The third fort grows naturally in Carolina, from whence the feeds were fent me by the late Dr. Dale: this hath a perennial root, which fends up feveral fquare ftalks, which are clofely covered with brownilh hairs; thefe rife between two and three feet high, garnifhed with leaves which are very unequal in their fize, thofe at the bottom, and alfo toward the top, being above three inches long, and one inch and a quarter broad, whereas thofe in other parts of the ftalk are not half fo large; they are rough on their upper fide, hairy below, and fawed on their edges, ftanding oppofite: all the lower part of the ftalk, but immediately below the foot-ftalks of the flower-heads, there are three large leaves ftanding round the ftalks; between thefe arife two flender hairy foot-ftalks, about three inches long, one on each fide the ftalk.; thefe fuffain fmall heads of flowers, fhaped like thofe

of the fcabious; they are fhitt, fhaped like thofe of the other, but fmaller; the bradtea immediately under the empalement, fpread out like rays. This plant flowers in September in this country; but never ripens its feeds here.

The feeds of the fourth fort were fent me from Carolina, by the late Dr. Dale; this hath fome appearance of our common fort, but the ftalks do not grow more than half fo high, and divide into many long fide branches; the leaves are fmaller and rougher, and the whorls of flowers are produced half the length of the branches, whereas the common fort hath rarely more than two; the bradtea at the bafe of the empalement is alfo much longer. This flowers in June and July, and hath a perennial root.

The fifth fort was fent me by the late Dr. Dale, from Carolina; this hath a perennial root, which fends up ftrait hairy ftalks, almoft round; the joints of thefe are four or five inches afunder, at each of thefe come out two oblong leaves, hairy on their under fide, ftanding upon fhort fobt-ftalks; at the bottom of thefe come out on each fide a flender branch, half an inch long, having two or four fmall leaves, fhaped like the other. The flowers are produced in fmall whorls, ftanding thinly; thefe are white, and the bradtea are longer than the empalement. This flowers in Auguft.

The fixth fort is a native of Egypt, from whence the feeds were fent to Europe, and the plants have for fome years paff grown in many curious gardens. It hath a *perennial root*, the ftalks rife a foot and an half high, garnifhed with oval leaves, having many tranfverfe deep furrows, of a dark green colour, placed oppofite, at about five or fix inches afunder. There are commonly two or four fide branches from the main Item, produced toward the bottom; and the whorls of flowers are produced at every joint toward the upper part of the ftalks: thefe are pretty large and hairy. The flowers are fomewhat larger than thofe of the common Field Bafil, and are of a deeper colour, ftretching a little more out of the empalement. The leaves of this have at firft fight much the fame appearance; but when they are obferved with attention, the difference is foon obferved between the two forts: but the greateft difference is in the leaves and whorls of flowers being placed at a greater diftance, and the ftalks growing fpardely in this fpecies; nor do the plants continue fo long as thofe of the common fort.

This fort flowers in June, commonly a fortnight or three weeks before the common Field Bafil, and the feeds ripen in September; which, if permitted to fcatter, the plants will come up in diltumn; and if the winter proves favourable, they will live in the open air, provided they grow on a dry foil; but in moift ground they are frequently deftroyed, efppecially when the plants are young.

This plant approaches near to the Clinopodium Orientale Origani folio, flore minimo. Tour. Cored. 12. But by comparing this with a fpecimen of that fort from the Paris garden, I find the leaves of that are fmoother, and placed much nearer together on the ftalks than thofe of this fort; the flowers are fmaller, fo that it may be deemed a diftinct fpecies, as thefe differences are permanent, and do not alter in any of the plants which arife from the feeds.

Thefe plants may be propagated by feeds, and alfo by parting their roots, the latter is generally practifed in England, becaufe few of the forts perfed their feeds here. The beft time to tranfplant and part their roots is in autumn, that they may take root before winter. If thefe are planted in a dry foil, they are all, except the third fort, hardy enough to thrive in the open air in England, and require no other care but to keep them clean from weeds, and every othef year they may be tranfplanted and parted. The third fort muft be planted in pots, and in winter fheltered under a frame, where the plants may enjoy the free air in mild weather, but fcreened from froft, otherwife they will not live in this country.

CLITORIA. Lin. Gen. Plant. 796. Ternatea. Tourn. Aft. Reg. 1706. Clitorius. Dill. Hort. Elth. 76. We have no English title for this plant.

The CHARACTERS are,
The flower hath a permanent empalement of one leaf which is tubular* creft, and indented in five parts at the top. The flower is of the butterfly kind, having a large spreading ftandard, which is ere ft, and indented at the top -, the two wings are oblong, obtufe, and fhorter than the ftandard, which is do fed. The keel is fhorter than the wings \ it is roundifh and hooked \ it hath ten ftamina, nine of which are joined, and one ftands feperate, which are terminated by fingle fummits. In the center is fituated an oblong germen, fupporting a rifing ftyle, crowned by an obtufe ftigma. The germen afterward becomes a long, narrow, compreffed pod, with one cell, opening with two valves inclofing feveral kidney-fhaped feeds.

This genus of plants is tanged in the third fection of Linneus's feventeenth clafs, intitled Diadelphia Decandria; the flowers of this fection have ten ftamina, which compofe two bodies.

- The SPECIES are,
1. CLITORIA (*Ternatea*) foliis pinnatis. Hort. Cliff. 360. *Clitorea with winged leaves.* Ternatea flore fimplici caeruleo. Tourn. Acad. Reg. Sc. 1706.
 2. CLITOREA (*Brafiliana*) foliis ternatis, calycibus campanulatis folitariis. Hort. Upfal. 215. *Clitoria with trifoliolate leaves, and a fingle flower with a bell-fhaped empalement.* Planta leguminoia Brafiliana, Phafeli flore, flore purpureo maximo. Breyn. Cent. 75. tab. 32.
 3. CLITORIA (*Virginiana*) foliis ternatis, calycibus campanulatis fubgeminis. Flor. Virg. 83. *Three-leaved Clitoria with two flowers joined, whofe empalements are bell-fhaped.* Clitorius trifolius flore minore caeruleo. Hort. Elth. 90. tab. 76.
 4. CLITORIA (*Mariana*) foliis ternatis, calycibus cylindricis, Lin. Sp. Plant. 753. *Clitoria with trifoliolate leaves, and cylindrical empalements to the flowers.* Clitorius Marianus trifolius fubtus glaucis. Pet. Hort. Sice. 243.

The firft fort grows naturally in India; the feeds of this were firft brought to Europe from Ternate, one of the Molucca Iflands, and this induced Dr. Tournefort to give the title of Ternatea to this genus. There is a variety of this with white flowers, and another with large blue flowers, which make a fine appearance. The feeds which I received of the latter, produced all the plants with very double flowers, without the leaf variation; but in cold feafons the plants do not produce any pods here.

This rifes with a twining herbaceous ftalk to the height of four or five feet, in the lame manner as the Kidney-bean, and requires the like fupport for in the places where it grows naturally, it twills itfelf about the neighbouring plants; the ftalks are garnifhed with winged leaves, compofed of two or three pair of lobes, terminated by an odd one; thefe are of a beautiful green, and are placed alternate on the ftalks; from the appendages of the leaves, come out the foot-ftalks of the flower; each of thefe is encompassed by two very fine leaves about the middle, where they are bent, fupporting a very large, gaping, beautiful flower, whofe bottom part feems as if growing to the top.

The flowers have a green membranaceous empalement, which is cut into five parts. The ftandard of the flowers is large, and is fpread open very wide; and the flowers are of fo deep a blue colour, as to ftain paper, after having been many years dried, almoft as blue as indigo; thefe flowers are fucceeded by long (lender pods, containing feveral kidney-fhaped feeds.

The fecond fort grows naturally in the Braffils, from whence thefe feeds were brought to Europe. This hath a twining ftalk like the former, which rifes five or fix feet high, garnifhed at each joint with one trifoliolate leaf, Sanding upon a long foot-ftalk. The flowers come out fingly from the foot-ftalk of the leaves, ftanding upon pretty long foot-ftalks, which

are encompassed about the middle: with two filial oval leaves; the flowers are very large, the ftandard being much broader than that of the firft fort, and the two wings are larger; the flowers are of a fine blue colour, fo make a fine appearance. The flowers appear in July, and in warm feafons the feeds will ripen in autumn, loon after which the plants decay.

There is one with a double flower of this fort, which I raifed in the Chelfea garden fome years paft, from feeds fent me from India *, but the plants did not produce feeds here, and being annual, the fort was loft. The flowers of this were very beautiful.

The feeds of the third fort were fent me from the Bahama Iflands; this feeds out from the root two or three (lender twining ftalks, which rife to the height of fix or feven feet, garnifhed at each joint with one trifoliolate leaf, whofe lobes are oblong and pointed. At the oppofite fide of the ftalk, the foot-ftalk of the flower aries, which is little more than an inch long, naked, and fupports a fingle flower, which is of a purple colour within, but of a greenifh white on the outfide, not half fo large as either of the former: thefe flowers are each fucceeded by long, (lender, compreffed pods, ending in a point, which contain one row of roundifh kidney-fhaped feeds. This fort flowers in July and Auguft, and the feeds ripen in autumn.

The feeds of the fourth fort were fent me from Carolina, where the plants grow naturally. This rifes with a twining weak ftalk about five feet high, garnifhed with trifoliolate leaves like the former, whole lobes are narrower, and of a grayifh colour on their under fide -, the flowers come out by pairs on the foot-ftalks 5 their empalements are cylindrical. The flowers are fmall, and of a pale blue colour within, but of a dirty white on the outfide. This flowers in Auguft, but rarely ripens any feeds in England.

All thefe forts are annual with us in England, fo that unlefs the feeds ripen, the fpecies are loft; and as the two forts with double flowers have not formed any pods in this country, fo far as I have been able to learn, therefore the feeds of thefe muft be procured from the countries where they naturally grow. Indeed thefe are fuppofed to be only varieties, which accidentally arife from the fingle. If this be true, I cannot account for the fuccefs of thofe plants which grew at Chelfea, for they were all of the lame double kind, without the leaf variation *, and this was not from a fingle experiment, but in three different years when I received the feeds, the plants did all of them produce double flowers.

The feeds of thefe plants muft be fown upon a good hot-bed early in the fpring; and when the plants are two inches high, they fhould be carefully taken up, and each planted in a fmall pot filled with light frefh earth, and plunged into a hot-bed of tanners bark* obferving to fhade them till they have taken frefh root, and refrefh them with water as they may require it. After they are well rooted in the pots, they muft have air every day in proportion to the warmth of the feafon, to prevent their drawing up weak; their waterings fhould be repeated * 2 or three times a week, but they fhould not have too much at each time. As thefe plants have climbing ftalks, they will foon grow too tall to remain under common frames, therefore they muft then be removed into the ftove, and plunged into the bark-bed; but if their roots have tilled the pots, they fhould be removed into larger, and afterward they muft be treated in the fame manner as other plants from the fame countries,

CLUSIA. Lin. Gen. Plant. 577. Plum. Nov. Gen. 20. tab. 20. The Balfam-tree.

The CHARACTERS are,
// bath an fabricated mpalement, compofed of roundifh concave leaves which fpread open, it bath five or fix large, roundifh, concave, fpreeding petals. In the bottom is fituated a globular neSlarium, including the germen, which is pervious at the top, from which place the ftigma arifes.

// hath a great number of stamina, which are shorter than the petals, terminated by single summits. The oblong ovalgermen is terminated by a plain star-like stigma, with six obtuse indentures. The germen afterward becomes an oval capsule, with six furrows, and six cells, opening with six valves, which spread in form of a star, including many angular seeds fixed to a column, surrounded with pulp.

This genus of plants is ranged in the first section of Linnaeus's twenty-third class, intitled Polygamia Monoclea, having male, female, and hermaphrodite flowers on the same plant.

The SPECIES are,

1. CLUSIA (*Flava*) foliis aveniis corollis tetrapetalis. Jacq. Amer. 34. *Clusia whose leaves have no veins, and the flower has four petals.* Terebinthus folio fingulari, non alato, rotundo, fucculento flore pallidè luteo. Sloan. Hift. Jam. 2. p. 97. *Commonly called Balsam-tree in America.*

2. CLUSIA (*Venosa*) foliis venosis. Lin. Sp. Plant. 510. *Clusia with veined leaves.* Clusia flore roseo minor, fructu flavescente. Plum. Nov. Gen. ii

There are three varieties of the first sort, which differ in the size and colour of their flowers and fruit; one hath a white flower and scarlet fruit, another hath a rose flower and a greenish fruit, and a third hath a yellow fruit: but these are supposed to be only femal variations, though Plumier has enumerated them as distinct species, but as the plants have not flowered in England, I can give no particular account of their difference: the singular beauty of the leaves of this plant, renders it worthy of a place in every collection of rare plants.

The first sort is pretty common in the British Islands of America, where the trees grow to the height of twenty feet, and shoot out many branches on every side, garnished with thick, round, succulent leaves, placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover: these are of different colours in different plants, some being red, others yellow, some white, and some green. After the flowers are past, they are succeeded by oval fruit, which are all of different colours in different plants: from every part of these trees there exudes a sort of turpentine, which is called in the West Indies Hog-gum; because they say, that, when any of the wild hogs are wounded they repair to these trees, and rub their wounded parts against the stems of them, till they have anointed themselves with this turpentine, which heals their wounds. The turpentine of these trees is also greatly recommended for the cure of sciaticas, by spreading it on a cloth, and applying it as a plaster to the part affected.

The plants are at present very rare in Europe: there were some years ago some fine plants in the garden of Mr. Parker, near Croyden in Surry, these were brought over, growing in tubs of earth, from Barbadoes, which is the best method of procuring them; for the seeds seldom succeed, and the young plants grow so slowly, as not to make any figure in some years; but in the bringing over the plants, great care should be had, that they do not receive much wet; for as these plants have very succulent stems, moisture will cause them to rot.

The plants are tender, so they must be constantly kept in the stove, otherwise they will not live through the winter in England, they must also be watered very sparingly, especially in winter, for they naturally grow in those parts of the islands, where it seldom rains, therefore they cannot bear much moisture.

They may be propagated by cuttings, which must be laid to dry when they are cut off from the plants for a fortnight or three weeks, that the wounded part may be healed over, otherwise they will rot. When the cuttings are planted, the pots should be plunged into a hot-bed of tanners bark, and now and then gently refreshed with water: the best time for planting these cuttings is in June or July, that they may

be well rooted before the cold weather comes on in autumn. In winter these plants may be placed upon stands in the dry stove; but if in summer they are plunged into the tan-bed, they will make great progress, and their leaves will be large, in which consists the great beauty of these plants.

The second sort was discovered by the late Dr. Houc-toun, growing naturally at Campeachy, from whence he sent me some dried samples and seeds: this hath very large oval spear-shaped leaves, ending in points, which are placed alternate on the branches, and have several ribs, which go off from the midrib alternate, rising upward to the side of the leaves; and also a great number of small veins, running horizontally between these ribs. The borders of the leaves are faded, and their under sides are of a shining brown colour. The branches are covered with a woolly down, and the flowers are produced in loose spikes at the end of the shoots; these are smaller than those of the former sort, and are of a rose colour. This tree rises to the height of twenty feet; it is propagated by seeds, which must be obtained from the countries where the trees naturally grow, for there can be little hopes of obtaining any of the seeds in Europe. The plants are tender, so must be placed in the tan-bed of the bark-stove, otherwise they will not thrive in this country; and they must be treated in the same manner as is directed for other tender plants from the same countries.

CLUTIA. This genus of plants was constituted by the learned Dr. Boerhaave, professor of botany in the university of Leyden, in honour of Augerius Clute, a curious botanist.

The CHARACTERS are,

It is male and female in different plants. The male flowers have a large spreading empalement, composed of five oval concave leaves & they have five heart-shaped petals which are shorter than the empalement, and spread open. They have five exterior nectariums, which are situated in a circle at the bottom of the petals & five interior, which are situated within the other, having small apices with a mellow liquor, and five stamina situated in the middle of the style, which spread horizontally, terminated by roundish summits: these have no germen, but a long truncated styk in the middle of the stamina. The female flowers have permanent empalements, and petals like those of the male; these have five double exterior nectariums but no interior; they have a roundish germen, supporting three bifid reflexed styles the length of the petals, crowned by obtuse stigma: the germen afterward becomes a globular capsule, with six furrows, and three cells, each containing a single seed.*

This genus of plants is ranged in the thirteenth section of Linnseus's twenty-second class, intitled Dioecia Gynandria. This section and class include those plants which have the different sexes on separate plants, and the male flowers have their stamina adhering to the style.

