | Sind.—In 1888-89, <sup>twe on</sup> ty <sup>vear for</sup> which statistics are available 72,876 acres were under the crop.<br>Central Provinces.—These Provinces appear to possess the largest a under Lathyrus in all India. Thus in 1887-88 the total area under the constant was 357,883 acres, an increase of more than 100,000 acres on the <i>aver</i> area for the preceding four years, which was approximately 250, acres.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Berar.<br>107                                                     | <i>Berar.</i> —The area under the crop in this region appears to be markably constant. Thus, during the past five years, it has only var some 9,000 acres from 46,500 to 53,900, the latter figure being retur for the year 1888-89.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| оп.<br>108                                                        | Oil.—O'Shaughnessy states that the oil expressed from the seeds i<br>powerful and dangerous cathartic. Church gives o''9 per cent, as<br>proportion of oil contained in the seed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| FOOD&<br>FODDER.<br>109                                           | Food and FodderAs already stated, this pea is cultivated principal<br>as a fodder, but being very cheap and easily grown it is considerably used<br>food by the poorer classes, largely so in times of scarcity. It is also used to<br>considerable extent to adulterate <i>ddl</i> from which it can scarcely be distinguished. The following chemical composition is given by Church : wa<br>io'i; albuminoids, 31*9; starch and fibre, 53*9; oil, 0*9; ash, 3*2. The m<br>rient ratio is about 1: 175, while the nutrient value is nearly 87.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Poisonous<br>property.                                            | A recent analysis by Astier has revealed the presence in the grain of volatile liquid alkaloid, probably produced by some proteid ferment, wh exhibits the toxic effects of the seeds, and the action of which is destroy by heat. The evil effects of habitual consumption of the seeds have lebeen known, and though the subject is one which has been much discuss there appears to be no doubt that continued use of this article of or has a tendency to produce paralysis. In one district of Bengal alo according to Irving, nearly 4 per cent, of the population suffered frist oxic effects in 1860. That observer went into the subject most ext sively, and found that if used occasionally and in small quantity, the rest were constipation, colic, or some other form of indigestion. But, on other hand, if freely employed, and especially without admixture with od sorts of grain, he found palsy to be a frequent sequel. Dr. Irving's rest further showed that ill-effects were more apt to occur in the rainy seas and that the great majority of sufferers were males, the proportion in cases which came under his observation being 6* 11 males to 0*59 females. During the years from 1829 to 1834 the grain formed, by a series accidents, the chief food of some of the eastern villages of Oudh, and, app rently, as a direct result, many cases of sudden paralysis of the lower eximities ensued. The circumstances which gave rise to this condition and characteristic features of the disease were carefully described by Color Sleeman, from whose account the following may be quoted :— •' In 1829 the wheat and other spring crops in this and the surround villages were destroyed by a severe hail-storm; in 1830 they were deficit from the want of seasonable rains, and in 1831 they were destroyed bight. During these three years the <i>kasdri</i> which, though not sown itself, is left carelessly to grow among the wheat and other $R^{Art}$ and given in the green and dry state to cattle, remained uninjured, a thrived with great luxuriance. In 1831 they reaped a rich crop |

| Habitat.—A common plant of the sandy coasts of India from Bengal to Ceylon, Madras, and Malabar; very plentiful at Kardchi and Goa.<br>Medicine.—" In Bombay <i>pathri</i> is given to buffaloes to promote the secretion of milk " ( <i>Dymock</i> ). According to <b>Murray</b> the JUICE is used as a soporific for children in doses of half a <i>massa</i> , and is also externally applied in rheumatic affections, mixed with the oil of <b>Pongamia glabra</b> , or the juice of the leaves of Vitex leucoxylon.                                                                                                                                                                                         | MEDICINE.<br>Juice.<br>''5 |
| Agricultural Use.—In the Madras Manual of Administration it is stated<br>that this is one of the most important sand-binding plants on the coast.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | AGRICUL-<br>TURAL USE.     |

LAVANDULA The true Lavender. vera Habitat-A fragrant herb found in the Canaries, Portugal, and Eastward throughout the Mediterranean region to Constantinople and Asia Minor. OIL. Oil.—It appears doubtful whether an oil is, or ever has been, distilled 118 from this species. Certain authors, however, affirm that it is the source ot the true oil of spike, used by painters on porcelain, and for artists' varnishes. At the present day, however, most if not all the oil of spike of commerce is derived from L. spica, *DC*, another European species. MEDICINE. Dried Plant. Medicine.—The DRIED PLANT and the FLOWERS have long been employed medicinally. Diosco.rides mentions the plant, and states that it is called 119 Stoechas, from the fact that it is found in the Steechades, a group of islands Flowers. on the south coast of Gaul. According to Sprengel it is the 'fyvov ° 120 Theophrastus. In early European medicine the flowers were known as Flores Steechados, or Steechas arabica, and held a place in the London Pharmacopoeia down to 1746. In the East the herb has also long been prized, and is frequently mentioned by ancient writers on medicine. At the present day it is a regular article of import into Bombay from the Persian Gulf. Dymock writes, "It is much used by native practitioners, who consider it to be resolvent, deobstruent, and carminative, and prescribe it in chest affections; they also think that it assists in expelling bilious and phlegmatic humours." Irvine states that it is used in Patna for the preparation of scents, and in doses of grs. 40 to § oz. in infusion as a refrigerant. According to Dymock the price in Bombay is R8 per maund of 37J ft. Lavandula vera, DC, Prodr., XII., 145. 121 References.—Pharm. Ind., 165; O'Shaughnessy, Beng. Dispens., 45<sup>8</sup>> Flück. & Hanb., Pharmacog., 476; Bent. & Trim.. Med. Pl., W > \*\*\* Book Pharm., 1879, 466; Spons, Encycl., 1423; Balfour, Cyclop., \*'-> 687; Smith, Die, 241; Kew Reports, 104. Habitat.—A native of South Europe and the Mediterranean shores, extending into Western Africa; introduced into England, where it is now extensively cultivated for the spikes of flowers from which a volatile oil is distilled. Oil.—From the herb an oil is obtained by distillation which is pale yellow OIL. with grateful odour, and bitter, aromatic taste. The characteristic pro-122 perties of the plant have been developed to an enormous extent by English cultivation and soil. But they are not equally developed, for, indeed, there are only two districts that can be said to suit the plant: these are Mitcham in Surrey and Hitchin in Hertfordshire. In the latter locality over 50 acres are annually under cultivation. The bushes are grown in rows 4 feet apart. the plants being 3 feet removed from each other; an acre so planted contains about 3,547 bushes. When about four yearr jld they yield the best otto, and are improved by keeping back the flo .ring. An acre should yield about six to seven quarts of otto. Essence o," l'avender is best prepared by distilling a mixture of essential oil of lavender with rectified spirit, in the proportions of 4 oz. of the former to 5 pints of the latter (60 over proof), with 1 pint rose water. (*Piesse on Perfumery*.) The cultivation of layender does not appear to have been attempted in MEDICINE. Oil. India except to a small extent in the Nilghiri Botanic Gardens, but there  $s^{\text{seem}}$  jr<sup>5 to</sup>  $\wedge^{e n_0 reason wn v ll} s^{n_0}$  uld not do well on the Himalaya. 123J<sup>TM</sup>cdiciae.—In the Pharmacopoeia of India three preparations are de-Spirit. 124 scribed as officinal-an OIL, a SPIRIT, and a COMPOUND TINCTURE. Of Compound Fincture. these the oil is rarely administered internally in its simple form, and is employed almost entirely for disguising the unpleasant odour of ointments and otner preparations. The spirit and tincture (diluted preparations of the oil), 125

Stocks found it indigenous in Baluchistdn, and Brandis states that it is perhaps wild in Central India. De Candolle writes that, owing to the shrub being at the present day more or less wild in all the warm regions of Western Asia and Africa to the north of the equator, he finds it difficult to ascertain its original area. From a consideration of the vernacular-names in several languages, however, and particularly owing to the wide dispersion of the Persian</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |         |

ages, nowever, and particularly owing to the wide dispersion of the Persian word *panna*, he is inclined to the opinion that the plant first grew on the borders of Persia, and that its use, as well as its cultivation, probably spread from that region west into Africa and eastward to India. This opinion would appear to be supported by the fact that the use of the dye as a cosmetic, in India at least, is evidently of Muhammadan or Western origin.

| CULTIVA-<br>TION.<br>127 | Cultivation.—The henna plant is commonly cultivated in all the prov-<br>inces of India, partly for the sake of its dye and fragrant flowers, partly<br>as a hedge plant. The following account by Major Oavies of its cultiva-<br>tion in Shahptir, may be quoted From Baden Powell's <i>Panjáb Products</i> , as<br>descriptive of the method which 19 likely to produce the greatest amount of<br>dye:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | dye:—<br><sup>w</sup> The soil is prepared by repeated ploughings, not less than sixteen,<br>and heavy manuring. Before sowing, the seed is allowed to soak, in water<br>for twenty-five days. It is then spread on cloth and allowed to dry par-<br>tially. The plot of land in which it is proposed to grow the <i>rnendhi</i> is then<br>formed into small beds, and some days before sowing these are kept flood-<br>ed. The seed is scattered on the surface of the water, and with it sinks<br>into the ground. For the first three days after sowing, water is given regu-<br>larly night and morning, after that only once a day. The young plant first<br>shows above ground on the fifteenth day, after which water is only given<br>every other day for a month, when it is supplied at intervals of three days, and<br>this is continued for another month, by which time the plants have become<br>nearly two feet high. They are now fit for transplanting. The mode of<br>conducting this operation is as follows :—The young plant on being taken<br>out of the ground is reduced by nipping off about six inches from the cen-<br>tre shoot. After having been subjected to this treatment, the young<br>plants are singly put into holes, previously dug for them, at distances of<br>about a foot from each other. They are then watered daily until they<br>have recovered the shock of transplanting, and afterwards, as they may re-<br>quire it. The fields are weeded regularly once a month. The first year<br>nothing is taken from the plants, but after that they yield, for years without<br>intermission, a double crop. At each cutting, about nine inches is taken<br>from the top shoots of the plants. The two crops are got in <i>Baisakh</i><br>(April and May) and <i>Katak</i> (October and November) of each year. |
|                          | "The labourers employed in planting out the <i>mendhi</i> are liberally fed as<br>long as the operation lasts, and a distribution of sweetmeats takes place<br>when it is over. The season for sowing is during the month of <i>Baisakh</i> ,<br>that of transplanting, <i>Saivan</i> (July and August). A year's produce of an<br>acre of well-grown <i>mendhi</i> is twenty maunds of dry leaves, of which about<br>six maunds are gathered in the spring, and the rest during the autumn<br>months, and the same plants continue to yield for twenty or twenty-five<br>years <sup>*</sup><br>"The selling price of the leaves averages a rupee for twelve seers, so<br>that the value of the crops per acre is about R66. After the first year the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ļ                        | expenses of cultivation do not much exceed those? of other crops. The pro-<br>duce of the <i>mendhi</i> grown in this district is nearly all carried across the<br>Ihelum and sold in the northern districts, none of it finds its way to the<br>south."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | Sind.—Reports from district officers inform us that in the Surat and<br>Hyderabad districts it is grown in gardens as a hedge, the leaves being<br>used for the dye. In the Shikarpur district it is also cultivated, the profit<br>accruing therefrom being estimated at 50 per cent. On every 100 square feet<br>of soil two seers of seed are sown in February. The seed germinates in about<br>en or twelve days; when a foot high, the plants are transplanted and in<br>our months the crop is fit to yield its leaves for dyeing. The average<br>quantity of dye produced in Shikarpur is said to be 5,000 maunds, of<br>which LDOO maunds are consumed locally, and the rest is exported to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| W. Pro-<br>vinces.       | Sukkur and other places.<br><i>Bengal</i> and the <i>North-West Provinces</i> *—Henna is quite as common in hese provinces as elsewhere, and, according to Gamble, is occasionally ound in cultivation in the Terai.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Flowers.                                    | pcedia it is stated that this otto is " remarkably and delightfully fragrant.<br>Olivier states that a fragrant water distilled from the flowers wa<br>known to the Jews, and was employed in baths, and as a perfume in religio"<br>ceremonies, such as marriage, circumcision, and the feast of Courbar<br>Bieram. The ancient Egyptians made a similar use of the flowers for<br>the purpose of perfuming the oils and ointments with which they anointer<br>the body, and for embalming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MEDICINE.<br>135                            | Medicine.— <i>Henna</i> has been employed a''d esteemed as a median<br>from the remotest times. It was used by the Egyptians as an astringen<br>Dioscorides mentions it under the name of <i>Kvirpos</i> . Pliny says that the<br>most esteemed cypress of Egypt comes from Canope, on the banks of the<br>Nile; the second from Ascalon in Judxa; and the third from the island of<br>C)prus. Prosper Alpinus also makes reference to the drug, stating the<br>invalids procure ease by inhaling the perfume of the flowers, and the<br>applying them to the forehead. Avicenna compares the properties of<br><i>henna</i> with those of dragon's blood, and states that its leaves possess the<br>same property of curing ulcers, and that a decoction of them is employed in<br>cases of inflammation and burns, and as a remedy against ulcers of the<br>mouth.                                                                                                                                                                                                                                                                         |
| Leaves.<br>I36                              | In India <i>henna</i> is much esteemed by Muhammadans, indeed, a trad<br>tion exists that their prophet spoke of it as <i>syyadu ridhm=the</i> best of herb<br>Arabic and Persian writers describe the LEAVES as a valuable extern<br>application in headache, combined with oil so as to form a paste, to whic<br>resin is sometimes added. "They are also applied to the soles of the fe<br>in small-pox, and are supposed to prevent the eyes being affected by the<br>disease. Applied to the hair and nails, as already described, they have the<br>reputation of promoting healthy 'growth. An ointment made from the<br>leaves is said to have valuable healing properties, and a decoction is use                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Bark.<br>137                                | as an astringent gargle. The BARK is given in jaundice and enlarg<br>ment of the spleen, also in calculous affections, and as an alterati-<br>in leprosy and obstinate skin diseases; in decoction it is applied to burn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Seeds.<br><sup>B</sup> 8<br>Flowers.<br>139 | scalds, &c. The SEEDS, with honey and tragacanth, are described a cephalic. An infusion of the FLOWERS is said to cure headache and to a good application to bruises; a pillow stuffed with them has the reput tion of acting as a soporific. An ointment is also used as an extern application to bruises * (Dymock). Ainslie states that in Southen Ind the <i>Lytians</i> " prepare a kind of extract from the pale-yellow, strong-sme ing flowers, as also from the leaves and tender shoots, which they consid as a valuable remedy in cases of lepra and other depraved habits of the tender shows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Medicinal Properties of the Henna Plant (J. Murray.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | aiba.             |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| body; prescribing it in the quantity of half a tea-spoonful twice in the<br>twenty-four hours." Dymock remarks that " in the Konkan the leaf juice<br>mixed with water is given as a remedy for spermatorrhoea, and with milk<br>in the condition popularly known as' hot and cold fits."" <i>Henna</i> occupies a<br>place in the non-officinal list of the Pharmacopoeia of India, where attention<br>is specially drawn to its use in "that obscure affection termed 'burning<br>of the feet' often met with in India." Dr. Grierson is quoted as mention-<br>ing an obstinate case benefited by the use of the leaves, and it is stated that<br>"the editor, when in Burma, witnessed, in some cases, a great amount of<br>temporary relief to the distressing sensation of burning, from this remedy,<br>when numerous other means had previously failed. The fresh leaves<br>beaten up into a paste with vinegar and applied as a poultice to the soles<br>of.'he feet, was the common mode of application, but some patients obtained<br>greater relief from using strong frictions with the bruised leaves over the<br>part. Like all other remedies, however, they not unfrequently fail to<br>afford more than temporary relief."<br>It may be of interest to note that Honigberger mentions a use of this<br>plant not dealt with by other writers. Remarking on a severe attack of<br>rheumatism from which he suffered in Greece, he writes, "Amongst the<br>many remedies which I applied, Lawsonia inermis proved the most effec-<br>tual. Every evening before going to bed, I applied to the affected part<br>the pulverized herb, with as much water as was sufficient to make a soft<br>poultice. In the morning I washed it off, but the place continued red;<br>it is the same herb with which the fair sex in the" East stain their hands<br>and feet."                                                                                                                           | MEDICINE.         |
| CHEMICAL COMPOSITION.—The only chemical substance of medicinal value known to be contained in <i>Henna</i> leaves is an astringent principle. Berthelot supposed them to contain gallic acid; later investigations l.y M. Abd-el-Aziz Herraory have shown that the colouring matter consists of a sort of tannin to which he gave the name of <i>Hennotannic add</i> . Dymock, quoting from <i>Journal de Pharmacie, January 18639</i> writes:" This principle is brown, of a resinoid appearance, and soluble in boiling water* It possesses the properties of tannin, such as blackening the sesqui-salts of iron, and precipitating gelatine. It reduces oxide of copper in Trommer's test, and heat decomposes it, with the production of crystalline needles which reduce nitrate of silver." SPECIAL OPINIONS.—§ " A decoction of <i>mendhi har</i> and <i>hath</i> is used for gonorrhoea as an injection ( <i>Surgeon-Major C. W. Calthrop, M.D., Morar</i> ). " The fresh leaves, beaten into a paste with vinegar or lime juice, are said to be useful in cases of burning of the feet'" ( <i>Civil Surgeon J. H. Thornton, B.A., M.B, Monghyr</i> ). " A poultice of the fresh leaves has a soothing effect when applied to swollen and painful parts; it is also used to harden the skin of newly healed wounds" ( <i>Civil Surgeon J. Anderson, M.B., Bijnor, North-Western Provinces</i> ). " An infusion made from the leaves has been found particularly useful in cases of scurvy and ulcers of all kinds. In cases of ulceration of the mouth, it is a valuable remedy, used as a gargle " ( <i>Civil Surgeon F F. Perry, Jullundur City, Panjdb</i> ). "In Belgaum the seeds are called <i>isbon</i> and are considered useful in delirium. They are given internally" ( <i>C. T. Peters, M B., Zandra, South Afghanistan</i> ). "'The leaves, both dry and green mashed with water and applied to the body, relieve prickly heat." ( <i>Surgeon-Major A.S.G, fayakar, Muskat</i> ). | Chemistry.<br>140 |
| Juyukur, Muskur).<br>Structure of the Wood — Crev bard close-grained used for tool band-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | TIMPED            |

Structure of the Waod.—Grey, hard, close-grained, used for tool hand-les, tent pegs, &c.

Domestic—This handsome shrub has always been a favourite garden plant in the East from the times of the ancient Egyptians to the present

| DOMESTIC.        | day. Thus Solomon writes, "My beloved is unto me as a cluster of<br>camphire in the vineyards of En-gedi." The use of the otto by the<br>Jews has been already referred to, and they also had a custom, ?<br>sprinkling the flowers on the garments of the newly-married. In India it<br>is much cultivated as a garden plant and for hedges, and is held in parti-<br>cularly high esteem by Muhammadans, who consider its flowers amongst<br>the most suitable with which to compose a posy to be presented in token<br>of esteem and honour. The utilisation of the otto and dye for domestic<br>purposes has already been described.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                  | LEAD, Ball, in Man. Geology of Ind., Ill, 281-311.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                  | This metal rarely occurs anywhere in the metallic or native state, <sup>an&lt;</sup> ?- <sup>a</sup> J?" pears never to be found in this condition in India. Its commonest ore is tje sulphide, or galena. Many of the other ores are of little interest save to tne mineralogist, but bournonite or antimonial lead, cerussite, or the carbonate, pyromorphite or phosphate, mimetite or arsenate, and crocoisite or chromate, are all of economic importance. Many compounds of lead which do not occur abundantly in nature, but which are extensively used in the arts for pigments, dyeing, glass-making, medicine, & c, are artificially prepared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Man—Madras, Cuddapah, 26, 27; Madras, Man. qj Admin., 11., App. <w></w><w></w></li> <li>Worked in India, Ball states that there is probably no metal of which the ores have been worked to so large an extent in ancient times, excepting those of iron. This is testified to by the number of, old mines in Southern India, Rajputana, Baltchistan, and Afghanistan It is possible that in some at least of these cases the galena may have been chiefly worked for the silver which it contained. Ball states that ores of lead are found in Peninsular India, in the rocks of metamorphic, submetamorphic, and lower Vindhyan ages only; but that in the extra-peninsular area they occur in, at least, one younger formation, namely, in the cretaceous rocks of Balutchistan.</li> </ul> |