The SPECIES are,

1. CLUTIA (*Alaternoides*) foliis sessilibus lineari-lanceolatis floribus foliariis erectis. Hort. Cliff. 500. *Clusia with linear spear-shaped leaves fitting close to the stalks, and solitary erect flowers.* Alaternoides Africana telepii legitimi imperati foliis. Hort. Amft. 2.
2. CLUTIA (*Pulchella*) foliis ovatis integerrimis, floribus lateralibus. Lin. Sp. Plant. 1042. *Clusia with oval entire leaves, and flowers growing from the sides of the branches.* Frutex -Ethiopicus, portulace folio, flore ex albo virecente. Hort. Amft. 1. p. 177.
3. CLUTIA (*Eleutheria*) foliis cordato lanceolatis. Flor. Zeyl. *Clusia with heart spear-shaped leaves.* Ricinus dulcis arborefcens Americanus, populnea fronde argentea. Pluk. Aim. 321.

The two first sorts are natives of Africa, from whence they were brought to some curious gardens in Holland, and have since been communicated to most of the botanic gardens in Europe. The first sort with male flowers has been long an inhabitant of some curious gardens in England, the other with female flowers has been lately introduced,

The feccmd fort has alfo been fome years in the Eng- I lilh gardens, where we had not that fort with male flowers till lately, when I was favoured with one by my learned friend Dr. Job Batter, of Zirkzee in Holland.

The firft fort rifes with a Ihrubby ftalk to the height of fix or eight feet, putting out many fide branches which grow eredfc; thefe are garnifhed with fmall, linear, fpear-fhaped leaves, placed alternate, fitting clofe to the branches: they are of a grayifh colour and entire. The flowers come out from the joints, at the fetting on of the leaves: toward the upper part of the branches thefe are fmall and of a greenilh white; they appear in June, July, and Auguft, but being fmall make no great appearance.

The fecond fort rifes about the fame height with the firft, but hath a ftronger ftem; the branches are garnifhed with oval leaves, which are much larger than thofe of the firft fort, (landing upon foot-ftalks which are an inch long; they are of a fea green, and entire; the flowers are like thofe of the firft fort in fhape and colour, but thofe on the male plants are fmaller, and grow clofer together than thofe of the female, but both are fuftained upon (hort foot-ftalks. Thefe flowers appear at the fame time as thofe of the firft fort, and the feeds ripen in autumn. I have raifed feveral of thefe plants from feeds, which have all proved female, the fame as the parent plant.

Thefe plants are eafily propagated by cuttings during any of the fummer months: if the cuttings are planted in fmall pots, and plunged into a very moderate hot-bed, and (haded from the heat of the fun in the middle of the day, they will foon take root, and (hould then be inured to the open air, otherwife they will draw up very weak: afterward thefe plants may be each put into a feparate fmall pot, and placed in a flickered fituation, where they may remain until the middle of Oftober, or later, if the weather continues mild, when they (hould be removed into the green-houfe, and placed where they may have the free air in mild weather, for they only require to be prote&ed from froft, therefore require no warmth in winter; but if the green-houfe is (hut up too clofe, or the plants are much (haded by others, the tender (hoots are fubjedt to grow mouldy, which deftroys more of thefe plants than the cold. In fummer they muft be placed abroad in a (heltered fituation, with other hardy exotic plants.

As thefe plants are always green, they took well in the green-houfe during the winter feafon; and in fummer, when they are placed in the open air with other exotic plants, they make a pretty variety.

The third fort grows naturally in India, from whence the feeds were brought. This rifes with an upright Ihrubby ftalk, not more than three or four feet high in England *, but in the places where it grows naturally, it rifes upward of twenty feet high, and fends out matny branches at the top, fo as to form a large fpreading head: the branches arc garnifhed with leaves, (haped like thofe of the black Poplar, which are of a lucid green, and are placed alternate (landing upon (lender foot-ftalks. As theft plants have not yet flowered in England, I can give no account of them, but the feed-veffels are very like thofe of the fecond fort.

This plant will live through the winter in an airy glafs-cape, without artificial heat; but in that fituation they (hould have very little water, for the plants abound with a milky juice like the Euphorbia, fo muft at no feafon of the year have too much wet. If thefe plants, when young, are placed in a very moderate warmth in winter, it will greatly forward their growth, but they muft not have too much heat, fbr that will force them too much; and when the plants have obtained ftrength, they may be treated more hardily. This fort may be propagated by cuttings during the fummer feafon j but the cuttings (hould be laid in a dry place for a few days, when they are taken from the old plants, that their wounded parts may dry and be healed over before they are

planted. Thefe muft be planted in fmall pots filled with light fandy earth, and plunged into a moderate hot-bed of tanners bark; and if the feafon is very warm, the glaffes (hould be (haded in the heat of the day, and raifed up to admit frefli air to the cuttings every day; thefe muft be fparingly watered. When they have taken root, and begin to (hoot, they muft have a greater (hare of air, and by degrees be inured to the open air *, and when their roots have filled the pots, they (hould be carefully parted, and each planted in a feparate pot of the fame light fandy earth *, then they (hould be placed on the back part of the (love, behind the other plants, where they may be fcreened from the fun till they have taken frefli root, after which they may be brought forward, and expofed gradually to the open air. In the fummer they fhould have free air confantly in warm weather, but they muft be fcreened from heavy rain; and in winter placed in an airy glafs-cape, where they may enjoy the fun, and during that feafon have very little wet.

CLYPEOLA. Lin. Gen. Plant. 723. Jonthlafpi. Tourn. Infl. R. H. tab. 99. Treacle Muflard.

The CHARACTERS are,

The flower bath a permanent empalement cotnpofed of four oblong oval leaves. It hath four oblong entire petals* placed in form of a crofs* and jixftamina which are Jhorter than the petals* two of which ftanding oppofite are jhorter than the other* terminated by Jingle fummits. In the center is fituated a round jh compreffedgermen* fupporting a Jingle ftyle* crowned by an obtufe figma. The germen afterward becomes an orbicular pod* which is compreffed* ere Si* and indented at the top* with a longitudinal Jiffure* opening in two cells* containing round compreffed feeds.*

This genus of plants is ranged in the firft feaion of Linnaeus's fifteenth clafs, intituled Tetradynamia filiculofa, the flower having four long and two (horter (lamina, and the feeds growing in (hortpods.

The SPECIES are,

1. CLYPEOLA (*Jonthlafpi*) filiculis unilocularibus monofpermis. Hort. Cliff. 329. *Clypeola with pods* banking but one cell and a Jingle feed. Jonthlafpi minimum fpicatum lunatum. Col. Ecp. 1. Leajl Buckler Muf-tard with fpiked flowers.*
2. CLYPEOLA (*Maritima*) filiculis bilocularibus ovatis difpermis. Sauv. Monfp. 71. *Clypeola with oval pods having two cells and two feeds. Thalpi Alyffon dictum maritimum. C. B. P. 107.*

This genus of plants was named Jonthlafpi by Fabius Columna, and the fame title was continued by Dr. Tournefort, and other late writers on botany before Dr. Linnaeus, who has altered the name to this of Clypeola.

The firft fort is a low annual plant, which feldom rifes more than four inches high 5 the (lender branches commonly lie prostrate on the ground; thefe are garnifhed with fmall leaves, narrow at their bafe, but are broader at their ends, where they are obtufe. The flowers are produced in (hort clofe fpikes at the extremity of the branches, which are fmall, yellow, and compofed of four petals, placed in form of a crofs; thefe are fucceeded by orbicular compreffed feed-veffels, each having one cell, containing a fingle feed. It flowers in June and July, and the feeds ripen in autumn.

The fecond fort is perennial. This fends out from the root feveral (lender branches, which divide again into many fmaller, that lie prostrate, garnifhed with very narrow hoary leaves, fitting clofe to the branches. The flowers are produced in fpikes at the end of the branches; thefe are fmall, yellow, and (haped like thofe of the other fort, but the (pikes terminate in a roundiffi bunch. It flowers in June, and the feeds ripen in autumn.

Thefe two forts are low plants, which grow naturally in the fouth of France, Spain, and Italy, and are preferred in botanic gardens for the fake of variety, but have little beauty; their leaves and ftalks are of a hoary white, which is much lighter in the warm countries

C N E

countries than in England; these are propagated by feeds, which should be sown upon a border of light earth where they are to remain, and will require no other culture, but to thin them if they come up too close, and keep them clean from weeds. The feeds may be sown either in the spring or autumn; those which are sown in autumn will grow much larger, and flower earlier than those which are sown in the spring, and from them there will be a greater certainty of having ripe feeds. If the feeds scatter, the plants will come up, and, if kept clean from weeds, they will thrive without farther care.

The second sort is a perennial plant, so should be sown upon a warm border and on a dry soil. This grows naturally on the borders of the sea, in the south of France and Italy *, but when it is cultivated in a garden, if the soil is rich and moist, the plants generally grow luxuriant in summer, and are thereby too replete with moisture, so that they are frequently killed by the frost in winter *, but when they grow on a poor, dry, gravelly soil, their stalks will be short, ligneous, and tough) so will endure the cold of this climate, and continue several years. This is propagated by feeds, which should be sown where the plants are designed to remain; or if any of them are removed, it should be done when the plants are young, for they do not bear transplanting well, when they are grown pretty large.

CNEORUM. Lin. Gen. Plant. 47. Chametea. Tourn. Inf. R.H. 651. tab. 421. Widow-wail.

The CHARACTERS are,

The flower hath a small permanent empalement, indented in three parts. It hath three narrow oblong petals, which are creft, and three stamina which are shorter than the petals terminated by small summits. In the center is situated an obtuse three-cornered germen, supporting a firmer style, crowned by a trifid spreading stigma. The germen afterward becomes a globular dry berry, with three lobes, having three cells, each containing one round seed.*

This genus of plants is ranged in the first section of Linnaeus's third class, intitled Triandria Monogynia, the flower having three stamina and one style.

We have but one SPECIES of this genus, viz.

CNEORUM [*Tricoccum*]. Hort. Cliff. 18. Widow-wail. Chamelasa Tricoccos of Dodonaeus and Caspar Bauhin.

This is an humble shrub, which seldom rises more than two feet and a half high in this country, but spreads out on every side with many lateral branches, so as to form a thick bush. The stems are ligneous, and almost as hard as those of the Box-tree, and the wood is of a pale yellow colour under the bark: the branches are garnished with thick stiff leaves, of an oblong oval shape, about an inch and a half long, and a quarter of an inch broad, of a dark green colour, having a strong vein or rib through the middle. The flowers are produced singly from the wings of the leaves, toward the extremity of the branches, which are of a pale yellow colour, composed of three petals, which spread open, and a round germen at the bottom, having a single style, which doth not rise above half the length of the stamina, which are three in number, hanging erect, and are situated between the petals. After the flowers are fallen, the germen becomes a fruit, composed of three feeds joined together after the same manner as those of *Tithymalus* or *Spurge* *, these are first green, afterwards turn of a brown colour, and when ripe are black. The flowers begin to appear in May* and are succeeded by others during the summer months; and, when the autumn proves favourable, these shrubs will continue in flower till the end of October.

As this is a low evergreen shrub, it may be very ornamental, if placed in the front of plantations of evergreen trees and shrubs; for as the branches grow pretty compact, and are well garnished with leaves, it will hide the ground between the taller shrubs better than most other plants, and, being a durable

C N I

shrub, will not want to be removed: it rises better from scattered feeds, than if sown with care.

This was formerly preserved in green-houses, and thought too tender to live in the open air in England 5 but of late years people have planted it in the full ground, where it resists the cold of our ordinary winters very well, and is seldom injured but by extreme hard frosts; nor do these kill the plants which grow upon dry, rocky, or rubbishy soils, where their shoots are generally short and firm 5 but in moist rich ground, where the shoots are more luxuriant, they are sometimes injured.

It is propagated by feeds, which should be sown in autumn soon after they are ripe, and then the plants will come up the following spring; whereas those which are not sown till the spring, will remain a year in the ground, and often miscarry: these feeds may be sown in a bed of common earth, covering them half an inch deep, and will require no other care but to keep the plants clear from weeds the following summer; and in the autumn following, the plants may be transplanted where they are to remain.

CNICUS. Lin. Gen. Plant. 833. Tourn. Inf. R. H. 450. tab. 257. Bleffed Thistle.

The CHARACTERS are,

*The empalement of the flower is composed of many oval scales, placed over each other; those toward the top are terminated by branching spines. The flower is composed of several hermaphrodite florets, which are uniform *, these are funnel-shaped, and cut at the top into five equal segments, standing erect, each having five short hairy stamina, terminated by cylindrical summits. In the center is situated a short germen, crowned with down, supporting a slender style, terminated by an oblong stigma. The germen afterward becomes a single seed, crowned with down, and shut up in the empalement.*

This genus of plants is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia /Equalis. The plants of this section have only hermaphrodite flowers, which are fruitful.

The SPECIES are,

1. CNICUS (*Eriophyllum*) caule erecto, foliis inferioribus laciniatis, superioribus integris concavis. Hort. Cliff. 394. *Cnicus, with an upright stalk, whose lower leaves are lacinated, the upper entire and concave.* Cnicus pratensis, Acanthi folio, flore flavescente. Tourn. Inf. 450.
2. CNICUS (*Spinosiffimus*) foliis amplexicaulibus, sinuato-pinnatis, spinosis, caule simpliciter, floribus sessilibus. Lin. Sp. Plant. 826. *Cnicus with winged, sinuated, prickly leaves embracing the stalk, and flowers fitting close on the top.* Cirsium Alpinum spinosiffimum, floribus ochroleucis inter flavescencia folia congestis. Haller. tab. 20.
3. CNICUS (*Cernuus*) foliis cordatis, petiolis crispis spinosis amplexicaulibus, floribus cernuis. Hort. Upsal. 251. *Cnicus with heart-shaped leaves, having curled prickly foot-stalks which embrace the stalks, and a nodding flower.* Carduus foliis ex cordato-lanceolatis, margine serratis & spinosis, squamis calycum membranaceis, lacris spinosis, capitulis nutantibus. Flor. Sib. 2. p. 47-

The first sort grows naturally in the northern parts of Europe. Mr. Ray found it growing on the Rhine near Basil. This hath a perennial root, which sends out many long jagged leaves, spreading on every side near the ground, so as to form a thick tuft; these are jagged almost to the midrib, in form of a winged leaf. The stalks are striated, smooth, and rise above four feet high, dividing at the top into smaller branches: the leaves which grow upon the stalks are entire, heart-shaped, concave, and embrace the stalks, and are sowed on their edges, each indented ending in a weak spine: the stalks are terminated by large heads of flowers, growing in clusters; they are of a whitish yellow colour, and inclosed in a scaly empalement, and are succeeded by small oblong feeds, crowned with a bristly down. It flowers in June, and the feeds ripen in autumn*

This fort may be propagated by feeds, or parting the roots \ the latter is commonly praftiled where there ate any of the plants, but the feeds are more eafily conveyed to a diftant place. The beft time to part the roots is in autumn *, it delights in fhade, and requires no farther care but to keep it clean from weeds.

The fecond fort grows naturally on the Alps, and on the piountains of Auftria. This rifes with an upright fingle ftalk near four feet high, garnilhed with finuated leaves, which are very prickly, and embrace the (talks with their bafe. The flowers afe produced at the top of the ftalk, furrounded by a clutter of broad prickly leaves, fitting clofe to the ftalk *, they are of a whitifli yellow, and appear at the fame time with the former fort. It is a perennial plant, which may be propagated in the feme manner as the former," and requires a moift foil and a lhady fituation.

The third fort grows naturally in Siberia, from whence the feeds were fent to the imperial garden at Peterburgh, where they fucceeded, and produced feeds, part of which were fent me by the profefibr of botany; this hath a perennial root, compofed of thick flefhy fibres. The leaves which rife immediately from the root are near a foot long, and near fix inches broad in the middle, diminifhing toward each end, and at a little diftance from the bafe are much contradted, but are wider at the end *, thefe have fcarce any foot-ftalks; they are of a deep green on their upper fide, but white on their under, and fliarply fawed on their edges. The ftalks rife more than fix feet high, fending out on each fide fmall branches above a foot long; the ftalks are {mated, and of a reddifh colour; they are garnifhed with heart-fhaped leaves, which almoft embrace the ftalks with their bafe, and are of the fame colour with thofe below *, each branch is terminated by one large globular head of yellowifh flowers, included in a fealy empalement, each feale ending with a fharp fpine. This flowers in June, and the feeds ripen in autumn. It may be propagated in the fame manner as the two former forts, but requires a moift foil and fliady fituation j and if the weeds are kept down, there will be no farther care required. The inhabitants of Siberia eat the tender ftalks of this plant, when boiled, inftead of other vegetables.

This is a perennial plant, which may be propagated by parting the roots : the beft time for doing of this is in autumn, that the plants may get good root in winter *, for thofe which are tranfplanted in the fpring, do not flower well the firft year, unlefs they are planted in a moift foil. As thefe plants grow very large, they are not proper furniture for fmall gardens, • where they will take up too much room *, for they fhould not be planted nearer than four feet from each other, for if they are too near any other plants, they will rob them of their nourifhment; for the roots of thefe extend to a great diftance, fo that two or three of thefe plants, for variety, are fufficient for any garden, which may be planted at a diftance from choicer plants.