| As the working of lead ores in India is at present exceedingly unimport-<br>ant and precarious, it does not appear to be necessary to enter into a full<br>account of the localities in which they are to be found. For such informa-<br>tion the reader is referred to the long and exhaustive account by Ball ( <i>loc.</i><br><i>cit.</i> ). The following short description of the principal localities kindly fur-<br>nished by Mr. Medlicott ( <i>late Director of the Geological Survey</i> ) may-<br>suffice for the purposes of this work :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | LOCALITY.                                               |
| "At Jungamrazpilly or Baswapur, in the Cuddapah district of Madras,<br>argentiferous galena occurs and was formerly very extensively worked, but<br>the workings have been long deserted. Gazalpully, or Baswapur, in the<br>Karnúl district, is also another locality for similar ores. Deposits of galena<br>containing silver occur in the Bhaugulpur district, and have been more or<br>jess worked at various times. There are some galena deposits, rich in<br>silver, at Dhadka in the Manbhúm district. In the Central Provinces, lead<br>ores have been found in Sambalpur at Falpuchia, Zhunan, and Pad am pur,<br>and in Raipur at Chicholi. In Rájputana, galena occurs and has been<br>mined for in Ajmir, Alwar, and Udaipur. In Balúchistán there are ancient<br>lead mines at Sekran of considerable extent, but long deserted. In the<br>Panj£b argentiferous galena occurs at Manikaru in the Kulu district.<br>Lead mines and works were started a few years ago near Subathu in the<br>Simla district, and mines have been for long worked by natives in Sirmur." |                                                         |
| Dye and Pigment.—The RED OXIDE OF LEAD or red lead is largely<br>used as a pigment. It is made in certain jjarts of the country by exposing<br>melting lead to a stream of air, and is also imported. It is not only largely<br>employed for painting and decorating, but is also used for religious pur-<br>poses by the Hindus, who make marks with it on their idols, and on their<br>money at certain seasons for good luck. Boulders may frequently be seen<br>in the Himálaya marked with a patch of red lead, which is supposed to<br>convert them into idols or objects of worship. All married Hindu women<br>employ red lead as a paint for the forehead.                                                                                                                                                                                                                                                                                                                                                                                                                   | DTE ft<br>PIGMENT.<br>Red Lead.<br>145                  |
| The yellow CHROMATE OF LEAD or <i>peori-iailayti</i> , so called from its resemblance to the Hardwari <i>peori</i> , is imported from Europe. It is used in dyeing and as a pigment for all shades of yellow, from the palest primrose to deep orange chrome; and is also considerably employed in calico-printing, the colouring material being formed in the cloth. The process employed is described by Crookes as follows: "24 ozs. of white sugar of lead (acetate) are dissolved in each gallon of water and thickened with 4ft of gum. The solution is printed on the cloth which is then dried and passed for two minutes through a cold bath of bichromate of potash and common salt, containing 6 ozs. of bichromate of potash and 24 ozs. of salt to the gallon. The cloth is finally well washed and dried." By this means yellow chromate of lead is precipitated in the fibres of the cloth. By slightly varying the chemical process different shades are obtained, and the process is applicable to yarns as well as to cloth.                                        | Chromate.<br>146                                        |
| The ACETATE and SUBACETATE are occasionally employed as mordants<br>and for the production of lakes, but the colours obtained are inferior, and<br>are apt to blacken in the presence of sulphur. A lead mordant is, how-<br>ever, in common use for fixing aniline purple and mauve.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Acetate.<br>147                                         |
| NITRATE OF LEAD is employed in mixing murexide purple, and it, as well<br>as the SULPHATE, may be used instead of the acetate for producing chro-<br>mate of lead in cotton goods.<br>PLUMBITE and PLUMBATE OF SODA are also occasionally similarly<br>employed.<br>WHITE LEAD (the CARBONATE) is employed largely as a ground colour,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Nitrate.<br>I48<br>Sulphate.<br>149<br>Plumbite.<br>150 |
| and as a> white paint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | White Lead.<br>151                                      |
| а т 151                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                         |

| LEAD.                | Various uses of Lead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| medicine.<br>152     | Medicine.—The monoxide or litharge (PbO.), the carbonate, acetate<br>subacetate, nitrate, and iodide are officinal in the Indian Pharmacopoeia<br>All these salts, except the acetate, are employed externally only, as sedative<br>and cooling astringents, in various skin diseases. The acetate is similarly<br>used, but is also administered internally as an astringent and haemostati<br>The properties and applications of the officinal salts are too well known to<br>require further description.                                                                                                                                                                                                                                                                                                                            |
|                      | Preparations of lead have long been similarly employed, and valued m<br>Indian medicine. Thus U. O. Dutt states that the Sanskrit name for Galen<br><i>—anjana</i> —literally signifies " <i>the</i> collyrium," and was applied to the sub<br>stance, owing to the fact that it was considered the best medicine for the eyes.<br>It is largely used at the present day as an application to the eyes, and is sup<br>posed to strengthen the sight, improve the appearance of the eyes, a~d P <sup>re</sup>                                                                                                                                                                                                                                                                                                                            |
|                      | serve them from disease. In ophthalmia, blepharitis, and allied diseases o<br>the conjunctiva it is prescribed in various preparations. U. C. Dutt describe<br>two of these as follows:—(i) Galena is heated over a fire, cooled in a d*j <sup>coc</sup><br>tion of the three myrobolans for seven times in succession, then rubbed up                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                      | with human milk. (2) To one part of purified and melted lead, add at<br>equal proportion of mercury and two parts of galena, rub them all togethe<br>emu LCUULC IU puwucr. nuw aua campnor, equal in weight 10 um^*"<br>part of the mass, and mix intimately. {Mat. Med., Hindus.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                      | Metallic lead purified, by pouring the molten metal into the milky juic<br>of Calotropis gigantea, is also employed in Sanskrit medicine. It is re-<br>duced to powder by again melting it in an iron cup, adding to it one<br>fourth part of its weight of <i>yavakshara</i> (impure carbonate of potash) and                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                      | powdered tamarind shells, and agitating with an iron rod till the mass<br>is reduced to fine powder. The preparation thus produced consists of an<br>impure carbonate of lead. It is supposed to be a valuable remedy in vari<br>ous forms of urinary disease. A lead probe is preferred for the application                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                      | of collyria to the eyelids.<br>Litharge is unknown in Sanskrit medicine, but is said by Ainslie to bused by the •• Tamools '' for the preparation of certain <i>kdlümbús</i> or plasters and to be placed by the Arabs amongst their anodynes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| OMESTIC &<br>SACRED. | Red lead is described in Sanskrit medicine as useful for external appli<br>cation in cases of eruptive skin diseases. It is applied in the form of an<br>oil, or liniment, and mixed with black pepper and butter as an ointment.<br>Domestic and Sacred.—The ordinary industrial uses of lead and its salt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 153                  | require no comment. The metal is comparatively little employed by the<br>natives of India owing to its scarceness. Red lead is, as already stated<br>used to a considerable extent as a pigment for several religious purposes.<br>Galena is employed not only as a medicinal application to the eyes, but<br>also as a cosmetic in the place of antimony. It is also utilised to a con-<br>siderable extent for glazing pottery.                                                                                                                                                                                                                                                                                                                                                                                                       |
| TRADE.               | Trade.—No statistics can be given regarding the inland trade in lead<br>since it is not sufficiently important to be returned separately. The import                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Imports.             | trade from foreign countries is, however, considerable, having amounted, in the year under consideration to 113 130 cwt, valued at R 15 88 631                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 154                  | the year under consideration, to 113,130 cwt., valued at R 15,88,631. J <sup>1</sup> addition Government imported 49,285 cwt., valued at R4.62,535. The trade has also increased very considerably during the past ten years. Thus, during the five years ending 1883-84, the imports (private) averaged 70,758 cwt., valued at R10,05,1,6, while in a similar period ending 1888-89 wood we do 100,256 cwt., valued at R12,63.241. This increase of about 30,000 cwt is believed to have been almost entirely caused by a development of the tradefine time for tea-chests, the imports of which have increased in S e ${}^{3} \wedge {}^{5} \wedge {}^{4} + {}^{1} 2$ ${}^{1883 \times 84 \times 10}$ ${}^{661 \times 15}$ cwt. in 1888-89. The imports in the other descriptions enumerated in the trade returns, <i>vie.</i> , pig. |

Leather.

| wear and tear. The final result of the processes ordinarily employed is a   |
|-----------------------------------------------------------------------------|
| chemical combination of certain constituents of the skin with tannin. Two   |
| other processes are, however, occasionally followed, by one of which "tawed |
| leather" is produced, through the action of mineral salts, by the other     |
| " shamoyed leather " is formed, in which the skins are combined with oils   |
| or fatty substances.                                                        |

The Natives of India have long been acquainted with the methods used in tanning, though it is very doubtful if they have ever made leather of superior quality. They employ for this purpose the hides of the buffalo, bullock, and cow, also the skins of goats and sheep. For an account of these the reader is referred to the article on Hides, pp. 248-251; also to that on Skins. Vol. VI.

The following note by Captain John Stewart, R.A., on the methods pursued at the Government Tannery, Cawnpore, may be reprinted from the Records of the Government of India, Revenue and Agricultural Depart156

Re-exports. 155

ore, and various kinds of wrought lead other than sheeting for tea-chests, TRADE. Imports.

ore, and various kinds of wrought lead other than sheeting for tea-chests, have remained comparatively steady. The imports on account of Government have increased from an average of 6,854 cwt., valued at R60,769 in the quinquennial period ending 1883-84, to 17,099 cwt., value R 1,98,220 in that ending 1888-89 (the figures of weight are defective, those of value accurate). The amount of the metal im-ported, however, fluctuates very erratically year by year, and consists almost entirely of pig lead for ordnance purposes.

annost enurely of pig lead for ordnance purposes. The greater part of the general imports comes from the United King-dom. Thus in the year under consideration the sources of supply were as follows:—The United Kingdom, 04,262 cwt.; France, 15,788 cwt.; Italy, 2,111 cwt.; Belgium, 825 cwt.; Ceylon, 97 cwt.; and other countries 47 cwt. The shares of the seaboard presidencies and provinces in the imports were—Bengal, 76,407 cwt.; Bombay, 30,023 cwt.; Sind, 3,415 cwt.; Madras, 2,339 cwt., and Burma, 946 cwt. RE-EXPORTS —With the increase in imports a corresponding in the increase.

RE-EXPORTS.—With the increase in imports a corresponding increase has taken place in the re-export trade, which is, however, very unimportant. In the five years ending 18^3-84 it averaged 2,658 cwt, value 829,707, while, in a similar period ending" 1888-89, it averaged 3,962 cwt., value £39,136. Nearly the entire trade is in pig-lead. In 1888-89, the whole re-export amounted to 5,095 cwt., value 656,330, of which 1,612 cwt. went to Arabia; 1,272 cwt. to Turkey in Asia; 899 cwt. to China; 690 to Persia, and un-important quantities to other countries. Nearly the entire export was from Bombay.

LEATHER.

Leather consists of hides and skins of certain animals, separated from fleshy and fatty matters and prepared by means of chemical agents in such a way that they resist the influences to which they are naturally subject. Skins in their fresh state are tough, flexible, and apparently well suited for clothing, &c.; but on drying they become hard, horny, pervious to water, and finally putrid. These changes are prevented by the processes of the leather manufacturer, and at the same time the skm is rendered stronger, more impermeable to water, more supple and less likely to be affected by

LEATHER.

| West cured hides. Patna, Dacca, and Durbungah cures, though the hide<br>are not in themselves superior, are far preferred. The finest hides of this<br>description are those killed at Agra, Delhi, and Meerut. Much damage<br>is done to the hides by branding on the butts and shoulders.<br>••GOAT AND SHEEP SKINS are always obtained green from the loca<br>market; goat skins are generally very good 5 sheep are poor and small.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | s<br>e                                                                                                                     |
| MATERIALS USED IN TANNING, &c.<br>"Lime is brought into Cawnpore, chiefly from the Banda District, and<br>is used for loosening the hair and flesh of hides and killing the grease. I<br>should be taken in lump, unslaked.<br>"Babul bark is obtained locally, the wood being extensively used for<br>firing. The bark season extends from January to June, that is, the spring<br>of tKe year, when the sap is upon the trees; from six to ten-year old trees ar<br>the best for bark. The bark should be peeled from the trees immediately<br>after they are cut down. The natives are rather careless in this particular<br>and greatly injure the bark, for, to get it separated from the wood, they bea<br>it with wooden mallets, and gash it about to get it loose; they then peel it of<br>by hand; each gash is a wound in the bark through which the tannin es-<br>capes. In England a peeling iron is used, and long strips of bark ar<br>taken off without any beating, but of course this must be done before th<br>sap has dried. The tannin is contained in the white or inner stratum on<br>the bark. The tannin is stronger in babul than in oak bark, but the quality<br>is not considered so good.<br>"Experiments tried lately in England by Professor Abel, the Chemiss<br>to the War Department, proved babul to have keeping qualities quit | d MATERIALS<br>USED IN<br>TANNING,<br>168<br>White OP<br>stone lime.<br>169<br>Babul Bark.<br>170<br>f<br>e<br>e<br>f<br>y |
| equal to oak bark, if not superior; it is thus a valuable tanning agent<br>But it has more colouring matter, that is, it gives a reddish liquor, and thi<br>is somewhat against it, but a great advantage is found from mixing with<br>it, <i>hurr</i> , or <i>bahaira</i> (the myrobalan of commerce—the dried fruit of Termi<br>nalia Chebula,), which is plentiful in the market, and is used extensively a<br>a dye. The liquor from the <i>hurr</i> , or <i>hurra</i> , is a powerful tan, and thoug<br>it is not reported to be of a quality that would make good leather of itsel<br>it is highly esteemed in England to mix with other tanning agents, owing t<br>the bright colour it imparts, and herein is its usefulness in combination<br>with <i>babul</i> . The <i>hurr</i> is a product of the forest, and is very common, but                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | s<br>s<br>h<br>- Myrobalan.<br>s<br>171<br>f,<br>o<br>n<br>t                                                               |
| the natives of Cawnpore use it only as a dye. <i>Sumach</i> is another tannin substance, which has been used in small quantities at this tannery, but onl for finishing and imparting colour. It is imported from England and therefore very expensive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | y 172                                                                                                                      |
| "Cu&ch is a very powerful astringent and rich in tannin. It is the inspissated juice of Acacia Catechu (the <i>khair</i> of the forests), and is used by the natives as a dye and is also eaten with $pán$ ; its tannin is three of four times stronger than that of oak, but of poor quality; the leather made of it is of dark colour and does not last well, but tans so quickly and there fore so cheaply, that it is used extensively in England: such leather is believed to be unsuited for wear in this climate. At Cawnpore the Cutc is employed only for darkening colour when that is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | d Japonica<br>or Kutch.<br>e 173<br>e-                                                                                     |
| " <i>Divi-Divi</i> is the pod of a shrub that is a native of South America, bu<br>grows well in the Madras and Bombay Presidencies; it is called th<br>Caesalpinia coriaria. The pod is exported from Bombay to England, bu<br>in small quantities. The tannin is strong and considered good for mixin<br>with barks. The shrubs were grown at Cawnpore from seed and a planta<br>tion of about 6,000 or 7,000 trees is doing well. The barks of <i>Sal. Asaina</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | e 174                                                                                                                      |

| TANNING.                          | regarding Indian tans the reader is referred to the article on • Tanning<br>materials, Vol. VI.)                                                                                                                                                                                                                                                                                                                                                                                               |
| <sup>Cod-oil.</sup><br>176        | <sup>14</sup> The only oil used for currying is cod-oil; it is obtained from England,<br>and is the best known for the purpose. Indian fish-oil would answer, »<br>more carefully extracted. Mutton or goat tallow is used either alone or                                                                                                                                                                                                                                                     |
| Tallow<br>dubbing.                | mixed with cod-oil; in the latter state, it is called "dubbing," which is<br>applied to all leather intended for harness straps, or like pliable purposes.                                                                                                                                                                                                                                                                                                                                     |
| 177                               | OPERATIONS OF THE TANNERY.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Labour.<br>178                    | <sup><i>u</i></sup> Native tanners and curriers are all of the <i>Chamar</i> caste; the former are <i>Runghtas</i> , a trade class of that caste; such labour is very plentiful about Cawnpore. The wages vary from R5 to R9 per mensem according to skill.                                                                                                                                                                                                                                    |
| Liming.<br>179                    | The hide when received green is only washed and put into a pit pi<br>milk of lime, but if it has been salted and dried out, it has to be soared in<br>soft water before it can go into lime. It is often so hard dried that it wi<br>not soak down, and heavy fulling stocks are required to break it down ana                                                                                                                                                                                 |
| Unhalring<br>and fleshing.<br>180 | soften it ready for the liming process,<br>"The hides are first put into weak lime and then into stronger, until the<br>hair is loosened and the skin 'plumped' up; they are then placed over<br>tanner's beams made of cast iron and convex, so that a two-handled, blunt <sub>f</sub><br>concave knife can be worked over them to push off the hair. When this                                                                                                                               |
|                                   | has been accomplished, the hide is turned over on the same beam, and the flesh and fat which was left on and has now become loosened by the $*^{2^n}$ of the lime, is shaved off by means of a two-handled, concave, fleshing $k^{n_1}$ which has sharpened edge, and takes off a greater or less shaving as required. Some dexterity is needed in this work, as a slip of the km may shave too deep and cut into the hide. The most skilled tanners ar employed in this and called 'beamsmen' |
| Use of Lime.<br>ISI               | "There is great diversity of opinion in the trade as to the use of lime.<br>It is generally allowed that it is an evil but a necessary one; it is not & for leather, but the hair and flesh must be removed, and there is no sate way of doing so. In the French ajid in some of the American tennene the hair is removed by sweating the hides and producing partial decomposition, but this would be too dangerous in a climate like that or Ind 5'                                          |
| Graining or<br>Bating.<br>182     | "Lime being an evil, it becomes necessary, after it has done its work, to<br>rapidly obliterate all traces of it in the texture of the hide, and this $tor/t^* \wedge$<br>the second process of the tanning and is called 'bating' Sole $le \& n e^{-1}$<br>does not require this process, but for all harness and dress leather and, tor                                                                                                                                                      |
|                                   | every soft purpose it is essential. The hides after being unhaired, fleshed,                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ran gralner.<br>183               | and washed, are thrown into a pit called a 'grainer/ in which bran ana<br>water have been allowed to ferment; the acid thus produced removes trie<br>lime from the texture of the skin and loosens and distends the pores, so thac<br>they are cleaned of every foreign substance and brought into a state nigniy                                                                                                                                                                              |
|                                   | sensitive to the action of tannic acid. $f$ r<br>"Much caution is needed in India in the management of grainers, for 11<br>the hides are left a few minutes too long, the acid dissolves the gelatinous<br>materials, the action being quicker than in England owing to the higher<br>temperature.                                                                                                                                                                                             |
| geon or hen<br>mg gralner.<br>I84 | "Bran being sometimes expensive, the ammonia from pigeon or hen<br>dung has been tried with some success; this is a usual grainer in England,<br>but there have been difficulties in collecting- sufficient quantities of it at                                                                                                                                                                                                                                                                |
| tale liquor<br>grainer.<br>185    | Cawnpore, and even when procured, it is often so full of extraneous sub-<br>stances that bran is preferable.<br>"The native tanners of Cawnpore use a grainer of stale fermenting tan<br>liquor, and this is so inexpensive that it is used for all heavy leather in the                                                                                                                                                                                                                       |
| <del>-</del>                      | Government tannery. It is notable that the French use stale rotten liquors L. 185                                                                                                                                                                                                                                                                                                                                                                                                              |