It is alfo propagated by feeds, which may be fown in the fpring on a bed of common ground, in the fame manner as the other forts -, and will only require to be thinned, and kept clean from weeds till autumn, when they may be tranfplanted where they are defigned to remain.

5. COCHLEARIA (*Armoracia*) foliis radicalibus lanceolatis, crenatis, caulinis incifis. Hort. Cliff. 332. *Scurvy Grafs whose lower leaves are fpear-Jhaped and crmated* and thofe on the ftalks jagged.* Raphanus Rufficanus. C. B. P. 96. *HorfeRadijh.*
6. COCHLEARIA (*Glaftifolia*) foliis caulinis cordato-fagittatis, amplexicaulibus. Hort. Cliff. 332. *Scurvy Grafs whose upper leaves are arrow-pointed, beart-Jhapedj and embrace the ftalks.* Cochlearia altiffima glafti folio. Inf. R. H. 216.

The firft fort grows naturally on the fea-fhore in the north of England, and in Holland, but is cultivated for ufe in the gardens near London. This is an annual plant, for the feeds are fown, and the plants decay within the compafs of one year, but the feeds fhould be fown early in autumn; this hath a fibrous root, from which arife many round fucculent leaves, which are hollowed like a fpoon -, the ftalks rife from fix inches to a foot high; thefe are brittle, and garnifhed with leaves, which are oblong and finuated. The flowers are produced in clutters at the end of the branches, confiding of four fmall white petals, which are placed in form of a crofs, and are fucceeded by fhort, roundifli, fwelling feed-veffels, having two cells, divided by a thinjpartition; in each of thefe is lodged four or five roundifli feeds. It flowers in April, and the feeds ripen in June, foon after which it decays.

This fort is propagated in gardens for medicinal ufes, which is done by lowing the feeds in July, foon after they are ripe, in a moift fhady fpot of ground; and when the plants are come up, they fhould be thinned, fo as to be left at about four inches diftance each way. The plants that are taken ouc may be tranfplanted into other fhady borders, if there is occafion for them, otherwife they may be hoed out (as is pra&ified for Onions, Carrots, &c.) and at the fame time all the weeds may be hoed down, fo as to clear the plants entirely from them, that they may have room to grow ftrong. In the fpring thefe plants will be fit for ufe; and thofe that are fuffered to remain will run up to feed in May, and perfect their feeds in June. If this plant is fown in the fpring, the feeds feldom grow well, therefore the beft time is fown after they are ripe. The plants rarely live after producing feeds, fo that it fhould be fown every year, to have it for ufe. .

The Sea Scurvy Grafs is alfo ufed in medicine -, but this grows in the fait marflies in Kent and Eflcx, where

where the water overflows it, almost every tide, and can rarely be made to grow in a garden, or at least 10 htr longer there than one year; but it being easily gathered in the places before-mentioned, the markets are supplied from thence by tile herb-women, who make it their business to gather herbs.

This fort differs from the first in the shape of its leaves, these being longer, and situated on their edges. It flowers a little later in the season; both these sorts are used in medicine.

The little Welch Scurvy Graft is a biennial plant, and may be preserved in a garden, if planted in a frosty soil and a shady situation. This is perceived in curious gardens of plants, but is not of any use in medicine, though it is by far the warmest and most pungent of all the forts. This grows plentifully in Italy, as seen in DJvis's Streights.

The fourth sort is a low trailing plant, whole (talks grow six inches long, and lie prostrate on the ground; the leaves are angular, and in all appearance like those of Ivy. This is found growing naturally in some parts of England, and is annual. It flowers and feeds about the same time as the first fort.

The sixth sort is a biennial plant, which usually grows about a foot and a half high, with upright stalks, garnished with angular heart-shaped leaves, embracing the stalks with their joints, the flowers are produced in loose spikes at the end of the branches; they are very small, white, and are succeeded by short swelling pods filled with round seeds. It flowers in May, and the seeds ripen in July and August. This may be propagated by seeds as the common fort, and if sown in autumn, will more certainly succeed than in the spring.

The Morie Radiis propagated by cuttings or buds from the sides of the old roots. The best season for this work is in October or February in the former for drylands, the latter for moist, the ground should be trenched at least two spits deep, or more if it will allow of it. The manner of planting it is as follows: provide yourself with a good quantity of offsets, which should have a bud upon their crowns, but it matters not how short they are; therefore the upper part of the roots which are taken up for use, may be cut off about two inches long with due regard to it, which is esteemed the best for planting. Then make a trench ten inches deep, in which you should place the offsets at about four or five inches distance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a second trench in like manner, and continue the same till the whole spot of ground is planted. After this, remove the surface of the ground even, observing to keep it clear from weeds, until the plants are so far advanced, as to be strong enough to overbear and keep them down. With this management the roots of the Horfe Radish will be long and straight, and free from small lateral roots, and the second year after planting will be fit for use. True, they may be taken up the first year, but then the roots will be short (tender; therefore it is the better way to let them remain until the second year. The ground in which this is planted ought to be very rich, otherwise the roots will make but a small progress.

der the title of Monoica Hexanilia, the same plant! having hermaphrodite and female flowers, the hermaphrodite having six stamens.

We know but one SPECIES of this genus, viz. Co cos (Nunera) Trontibus pinnatis, foliis enfimbri- buri raphicatu. Jacq. Hilt. IUI. Cree Nut nrtrb winged bratitbi, -ebsiptitit leaves art furd-jheptd and f&ldai. Palma Imlica coccifera angulola, C. B. F. 502. This tree is cultivated in both Indies, but is generally supposed to grow naturally in the Maldives, and other adjacent islands of the East-Indies. The trees grow to a great height in their native places, but their stems are composed of strong fibres like net-work, which lie in several lamina over each other, out of which come the branches (or rather leaves,) which grow twelve or fourteen feet long. The stalks are garnished with sword-shaped small leaves, whose borders fold backward: the broad leaves which push out from the stem when planted, are very different from those which are afterwards produced, for they are very broad, and have many folds in each: whereas, after leaves have a broad midrib, of great length, on which the smaller fibres are placed alter-

nate; these are from six to eight or nine inches long, and are triangular, having very sharp points, and are very brittle. The flowers come out round the top of the trunk of the tree in large clusters; they are enclosed in a large tubular calyx, and the nuts afterwards are formed in large clusters; these are included in large net-work covers, which adhere closely about them; the nut has a hard shell, with three holes at the upper end. The kernel is large, firm, and the lower part of the shell, when tinted with red, is used with yucca liquor, which the inhabitants of the countries where the trees grow, call milk, and they are very fond of it. From this milk I have been informed by persons of credit, there has been extracted a great quantity of oil in Jamaica. The plains are planted by planting the nuts in the furrows where they are designed to be raised for the plants will not bear transplanting, until they are formed whilst they are very young, for their roots are deep and wide; so that if they are cut or broken, the plants will not survive it, which is generally the case with most of the kind of trees.

Where any persons are desirous of having a plant or two of this kind, they should procure some of the nuts from the nearest plantation of their growth, which, on their arrival in England, should be put in a warm bed of tan, or bark, tying them on one side, that the young ones may grow out from one of the three holes may not be injured by wet, covering them about six inches deep with the tan. In this situation, if the nuts are good, they will put out roots in six weeks or two months, so should be then carefully taken up, and each planted in a separate pot filled with kitchen-garden earth, and plunged into the tan-bed in the tub, where the plants should always remain, for they are too tender to thrive in any other situation, but as the plants advance in their growth, they should be shifted into larger pots or tubs, being careful not to cut or tear their roots in the transplantation.

This is one of the most useful trees to the inhabitants of America, who make many uses of it from the several parts of it. The outer cover of the nuts is made into cordage; the shells are used into drinking bowls, the kernel of the nuts is for them a wholesome food, and the milk is cooling liquor. The leaves of the tree are used for thatching of their houses, and are also wrought into baskets, and many other things which are made of them.

pointed nut* with one cell, boning a fingle fed of the fame form.

This genus of plants is ranged in the third fection of Linnaeus's eighth genera, intitled O&andria Trigynia, the flowers having eight ftamina and three ftyles.

The SPECIES are,

1. COCCOLOBA (*Uvifera*) foliis cordato-fubrotundis nkidis. Lin. Sp. 523. *Sea-fide Grape with neat, roundifh* heart-fhaped leaves.* Guajabara racemofa, foliis coriaceis fubrotundis. Plum. Nov. Gen.
2. COCCOLOBA (*Rubefeens*) foliis orbiculatis pubefcentibus. Lin. Sp. 523. *Sea-fide Grape with orbicular hairy leaves.* *Scortea arbor Americana, ampliflimis foliis averfapartenerisextantibus.* Pluk. Phyt. 222. f. 8.
3. COCCOLOBA (*Punffata*) foliis lanceolato-ovatis. Lin. Sp. 523. *Sea-fide Grape with oval fpear-fhaped leaves.* *Uvifera arbor Americana, fruftu aromatico pun&ato.* Pluk. Aim. 394.
4. COCCOLOBA (*Excoriato*) foliis ovatis, ramis quafi ex-corticatis. Lin., Sp. 524. *Sea-fide Grape with oval leaves* and the branches cafting their bark.* Guajabara alia racemofa, foliis oblongis. Plum. Icon. 146. f. 1. *Called Mountain Grape.*
5. COCCOLOBA (*Tenuifolia*) foliis ovatis membranaceis. Amon. Acad. 5. p. 55j. *Sea-fide Grape with oval membranaceous leaves.*

The firft fort rifes with many ligneous items to the height of ten or twelve feet, having feveral knots or joints* covered with a gray bark: at each joint is fet on one large, roundifh, fsmooth leaf, a little indented at the top. The flowers come out from the foot-ftalks of the leaves, in long bunches like thofe of Currants; they have no petals, but the empale Ant is cut into five fegments, including eight awl-fhaped ftamina, terminated, by twin fummits. The germen afterward becomes a fucculent berry, including an oval-pointed nut, having one feed of the fame form.

The fecond fort feldom rifes fo high as the firft, but divides into feveral lateral branches, garnifhed with large roundifh leaves, having feveral deep veins* the flowers and fruit come out from the fide of the branches in like manner as thofe of the firft, but are larger.

The third fort is a lower fhrub than either of the former; the leaves are oval and fpear-fhaped -, the fruit is fmaller, fomewhat aromatic, and ipotted; thefe proceed from the fide of the branches in like manner as the former forts.

The fourth fort grows to a much larger fize than any of the other; the leaves of this are much larger, of an oblong oval form, very fsmooth, and of a lucid green: from the wings of the leaves, the flowers and fruit are produced, which are in form like thofe of the other forts, but are larger.

The fifth fort is of humbler growth than either of the former; the leaves are membranaceous, of an oval form; the flowers and fruit are fmaller than thofe of the other forts. Thefe plants all grow naturally in the warm iflands of America; ibme of them on the fea-fhores, where they form very clofe, almoft impenetrable thickets *, the fruit of the firft fort are frequently eaten by the inhabitants of the iflands, but dpecially by the negroes. Thofe of the other forts are food for birds.

The plants of all the forts are eafily propagated by feeds, when they can be obtained frch from the places of their natural growth (for none of the forts have as yet produced either fruit or flowers in England.) The feeds fhould be fown in fmall pots filled with earth from the kitchen-garden, and plunged into a hot-bed. If the feeds are good, and the bed of a proper temperature of warmth, the plants will appear in five or fix weeks after, which will be fit to transplant in about a month after -, when they fhould be ftaken out of the pots, feparating their roots carefully, and each planted in a feparate fmall pot filled with the like earth, plunging them into a hot-bed of tanners bark, being careful to (hade them in the day-time, until they have taken new root; after which they

Should be treated in the fame way as other tender exotic plants, which require to be kept conftantly in the bark-ftove.

CODLIN-TREE. SeeMALus.

COFFEA. Lin. Gen. Plant. 209, Juff. A & Reg. Scien. 1713. Jafminum. Com. Cat. The Coffee-tree.

The CHARACTERS are,

the flower hath a fmall impalement divided into four parts fitting upon the germen. It hath one petal which is funntUfhaped* having a narrow cylindrical tube* which is much longer than the empalement* but is plain at the top* where it is indented in five parts. It hath five ftamina which are faftened to the tube* and are terminated by longftender fummits. The roundifh germen fupports afingle ftyle* crowned by two thick reflexedftignas. The germen afterward becomes an oval berry* containing two bemifpherical feeds* plain on one fide* and, convex on the other.*

This genus of plants is ranged in the firft fection of Linnaeus's fifth clafs, intitled Pentandria Monogynia, the flower having five ftamina and one ftyle 5 it hath been generally included in the genus of Jafmines *, but as the flowers of Jafmine have but two ftaipina, fo by Linnaeus's fyftem, this is feparated and ranged in another clafs.

We have but one SPECIES of this genus, viz.

COFFEA (*Arabica*.) Hort. Cliff. 59. The Coffee-tree. Jafminum Arabicum Caftaneae folio, flore albo odoratiffimo, cujus fru&us Coffea in officinis dicuntur nobis. Juff. Aft. Par. 1713.

This tree is fuppofed to be a native of Arabia Felix, where it was firft cultivated for ufe, and to this day, is the country from whence the beft Coffee is brought to Europe, though the plant is now propagated in many parts of India and America; but the produce of thofe countries being greatly inferior to that of Arabia, hath occafioned its prefent difrepute in England, fo that it is fcarce worth importing; but this might be remedied, if the Coffee planters in the Weft Indies could be prevailed on to try a few experiments, which I (hall hereafter propofe, being founded on thofe which have been made in England, upon the berries produced here. But I (hall firft treat of the plant, with its culture in England.

This is a low tree in the native country of its growth, where it feldom rifes more than fifteen or eighteen feet high, but in England I have not feen any above ten or twelve. The main ftem grows upright, and is covered with a light brown bark; the branches are produced horizontally and oppofite, which crofseach other at every joint, fo that every fide of the tree is fully garnifhed with them: the lower branches being the longeft, the others gradually decreafing to the top, form a fort of pyramid; the leaves are alfo produced oppofite; thefe when fully grown, are about four or five inches long, and one inch and a half broad in the middle, decreafing toward each end; the borders are waved, and the furface is of a lucid green. The flowers are produced in clufters at the bafe of the leaves, fitting clofe to the branches; thefe are tubulous, fspread open at the top, where they are divided into five parts, and are of a pure white, with a very grateful odour, but of fhort duration: they are fucceeded by oval berries, which are firft green, when fully grown, they turn red, and afterward change to black when fully ripe; thefe have a thin pulpy (kin, under which are two feeds joined, which are flat on the joined fides, with a longitudinal furrow, and convex on their outer fide.

As the Coffee-tree is an Evergreen, it makes a beautiful appearance at every feafon in the ftove, but particularly when it is in flower *, and alfo when the berries are red, which is generally in the winter *, fo that they continue a long time in that ftate, therefore there is fcarce any plant that more deferves a place in the ftove than this.

It is propagated by the berries, which muft be fown foon after they are gathered from the trees, for if they are kept out of the ground a fhort time they will not grow. I have frequently fent the berries abroad

by the poft, but when they have been a fortnight in their journey they have all failed; and this has conftantly happened every where, for the berries which were fent from Holland to Paris did not grow, nor did thofe which were fent from Paris to Eiigland grow; fo that wherever thefe trees are defired, the young plants muft be fent, if it be at any diftance from the place where they grow.

The berries fhould be planted in fmall pots, filled with light kitchen-garden earth, and plunged into a hot-bed of tanners-bark; the pots muft be watered gently once or twice a week, but the earth muft not be too moift, left it rot the berries. If the bed be of a proper temperature of warmth, the plants will appear ki a month or five weeks time, and in about two months more will be fit to tranfplant. For as many of the berries will produce two plants, fo the iboner they are parted, the better their roots will be formed; for when they grow double till they have made large roots, they will be fo intermixed and entangled, as to render it difficult to feparate them without tearing off their fibres, which will greatly prejudice the plants. When thefe are tranfplanted, they muft be each put into a feparate fmall pot, filled with the fame earth as before, and plunged into the tan-bed again; which fhould be ftirred up to the bottom, and if required, fome new tan fhould be mixed with it, to renew the heat. Then the plants fhould be gently watered, and the glaffes of the hot-bed muft be fliaded every day till they have taken new root; after which the plants fhould have free air admitted to them every day, in proportion to the warmth of the feafon: during the fummer they will require frequently to be refrelhed with water, but they muft not have it in too great plenty: for if their roots are kept too moift, they are very fubjeft to rot, then the leaves will foon decay and drop off, and the plants become naked; when, this happens, they are feldom recovered again. The firft fign of thefe plants being difordered, is, their leaves fwearing out a clammy juice, which attracts the fmall infefts, that too frequently infeft the plants in ftoves; when they are not in health, thefe infe&s cannot be deftroyed, till the plants are recovered to vigour: for although the plants are ever fo carefully walhed and cleaned from them, yet they will be foon attacked by them again, if they are not recovered to health, for thefe infe&s are never feen upon any of the plants while they are in perfect vigour; but when they are difordered, they foon ipread over all the leaves and tender parts of the plants, and multiply exceedingly; fo that upon the firft attack, the plants fhould be fhifted into freffi earth, and all poffible care taken to recover them, without which all the walhing and cleaning of the plants will be to little purpofe. The diforders attending the Coffee-trees, generally proceed from either being put into pots too large for them, nothing being of worfe confluence than over potting them 5 or from the earth being too ftiff, or overhung by other plants, or being over watered. If thefe are properly taken care of, and the ftove kept always in a proper temperature of heat, the plants will thrive, and produce plenty of fruit.