| TANNING.                                | brought up again by means of the pump; thus they are kept moving<br>which is very important, as it retards the formation of gallic acid which is<br>injurious to the tannin, and which is but too apt to form in hot weather.<br>"Babul bark and myrobalans are infused together, and the addition of<br>the latter adds great strength, and takes away from the deep colour of the<br>liquors.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| rime taken in<br>tanning.<br><b>194</b> | *' The hides are kept three or four months in layers, and by that time in<br>general the tannin has penetrated right through them, and they are tanned.<br>Buffalo hides take from nine months to a year from first to last according<br>to weight and substance; cow hides are tanned in from four to six months<br>sheep and goat skins are done in tubs, and take from a month to two<br>months.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                         | "The climate of India is favourable to the penetration and combination<br>of tannin with the gelatine of hides. The chief danger to be guided<br>against is the fretting of liquor and production of gallic acid, a compound<br>more readily produced in Indian Tanning owing to the atmospheric heat.<br>"After the hides are tanned, they can be dried and stored, but in this<br>country they are apt to dry so hard, and to darken so much by the action<br>of light and air that it is thought best to curry them at once, especially for<br>harness work or dress leather. For sole leather or crop hides no currying<br>is required, but they are struck, that is, pressed down and rolled, and then<br>stored.                                                                                                                |
|                                         | NATIVE PROCESS OF TANNING.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Native<br>tanning,<br>195               | <sup>w</sup> Native tanners carry out the liming process very much like that described ; they, however, rather overlime the hides according to English ideas. Their grainer is very effectual as far as softening the skins; they then rinse out all moisture, and, while the pores are yet opened, they work the hides in liquor, and afterwards sew the hide up into a bag having one end open. This bag is filled with finely pounded bark and hung up over a pit from which liquor is ladled into the bag, and there a v&y strong infusion is formed which percolates through the pores of the hide. This tannin therefore goes right through the hide, but it has not time to make the chemical combination, which is considered so essential for the leather. Native tanning does not occupy more than a week.                  |
| Currying.<br>196                        | CURRYING.<br>•• For harness and all dressing purposes, the currying is a most necessary<br>and important process. By tanning, the hide has become leather, but it is<br>not fit for use without currying. This consists of a number of manipula-<br>tions, e.^., stoning, shaving, scouring, oiling, reshaving or flattening, setting,<br>resetting, dubbing and finishing.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Stoning.<br>197                         | "For ordinary harness leather a buffalo hide, as it comes from the tar<br>pits, is hung up till it is half dry, when it is stoned out with a rough stone                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| {Shaving.                               | on a flat table, to straighten it as much as possible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 198                                     | <ul> <li>"It is then thrown over a currier's beam, an upright thick plank faced with Lignum vitae. This is the beam board for shaving on. The hide is smoothed down the board, and the currier, with a two-handled shaving knife, having a turned edge, takes off the outer flesh and inequalities from</li> <li>the flesh side, in fact, levels the hide as nearly as he can do so, having regard to economy in not wasting leather. The object of this shaving is to get the hide to lie flat on a table, so that the scouring stones and sleeper may touch each part of the surface with equal pressure and thus thoroughly clean it as well as press out all dirt and bloom or server the denosit from the surface with equal pressure and thus thoroughly clean it as well as press out all dirt and bloom or server.</li> </ul> |
| Preparing the<br>shaving<br>knife       | clean it, as well as press out all dirt and bloom, or earthy deposit from the<br>bark that remains in the tissue.<br>'« The preparation and use of the currier's shaving knife requires skilled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Native<br>currying.<br>212 | "The natives neglect the currying process of their leather. There is no<br>trade corresponding to the currier's in this country. The best harness-<br>makers curry their leather before cutting it up into straps, in fact they curry<br>it in strips of a foot wide, and apply tallow only; very often they appJy nothing<br>but buttermilk, which gives the leather a very bright appearance, but the<br>moisture very soon evaporates, and the leather becomes hard and brittle."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Leäther.                   | BEST KINDS OF NATIVE LEATHER,<br>As above stated the usual product of the Indian tanner is a har J, im-<br>perfect, thick leather which is very pervious to water, and is not at all dur-<br>able. In certain localities, however, fancy leathers are produced of a very<br>good quality. Perhaps the best of these is the soft wash-leather of the<br>Kangra and Hushiarpur districts of the Pan fab, and the red skins<br>of Nurpur. The former is of a very soft texture, of a greenish buff colour,<br>and so thin and pliable as to be made into gloves, or the breeches which are<br>constantly worn by the Kangra hill-men in the colder months. The method<br>of preparation is described by Baden Powell as follows:—" First, the skin<br>is wetted, and then steeped in a matka or earthen pot full of lime and water,<br>the mixture to be sufficient in quantity to cover the skin is thin, twenty<br>days of this treatment suffice; if thick, one month. After this the skin is<br>washed in clean water, and then well rubbed with the dried and powdered<br>leaves of the <i>dhao</i> tree (Anogeissus latifolia, <i>Wall.</i> ) for two hours succes-<br>sively. After the rubbing is over the leaves and skin are put together in a<br>vessel and water added. Next day the skin is tied on a stick and wrung out,<br>(as a <i>dhobi</i> does clothes). Again it is steeped in a fresh solution of the<br>leaves, and this process of steeping and wringing out is repeated for four days<br>consecutively; fresh leaves are to be used each time. The skin is then sewed<br>up with a <i>munij</i> string, into the form of a hollow sack, filled with <i>dhao</i> leaves,<br>and hung up. On being taken down it is reversed and hung up again by<br>the other end; this ensures both ends being well impregnated with the solu-<br>tion—the process occupies two days. The skin is then opened out, dried,<br>well rubbed with oil, and eventually washed. When dry it is scraped with<br>an iron implement called <i>rambi</i> , and is thereafter again rubbed with oil.<br>After three or four days it is washed in cold water and dried. It is then<br>rubbed with a mixture of curds and water and again dried, the |

|                                                                       | Total L:<br>L. 215                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | akhs R 37                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 5*93                                                                                                                                                                                                                                                                                                                                                                                   | 7 <sup>f</sup> o6                                                                                                                              |

Trade in Leather.

## (J. Murray.) LEBIDIEROPSIS

orbicularis. TRADE. The imports in 1889-90 (details not given) were valued at 18\*48 lakhs of Imports. rupees, against 16\*69 in 1888-89. The figures of trade here quoted are exclusive of those of boots and shoes, the imports of which average about 12 låkhs rupees. The United Kingdom is the largest supplier of these, and Bengal and Bombay take by far the greatest share between them. Frontier. FRONTIER TRADE.—The imports from across the frontier average 1\*20 216 lakhs of rupees. The average exports are about R2f lakhs (chiefly manufactured leather) : the trade is mainly between Kábul and the Panjáb. The RE-EXPORT TRADE is small and unimportant. The average for the Re-export. five yeaVs ending 1883-84 was 25 cwt. of unwrought leather, valued at 217 R 14,566, and manufactured leather, value R3O,6io. During the past five years the average in both cases was smaller, viz., 21 cwt. of unwrought leather, valued at {£2,721, and manufactured, valued at R 19,023. The re-export trade is principally between Bombay and the United Kingdom. Exports-Indian. EXPORTS OP INDIAN LEATHER.—The exports of unwrought leather have slightly increased in quantity but diminished in value during the period 218 under consideration; the exports of manufactures have slightly increased in value. Thus, in the five years ending 1883-84, the average was 184 cwt. of unwrought leather, value, ^14,566, and manufactures to the value of R22,295, while during a similar period ending 1888-89, the average was 291 cwt., value ££14,382, of unwrought leather, and the manufactured article to the value of R26,368. In the above statistics a small quantity of saddlery and harness, annually exported as Government stores to Aden, have not been included. In 1888-89 the value of this amounted to only R119. In conclusion it maybe noticed that the above figures show a steady increase in the amount of leather imported from Europe, notwithstanding the concurrent development of the Indian tanning industry. Also, that the amount of unwrought leather imported has increased in a higher ratio than the amount of leather manufactures, thus shewing a development in the demand for European leather, presumably intended to be manufactured in this country. LEBIDIEROPSIS, MilellMrg.; Gen. PL, III., 268. A genus of EUPHORBIACEA reduced in the Genera Plantarum to Cleistanthus, Hook./. Lebidieropsis orbicularis, *Müell.-Arg.*; EUPHORBIACE\*. 219 This species is reduced to **Cleistanthus collinus**, Benth., in the Flora of British India, V., 274. Sir J. D. Hooker, however, remarks that "the genus Lebidieropsis should probably be restored; the globose seeds differ wholly from those of any other Cleistanthus." When the description of the genus **Cleistanthus** was written in Vol. It. of this work, this species was inadvertently omitted, all the economic information regarding the plant in India being described by Bed do me, Gamble, Brand is, and others under Lebi**dieropsis.** The description may, therefore, for the purposes of this work, be given here. | Medicine.—Many distinct species of leech appear to be met with in<br>India, but they have not been scientifically determined. Several are used<br>n^edicinally and have long been known and valued by Sanskrit writers.<br>Busruta gives a detailed account of the different forms and of their habits,<br>modes of application, &c. He describes twelve kinds, six of which, he says,<br>are venomous, six useful. The former live near putrid fish and animals, in<br>foul stagnant pools, and are to be avoided; the latter inhabit clear and deep<br>pools which contain water-lilies and other sweet-smelling plants. Of these,<br>he states, that the middle-sized are the best. He directs that they should<br>be kept in a new water-pot, in which some clay, grass, or fresh leaves of<br>aquatic plants and water have been put, and that they must be fed on the<br>roots of water-lilies and dry flesh. When the leech is sluggish, he recom-<br>mends that a drop or two of milk should be applied to the part on which<br>it is required to fix, or that a slight scarification should be made. The<br>leech is induced to drop off by sprinkling salt on its head, and is cleaned<br>by stripping. {U. C Dutt, Mat. Med. Hindus, 275.}<br>The use of the leech was probably adopted from the Hindus by the<br>Muhammadans, with whom it is now greatly in vogue. At the present<br>time, the leeches used in Bengal are chiefly caught in tanks in the neigh-<br>bourhood of Baraset, by persons who collect them by entering the water<br>and allowing the leeches to catch hold of their legs. They are chiefly<br>gathered in May as the tanks begin to dry up. But the best leeches are<br>said to be obtained from the North-Western Provinces, chiefly from Sheko-<br>abad. Large numbers are, however, also caught at Patiala in the Panjdb.<br>SPECIAL OPINIONS.—§ "Leeches boiled with honey are used as a local<br>application for tonsilitis, and dried and rubbed with aloes as a local re-<br>medy for hsmorrhiods" {Dr. Emerson}, «* Boiled and ground up, they<br>are employed as an application to make the hair grow (Surgeon-Major<br>C. W. Calthrop, M.D., Morar). | MEDICINE.<br>246     |
| LEERSIA, Swart*.; Gen. PI., III, m <sub>7%</sub>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 7                    |
| A genus of aquatic grasses comprising five species, of which one occurs in<br>India. They are similar in habit to Oryza, but the spikelets are smaller, the<br>glumes (of which there are only two) are also thinner, and there is no pale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                      |

| FODDER.<br>248 | Fodder.—Symonds states that horses and cattle are fond of this grass,<br>a remark confirmed by Australian writers, who assert that it is one of the<br>most esteemed of the aquatic grasses of Eastern Australia. Baron yon<br>Mueller mentions that it is regularly cultivated for fodder in the Philip-<br>pines, in the same way as rice.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 249            | Leingatlg, a sort of earth found everywhere in Manipur and used for imparting a <i>khaki</i> colour to cloth (see Pigments); also employed as an article of food (see Clays, Vol. II., 361).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 250            | <b>LEMNA,</b> <i>Linn.; Gen. PL, III., 1001.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                | A genus of water plants, popularly known as "duck-weeds," which be-<br>longs to the Natural Order LEMNACE^B, and comprises seven speiijes,<br>natives of fresh waters of temperate and tropical regions. Of these five<br>are (according to <i>Kurg, Linn. Soc. Jour., IX., 264</i> ) natives of India,<br>namely, L. gibba, <i>Kurz,</i> L. minor, <i>Linn.,</i> L. oligorrhiza, <i>Kure,</i> L. <b>polyr-<br/>rhiza</b> , <i>Linn.</i> , and L.trisulca, <i>Linn.</i><br>Certain of these species, particularly L. minor, frequently invade<br>flooded rice fields, and by their thick growth on the surface of the water<br>are supposed by Natives to do much damage to the crop. Dr. Q. Watt,<br>in a recent paper on Adhatoda Vasica, has shown that the leaves and twigs<br>of that plant are applied to rice land, not only as a green manure, but<br>also for the purpose of killing the aquatic weeds, which would otherwise<br>greatly injure the crop. He writes, ° The natives pointed to fields that had<br>been treated in this way; and there could be no mistake that these were<br>clean or free from the green scum caused through floating duck-weeds.<br>(Lemnas) and submerged <b>Charas</b> " ( <i>Select, from the Rec. of the Govt. 0</i> )<br><i>Ind., Rev. and Agric. Dept. (June 22nd, 1887), (•• 69)-</i> Dr. Watt, how-<br>ever, suggested that this antiseptic property might be extended to the de-<br>struction of the pests on other crops, such as sugar-cane, tea and coffee, be-<br>sides the weeds in the rice fields.<br>The leaf of <b>Lemma</b> has acrid properties and is employed medicinally in<br>China, being deemed cooling, diuretic, antiscorbutic, astringent and altera-<br>tive. It is used in cutaneous diseases, and as a wash for ophthalmia,<br>carbuncles, and syphilitic sores. In India the duck-weeds appear to be put<br>to no economic use, excepting with other water plants in refining sugar<br>(See Hydrilla, p. 311 ; also Saccharum officinarum). It is, however, note-<br>worthy that the members of this genus are very rich in inorganic sub-<br>stances, and have, accordingly, been recommended for use as manure. In<br>a specimen of L. minor, Herve Mangon found '—Nitrogen, 3*6; silica, 07 :<br>lime |