I have made trial of feveral compofitions of earth for thefe plants, but have found none of them equal to that of a kitchen-garden, where the foil is naturally loofe, and not fubjeft to bind; and if it has conftantly been well wrought and properly dunged, this without any mixture is preferable to any other.

The plants fhould not be too often tranfplanted, for that will greatly retard their growth. If they are new potted twice a year at moft, it will be fufficient; though unlfs the plants make great progrefs, they will iiot require to be removed oftener than once in a year, which fhould be in fummer, that they may have time to get good roots again before winter. During the warm weather in fummer, thefe plants fhould have a large ihare of air, but they muft not be wholly expofed abroad at any feafon: for although they may have the appearance of thriving in the open air

during the heat of fummer, yet when they are removed into the ftove again, their leaves will fall off, and the plants will make but an indifferent appearance the following winter, if they fhould furvive it: therefore it is the better method to keep them conftantly in the ftove, and admit a proportionable fhare of air to them every day, according to the heat of the feafon; they will require water two or three times a week in warm weather, but in the winter they muft have it more fparingly; and the ftove in which they are placed, fhould be kept to the heat affigned for the Ananas upon the botanical thermometers.

There has been fome of thefe plants propagated by cuttings, and alfo from layers; but thefe are long before they make roots, and the plants fo raifed, are never fo ftrong and thriving as thofe which arife from berries, therefore where the berries can be produced, it is much the beft method to propagate the plants by feeds.

When the plants are tranfplanted, their roots fhould not be too much cut or trimmed, the decayed or rotten fibres fhould be pruned off, and thofe which are clofely matted to the fide of the pots fhould be trimmed, but not cut too near to the item; for the old fibres do not put out new roots very kindly, e&pecially thofe which are become tough, fo that there fhould always be a fufficient number of young fibres left to fupport the plants, till new ones are produced.

The Coffee plants were firft carried from Arabia to Batavia by the Dutch, and from thence they were afterward brought to Holland, where great numbers of the plants were raifed from the berries which thofe plants produced, and from thefe moft of the gardens in Europe Hive been furnifhed. A great number of thefe young plants, which were raifed at Amfterdam, were fent to Surinam by the proprietors of that ifland, where the trees were foon propagated in great plenty, and from thence the plants have been difperfed to moft of the iflands in the Weft Indies: for as the plants raifed from the berries, produce fruit in two years from planting, and in the warm countries fooner, fo plantations of thefe trees may be foon made in any of thole countries, where the temperature of the air is proper for their produftion, but the trees will not grow in the open air any where if there is a winter Hb that in all countries without the tropics, they cannot be expected to grow abroad.

The French have made great plantations of thefe trees in their fettlements in the Weft Indies, and alfo in the ifle of Bourbon, from whence they import great quantities of Coffee annually to France; which although greatly inferior in quality to the Arabian, yet h is confumed, otherwife they would not continue that branch of commerce. In the Britifh colonies of America, there have been fome large plantations made of Coffee-trees: and it was propofed to the parliament, fome years paft, to give a proper encouragement for cultivating this commodity in America, fo as to enable the planters to underfell the importers of Coffee from Arabia. Accordingly there was an abatement of the duty payable on all the Coffee which fhould be of the growth of our colonies in America, which at that time was fuppofed would be a fufficient encouragement for the planters to improve this branch of commerce: but the productions of thofe countries, being greatly inferior in quality to that of Arabia, hath almoft ruined the projet; and unlfs the planters can be prevailed on to try fome experiments to improve its quality, there can be little hope of its becoming a valuable branch of trade; therefore I fhall beg leave to offer my fentiments on this article, and fincerely wifh what I have to propofe may be found ufeful for the inftru&ion of the Coffee planters; for as my opinion is founded upon experiments, fo it is not mere theory or fuppoftion.

The great fault of the Coffee which grows in America, and alfo in the ifle of Bourbon, is the want of flavour, or having a difagitable one. The berries

we much larger than those which are imported from Arabia, and consequently have not so much spirit or flavour. This may be owing to several causes, the first is that of its growing in a soil too moist, which is always known to increase the size of fruit and vegetables, but their quality is greatly diminished thereby. The second is from the gathering of the berries too soon; for I have been credibly informed, that it is the constant practice of the planters* to gather the fruit when it is red: at which time the berries are much larger, and of greater weight, than those which are permitted to ripen perfectly on the trees, which is not till they are turned black, and their outer pulp becomes dry, and the skins shrink: then the berries are much smaller than before, and the outer cover will easily separate from the berry; which I have always been informed, has been the complaint of the planters, that this was with great difficulty and trouble effected. A third cause I imagine may be in the drying of the berries when gathered; which must be constantly attended to, for they cannot be too much exposed to the sun and air in the day time, but they must be every evening removed under cover, and carefully screened from dews and rain, nor should they be placed near any sort of liquid or moisture, for these berries are very subject to imbibe moisture, and thereby acquire the flavour of the liquid or if it be pure water, the berries will be enlarged, and the flavour diminished by it, as from many experiments I can affirm: for a bottle of rum being placed in a closet, in which a canister of Coffee berries closely stoppered, was hanging on a shelf at a considerable distance, in a few days had so impregnated the berries, as to render them very disagreeable; the same alibi has happened by a bottle of spirits of wine (landing in the same closet with Coffee and Tea, both which were in a few days spoiled by it. Therefore from many experiments of this nature, which I have made with Coffee, it appears to me that it should never be brought over in ships freighted with rum, nor should the berries be laid to dry in the houses where the sugars are boiled, or the rum distilled. I have also been informed by a gentleman who has a very good estate in Jamaica, and who has lived many years in that island, that the planters frequently boil the Coffee berries before they are dried. As this information comes from a gentleman of great skill and veracity, so I cannot doubt of the fact and if so, this alone is sufficient to spoil the best Coffee in the world so that I am at a loss to guess the reason for this practice, which, as it appears to me, can only be intended to increase the weight, therefore must be imputed to avarice, the bane of every public good.

There was some time past an imperfect account printed in the papers, of the cause why the American Coffee was not so good as that which comes from Arabia, in which it is supposed, that the goodness of the latter proceeded from the length of time which the berries had been kept: therefore the author proposes that the American Coffee berries should be many years kept, which he says will render them equally good. This is contrary to all the experience I have had, or can learn, from those who have seen the whole progress of Coffee in Arabia, with their manner of drying and packing it to send abroad; for two gentlemen who had lived there some years assured me, that the berries, when first gathered, were much better than those which are kept any time. And a curious gentleman who resided in Barbadoes two years, also told me, that he never drank better Coffee in any part of the world, than what he made from the fresh berries which he gathered himself, and roasted as he had occasion for them; which is also confirmed by the trials which have been made with the berries which grow in the stoves in England, which make a better flavoured liquor, than the best Arabian Coffee berries which can be procured in England; therefore I wish those who are inclinable to cultivate these trees in America, would make

choice of a soil rather dry than moist, in which the trees will not make so great progress as those which grow in a wet soil, nor will the produce be so great, but as the quality of the produce will be so much improved, it will certainly be of greater advantage to them.

The next thing is, to permit the berries to remain so long upon the trees, till their skins are shrivelled and turned very black, which it is true will greatly diminish their weight, but then the commodity will be more than double the value of that which is gathered sooner.

When the berries are fully ripe, they should be gathered, or rather shaken from the trees, when they are perfectly dry, and spread abroad upon cloth: in the sun to dry, carrying them every evening under cover, to prevent the dews from falling on them, or the rain if any should happen: and when they are perfectly dry, they should be carefully packed up in cloths or bags, three or four times double, and consequently kept in a dry situation: and when they are shipped for England, it should be on board those vessels which have no rum, lest the Coffee should imbibe the flavour, which cannot be prevented when flowed in the same place. For some years past, a Coffee ship from India had a few bags of pepper put on board, the flavour of which was imbibed by the Coffee, and the whole cargo spoiled thereby.

As the quantity of Coffee now consumed in Britain is very much increased of late years, so it will certainly be worthy of public consideration, how far it may be necessary to encourage the growth of it in the British colonies: and certainly it deserves the attention of the inhabitants of those colonies, to improve this commodity to the utmost of their power and not to have so much regard to the quantity, as to the quality of it; for although the former may appear to have the advantage of the latter in point of profit, yet the goodness of every commodity must always claim the preference, and thereby will be found of more lasting advantage to the cultivator.

COIX. Lin. Gen. Plant. 927. *Lachryma Jobi*. Toum. Inf. R. H. 531. tab. 306. Job's Tears.

The CHARACTERS are,

// both male and female flowers on the same plant; the male flowers are disposed in a tuft spike the chaff of these have two valves, inclosing two flowers, the valves are oblong and bearded; the petal has two oval valves* the length of the chaff, with narrow beards: these have each three hairy stamens, terminated by oblong four-cornered summits. there are a few female flowers situated at the base of the male spike in the same plant, these have bivalvular chaff; the valves are roundish, thick, and smooth \ the petal hath two oval valves, the outer being larger and bearded at both ends. They have a small oval germen, supporting a short style divided into two parts, crowned by two horned stigmas which are longer than the flower, and covered with fine hairs; the germen afterward becomes a hard, roundish, smooth seed.

This genus of plants is ranged in the third section of Linnaeus's twenty-first class, intitled Monoecia Triandria. The plants of this class have male and female flowers on the same plant, and the flowers of this section have three stamens.

The SPECIES are,

C O L D signifies something devoid of heat, or which does not contain in it any particles of fire; according to which definition, cold is a mere negative term. And this is agreeable to the sentiments of most of our modern philosophers, who suppose cold to consist in a mere privation or diminution of heat.

Others much on the same principle* define cold, to be that state of the minute parts of a body, wherein they are agitated more slowly and faintly than those of the organs of feeling. And in this sense, cold is a mere term of relation: and hence the same body becomes liable to be perceived hot or cold, as the particles of it are in greater or lesser degree of motion than those of the sensible organ.

Heat is supposed to consist in a particular motion of the parts of the body; and hence the nature of cold, which is its opposite, is easily deducible; for we find that cold extinguishes, or rather abates heat. Whence it seems to follow, that those bodies are cold, which check and restrain the motion of the particles, wherein heat consists.

There are three kinds of bodies that can do this; viz. either those whose particles are perfectly at rest, or those whose particles are indeed agitated, but with less violence than those of the hot body to which they are applied; or, lastly, such whose particles have a motion proper for exciting the sensation of heat, but move with a different determination, so as to retard and change the motion of the particles of the organ.

Hence three different kinds of cold, or cold bodies, do proceed.

The first, That cold is common to all hard bodies; which consists in the rest of their parts.

The second is, That which arises from plunging any part of the body in water, which consists in this, that the parts of our praeordia, being more briskly agitated than those of the fluid, communicate part of their motion to it.

The third, The cold felt on the collision of warm air with a pan, or in blowing hot breath out of our mouth with the lips close shut, which consists in this, that the direct motion of the particles of air does, in some measure, change and rebate the motion and determination of the parts of the body; and hence it is, that a cold body cannot cool another without heating itself.

Hence also it proceeds, that the more the parts of a frigid body are at rest, the more the particles of a warm body that is applied to heat them, must lose of their motion, and consequently of their heat.

Thus, there being more quiescent parts in marble than in wood, which is full of pores and interstices, the marble is felt colder than the wood: and hence also we may understand why air near marble, and other dense bodies, feels somewhat colder than in other places.

On this principle the two latter kinds of cold appear somewhat more than privations: the particles inducing the cold may be esteemed real frigorific corpuscles; and coldness may be deemed a real quality, as well as hotness. These particles do not only check the agitation of those continually diffused from the inner parts of an animal to the outer; but having an elastic power, they bend, and hang about the filaments of the body, pinch and squeeze them; and hence is that acute pungent sensation called cold.

That cold is more than a mere relation or comparison, is evident from its having real and positive effects; such as freezing, congelation, condensation, rarefaction, bursting, &c.

Dr. Clarke takes cold to be owing to certain nitrous and other saline particles, endowed with particular figures proper to produce such effects. Hence sal-armoniac, salic petre, salt of urine, and many other volatile and alkalizate salts, mixed with water, increase its degree of cold very sensibly.

Hence also comes that popular observation, that cold prevents corruption; which, however, must not be admitted without an exception \ since if an hard po-

rous body have its interstices filled with water* and this be too much dilated by freezing, the including body will be burst. And thus it is that cold proves destructive to the parts of some plants: as it happened in the winters, anno 1728, and 1739-40, in several trees, whose trunks were much exposed to the louth-west, the sap being thereby rarefied by the warmth of the sun, which, for several days, at the beginning of the severe frost, (gone with an uncommon heat, and the nights coming on to extreme cold, whereby the rarefied sap was so suddenly condensed, that the sap-vessels could not contain it, and thereby burst off* the bark of many trees almost from top to bottom -, and this chiefly on the south-west side of the trees; as it did of several large trees in the physic-garden at Chelsea; and several Pear, and other fruit-trees, in the nurseries of Mr. Francis Hunt at Putney, &c. And thus it is that great quantities of trees are rendered shaken, and the timber, when cut, of little value-, which is generally the case in very severe winters. In the hard frost of the year 1739-40, there was great damage done to the Oak-timber in most parts of England, by the frost penetrating to the sap-vessels of the trees; and by freezing the sap, the vessels could not contain it, but burst with great noise* so that the woods resounded with a noise somewhat like the breaking down of the branches of trees, when they are lopping.

Dr. Boerhaave says, That there is no such thing in all nature as absolute cold, that the most severe he had ever known, was in the year 1728, that then the water would freeze while it ran down his hand; and yet even then the cold was not so complete, but that he could make an artificial cold greater by twelve degrees.

Though much might be said as to the effects of cold on plants, I shall only conclude with an observation of the Reverend Dr. Hales, who, in the conclusion of his excellent treatise of Vegetable Statics, says 5

The considerable quantity of moisture, which is perspired from the branches of trees during the cold winter season, plainly shews the reason why, in a long season of cold north-easterly winds, the blossoms, and tender young-set fruit and leaves, are, in the early spring, so frequently blasted, viz. by having the moisture exhaled faster than can be supplied from the trees -, for, doubtless, moisture rises slower from the root, the colder the season is, though it rises, in some degree, all the winter; as is evident, as he says, from his sixteenth experiment in the said book.

And from the same cause it is, that the leafy spires of Corn are by these cold drying winds often faded, and turned yellow; which makes the husbandman, on these occasions, wish for snow: which, though it be very cold, yet it not only defends the root from being frozen, but also screens the Corn from these drying winds, and keeps it in a moist, florid, supple state.

It seems therefore to be a reasonable direction, which some authors, who write on agriculture and gardening give, viz. During these cold drying winds, when little dew falls, to water the trees in dry soils, in the blossoming season, and while the young-set fruit is tender*, and provided there is no immediate danger of a frost, or in case of continued frost, to take care to cover the trees well, and at the same time to sprinkle them with water; which is imitating nature's method of watering every part.

As to sloping shelters over wall-trees he says, I have often found, that when they are so broad, as to prevent any rain or dew coming at the trees, they do more harm than good in these long easterly drying winds, because they prevent the rain and dews falling on them 5 which would not only refresh and supple them, but also nourish them: but in case of (hard frost after a shower of rain, these shelters and other fences must needs be of excellent use to prevent the almost total definition occasioned by the freezing of the tender parts of vegetables, when they are saturated with moisture.

COL

COLDENIA. Lin. Gen. Plant. 159. This plant was first named by Dr. Linnæus, in honour of Dr. Colden, of North America, who is a very curious botanist, and has discovered several new plants which were not known before.

The CHARACTERS are,

The empalement of the flower is composed of four erect leaves, which are long as the petal. It hath a funnel-shaped flower of one petal, spreading at the top, and obtuse; it hath four stamina, which are inserted in the tube of the petal, terminated by roundish summits. In the center is situated four oval germen, each supporting a hairy style the length of the stamina, crowned by permanent stigmas. The germen afterward become an oval, compressed, rough fruit, with four cells, terminated by four beaks, inclosed by the empalement, each of the cells containing a single seed, convex on one side, and angular on the other.