| DeCandolle writes: "The lentil appears to have existed in western temperate Asia, in Greece, and in Italy, where its cultivation was first under-<br>taken in very early prehistoric times, when it was introduced into Egypt. Its cultivation appears to have extended at a less remote epoch, but still<br>hardly in historic time, both east and west, that is, into Europe and India."<br>The lentil has been cultivated in the East, in the Mediterranean basin, and<br>in Switzerland, from prehistoric times. According to Herodotus, Theo-<br>phrastus, and others, the Egyptians used it largely. The ancient Jews<br>also employed it to a considerable extent as an article of food, the hulled<br>pulse having probably formed Esau's mess of red pottage. Aristophanes<br>mentions it as an article of food of the poor among the Greeks, by whom<br>it was known as "<\$a)cof." By the Latins it was known and used under<br>the name of "lens," the derivation of which is doubtful, but the dissimi-<br>larity of the Latin and Greek words show that the species probably existed<br>wild in each country before it was cultivated. Another proof of its ancient<br>existence in Europe is the fact that lentils have been found in the lake-<br>dwellings of St. Peter's Island, Lake of Bienne, which are of the bronze<br><b>age {DeCandolle</b> }.<br>From a consideration of the Sanskrit, Persian, and Arabic names of<br>the lentil, and the evident connection of most local Indian names with these,<br>DeCandolle arrives at the opinion that the plant was not known in India<br>before the invasion of the Sanskrit-speaking races.<br><b>Cultivation.</b> —The lentil is at the present day cultivated in all parts<br>of helic arrively in the Greet Deriver and Madues. For environment                                                                                                                                                                                                                                                                                                                                                                                                                    | <ul> <li>Origin Cult. | Panjab. 1<br><b>254</b>    | <i>The Panjdb.—It</i> is commonly cultivated all over this Province, and is said to be grown as high as 5,500 feet on the Chenab, and in parts 01 Ladak at 11,500 feet. The following remarks, extracted from the Settlement Report of the Jhang District, may be taken as typical of the methods in general use throughout the Province :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                            | <sup>if</sup> Area under cultivation 2,404 acres. <i>Massur</i> is a <i>sailaba</i> (inundation, crop, and is never sown on other soils. Either new alluvial soils, or light lands that are not good enough for wheat, are selected. <i>Massur</i> is often the first crop sown on new <i>sailab</i> lands, or it may follow <i>mattar</i> (Lathyrus <b>sativa</b> ). The land is ploughed once or twice, and the seed is sown broadcast. One ploughing takes place after the seed is sown. <i>Maggan-Poh</i> (December-January) are the months for sowing, from 1 to \\panapis^vkanal (or30te <b>45ft</b> of seed per acre) being the amount used. The crop ripens in the enc of <i>Chait</i> and the beginning of <i>Baisdkh</i> (March-April). It is reaped, noi pulled. The yield is light, and the crop is subject to much the same in juries as gram ( <b>Cicer arietinum</b> ), the pods being attacked by caterpillars Rain, wind, and thunder are hurtful when the plant is in flower. "During the past five years the acreage under the pulse has been returned as follows :—1884-85, 170,975 acres; 1885-86, 100,820; 1886-87, 142> <sup>121</sup> 1887-88,146,931; and 1888-89, 159,461 acres. |
| NW. Prov-<br>inces.<br>255 | <i>North-West Provinces.—The</i> following account of the method pursuec<br>in these Provinces is given by Messrs. Duthie & Fuller:—" Lentils an<br>grown as a cold-weather crop under much the same conditions as peas. J*<br>the Tarai district the area under them constitutes nearly 7 per cent, of tx<<br>total <i>rabi</i> cropped area; in the Rohilkhand Division it amounts to 2 pe<br>cent., and in the districts of the Benares Division to 1*3 per cent. In n<<br>other division does it reach so high a proportion as 1 per cent., being nex<br>largest in the Meerut and Allahabad Divisions (08 to 07 per cent.), an<<br>smallest in the Agra and Jhansi Divisions (o'l to 0*3 per cent.), whici<br>together comprise the driest tract in the Provinces. Taking the thirty tem<br>porarily-settled districts as a whole, <i>mastr</i> is grown on almost exactly 1 p <sup>e</sup><br>cent, of the total <i>rabi</i> cropped area.                                                                                                                                                                                                                                                           |
|                            | It is grown on all kinds of soils, but chiefly in low-lying land. It i comparatively seldom grown after an autumn fallow, but most commonl follows early rice. It is often sown while the rice stalks are standing, an allowed to grow up amongst them. Three ploughings are as a rule suft cient.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                            | The quantity of seed per acre varies with the condition of the grounc<br>but is commonly about 1 maund. The average produce from unirri<br>gated land is from 6g to 8 maunds of grain, but with irrigation from 10 t<<br>12 maunds would not be an excessive outturn. The average area und*,<br><i>mastir</i> in the thirty temporarily-settled districts as deduced from the agn<br>cultural returns of 1878-79-80 was 15,961 acres irrigated, and 98,264 <sup>aC</sup> f <sup>e</sup><br>dry, giving a total of 114.225 acres, of which much the largest prope>ttiof<br>a total of 42,388 acres, was in Rohilkhand." The acreage during the pa-<br>five years has been as follows: — 1884-85, 137,597; 1885-86, 140M <sup>0</sup><br>1886-87,169,832; 1887-88, 169,949; 1*88-89, not received.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Provinces.<br>256          | <i>Central Provinces.</i> —*). B. Fuller, Esq., C.S., reports as follows :-<br><sup>11</sup> Ervum Lens is grown throughout the Provinces as a <i>rabi</i> or cold-weathe<br>crop. Its cultivation is larger in the Narbadda Valley, the Satpura Dil<br>tnct, and Chhattisgarh. In the Nagpur country it is less popular.<br><b>L. 256</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| CULTIVA-<br>TION.  | A consideration of the preceding reports and extracts shows that the crop is universally a cold weather one; that it is especially suited to rich, moist, low-lying soils; that with a fair amount of seed (about 1 maund) it yields from 6 to 8 maunds an acre, and if irrigated 10 to 12 maunds; and that the soil requires little preliminary working, and the crop little after-attention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                    | Church remarks that the yield might be increased if more pains were<br>taken in the selection of seed for sowing, since there are some varieties of<br>the lentil, which produce seed weighing twice as much as the small com-<br>mon sort, and which, notwithstanding this, do not make a proportionately<br>increased demand upon the resources of the soil. The total area under the<br>crop in the districts from which statistics are forthcoming averages be-<br>tween 6co,oco and 750,000 acres, but these figures do not include Bengal,<br>Oudh, Burma, Assam, Central India, and the Native States.                                                                                                                                                                                                                                                                             |
| medicine.<br>262   | Medicine.— Lentils have long held the reputation of being useful medi-<br>cinally in cases of constipation and other intestinal affections. It is prob-<br>able, however, that they have no special value in such cases. In the form<br>of a paste or poultice, the pulse is used as an application to ulcers occur-<br>ring after small-pox.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                    | SPECIAL OPINIONS.—§" I have found lentils of great use in the treat-<br>ment of chronic and obstinate constipation " {Surgeon-Major C. W. Cal-<br>throp, M.D., Morar). "A paste prepared from the seeds is a useful cleans-<br>ing application in cas*s of foul and indolent ulcers " (Assistant Surgeon<br>T. N. Ghose, Meerut).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FOOD.<br>263       | Food.—The lentil, as already indicated, is a food of the greatest anti-<br>quity, and has for many centuries been much prized by the natives of most<br>Eastern countries. In Egypt, Syria, and other Eastern countries it is<br>parched and eaten at the present day, and is considered one of the best<br>foods for those who undertake long journeys. In India it is eaten as <i>ddl</i> ,<br>flavoured with various aromatics and carminatives, also as a component<br>part of the dish called <i>kichri</i> , and is considered the most nutritious of the<br>pulses. If too freely indulged in, however, it is supposed to be heating and<br>apt to give rise to eruptions. The young pod is also occasionally eaten as<br>a vegetable, and the dry leaves and stalks are employed as a fodder for<br>cattle.<br>The ground pulse mixed with a little flour of barley or some other |
|                    | cereal, and common salt, is sold in Europe, under the names of Ervalenta<br>or Revalenta, as a food for invalids.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CHEMISTRY. 264     | CHEMICAL COMPOSITION.—Church gives the following as the aver-<br>age composition :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| MEDICINE.<br>Seeds.<br>279                | THE PEPPER GRASS or PEPPERWORT.<br>References.—Dymock, Mat. Med. W. Ind., 55: Pharmacog. Indica, I., ri8.<br>Habitat.—A herb of which the indigenous area extends from Southern<br>Europe to Siberia.<br>Medicine.—Dr. Dymock and the authors of the Phartnacographta<br>Indica describe the medicinal SEEDS, called towdti, as products of this plant.<br>The origin of these seeds, which are imported into Bombay from Persia, ha*<br>for long been a subject of dfscussion. By some English writers they have<br>been attributed to Malva sylvestris, by others to Cheiranthus Cheiri, but<br>Dymock has pointed out that, owing to the nature of the fruit, neither of<br>these suppositions can be correct. Again, Stewart states that in the Pan-<br>jab and Sind Matthiola incana, R. Br., is valued for its seeds, which consti-<br>tute one of the several kinds of todri* The authors of the Pharmacogra-<br>phia Indica commenting on this write: "In short this Persian name ap-<br>pears to have much the same meaning as the Xevxhiov of the Greeks, being<br>applied loosely to several Spring flowers." Dr. Dymock, however, has<br>arrived at the conclusion that at least." some of the towdri seed is doubt-<br>less the produce of L. Iberis, Linn." *<br>Mir Muhammad Husain described the seeds and the plant which<br>was supposed to yield them, and believed them to be "hot in the second<br>ucgree, and moust in the natic; some say gry. rroperties approximation<br>fattening the body and purifying the blood." Commenting on this Dy-<br>mock writes: "The drug is in general use for the above-mentioned proper-<br>ties, which are attributed by the natives to most of the cruciferous seeds"<br>Again, in describing the properties of L. Iberis, he writes: "This plant<br>was known to the ancients and employed as a rubefacient in rheumatism;<br>the seeds taken internally were prescribed in rheumatism and dropsy. Ac-<br>cording to Pliny they were first used by Damocrates. Corre and<br>L. 279 |