This genus of plants is ranged in the third section of Linnæus's fourth class, intitled Tetrandria Tetragynia, the flower having four stamina and four styles.

There is but one SPECIES of this genus, viz.

COLDENIA (Procumbens). Flor. Zeyl. 79. This is by Dr. Pluknet titled, *Teucris facie biihagarica tetra-coccus rostrata*. Aim. 363.

This is a native of India, from whence the seeds have been brought to some of the curious botanic gardens. It was sent me by Dr. Linnæus, professor of botany at Upsal in Sweden. It is an annual plant, whose branches trail on the ground; they extend near a foot from the root, and divide into many smaller branches, garnished with (short leaves, fitting close to them) these are deeply crenated on their edges, and have several longitudinal veins -, they are of a glaucous colour, and come out without order. The flowers are produced at the wings of the leaves, growing in small clutters; these have one funnel-shaped petal cut into four segments at the top; they are of a pale blue colour, and very small 5 they have four stamina and four styles, having hairy stigmas. "When the flower decays, the germen becomes a fruit, composed of four cells, wrapped up in the empalement, each containing a single seed.

This plant is propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each put into a separate small pot, plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root -, after which they should have air admitted to them every day in proportion to the warmth of the season, and gently watered two or three times a week in warm weather, but they must not have too much moisture. These plants must remain in the hot-bed, where they will flower in June, and the seeds will ripen in September.

COLEWORTS. See BRASSICA.

COLLINSONIA. Lin. Gen. Plant. 38. The title of this plant was given to it by Dr. Linnæus, in honour of Mr. Peter Collinson, F. R. S. a most distinguished promoter of botanical studies, and the first who introduced this plant, among many others, to the English gardens.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five equal segments at the top, the three upper being reflexed, and the two under erect. "The flower is funnel shaped, of one petal which is unequal, and much longer than the empalement, cut into five parts at the top, the upper being short and obtuse, two of them being reflexed the lower up or beard is longer, ending in many points. It hath two long bristly stamina which are erect, terminated by incumbent summits. It hath a quadrifid obtuse germen, with a large gland, supporting a bristly style the length of the stamina, crowned by a pointed bifid stigma. The germen afterward becomes a single roundish seed, situated in the bottom of the empalement.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia the flower having two stamina and one style.

COL

We have but one SPECIES of this plant, viz.

COLLINSONIA (Canadensis) foliis cordatis oppositis. *Co*
lymbia with heart-shaped leaves growing opposite.

This plant was brought from Maryland, where it grows wild, as it also does in many other parts of North America, by the sides of ditches, and in low moist ground, where it usually rises to the height of four or five feet but in England it seldom grows above three feet high, and unless it be planted in a moist warm situation, or in dry weather is duly watered, it rarely flowers well; therefore many people keep the plants in large pots, for the more convenient watering them, but these plants seldom produce good seeds; whereas those which are planted in the full ground, and are constantly watered, will ripen seeds very well in good seasons.

This hath a perennial root. The stalks decay in the autumn, and fresh shoots come out in the spring. The stalks are square, garnished with heart-shaped leaves, placed opposite, which are sawed on their edges. The flowers are produced at the extremity of the stalks in loose spikes, these have long tubes, and are divided into five parts at the top; they are of a purplish yellow, and the lower segment is terminated by long hairs. The flowers appear in July, and the seeds ripen in autumn.

This plant may be easily propagated by parting the roots in October. These roots should be planted at three feet distance, for they require much nourishment, otherwise they will not thrive. This plant will live in the open ground, if it is planted in a sheltered situation.

COLUMBINE. See AQUILEGIA.

COLUMNÆA. Plup. Nov. Gen. 28. tab. 33.

Lin. Gen. Plant. 710. The title of this genus was given to it by Plumier, in honour of Fabius Columna, a nobleman of Rome, who has published two curious books of botany.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five parts at the top; it hath one petal, of the (ringent) or grinning kind, having a long swelling tube, divided above into two lips, the upper being erect, concave and entire; the lower is divided into three parts which spread open: it hath four stamina, two being longer than the other, these are inclosed in the upper lip, and are terminated by single summits. In the center is situated the roundish germen, supporting a slender style, crowned by a bifid acute stigma. The germen afterward becomes a globular berry with two cells, fitting on the empalement, and is of the same magnitude, containing several oblong seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiosperma. The flowers of this class have two long and two (short stamina, and those of this section have their seeds inclosed in a capsule.

We have but one SPECIES of this plant in the English gardens, viz.

COLUMNÆA (Scandens). Lin. Sp. Plant. 638. Columnæa scandens, Phoeniceo flore, fructu albo. Plum. Nov. Gen. 28. *Climbing Columnæa with a scarlet flower and a white fruit.* Plumier mentions a variety of this, with a yellowish flower and a white fruit. But this is only a femal variation supposed to have accidentally arisen from the seeds of the first.

I received seeds of the scarlet sort from Carthage in New Spain, where the plants grew naturally. This hath a climbing stalk, which fattens itself to the neighbouring plants, whereby it is supported. The leaves are oval, sawed on their edges, and stand upon short foot-stalks 5 these, and also the stalks, are very hairy; but the plants decayed the following year, before they produced any flowers, so that I can give no description of them.

These plants are natives of the warmest parts of America, so are too tender to live in England, unless they are preserved in the stove, they are propagated

by feeds, which muft be fown in a good hot-bed; and when the plants come up, they muft be treated in the fame way as other tender exotic plants which are kept in the bark-ftove.

COLUTEA. Tout a. Inft. R. H. 649. tab. 417. Lin. Gen. Plant. 776. Bladder Sena.

The CHARACTERS are,

// hath a bell-Jhaped permanent impalement of one leaf, indented in five parts, The flower is of the butterfly kind. Theftandard, wings* and keel* vary in their figure in different fpecies. It hath ten ftamina* nine of which- are joined* the other ftands feparate^ which are terminated by Jingle fummits. In the center is ftuated an oblong germen, which is cemprejfed* fupporting a rijing • fijk* crowned by a bearded line, extended from the middle of the upper part of theftyle. The germen afterward becomes a broad fwelcn pod with one cell, including feveral kidney-Jhaped feeds.

This genus of plants is ranged in Linnseus's third fection of his ieventeenth clafs, intitled Diadelphia Decandria. The flowers of this clafs have ten ftamina, nine of which are joined, and the tenth Jlands feparate.

The SPECIES are,

1. COLUTEA (*Arborefcens*) arborea, foliolis obcordatis. Hort. Cliff. 365. *Tree Bladder Sena with heart-jhaped lobes.* Colutea veficaria. C. B. P. 396. *Common Bladder Sena.*
2. COLUTEA (*Iftria*) foliolis ovatis, integerrimis, caule fruticofo. *Shrubby Bladder Sena with oval leaves which are entire.*
3. COLUTEA (*Orientalis*) foliolis cordatis minoribus, caule fruticofo. *Bladder Sena with fmaller heart-jhaped leaves* and a Jhrubby ftalk.* Colutea Orientalis flore fanguinea colons, lutea macula notato. Tourn. Cor. 44.
4. COLUTEA (*Frutefcens*) fruticofa foliolis ovato-oblongis. Hort. Cliff. 366. *Shrubby Bladder Sena with oblong oval leaves.* Colutea flEthiopica flore Phceniceo, folio Barbaejovis. Breyn. Cent. 1. 73. *JEthiopian Bladder Sena with a fcarlet flower.*
5. COLUTEA (*Americana*) foliolis ovatis, emarginatis, leguminibus oblongis compreffis acunrynatis, caule arboreo. *Bladder Sena with oval leaves indented at the top* oblong* compreffed* pointed pods* and a tree-like ftalk.* Colutea Americana, veficulis oblongis compreffis. Houft. MSS. *American Bladder Sena with oblong compreffed pods.* Dr. Pluknet titles it Colutea Verae Crucis veficaria. Aim. 111.pl. 165. f. 3. *Bladder Sena of Vera Cruz.*
6. COLUTEA (*Herbacea*) herbacea foliolis linearibus. Hort. Upfal. 266. *Herbaceous Bladder Sena with narrow leaves.* Colutea Africana annua, foliolis parvis, mucronatis, veficulis compreffis. Hort. Amft. 2. p. 87. tab. 44.
7. COLUTEA (*Procumbens*) caulibus procumbentibus, foliolis ovato-line&ribus, tomentoifis, floribus alaribus pedunculis longiflimis. *Bladder Sena with trailing Jtalks* oval narrow leaves which are woolly* and flowers growing from the fides of the ftalks, with very long foot-Jtalks.*

The firft fort is commonly cultivated in the nurfery-gardens, as a flowering fhrub, to adorn plantations. This grows naturally in Auftria, in the fourth of France and Italy, from whence the feeds were originally brought to England; this hath feveral woody ftems, which grow to the height of twelve or fourteen feet, fending out many woody branches, garnifhed with winged leaves, compofed of four or five pair of oval lobes, placed oppofite, terminated by an odd one; thefe are indented at the top in form of a heart, and are of a grayifh colour. The flowers come out from the wings of the leaves upon (lender foot-ftalks, about two inches long, each fupporting two or three flowers of the butterfly kind, yhoft ftandard is reflexed and large^ . The flowtrs are yellow, with a dark-coloured mark on the petal j thefe are fucceeded, by inflated pods an inch and a half long, having a (earn on the upper fide, containing a fingle row of kidney-jhaped feed\$, fattened to a placenta. This

flowers in June and July, and the feeds ripen in autumn. There is a variety of this with reddifh pods, which is equally common in the gardens, and is fuppofed to be only an accidental variety, for the plants do not differ in any other part.

The feeds of the fecond fort were brought from the Levant by the Reverend Dr. Pocock, which fucceeded in the garden at Chelfea; and fince Dr. Ruffel, who'refided many years at Aleppo, brought over dried famples of this forty which he affures me grow common near that city. This fort feldom grows more than fix or feven feet high 5 the branches are very (lender, and fpread out on every fide, garnifhed with winged leaves, compofed of nine pair of fmall, oval, entire lobes, terminated by an odd one-, the flowers ftand upon (lender foot-ftalks, about the fame length of the former. The flowers are alfo like thofe, but are of a brighter yellow. This fort begins to flower early in May, and continues flowering till the middle of October.

The third fort wjis difcovered by Dr. Tournefort in the Levant, from whence he fent the feeds to the royal garden at Paris, where they fucceeded, and fince have been communicated to moft of the curious gardens in Europe. This hath a woody ftem, which fends out many branches on every fide, which do not rife above feven or eight feet high; thefe are not fo ftrong as thofe of the firft fort, and are garnifhed with winged leaves, compofed of five or fix pair of fmall heart-jhaped lobes, terminated by an odd one. The flowers proceed from the fide of the branches, Handing upon foot-ftalks, each fupporting two or three flowers, (haped like thofe of the firft fort, but fmaller; they are of a dark red colour, marked with yellow: thefe appear in June, and the feeds ripen in autumn.

The fourth fort grows naturally in Ethiopia, from whence the feeds were brought to Europe. This hath a weak fhubby ftalk, which fends out fide branches, growing ereft, garnifhed with equal winged leaves, compofed of ten or twelve pair of fmall, oval, oblong, hoary lobes. The flowers are produced at the upper part of the branches from the wings of the leaves, each foot-ftalk fupporting three'or four fcarlet flowers, which are longer than thofe of the other forts, and are not reflexed; thefe are fucceeded by inflated pods, containing one row of kidney-jhaped feeds. The ufual time of this plant producing its flowers is in June; but when the feeds are fown early in the fpring, the plants frequently flower the following autumn.

The fifth fort was fent me from La Vera Cruz, in New Spain, in the year 1730, by the late Dr. Houftoun. This hath a fhubby ftalk, which Yifes to the height of twelve or fourteen feet, fending out many branches, garnifhed with winged leaves, compofed of three pair of oval lobes, terminated by an odd one; thefe are indented at the top, and are of a light green. The flowers are of a bright yellow, and ftand two or three upon each foot-ftalk, and are fucceeded by compreffed winged pods near four inches long, which end in long points.

The fixth fort grows naturally at the Cape of Good Hope. This is an annual plant of little beauty, fo is rarely cultivated' but in botanic gardens for the fake of variety. It rifes with a (lender herbaceous ftalk about a foot and a half high, dividing upward into three or four branches, garnifhed with winged leaves, compofed of five or fix pair of very narrow lobes an inch long, which are a little hoary. The flowers are fmall, of a purplifh colour, Handing three together on (lender foot-ftalks, which are fucceeded by flat oval pods, each containing two or three kidney-flaped feeds. It flowers in July, and the feeds ripen in autumn, and the plant decays foon after.

The feeds of the feventh fort were fent me from the Cape of Good Hope, in 1753, which have fucceeded in the garden at Chelfea. This plant hath many (lender ligneous (talks, which trail on the ground, and

are divided into many smaller branches, garnished with winged leaves, composed of twelve or fourteen pair of small, narrow, oval lobes, terminated by an odd one; these, and also the stalks, are covered with a whitish down. The flowers are very small, of a purple colour, and stand upon very long (tender foot-stalks, each sustaining three or four flowers; these are succeeded by compressed pods little more than half an inch long, which are a little bent like a fiddle, each containing a single row of small kidney-shaped seeds. It flowers in June and July, and the seeds ripen in autumn. This is a perennial plant, which, if sheltered in the winter, will continue several years; but the branches do not extend more than a foot in length, and unless they are supported, always trail upon the ground.

The three first mentioned sorts are very hardy (shrubs, which thrive in the open air extremely well, so are generally propagated for sale in the nurseries-gardens; but the first sort hath been longer in England, so is more generally known and propagated than either of the other, which have* been but few years in the English gardens, nor has the third sort been long known in this country. This is not mentioned in any of the botanic books; but as the seeds ripen here very well, in a few years it may be in as great plenty as the first sort.

The three first sorts are propagated by sowing their seeds any time in the (spring, in a bed of common earth; and when the plants are come up, they must be kept clear from weeds; and the Michaelmas following they should be transplanted either into nursery rows, or in the places where they are designed to remain; for if they are let grow in the seed-bed too long, they are very subject to have downright tap-roots, which renders them unfit for transplantation; nor should these trees be suffered to remain too long in the nursery before they are transplanted, where they are to remain for the same reason.

The first sort will grow to the height of twelve or fifteen feet, so is very proper to intermix with trees of a middling growth in wilderness quarters; or in clumps of flowering trees, where the oddness of their flowers and pods will make a pretty variety, especially as these trees continue a long time in flower; for they usually begin flowering by the end of May, and from that time to September they are seldom destitute of flowers, but especially the second sort.

These shrubs make great hoots annually, which are frequently broken down by strong winds in the summer; so that if they are not (sheltered by other trees, their branches (should be supported, otherwise they will be broken and split off, whereby the trees will be rendered unfitly.

The third sort does not grow so tall as the common, but makes a more regular shrub and is less liable to split. The flowers of this sort are of a dusky red colour, spotted with yellow, so it makes a very pretty variety, and is as hardy as the common sort, therefore may be propagated by seeds in the same manner.

The fourth sort is tender, so will not live through the winters (when they are severe) in the open air in England; but in mild winters, if they are planted in a dry soil and a warm situation, they will thrive very well; and those plants which live abroad will flower much stronger, and make a finer appearance, than those which are preserved in the green-house; for these plants require a large (share of air, otherwise they are apt to draw up weak, so seldom produce their flowers in plenty; therefore when any of the plants are (sheltered in winter, they must be placed as near the window as possible, that they may have all the advantages of air; and in the spring they must be hardened, to bear the open air as soon as possible.

This sort is propagated by seeds as the former. If the seeds are sown early in the spring upon a warm border of light earth, the plants will flower in August; and, if the autumn proves favourable, they will sometimes ripen their seeds very well; but there are some persons who sow the seeds upon a moderate

hot-bed in the spring, whereby they bring their plants so forward as to flower in July, whereby the seeds are generally perfected from these plants. When the plants are transplanted, it should always be done while they are young, for they do not bear removing when they are large. This sort will sometimes live in the open air for three or four years; when they stand in a well (sheltered situation; and these will grow to have large heads, and make a very fine appearance when they are in flower; they will also continue much longer in beauty than those plants which are treated more tenderly.

The fifth sort grows naturally in warm countries, so is too tender to thrive in the open air in England. It is propagated by seeds, which must be sown on a hot-bed in the spring; and when the plants are two inches high, they should be each transplanted into a separate small pot filled with light earth, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken fresh root; after which they must be treated in the same way as other plants from the same climate, always keeping them in a stove, which should be of a moderate temperature of heat.