| LEPIDIUM<br><u>sativum.</u> | Cultivation of the Cress.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | that the plant has no known name in Sanskrit. In later Sanskrit works,<br>however, the medicinal uses of the seeds are described under the name of<br><i>Chandra sura</i> , a name probably of recent origin, since it does not appear<br>to occur in older Sanskrit works on medicine. DeCandolle enumerates<br>the localities in which the plant has been found, and concludes his remarks<br>as follows:—'' I am led to believe, by this assemblage of more or less<br>doubtful facts, that the plant is of Persian origin, whence it may have<br>spread, after the Sanskrit epoch, into the gardens of India, Syria, Greece, |

and Egypt, and even as far as Abyssinia.

Cultivation.—No statistics are available regarding the exact extent to which the cress is cultivated in India. It is, however, largely grown all over the country, not only for European consumption, but also as a pot-herb for native use. The following account of the best method.to pursue in its cultivation, quoted from Firminger's Gardening for India, may be found useful:-"Cress seed may be sown in the open ground when the rains cease in October. It is best to sow only a small quantity at a time, and to keep up a succession of sowings, at short intervals, during the cold season. As the *malts* rarely cut it for use till it is three or four inches high, it is as well to sow it broadcast, and rather thinly.

" If, however, it be required to be eaten, as is usual in England, when little more than the seed leaves are formed, it may be raised at nearly all times in the year. It is best in that case to make the sowings in  $l^{ar}$ £? shallow pans, filled with good light soil. The soil should be well watered and the seed then scattered thickly over its surface. Over a pan a covering should be placed till the seed germinates, and then be removed. In a few days the cress will be fit for cutting. In order to save seed, in the early part of the cold season, plants in the open ground at abcut six inches apart should be reserved. These by the commencement of the hot season will vield a plentiful supply of seed, which should be carefully stored away for future use."

Oil.—The SEED yields an oil, said to be very similar to that obtained from mustard seed. The only record of its preparation in India is by Lieutenant Hawkes (Report on Oils of Southern India, 37). It is described by SchUbler as brown-yellow, with a sp. gr. of 0-924, turning thick ana turbid at— $6^{\circ}$  (2i°F.) and solid at— $15^{\circ}$  (5°F.), and drying slowly. The following remarks by Lieutenant Pogson, extracted from a letter read before the Agri«-Hort. Soc. of India, may be quoted, as they show that the oil at one time received a certain amount of attention in India. He writes:--- "I would strongly recommend European landed proprietors to cultivate the common cress, or halim of India, for the sake of its oil. One hundred pounds of the seed on being pressed will yield no less than 57<sup>1</sup> of oil, whilst that of the sunflower gives but 15ft. [Journal (New Series), V,f. *Pro.*, xx%. No writer appears to have recorded the useful properties of cress-oil, but if the amount obtainable is even approximately that mentioned by Lieutenant Pogson, it w«ld appear to be worthy of greater attention than it has up to this time received.

Medicine.—The SEEDS are described by later writers on Sanskrit mędicine as tonic, alterative, useful in hiccup, diarrhoea, and skin diseases arising from disordered blood (U. C. Dutt). By Muhammadan writers the cress is identified with the Kaplapov of the Greeks, and the seeds are considered hot and dry in the third degree, aphrodisiac, and diuretic. They are recommended for the dispersion of certain chronic enlargements of the S?Jf2?V&c.' iVi as an alterative in various conditions supposed to be pro-?£ 2 w i<sup>y Cold humou TS</sup> (Dymock). Ainslie states that the 'Arabians place habit of \*<sup>TMon</sup>C''<sup>hei</sup>.' noterchat (vesicatoria); that the hakims are in the nabit of prescribing it as a stomachic and gentle stimulant. He remarks, L. 286

| however, that the latter doubt whether it does not sometimes, if imprudently given, bring about abortion. The <i>Vytians</i> esteem it, when bTsed "n3 mixed with lime-juice, as a valuable repellent in cases of local inflammation O'Shaughnessy quotes these remarks, and adds that he foundTeoW answer as a gentle and warm aperient.<br>By mcxiem practitioners of Indian medicine the seeds are considered usefulin dysentery and dysentencdiarrhoea, and also in febrile and catarr hal affections. Moodeen Sheriff, m his <i>Mat. Med. of Madras</i> , writes Externally it is of great service in all the diseases in which the mustard is resorted *to. The thick and very gummy mucilage of the seeds acts as a mechanical antidote m cases of poisoning by irritant substances, enveloping the poisonous particles and sheathing the mucous membrane of the stomach an* intestine. The same writer regards the seed as a more satisfactory rubefacient than those of mustard-seed prepared in India, and asserts that, in his opinion, if as carefully and finely ground as English mustard-flour, it would probably be superior to that also. He also states that the mucilage obtainable from the seeds may be used as a substitute for imported tragicanth and gum-arabic.                                                                                                                                                                                   | MEDICINE.                               |
| early part of this century, that the PLANT itself was administered incases<br>of asthma, cough with expectoration, and bleeding piles, and that the ROOT<br>was used in secondary syphilis and tenesmus. According to Be I lew the<br>seeds are also considered to be lactagogue in the Panjib, and are adminis-<br>tered, after being boiled with milk, to cause abortion.<br><i>Doses.</i> —" Of the seeds, from one to two and a half drachms; and of<br>the decoction from one to three fluid ounces; three or four times in the<br>twenty-four hours." <i>(Moodeen Sheriff.)</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Plant.<br>287<br>Root.<br>288           |
| CHEMICAL COMPOSITION.—"The herb and seeds distilled with steam yield a volatile aromatic oil which does not separate spontaneously from the watery distillate, but may be extracted therefrom by agitation with benzene. Three-fourths of the crude product boiled at 226-5° exhibited the composition of pure a toluonitril phenyl-acetonitril, or phenyl-methyl cyanide, $C_6H_5CH_3CN$ , and when heated to $207^0$ for a short time with hydrochloric acid, yielded phenyl-acetic acid'' ( <i>Watts, Dictionary of Chemistry, VIII., ft I., quoting from A. W. Hofmann</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Chemistry.<br>289                       |
| SPECIAL OPINIONS.—§" The decoction of the seeds is thus prepared:<br>Take of the seeds, bruised, six drachms; liquorice root, cut into small pieces<br>and bruised, one drachm; water, one pint and a quarter ; boil for 10 minutes<br>in a covered vessel, and strain when cool. The dose of the seeds is from<br>one to two drachms and a half; and of the decoction, from one to three fluid<br>ounces; three or four times in the twenty-four hours. The best medicinal<br>property of this drug, according to my own experience, is its usefulness in<br>dysentery and dysenteric diarrhoea. The coarse powder and the thick and<br>very gummy mucilage of the seeds appear well-suited to allay the irritation<br>of the mucous coat of the intestings in those diseases, and they thus relieve<br>or check their symptoms to a considerable extent. The coarse powder or<br>mucilage of course is not always sufficient to complete a cure by itself, but,<br>like many other remedies in dysentery, requires the assistance of some<br>other medicines according to the circumstances of each individual case.<br>The entire seeds swallowed with water have also some control over the<br>above-named diseases, in consequence of their property of becoming soft<br>and mucilaginous when moistened, but are much less efficacious in this<br>respect than their powder or mucilage" <i>[Honorary Surgeon Moodeen</i><br>Sheriff Khan B*hadur. | A genus of herbs or undershrubs belonging to the Natural Order LE-<br>GUMINOS <sup>^</sup> , which comprises some twenty to twenty-five species, of which nine<br>or ten are natives of India. None of the Indian species appear <i>to</i> be of eco-<br>nomic value, but it is possible that some, if not all, might be utilised as fodder.<br>L. stricta, the "Japan Clover," a Chinese or Japanese plant, has of late<br>years attracted much attention, in America, as a fodder plant. It is not<br>known how the plant was originally introduced into that country, but it is<br>supposed that it spread from a few seeds obtained from a cargo <sup>^</sup> of Japan<br>tea, and started gowth near Charleston about 50 years ago. The plant<br>has spread over large tracts and appears to possess many very valuable<br>properties. The <i>Indian Agriculturist</i> of January 1st, 1887, contains<br>the following:—" The plant is an annual but comes up year after >ear,<br>self-sown, and grows so vigorously, that it smothers many other grasses<br>with which it comes in contact. One writer is of opinion that it will<br>never be of real value as a crop to be cultivated like clover, and a New<br>York agricultural paper states that, although on rich, damp, soil, it will<br>grow as high as 18 inches, the leaves are small, and the stems too hard<br>and woody to make good hay. On the other hand, a Virginia farmer gives<br>his experience as entirely favourable to the plant. Ten years ago he pro-<br>cured some seed and sowed it on an acre in the middle of a 60-acre field,<br>being informed that it would spread all over the field and afford excellent<br>grazing. This turned out to be true, Japan clover and Bermuda grass<br>being the only fodders that kept green during the drought of 1885. Japan<br>clover, he adds, starts early and by July or August, when other fodders<br>are failing, it forms a heavy dense sod, and afford excellent grazing till<br>killed by sharp frost, but it starts again in the following' spring, and spreads<br>year by year. It will grow and form a sod on the thinnest land, and even<br>in roads and other bare places where nothing else will grow. In |          |

|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | latter consisting of lime, magnesia, potash, soda, phospheric and sulphuric acids. <sup>1&gt;f</sup>                                                                                                                                                                                                                                                                                                                       |
|                        | From these accounts it would appear that the plant is remarkably hardy, and has great powers of resistance to drought,—qualities which ought to render it an extremely useful fodder plant for India.                                                                                                                                                                                                                      |