The sixth sort is a low annual plant, which seldom grows more than a foot and a half in height; the flowers being small, and having little beauty, it is seldom preserved but in botanic gardens. The seeds of this sort must be sown upon a moderate hot-bed in the spring, and the plants must be planted into small pots, and brought forward in another hot-bed. In July they will flower, when they may be exposed in the open air, in a warm situation, where the seeds will ripen in September, and the plants will soon after decay.

The seventh sort may be raised on a moderate hot-bed in the spring, and afterward exposed to the open air in summer; but in winter they must be (sheltered under a frame, otherwise the frost will destroy them.

COLLIFLOWER. See BRASSICA.

COLUTEA SCORPIOIDES. See EMERUS.

COMA AUREA. See CHRYSOCOMA.

COMARUPYL. Lin. Gen. Pl. Jant. 563. Pentaphylloides. Tourn. Inf. R. H. 298. Marj's Cinquefoil.

The CHARACTERS are,

The flower hath a large spreading empalement of one leaf, divided into ten parts at the top, which is coloured. It hath five oblong petals, which are inserted in the empalement, but are much smaller. It hath twenty or more permanent Stamina which are inserted into the empalement* terminated by moon-shaped summits. It hath a great number of small roundish germen colle Redintoa bead, having Joint Jingle styles arising from their sides, which are crowned by single stigmas. The common receptacle afterward becomes a large fleshy fruit, having many pointed seeds adhering to it.*

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, intitled Icosandria Polygynia, the flower having many stamens and a great number of styles.

We know but one SPECIES of this genus, viz.

COMARUM (*Palustre*). Fl. Lapp. 214. Pentaphylloides palustre rubrum. Inf. R. H. 298. *Red Marj's Bastard Cinquefoil* 5 and the *Quinquefolium palustre rubrum** C. B. P. 326. *Red Marj's Cinquefoil*.

There is another variety of this, which grows plentifully in Ireland, and also in several places in the north of England, from whence I have procured many of the plants, which after one year's growth in the garden, have been so like the common sort, as not to be distinguished from it; so that the different appearance which it has in the places where it grows naturally, may be supposed to arise from the soil and situation. This is by Dr. Plukenet titled *Pentaphyllum palustre rubrum, crassis & villosis foliis Suecicum & Hibernicum*- Aim. 284. *Red Marj's Cinquefoil of Sweden and Ireland, with thick and hairy leaves*.

This plant hath creeping woody roots, which send out many black fibres, penetrating deep into the ground, from which arise many herbaceous stalks about

two feet high, which generally incline to the ground; these are garnished at each joint with one winged leaf, composed of five, six, or seven lobes, which rise above each other, the middle being the largest, the lower diminishing, and with their base embrace the stalks; these are deeply fawed on their edges, smooth above, of a light green, and hoary on their under side. The flowers are produced at the top of the stalks, three or four together on short foot-stalks; these have a large spreading empalement, which is red on the upper side, and divided at the top into ten parts, in the center fits the five petals, which are red, and not more than a third part the size of the empalement; within these are situated many germen, attended by twenty or more stamens, terminated by dark summits. After the flower is past, the receptacle which fits in the bottom of the empalement, becomes a fleshy fruit, somewhat like a Strawberry, but flatter, including a great number of pointed seeds. It flowers in July, and the seeds ripen in autumn.

As these plants are natives of bogs, they are with difficulty preserved in gardens, for they must be planted in a soil as near to that of their natural growth as possible; they are very apt to spread much at the root, when in a proper situation: so whoever is inclinable to preserve these plants, may remove them from the places of their growth in October; and if they are planted on a bog, there will be no danger of the plants succeeding. There are a few of these plants now growing upon a bog at Hampstead, which were planted there some years ago; but the nearest place to London, where they grow wild in plenty, is in the meadows near Guilford in Surry.

COMMELINA. Lin. Gen. Plant. 58. Plum. Nov. Gen. 48. tab. 38. Zanonina. Plum. Nov. Gen. 38. tab. 38. This plant was so called by father Plumier, from Dr. Commeline, a famous professor of botany at Amsterdam.

The CHARACTERS are,

It hath a permanent spathe, which is large, heart-shaped, compressed, and shut together. The flower hath six concave petals three or four of which are small and oval, (these are frequently taken for the empalement) the other are large, roundish, and coloured. It hath three nectarines (which have been supposed to be stamens,) these have proper stamens, which sit horizontal, and are shaped like a cross. There are three awl-shaped stamens, which recline, and sit about those of the nectarium, which are terminated by oval summits. In the center is situated a roundish germen, supporting a twining style, crowned by a single stigma. The germen afterward becomes a naked globular capsule, with three furrows, having three cells, *each containing two angular seeds.*

This genus of plants is ranged in the first section of Linnaeus's third class, intitled Triandria Monogynia, the flower having three stamens and one style; to this genus he has joined the Zanonina of Plumier, which was separated by that author from Commelina, because the flower has three petals, and his Commelina but two, whereas the several species of this genus most of them differ in the number of their petals, some having two green, and four coloured petals, others are equal, and some have four green, and but two coloured petals.

The SPECIES are,

1. COMMELINA (*Communis*) corollis inaequalibus, foliis ovato-lanceolatis, acutis, caule procumbente, glabro. Hort. Upfal 18. *Commelina with unequal petals, oval, spear-shaped, pointed leaves, and a smooth trailing stalk.* Commelina procumbens annua, faponariae folio. Hort. Elth. 93. tab. 78.
2. COMMELINA (*Ereffa*) corollis* inaequalibus, foliis ovato-lanceolatis, caule erecto, scabro, simpliciflora. Hort. Upfal. 18. *Commelina with unequal petals, oval spear-shaped leaves, and a single, upright, rough stalk.* Commelina erecta, ampliore subcaeruleo flore. Hort. Elth. 94. tab. 78.
3. COMMELINA (*Africana*) corollis inaequalibus, foliis lanceolatis, glabris, obtusis, caule reptante. Lin. Sp.

Plant. 41. *Commelina with unequal petals, smooth, spear-shaped, obtuse leaves, and a creeping stalk.* Commelina procumbens, flore luteo. Prod. Leyd. 538.

4. COMMELINA (*Tuberosa*) corollis aequalibus foliis ovato-lanceolatis, subciliatis. Hort. Upfal. 18. *Commelina with equal petals, and oval spear-shaped leaves, which are hairy on their under side.* Commelina radice anacampferotidis. Hort. Elth. 94. tab. 79.

5. COMMELINA (*Zanonina*) corollis aequalibus, pedunculis incrassatis, foliis lanceolatis, vaginis laxis marginibus hirsutis bracteis geminis. Lin. Sp. Plant. 61. *Commelina with equal petals, thick foot-stalks to the flower, spear-shaped leaves, a loose hood, and double bractea.* Zanonina graminea perfoliata. Plum. Nov. Gen. 38.

There are some other species of this genus, but those which are here enumerated, are all that I have seen growing in the English gardens.

The first sort grows naturally in the islands in the West-Indies, and also in Africa, this is an annual plant, which hath several trailing stalks, that put out roots at the joints, which strike into the ground, at each joint is placed one oval spear-shaped leaf, ending in a point, embracing the stalk with its base, and hath several longitudinal veins: they are of a deep green, and smooth. The flowers come out from the bottom of the leaves, included in a spathe, which is compressed and shut up, each having two or three flowers, standing upon short foot-stalks, composed of two large blue petals, and four small green ones, which have generally been termed the empalement of the flower; within these are situated three nectariums, each having a slender stamen fixed on the side; these surround the germen, which afterward becomes a roundish capsule having three cells, in each of these is lodged two angular seeds. It flowers in June and July, and the seeds ripen in autumn. The plant was titled Ephemeron flore dipetalo, by some of the older writers on botany.

The second sort grows naturally in Pennsylvania, from whence I received the seed; this hath a perennial root, composed of many white fibres; the stalks rise a foot and a half high, are upright, rough, herbaceous, and about the size of quills; these have a single leaf at each joint, shaped like those of the first sort, and embrace the stalks with their base; the flowers come out from the bottom of the leaves at the upper part of the stalk, fitting upon short foot-stalks; they are of a pale bluish colour, and are succeeded by seeds as the first sort. This flowers about the same time with the first, but the seeds do not often ripen in England.

The third sort grows naturally in Africa; this hath a fibrous root, which sends out many trailing stalks three feet long, which send out roots at every joint, and from them many more shoots are produced; so that where the plants are in a proper degree of warmth, and have room to spread, they will cover a large surface of ground. The leaves of this sort are very like those of the first, but the flowers are larger and of a deep yellow colour; the petals of this are heart-shaped, and the seed-vessels are larger. This flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally near Old Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houftoun. This hath a thick fleshy root composed of several tubers, somewhat like those of Ranunculus, several joining together at the top, where they form a head, and diminish gradually downward; from this arise one or two inclining stalks, which send out side branches from their lower parts; these are garnished with oval spear-shaped leaves, part of which have long foot-stalks, the others embrace the stalks with their base; they have short hairs on their under side, and toward the stalk, but are smooth above, of a deep green colour, and close every evening, or in cold weather. The flowers are produced toward the upper part of the stalks, from the bottom of the leaves, standing upon slender foot-stalks; these are composed of three blue petals which are pretty

COM

pretty large and roundish, and three smaller which are green; the feeds are like those of the other forts. It flowers in June, July, and August, and the feeds ripen in autumn, *loan* after which the folks respectively, but the roots may be preferred two or three years; it they sic plant in a llove in winter.

The fifth fort grows naturally in the West-Indies; the feeds of this were lent me from the island of Barbuda. This fifth trailing (talks like the fifth, which are garnished with narrow grassy leaves, embracing the stalks with their bast, etc. etc. etc. Juice of the emerald stalks, upon thick foot-talks, three flowers generally fining on each. The flowers have three equal large petals of a sky Hue, and three (smaller) which are green. The flower in July and August, but have not perfected feeds in England.

All the forts are propagated by cuttings, (1st first will grow if Town in the full ground but if the feeds are low upon a warm border of light earth in autumn, like plants will rise early in the Spring; ^{from} *dw* feeds grow readily be expected, if the *l* proves favourable; whereas those which are often in the ground, are under their feet. These plants live but little beauty, in that two or three of each fort, is *JW* many as most of choice to have; their fore if the feeds are *hym* in autumn where the plant is designed to remain, or the feeds permitted to eat, the plants will require no father care, but to keep them clear from weeds. The second fort hath a perennial root, this fourth right feeds in England, but the roots find out often, *!* plant is easily propagated. But it is tender to live in the full ground in winter, unless it has a warm flickered *B* it should be planted in pots, and (helmed) common frame in winter, and *ae* abroad in summer, the best time to transplant and put these roots about the end of March.

The other forts are tender, for their feeds must be sown on a moderate hot-bed in the Spring, and when the plants are two inches high, they should be transplanted to a fresh hot-bed to bring the plants forward; when they have taken fresh root, they should have 3 large shares of fresh air admitted to them every day in warm weather, to prevent their growing weak; and in June these may be carefully taken up, and transplanted on a warm border of light earth, observing to shade them till they have taken fresh root, after which they will require no other care, but to keep them clean from weeds. With this management the plants will produce good feeds. The third and fourth forts may be continued, if they are planted in pots, and in autumn placed in the bark-hove; or if the roots of the fourth are taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the Spring, placing them on a hot-bed forward their freshening, and these will produce stronger plants than those which rise from feed.

COMMONS and COMMON-FIELDS. See L a m

COMPARTMENTS are beds, plats, borders, and walks, laid out according to the form of the ground, and ingenuity of the artist, and depend more on a good fancy than any rule. These are divided into knots, flower-gardens, or parterres, of which there are great variety, and may be diversified infinitely, according to the fancy of the designer. Plain compartments are pieces of ground divided into equal square and round beds, marked out by the line, of equal length and breadth. Some permit to these squares, borders of two feet in breadth, and not more, if the plot is small; but if they be leifimably crissed, three fire borders with borders with borders, or upright hardy Thyme, or some other aromatic herbs or flowers, for their like of the greater neatness. And in order to prefer the paths and alleys of compartments from, even, and durable, they lay them with a coat of sand or gravel, two or three inches

COM

thick, keeping them hoed and cleared; most often there they will be observed.

These compartments were much damaged by the Trench, «*these gardens were all laid out into several compartments, alleys, beds, etc. etc. the manner of an garden in buildings; but these that, unnatural g-jidierii ^K- now justly* exploded, and a much better taste has since prevailed in the English gardens.

COMPOSTS are formed of compost, or compofica, /af. com. *compost*, or coolpbltre, £*/. compound or mix; -itid in hulshnd/y and gardening they signify several (of folk or variety) mixed together, in order to make a mixture for afflicting the nature of the soil in the work of vegetation, by way of amendment or improvement.

Composts are various, and ought to be different, according to the different nature, or quality of the soils which they are designed to improve: some according to the nature of the soil, some heavy, some light, or cloddy. A tight loose land requires, a compost of a heavy nature, and the (coming of deep ditches, ponds, etc. etc.)

So on the other hand, a land that is heavy, or cloddy, requires a light soil of 3 more sprightly and fiery nature, that will infiltrate and loosen the clods, which if they were not thus managed, would very much obstruct the work of vegetation.

The best use of compost is in the garden; and some prefer manure or tubs in final beds or borders of flower-gardens; which are here mentioned, and shall treat of those composts or dressings, which are used in gardens and fields, under the name of Soma and MANURE.

All these plants do best in a rich light soil, and some in a poor sandy soil, and some in a heavy soil. The best use of compost is in the garden; and some prefer manure or tubs in final beds or borders of flower-gardens; which are here mentioned, and shall treat of those composts or dressings, which are used in gardens and fields, under the name of Soma and MANURE. All these plants do best in a rich light soil, and some in a poor sandy soil, and some in a heavy soil. The best use of compost is in the garden; and some prefer manure or tubs in final beds or borders of flower-gardens; which are here mentioned, and shall treat of those composts or dressings, which are used in gardens and fields, under the name of Soma and MANURE.

Almost every one who hath a garden on this subject, hath dirt-steeled the produce of the upper part of the earth from a pasture ground. This is the principal ingredient in most composts; and is certain) a very good one, provided it has been mellowed, and mixed up with a quantity of earth proper for the plants; therefore the compost will require more care, and should be mixed a considerable time longer before they are used; that they may have the advantage of heat, and meliorate and improve them, and should be frequently turned over, that the parts may be well mixed and incorporated, and the clods well broken and killed. Almost every one who hath a garden on this subject, hath dirt-steeled the produce of the upper part of the earth from a pasture ground. This is the principal ingredient in most composts; and is certain) a very good one, provided it has been mellowed, and mixed up with a quantity of earth proper for the plants; therefore the compost will require more care, and should be mixed a considerable time longer before they are used; that they may have the advantage of heat, and meliorate and improve them, and should be frequently turned over, that the parts may be well mixed and incorporated, and the clods well broken and killed.

fotfri dung, from old hot-beds i or for the plants Which delight in a cool foil, a quantity of rotten Heats dung is preferable. The proportion of this mull be according to the quality of the earth; for if that is poor j there should be one third part of dung, but if it be rich, a fourth part oriel's will be sufficient. These, when well incorporated and the parts divided, will require no other mixture, unless the earth is inclinable to bind, in which case it will be proper to add some sand or sea-coal ashes to it *, if sea-sand can be easily procured, that is the best, the next to that is drift-sand; but that from pits is by no means proper. The proportion of this must be according to the nature of the earth, for if that is stiff, there must be a greater proportion used, but this should not exceed a fifth part, unless it is very strong, in which case it will require more, and a longer time to lie, and must be often turned over before it is used.

The next compost, which is designed for plants which do not require so good earth, and naturally grow on loose soils, should be half of the before-mentioned earth from a pasture, or that from a kitchen-garden and if these are inclinable to bind; there should be a third part sand, and the other part rotten tan, which will be of great use to keep the parts divided, and let the moisture pass off.

The composition for most of the succulent plants, is prepared with the following materials; the earth from a common, where it is light, taken on the surface, one half, the other half sea or drift-sand, and old lime-rubbish screened of equal parts; these, well mixed and often turned over, I have found to answer better than any other compost, for most of the very succulent plants.

The other sort of compost, which is designed for plants that delight in a very loose, light, rich earth; should be made of light earth taken from a kitchen-garden, which has been well dunged, and thoroughly wrought, like those near London, one half * of rotten tanners bark one third, and the other part mud from the scouring of ditches, or from the bottoms of ponds, where the soil is fat: but this mud should lie exposed in small heaps a whole year, and often turned over before it is mixed with the other, and afterward frequently turned and mixed, for eight months or a year before it is used.

In all mixtures, where rotten wood may be required, if the rotten tanners bark, which is taken from old hot-beds is used* that will answer every purpose of the other; and wherever sand is necessary in any compost, the sea-sand should always be preferred to all other, as it abounds with more salts; but this should not be used fresh, because the salts should be exposed to the air, which will loosen the particles, and thereby render them better adapted for the nutriment of vegetables.

There are some who have directed the life of rotten leaves of vegetables, as an excellent ingredient in most composts -, but from many years experience, I can affirm, they are of little use, and contain the least quantity of vegetable pasture, of any dressing which is used. Others, who never have had any experience in the culture of plants, have directed different composts for almost every plant; and these composts consist of such a variety of ingredients, as greatly to resemble the prescriptions of a quack doctor; for no person who has been conversant in the business of gardening, could be guilty of such gross absurdities: for it is well known, that a few different composts will be sufficient for all the known plants in the World. But those who pretend to give direction for the culture of plants from theory only, begin at the wrong end, for the true knowledge of gardening or agriculture, must be from experience, and is not to be obtained in 9 garret.

The several sorts of dressing for land, will be particularly treated under their respective titles, and in general they will be mentioned under the article of DONG and MANURE.

In making of any compost, great care should be had,

that the several parts are properly mixed together, and not to have too much of any one sort thrown together; therefore, when three or four several sorts are to be mixed together, there should be a man or two placed to each sort, in proportion to the quantity of each; for if two parts of any one sort are requisite to be added, there should be two men put to that, and but one to each of the other: and these men must be careful to spread each sort in such a manner over each other, as that they may be exactly mixed together. Another thing which should be observed is, never to lay these composts in too large heaps, but rather continue them in length, laying them up in a ridge, so that the sun and air may more easily penetrate through it: and, as these composts should (if possible) be made a year before they are used, that they may enjoy a summer's sun, and winter's frost, they should be frequently turned over, which will prevent the growth of weeds, and expose every part of the heaps equally to the sun and air, which is of great advantage to all sorts of composts; for the more they are exposed to the influences of these, the better will the earth be prepared for vegetation, which is evinced by the fallowing of land, which, when rightly managed, is equivalent to a dressing.

COMPOUND FLOWERS are such as consist of many florets, or semiflorets, or both together, which are included in one common empaleme;ic, fo make up what is commonly called one whole flower.

CONE. A cone is a hard, dry, feed-vegetal of a conical figure, consisting of several woody parts; and is, for the most part scaly, adhering closely together, and separating when ripe.

CONIFEROUS-TREES are such as bear cones; as, the Cedar of Lebanon, Fir, Pine, &c.

CONIUM. Lin. Gen. Plant. 299. Cicuta. Tounu Inf. R. H. 306. tab. 160. Hemlock.

The CHARACTERS are,

// is an umbelliferous plant-, the general umbel is composed of several small ones termed rays, which spread open, the rays or small umbels are also spread in the like manner. Both these have involucrems* composed of many brittle leaves. The petals of the greater umbel are uniform; each flower is composed of five unequal heart-shaped petals* which turn inward; they have five stamina* which are terminated by roundish funnits. The germen* which is situated under the flower* supports two reflexed styles* crowned by obtuse stigmas. the germen afterward becomes a roundish channelled fruit* divided into two parts* containing two seeds* which are convex and furrowed on one side* and plain on the other.

This genus of plants is ranged in the second section of Linnseus's fifth class, intitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. CONIUM (*Maculatum*) feminibus striatis. Hort. Cliffi 92. *Conium with striated feeds*. Cicuta major. C. B. P. 160. *Greater Hemlock*.
2. CONIUM (*Tenuifolium*) feminibus striatis, foliis tenuioribus. *Conium with striated feeds and narrower leaves*. Cicuta major, foliis tenuioribus. C. B. P. 160, *Greater Hemlock with narrower leaves*.
3. CONIUM (*Africanum*) feminibus aculeatis. Hort. Cliffi 92. *Hemlock with prickly feeds*. *Caucalis Africana, folio minore*, Rutse. Boerh. Ind. alt. Sp. 63.

The first sort grows naturally on the side of banks and roads in many parts of England -, this is a biennial plant, which perishes after it hath ripened feeds. It hath a long taper root like a Parsnep, but much smaller. The stalk is smooth, spotted with purple, and rises from four, to upwards of six feet high, branching out toward the top into several smaller stalks, garnished with decomposed leaves, whose lobes are cut at the top into three parts * these are of a lucid green, and have a disagreeable smell. The stalks are terminated by umbels of white flowers, each being composed of about ten rays (or small umbels) and have a great number of flowers, which spread open, each fitting upon a distinct foot-stalk ; the feeds are small and channelled, and like those of Anifed.

Aniferd. It flowers in June, and ihe feeds ripen in autumn. The incoatl fort differs from the firll, in having talk (talks, which arc not lb much Ipotted. Tht leave are much narrower, and ot' a paler green i and thidifference is confuit, for I have-cultivated it nca twenty years in the Chelfea garden, whtre it has no varied. The feeds were I at me from Germany where it grows naturally. Tliis is biennial as the former.

The third for: grows naturally near the C.ipe of Gox Hope, in Africa, from whence the feeds were farre the pbnc have been | preserved in some of their curious gardens of I Iams. Th feeds of this plant v/crufcu me by the lite Br. Boerhuave profeffjr ol" itowR at Leyten. This plant rarely grows more than nine inches high, tht lower leaves are divided fomewhaiiikedtoeof i he small wild Rue, and are of iigrayilh, colour; thoic i much narrower, but of die fame colour j theft arc trrmiiated by umbels of white flowers, each of th larger umbels being conipottt) ot" [bra: Itmdl UHCS the involucre hah three nart under the umbel. This (lowers in July and ripens in autumn, foiv ifcet which die plaa decay.

The first fort growi naturally in great plenty in the we Ji near Wobura, in Bedford!! markcu in London are generally : quid with tin. llowen. It is also cultivated in gj; linc for the fwceinels of the (loner), and formerly it gnay in great plenty on Hampdend^heath, but 01 late years it has been feldomfound there; fur lint, all the trees have Ixen dePiroycTj, the plants have n/- flowered there in formerly, nor have the roots increafed.

This hadi A slender fibrous roor, which L the iirUcc of the ground, and til creby propagates in great lenty. The leavei come 1 up by pairs; thefe are ;aikE, which are about three vrr; \ ed together in one cov*, andstlht 1 into two parts, each fuftaining a fnfjc leaf, • one of which riles a little above du other • the leaf vet iiv i fotir to 5vc iivihes long, and 1 near an inch, and a hilt' broad in the middle, lowering gradually to •: endsj tlicy h»v many longitudinal veat, running parallel

parallel to the midrib, which is not situated exactly in the middle, but diverges to one side; the footstalks of the flowers arise immediately from the root, on one side the leaves; these are naked, about five inches long, adorned toward their upper parts with pendulous white flowers, ranged on one side the stalk, which decline to one side; each flower stands upon a short separate foot-stalk, which are bending and crooked. The flowers are of the finest bell-shaped kind, their brims being reflexed, which are (lightly cut into six parts; they have six stamens, which are inserted in the petal of the flower, and are shorter than the tube, and a single style arising from the germen, which is triangular, crowned by a three-cornered stigma; the germen afterward becomes a globular berry, of a red colour when ripe, inclosing three roundish seeds. It flowers in May, from whence it has been titled May Lily. The seeds ripen in autumn. The flowers of this sort are used in medicine, they are esteemed cephalic and cordial, so are recommended for palsies, epilepsies, and spasms; there is prepared a conserve, and a compound distilled water of the flowers. This compound water is by the Germans titled *aqua aurea*, or *golden water*, because of its excellent virtues.

There is another variety of this mentioned with narrow leaves, which I suppose may arise from the soil, or situation, for the roots which I have taken up in places where they have naturally narrow leaves, when planted in the garden, have produced leaves as broad as the common sort; but the sort with red flowers has constantly continued the same above forty years, without any variation. The flowers of this are smaller, the stalks are redder, and the leaves of a darker green than those of the common sort; but as I have not propagated this sort by seeds, I cannot be sure if it is a distinct species, or only a femal variety.

The second sort I received from the Alps, where it naturally grows; this has retained its difference in the garden, where it grew in the same soil and situation with the common sort, so I make no doubt of its being a distinct species. The other with a double variegated flower is supposed to be only a variety of this, therefore I have not enumerated it as a different sort, but the flowers are much larger, and beautifully variegated with purple and white. I received a plant of this sort from the royal garden at Paris, which has flowered several years in the Chelsea garden, but the roots do not increase so much as the common sort.

These plants require a loose sandy soil, and a shady situation; they are propagated by parting of their roots, which multiply in great plenty. The best time to transplant and part the roots, is in autumn. They should be planted near a foot asunder, that their roots may have room to spread, for if they agree with the soil and situation, they will meet and fill the ground in one year. If these roots are planted in a rich soil, they will spread and multiply greatly, but will not be so productive of flowers.

The only culture which these plants require, is to keep them clean from weeds, and to transplant and separate the roots every third or fourth year, otherwise they will be so greatly matted together, as not to have proper nourishment, so the flowers will be small, and few in number.

The third sort is a native of the Alps and Appennines; the stalks of this (when growing in good ground) generally rise three feet high; they are taper, and garnished with oblong oval leaves placed alternate, embracing the stalks with their base; they have several longitudinal veins, resembling the leaves of white Hellebore: the foot-stalks of the flowers are produced from the wings of the leaves, which support four or five flowers on each; these flowers are larger than those of the common sort, but their tubes are more contracted, and are succeeded by pretty large berries, which when ripe turn of a bluish colour; it flowers in May and June, and the seeds ripen in autumn.

The fourth sort is the broad-leaved Solomon's Seal,

which is said to grow naturally in England, but I doubt ours is different from that mentioned by Caspar Bauhin under that title; for in two places where I have found it growing, the stalks were much shorter, the leaves were broader, and their borders turned inward, and this difference continues in the garden where it grows in the same soil and situation with the common sort.

The fifth sort is the common Solomon's Seal; this hath a fleshy white root, as large as a man's finger, which multiplies in the ground, and is full of knots, from whence it had the name of Polygonatum, or many knees. In the spring arise several taper stalks, which grow near two feet high, adorned with oblong oval leaves, placed alternate, having many longitudinal veins running parallel to the middle, and embrace the stalk with their base; these are ranged on one side of the stalk, and on the opposite side come out the foot-stalks of the flowers, which are about an inch long, dividing at the top into three or four smaller, each sustaining a single tubulous flower, cut into six parts at the brim, where it is green, the lower part of the tube being white, they have each six stamens, surrounding a single style, which arises from the germen, and is crowned by a blunt stigma; the germen afterward becomes a round berry, about the size of Ivy berries, each inclosing three seeds. This flowers in May, and the seeds ripen in autumn, and then the stalks decay.

The sixth sort rises with an upright stalk about two feet high, garnished with long narrow leaves, which stand in whorls round the stalk; there are generally five of these placed at each joint, which are four inches long, and half an inch broad, smooth, and of a light green. The flowers come out from the same joints, standing upon short foot-stalks, each supporting five or six flowers, which are smaller, and have much shorter tubes than either of the former sorts; they are of a dirty white, tipped with green, and (lightly cut into six parts at the top. It grows naturally in the northern parts of Europe.

The seventh sort grows naturally in most parts of North America; I have received plants of this from New England, Philadelphia, and several other places. This rises with an upright stalk near two feet high, garnished with oblong leaves, ending in sharp points; they are near five inches long, and two and a half broad, having three large longitudinal veins, with several smaller between, which join at both ends. The leaves are alternate, standing close to the stalks, and are of a light green on their upper side, but are paler on their under. The flowers are produced in branching spikes at the extremity of the stalks, each being composed of several small loose spikes of star-like flowers, of a pale yellow, which fall away without producing any seed. This flowers the latter end of May, or the beginning of June, and the stalks decay in autumn; but the root is perennial, and propagates by offsets.

The eighth sort is a native of the same countries as the last mentioned; this sends up stalks two feet high, garnished with many oblong leaves embracing the stalks with their base. The flowers are produced in single spikes at the top of the stalks, which are in shape and colour like those of the seventh; but these are succeeded by small red berries, about the size of those of the Lily of the Valley. This sort flowers the beginning of June, and the berries ripen in autumn.

All the sorts of Solomon's Seal are very hardy plants, they delight in a light soil and a shady situation, so are very proper to plant in wildernesses under tall trees, where if they are not crowded by lower shrubs, they will thrive and multiply exceedingly; and during the summer season will make an agreeable variety, the whole appearance of the plants being very singular.

They all multiply very fast by their creeping roots, especially when they are planted in a proper soil and situation. The best time to transplant and part the roots

roots is in autumn, fonn nfte: their stalks decay j those which art removed it that fealbn, wiilgtOW niucli frorger than thole which are planted in [fie Ipring, which is (he reifon of my preferring that feafon ; hut they- may be lately transplanted anv time a tier the filks decay, til) die roots begin to Jhoot in (he faring. As thfle roota areas: increafe, they fliouli) be planted ac a wide d... I each other, that the) may have room to fprcatl j for they ihould not be removed oftener than every third or fourth year, where they are expected to I to £ i w (Inina, and produce agootl number of (talks, in which their beauty confite. The only culture theft plants require, is la d g ound between them every Ipring, and keep them Inn from weeds.

The roots of the fifth fort are ufed in metticiw, and are greatly recommended for their efficacy in nil manner of contufons. The dffWed w«er of the plant clean the uee and beautifies the comulevion: a de-coft ion of it cures thic itch, anJ (uth like cutaneous aitempers.

The first sort is a very tommofi upon drj banks, and
in gravelly ground. . . . that parts of England, and
is generally a sign of gravel lying under the
surface. The roots of this weed very deep into to (he
gran, . . . from whence (bme cauntry people call it
Devils lumps.
I Vom the root arfei many <cak (talks, which trail

on the ground, and fulfil themselves about the rely-
bouring plants; these are furnished with triangular
arrow-pointed leaves. The flowers are produced
from the side of the branches, bearing long foot-
stalks, each sustaining a single flower, which is some-
times white, at other times red, and frequently is va-
riegated. This is a troublesome weed in gardens, so
should be constantly rooted out.
The second sort is also a troublesome weed in gar-
dens, when the roots are intermixed with those of
trees and shrubs, or under hedges, where the plants
cannot be easily destroyed; but in an open clear spot
of ground, where the plants are carefully hoed down
for three or four months, they may be effectually de-
stroyed; for when the stalks are cut, a
milky juice flows out, and this juice the more it
exhults and decays. The roots of this sort are petty,
and are white. The
stalks rise in bunches, twisting themselves
about trees or hedges, and are furnished with large
arrow-pointed leaves, which are torn at their base.
The flowers come out from the side of the branches
upon long foot-stalks, each sustaining one large white
flower, which are succeeded by roundish seed-vessels,
having three cells filled with seeds, which are convex
on one side and plain on the other. The flowers in
[tine, and the seeds ripen in autumn, soon after
when the stalks decay to the root; but as every small
piece of the root will grow, it renders this a trouble-
some weed to destroy.
The third sort grows roundly in Syria, where the
roots of the plants are wounded, and the
juice which receives the milky juice which
flows out, which is insipid, and afterward put up
and preserved in the manner in the
shops; it is a very juicy plant, and will thrive very
well in the open air in England, provided it is on a
dry soil. The roots of this weed, run deep into
the ground, and are covered with a dark bark. The
branches extend themselves on every side to the dis-
tance of four or five feet, they are slender, and trail
on the ground, if they are not supported, and are
furnished with narrow spear-shaped leaves. The
flowers are of a purple color, and come out from the
axils of the leaves, two sitting upon each long foot-
stalk, which are succeeded by roundish seed-vessels,
having three cells, filled with seeds shaped like those
of the former sort, but smaller. It flowers in June
and July, and the seeds ripen in autumn. If the
seeds of this sort are sown in the spring, in a border
of light earth, the plants will come up, and require
no other culture but to keep them clear from weeds,
and thin the plants where they grow too close, for
as the branches extend pretty far, the plants should
not be nearer than three feet asunder. The stalks
decay in autumn, but the roots will abide many
years.
The fourth sort is an annual plant, which grows
naturally in Asia and America, but has been long
cultivated for ornament in the English gardens, and
is generally known by the title of *Convolutus major*.
Of this there are three or four lasting varieties, the
most common hath a purple flower; but there is one
with a white, another with a red, and one with a
whitish blue flower, which with white seeds. All
these varieties I have cultivated many years, without
observing either of them change. If the seeds of
these sorts are sown in the spring, upon a
border where the plants are designed to remain, they will
continue to grow, but in open culture but to keep them clear from
weeds, and place some tall stakes down by them, for
their stalks to twist about, otherwise they will spread
on the ground, and make a bad appearance. These
plants, if they are properly supported, will continue to
grow to five or six feet high, they flower in June, July, and
August, and will continue till the frost kills them.
Their seeds ripen in autumn.
The fifth sort grows naturally in Jamaica, from
whence the late Dr. Huxham sent me the seeds; this
sort grows in bunches, which twist about the
ground,

ecs, and rile to a great height i the ICJUTS are fmooth, heart-shaped, . . .Jing in long points, and tl v ears at the base ire largei, ii-uuin^ Upon fig (lender foot-flalks. The . . . ufnihfirt is thai whole roora arc eaten, and U gene rail > titld Spanih Pontoe s thrfe (ouo arc annually imported from Spain and Portugal, where they ir/- greatly ouUivated for the table, but they are too lender to thrive well :n the open air in Eng- lajtd; they ire cultivated by the roow in die lame way is the common Potatoti but require much more rooai; fat uut many trail ing .(talks, which

extend four or fn fcei every waj-, and at their joints ferul out roots, which, in warm countries, grow to be large tubers, ta th« from a iingle root planted, funy or fifty large roou arc produced. TI. is ibmctimes piop^jated by vnty of Ckffiofiy ia but the roois fhould be planted on s hot-bril in the tpring-, anl ii" the plants arc kept covered in bi weather with glafk's they will prodmn flowers, j>alDy jmall roots vyll be productti fr^ni the joints ; but if they are expoled to the open air, they i Fiwke much progreei. The eighth fort grows DniraQji it La Vera Cruz in pain, from whence the feeds were itnt me by the late Dr. Houftoin. This riles with a ltrong wir-ling talk to the height of iwimy feet, dividing into Jeveral fmaller, whih i'siten tfaemfetvea nbout tiny of he ntighbourmg trees andihrubs-. thde arc gar- dled with Uavei in fliajn: of a hand, having Jeven . . . , which are fjicar-ftuped, and deeply cut on . . . ine in ftiwji pointj. The Doncn arc fingle or. (KV foot-flalk, whitli ire very lojig, . . . [npalment of the Dover is l'рге, l'pmding open, atid is dividixi deeply into five : . . ff in each of thde is lodged a fingle feek. This plane is ten-. er, fo the feeds ihould be fown on a hot bed in the fpring; and when the plants are fit . . . > remove, they muft be tranfplanted each into a le- parate pot filled with light earth, and plunged into a moderate hot-bed, obferving to fhade them from the fun till they have taken new roots; then they ihould have a large floue of air admitted to them every day, to prevent their drawing weak, and alfo ihould have moderate waterings thre or four times a week. When the plants are grown too tall to remain in the hot-bed, they muft be fhifted into larger pots, and placed in the bark-houfe, where, if they are allowed room, they will rife to a great height, and produce flowers, but it rarely produces feeds in England.