Murray.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | LEUCAS<br>linifolia,                                                                                                                                                                                                                                               |
| SPECIAL OPINIONS.—§ "The leaves are said to be useful in chronic<br>rheumatism" ( <i>Civil Surgeon</i> C. J. W. Meadows, Burrisal). "In North<br>Bengal the flowers of Leucas aspera, L. Cephalotes, and L. linifolia are<br>given warmed in a little honey for coughs and colds to children. The juice<br>of the leaves is applied to disperse painful swellings, and answers the same<br>purpose as tincture of iodine. Also given in skin diseases " (C. T. Peters,<br>M.B., Zandra, South Afghanistán).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | MEDICINE                                                                                                                                                                                                                                                           |
| Pood.—The LEAVES and TENDER SHOOTS are used as a pot-herb even<br>in ordinary seasons, and were largely utilised in the Deccan Famine of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | FOOD.<br>Leaves ft<br>Shoots. •<br><b>311</b>                                                                                                                                                                                                                      |

| APp., 19.<br>Habitat.—A common herb on the Himalaya at altitudes of 2,000 to<br>6 000 feet, from Simla to Bhután; found also in the plains from Chittagong<br>and Assam westwards to the Panjib, and southwards through the Deccan;<br>distributed to Afghanistán.<br>Oil.—The SEEds yield an oil, which is used medicinally in Chutia<br>Nagpúr ( <i>Campbell</i> ) and by the Manipuris as an adjunct in dyeing with<br>Rribia ( <i>Watt</i> ). SeeRabiasikkimensis,Ar«r£r.<br>MedicineThe PLANT is considered a mild stimulant and diaphoretic<br>and is considerably used in fevers and coughs. The OIL, as above stated,<br>is also said to be employed medicinally by the Santals, but Mr.<br>Campbell does not mention its therapeutic action. The fresh JUICE IS<br>used in certain localities as an external application in scabies. The FLOWERS<br>are administered in the form of a syrup as a domestic remedy for coughs<br>and colds.<br>Food.—The LEAVES are eaten as a pot-herb, in some parts ottne<br>country, and were largely used as an article of food in the Khandesh Dis-<br>trict during the famine of 1877-78-<br>Domestic and Sacred.—Stewart states that the LEAVES are stirred<br>UD with milk in the Panjab for the sake of the odour they impart. The<br>FLOWERS are sacred to Siva, and are frequently used as an offering.<br>L. Clarkei, Hook./.; FL Br. | these the first, sixth, and seventh have been recorded from the North-West<br>Himalaya; and another species, P. kamtschadalis, found in the same region,<br>is largely employed in the north of India in calico-printing, with the object<br>of imparting a peculiar perfume, and a very pale rose tinge to the cloth,<br>UmWicaria pustulata, several species of Gyrophora, and Urceofaria scru-<br>posa, have also been employed to yield red or brownish dyes in Europe.<br>Yellow dyes are obtained from Chlorea vulpina, Platysma juniperinum,<br>Parmelia caperata, and P. conspersa, Physcia flavicans, P. parietina,<br>P. lychnea, P. puhrerulenta, and P. candelaria. Certain of these are to<br>i>e found in India, others are represented by different species of the same                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | DIE.                  |
| genus.<br>Of the numerous dye-yielding lichens above mentioned the true ' Or-<br>chils " are alone of commercial importance. It therefore appears very de-<br>sirable that the question of the occurrence of Roccella in India should be<br>definitely settled, and that the amount obtainable and the localities where it<br>exists should, as far as possible, be accurately determined.<br>Medicine.—Several species of the genera Cladonia, Usnea, Ramalina,<br>Evernia, Cetraria, Sticta, Parmelia, Physcia, Peltigera, Partusaria, and<br>Peltidea were at one time extensively used as medicine in Europe, most<br>of which enjoyed a great reputation as demulcents, febrifuges, astringents,<br>tonics, purgatives, and anthelmintics. Peltigera canina was long regarded<br>as a specific for hydrophobia; Platysma juniperinum was supposed to be a<br>sovereign remedy for jaundice, and other species had attributed to them<br>equally imaginary properties.<br>At the present day only one species is regarded as really of remedial value,<br>namely, Cetraria islandica, or the Iceland moss. This, as above mentioned,<br>contains a very large proportion of lichenine, and is undeniably a valuable<br>demulcent in various dyspeptic and pulmonary complaints. Several species<br>of the same genus occur in India, and it is not unlikely that investigation<br>might prove certain of these to possess equally valuable properties. The<br>only lichens which are described as in general use as medicines in India<br>are Parmelia kamtschadalis, P. perlata, and P. perforata. The first has<br>been well known to Muhammadan writers for many centuries. The author<br>of the <i>Makhzan-el-Adwiya</i> describes it as astringent, resolvent, and aperi- | MEDICINE.<br>340      |
| ent, and states that when burnt the smoke relieves head-ache, and that the<br>powder is a good cephalic snuff.<br>Honigberger describes the same species as officinal at Lahore, and<br>writes, "The <i>Hakims</i> administer it in disorders of the stomach, dyspepsia,<br>vomiting, pain in the liver and womb, induration of the uterus, am enorrhcea,<br>calculi, and nocturnal spermatic discharges." He recommends its adminis-<br>tration in general pain, salivation, soreness of the throat, and toothache.<br>Ainslie mentions Parmelia perlata and P. perforata under the name of<br>Lichen rotundatus. He describes it as "a dry, pale-coloured rock-moss,<br>which the <i>Vytians</i> suppose to possess a peculiar cooling quality and prepare<br>with it a liniment for the head." In the first half of the present century this<br>ichen attracted attention as a diuretic, for which purpose it was first boiled<br>n water, then beaten into a pulp or bruised in a mortar, and placed as a poul-<br>tice over the renal and lumbar regions. Owing to its former reputation it<br>has been referred to in the Pharmacopoeia of India, but Waring remarks that<br>n all probability the continuous application of warmth and moisture by a<br>boultice of linseed or rice would be found equally efficacious.<br>Food and Fodder.—Many lichens form valuable articles of food and<br>odder in the arctic regions and arid steppes of Europe, where food of a bet-                                                                                                                                                                                                                                                                                                 | Food & Fodder.<br>341 |

| LICHENS.         | Economic Properties of Lichens.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| FOOD.            | ter kind is often scarce or altogether wanting. The principal of these are<br>Cetraria islandica (the Iceland moss), Cladina raagiferina, and C. sylva-<br>tica (the Keindeer moss), and several species of Gyrophora which constitute<br>the "Tripe de Roche." This substance when boiled is often eaten by<br>hunger. Another is the " Manna Lichen " (Lecanoraesculenta), which has<br>been described by Pallas as occurring on the steppes of Russia in little glo-<br>bular masses, as large as a walnut. Baillon writes:" It is believed tha these<br>masses, torn from the rocks, can be carried by the wind and deposited so<br>as to form thick beds, which have not unnaturally given rise to tho belief<br>in showers of manna. This must to all appearance be the manna of<br>the Hebrews, of which Parrot saw in several localities in Persia in 1828,<br>beds of over a foot in thickness. These facts agree with what has bee'<br>observed in Algeria, in which country men and animals can, in case of<br>necessity, subsist on this lichen. It is very rich in oxalate of lime, and<br>contains nearly a quarter of its weight of lichenine, along with a certain<br>amount of saccharine material, and a small quantity of a nitrogenous<br>matter."<br>The writer can find only one record of a lichen being employed as food<br>in India. In August 1886, Mr. Brougham, Assistant Conservator of For-<br>ests, Bellary, drew attention to a lichen called in Telegu <i>ratha pu</i> , or " rock<br>flower," which he described as used as a food by the inhabitants of that<br>district, and considered to be a delicacy. It was submitted for identifica-<br>tion to Kew, and was pronounced a species of Parmelia near perforata.<br>This fact was published in the <i>Indian FoPesierior</i> May 1888, with the result<br>that in July of the same year the following further information was communi-<br>cated. " The <i>rathi puvu</i> found in Bellary is probably identical with that<br>found on the large rocks on Horseley konda and Tettu hill in the Cudda-<br>pah District. Its use is unknown in the district, but some merchants from<br>Anantapur export a few bandy-loads annually. They pay |
|                  | May.<br>The business is very profitable, and the seigniorage rate might easily<br>be doubled without causing any hardship to the merchants. Collection by<br>departmental agency is being tried at present, and it is possible that this<br>may induce the Anantapur merchants to make higher bids for the right<br>of collection. The cost of collection and export and the profit obtained<br>are as follows :—                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| MEDICINE.<br>Leave.<br>363<br>1901.<br>364<br>Fpuit.<br>365 | Habitat.—A spinous glabrous shrub or small tree, native of dry hills in<br>various parts of India. It has been recorded from the North-West Himá-<br>laya in Simla and Kumaon, ascending to 4,000 feet, from the Monghyr hills<br>in Behar, from Assam, and from the Bombay ghats and Coromandel south-<br>wards. It flowers in April-May, and fruits in the rainy season.<br>Medicine. Rheede noticed the medicinal virtues of this plant, writing,<br>"The LEAVES are supposed to be a remedy for epilepsy; the ROOT is<br>purgative, sudorific, and employed for the cure of colic and cardialgia^ The<br>dried FRUIT is tonic, diminishes intestinal fermentation, has the power of<br>resisting the contagion of small-pox, malignant and pestilent feyers, and<br>is also considered an excellent antidote to various poisons, on which'account<br>it is much sought for, and forms an article of commerce with Arab and<br>other merchants." Graham, Drury, and others quote the above, but give<br>no record of actual observation of the uses and value of the plant as a me-<br>dicine. Lisboa states that the berry is much used as a tonic in Malabar,<br>where it forms an article of commerce, and that its red coloured mucilage is<br>considered to be an antidote against snake-bite and the poisons of other<br>venomous animals. |
| FOOD.<br>Fruit.<br><b>366</b>                               | Food.—The FRUIT, a round berry, is very acid, but is occasionally em-<br>ployed as an article of food by Natives. The authors of the <i>Pharmacogra-<br/>phia Indica</i> state that it is exported to the Arabian coasts, where it is used<br>as a condiment with fish, meat, &C, being powdered along with the spices<br>commonly used in cooking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| timber.<br>367                                              | Structure of the Wood.—Yellow, hard, and close-grained, weight 59ft per cubic foot; used for axles of oil-presses, rice-pounders, &c, and adapted for the lathe. ( <i>Lisboa</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Medicine.—Kurz remarks, "Yields excellent sassafras." It seems<br>possible that this plant may produce part of the "Sassafras of Nepal,"<br>supposed to be principally derived from Cinnamomum glanduliferum,<br><i>Meissn.</i> (See Vol. II., 317)                                                                                                                                                                                                                                                                                                                                                                                                        | 274                      |