The both fort is an annual plant. The feeds of this were lent me from Cam igni in Hew Spam, where the plant grows naturally. This riles with a twining stalk ten feet high, which is garnifhed with arrow-pointed leaves, white ears at the base are round The flowers are produced in small clusters, ftanding upon long foot-ftalks are Vclioy, and are fucceeded by three-cornered feed-vellids, having three cells, in each of thde are lodged two feeds. I im |Ltn. is annual, and too tender to thrive in the open air in England; fo the feeds ihould be in on a hot-bed in the fpring, and the plants may be aft- ward treated in the lame way as the eighth fort, with which nian.igaa i they will flower and produce ripe feeds. The feeds of the ninth fort were lent me from [J- maica by the late I)r. H utton, who foui id the plants growing naturally there in great plenty. This is an annual plant, riling witii [lender, fliff, twining l stalks, eight or nine feet high, g.iniihlrt! with heart-shaped jiavo. which -downy. The flowm ftaml mdiiv ng foot-O-ilk their are purple, and are fucceeded by roundifh feed-vellids, with three cells, contain nij fevtni Inwil Imls. This fort requires the fame treatment as the eighth, being KM raider Ed tlriv- air. The eleventh fort was few roc (TO the ifland of Barbuda. This is an annual plant, which riles with twining stalks four or eight feet high, garnifhed with oblong, oval, fmooth leaves. The flowers come out at every joint on a flender long-foot l.Ulu, each fupporting a large purple flower, whole round- meat 13 cut to the bottom, in two parts. The lead* and cipj'ule M like the Ic < the other fp- This is a tender plant, ftanding in the fame way as the eighth fort. JC tiered in the fame manner. The twelfth fort grows naturally in Cathagena in New Spain, ijQm wirtice l received the feed^ This is a tender plant, with ribs with ftiong winder stalks to the height of twelve or fourteen feet, and are garnifhed with leaves, divid- i into live , ftanding upon fhort foot-ftalks; the flowers ftand upon long foot-ftalks, each fustaining two purple flowers. I ix lial'M, Ic of a l light brown colour. This fort is tender, fo muft be treated in the fame way as the eighth. The thirteenth fort grows naturally about Teda in New Spixii. M r H : This hath a liguous stalk covered *ith a purpk-bjrk, H each twines about the tr<3, ami rif< to the l of thirty feet or tnwr, ami is ^arnitheii with lejevci, whi^ are deeply dididrii intti five flnarp j pointed lobes. The flowers (bnd u)>n long iiavr r. luier in tile middle ; (he) are VL:V Urge, and of a purple cotoyf; chcfte ate fucceeded by round feed-vellids, as large 15 anmMliii | Apple, divided into three cells, etefa containing I a very large fmooth feek. Tl) < plant is too tender to thrive ii the ojer air in England. lo muift be inited, in the fann too tall for rJw I here. I have had thde plants upward of twenty feet high, which have put out many fide branches, extending fo wide on every fide, as to cover moft of the neighbouring plants, fo that I was obliged to remove them into a cooler ftuation, where they would not thrive. The fourteenth fort grows naturally on the fra shores in moft of the iflands in the Weft-Indies, where the stalks trail on the ground, which are garnifhed with oval leaves, rounded at the top. The flowers are large, of a purple colour, and are produced by three, or very long foot-ftalks; thde are fucceeded by large oval feed-vellids, with three cells, each containing a fingle feek. This hath a perennial stalk, which trails on the ground, and fpreads to a great diftance, but is too tender to thrive in the open air in England, fo muft be treated in the fame manner as the eighth fort.

and may be continued two or three years in a stove; but it is apt to spread too far for a small stove, so that where there is not great room, it is not worthy of culture.

The fifteenth sort grows naturally in Jamaica; this rises with (lender twining stalks eight or ten feet high; the leaves of these are (haped a little like those of the common great white Convolvulus, but the foot-stalks, which are pretty long, do each sustain many purple flowers, growing in bunches. The seed-vessels of this sort are three-cornered, and have three cells, each containing a single seed. This is an annual plant, which requires a hot-bed to raise it, and must be kept in a glass-case or a stove, otherwise the seeds will not ripen here.

The sixteenth sort has been long preserved in several curious gardens in England. It grows naturally in the Canary Islands; this hath a strong fibrous root, from which arise several twining woody stalks, dividing into many smaller ones, these, where they have support, will grow more than twenty feet high, and are garnished with oblong heart-shaped leaves, which are soft and hairy. The flowers are produced from the wings of the leaves, several (landing upon one foot-stalk; these are for the most part of a pale blue, but there is a variety of it with white flowers. This plant flowers in June, July, and August, and sometimes ripens seeds here, but as the plants are easily propagated by layers, and also from cuttings, the seeds are not so much regarded; nor indeed will those plants which are raised by layers or cuttings produce seeds, though those which come from seeds seldom fail. As the leaves of this plant continue green all the year, the plants make a pretty variety in winter in the green-house, for it will not live abroad in winter in this country, though it only requires the same protection as Myrtles, and other hardy green-house plants. It may be propagated by laying down the young shoots in the spring, which generally put out roots in three or four months; then they may be taken from the old plants, and each planted in a separate pot filled with light earth, and placed in the shade till they have taken new root; after which they may be placed with other hardy green-house plants till autumn, when they should be removed into the green-house, and afterward treated in the same way as Myrtles, and other green-house plants. If the tender cuttings of this are planted during any of the summer months, in pots filled with light earth, and plunged into a moderate hot-bed, shading them from the sun, they will take root, and afterward should be treated as the layers.

The seventeenth sort is an annual plant; the seeds of it were sent me from Jamaica, where it grows naturally. This rises with a very (lender twining stalk four or five feet high, garnished with triangular leaves, which are pointed. The flowers grow in dufters, fitting close to the stalks, which are blue, and are succeeded by seeds like those of the fourth sort. This sort will not ripen seeds in England, unless the plants are brought forward on a hot-bed in the spring, and afterward* placed in a glass-case, where they may be defended from cold.

The eighteenth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houtton. This is one of the most beautiful kinds, the flowers being very large, and of a fine Rose colour. It rises with a winding stalk seven or eight feet high, which is garnished with heart-shaped leaves, ending in long (harp points; fitting upon very long foot-stalks. The flowers also have long foot-stalks, each supporting two flowers, whose empalement is divided deeply into five parts, the seeds of this are large, and covered with a fine down. This is an annual plant, which is too tender to thrive in the open air in this country, so the seeds (should be sown on a hot-bed in the spring, and the plants afterward treated in the same manner as is directed for the eighth sort.

The nineteenth sort grows naturally near the sea at Campeachy, from whence I received the seeds. This

hath strong, smooth, winding (stalks, which send out roots at their joints, and are garnished with arrow-pointed leaves, whose ears or lobes are obtuse; the flowers are large, of a sulphur colour, and fit upon very long foot-stalks, which proceed from the side of the stalks, each supporting one flower, with a large swelling empalement, these are succeeded by large, smooth, oval capsules, having three cells, each including one large smooth seed* This is a perennial plant, whose stalks extend to a great distance, and put out roots at the joints, whereby it propagates in plenty; but it is too tender to thrive in England* unless it is preserved in a warm stove, where it requires more room than can well be allowed to one plant. It must be treated in the same manner as the eighth sort.

The twentieth sort grows naturally in Africa, from whence the seeds were sent to the royal garden at Paris, and from thence I received it in 1730. This rises with a (lender winding stalk five or six feet high, garnished with heart-shaped arrow-pointed leaves; the flowers stand on long (lender foot-stalks 5 these are white, with purple bottoms. This sort may be treated in the same manner as the common great Convolvulus.

The twenty-first sort grows naturally in Spain and Italy. This is an annual plant, which rises about two feet high, with (lender twining stalks, garnished with oval leaves. The flowers are small, and of a bluish colour, each foot-stalk supporting one flower of little beauty, so is not often cultivated in gardens. If the seeds of this sort are permitted to scatter, the plants will rise in the spring, and require no other culture but to keep them clean from weeds, or if the seeds are sown in the spring, where the plants are to remain, they will flower in June, and the seeds will ripen in August.

The twenty-second sort grows naturally in Sicily, and also in the islands of the Archipelago. This hath a perennial root, which sends but many (lender (stiff stalks, twisting themselves round the neighbouring plants, and rise five or six feet high; these are garnished with leaves, which are divided into five or seven narrow lobes, and are of a soft texture, like latten, (landing on short foot-stalks. The flowers are produced from the side of the stalks upon long foot-stalks, which sustain two flowers of a pale Rose colour, with five (triples of a deeper red. This sort creeps at the root, so seldom produces seeds in England, but is propagated by shoots taken from the old plants. The best time for parting and transplanting these plants, is about the beginning of May, when they may be taken out of the green-house, and exposed in the open air; but the young plants which are separated from the old ones, should be placed under a frame, and (shaded from the sun till they have taken new root; after which they must be gradually hardened to bear the open air, to which they must be exposed all the summer; but in autumn they must be placed in the green-house, and may be treated in the same way as the Canary Convolvulus before-mentioned.

The twenty-third sort hath some appearance of the twenty-second, and hath been supposed to be the same species by some writers; but I have cultivated both many years, and never have found either of them alter, so that I make no doubt of their being distinct plants. This sort hath a perennial root like the former, which sends out many weak twining stalks, rising about three feet high, twisting about the plants which stand near it, or about each other, and if they have no other support, fall to the ground; these are garnished with leaves of different forms, some are (haped almost like those of Betony, being (lightly cut on their edges, others are almost heart-shaped, and are deeply cut on the sides, and some are cut to the midrib; they have a (hining appearance like latten, and are soft to the touch, (landing on (short foot-stalks. The flowers are produced on the opposite side from the leaves, having very long foot-stalks, each sustaining two flowers of a pale Rose colour, very like those

of the former species. It flowers in June, July, and August, but rarely ripens seeds in England. It has a perennial root, which feeds our cabbages, by which it is propagated in England, in the same manner as the last mentioned, and the plants must be treated in the same way.

The twenty-fourth sort grows naturally in Portugal, but hath been long cultivated in the flower-gardens in England for ornament; this is usually titled *Cerise de la Chine*, by the fondness and goodness. It is an annual plant, which hath several thick, herbaceous stalks, growing about two feet long, which do not arise from the other roots, but decline toward the ground, upon which many of the lower branches lie prostrate; these are furnished with spear-shaped leaves, which in close to the branches; the flower-stalks of the bottom come out just above the leaves in the June month, and on the same side of the stalks; these are about two inches long, each sustaining one large open bell-shaped flower, which in some is of a fine blue colour, with a white bottom; in others they are pure white, and some are beautifully variegated with both colours. The white flowers are succeeded by white seeds, and the blue by dark-coloured seeds, and this difference is partly constant in both; but those plants with variegated flowers, have frequently plain flowers of both colours intermixed with the striped; therefore, the only method to continue the variegation, is to pull off all the plain flowers when they appear, never suffering any of them to remain for seed.

The last is propagated by seeds, which should be sown on the borders of the flower-garden when they are delighted to remain. The usual method is to put two or three seeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the seeds all grow, there will be sufficient; the others should be drawn out carefully, so as not to disturb the roots of those which are left; after which they will require no other culture, but to keep them clean from weeds. If the seeds are sown in autumn, the plants will flower in May; but those which are sown in the spring, will not flower till about the middle of June, and will continue flowering till the frost stops them. 1 ht feeds much in August and September. 1 ibIT.

The twenty-fifth sort grows naturally in Italy and Sicily. This hath a perennial root, which runs deep in the ground, from which three or four upright branching stalks near two or three feet high, furnished with narrow leaves about two inches long, which rise to the top of the stalks; these are furnished with narrow pointed leaves, rising close to the stalks, which are hoary. The flowers come out singly on the side of the stalks, being very close to them, having scarcely any foot-stalks; these are of a very pale blue colour, and spread round about to the bottom. It flowers in June and July, but rarely produces any seeds in England. This sort is propagated in the same manner as the twenty-fourth, and the plants require the same treatment. This plant must have a dry soil and a warm situation, otherwise it will not live through the winter in the open air in England. As the stalks of this sort decay in autumn, so at the surface of the ground about their roots is covered with some old rottens bark, it will preserve them in the hardest frosts. The twenty-sixth sort is also in vogue. This is called *Salsola*, and *Salicaria*; it grows naturally on the sea-beaches in many parts of England, but cannot be long preserved in gardens. This hath many small, white, stringy roots, which spread wide, and send out several weak trailing branches, which twine about the neighbouring plants like the common nightshade, and are furnished with kidney-shaped leaves about the size of those of the lesser Celadine, standing upon long foot-stalks, and are placed in clusters of three or four together. The flowers are produced on the side of the branches in each joint. These are shaped like those of the first sort, and are of a reddish purple colour; they appear in July, and are succeeded by round capsules, having three cells, each containing one black seed, every part of the plant abounding with a milky juice. This is esteemed a good medicine to purge off watry humours, and is given in drops. The twenty-seventh sort grows naturally in the island of Crete. This is a perennial plant, having thick fleshy roots, which spread far in the ground, and shaded with a milky juice, which rises two or three inches above the surface, and from thence sends a reddest substance, which is equal to the last sort. From the root several thick woody bearing branches

are produced on the side, and at the top of the stalks, in small clusters, sitting close together, these are much smaller than those of the former sort, but are of a deeper Rose colour; this seldom produces seeds in England, but the roots propagate in plenty. It thrives in a light dry soil, and requires no other care but to keep the plants clean from weeds; it may be transplanted either in the spring or autumn. This is by some supposed to be the same as the last mentioned sort, but whoever has cultivated them, can have no doubt of their being different species.

The twenty-eighth sort grows naturally in Italy, Sicily, and the island of the Archipelago. It rises with straight woody stalks about three feet high, chiefly furnished with blunt, spear-shaped, fleshy leaves, which are placed on every side of the stalks; they are near two inches long, and a quarter broad, standing at their ends. The flowers are produced in clusters at the top of the stalks, being very close; they are of a pale Rose colour, and come out in June and July, but do not perfect seeds in England. This plant will live in the open air in mild winters, if it is planted in a light soil and a warm situation, but in hard winters it is destroyed; therefore some of the plants should be kept in pots, and sheltered under a common frame in winter, when it may enjoy the fire as in mild weather, and be provided with the frost, and in summer placed abroad with other hardy exotic plants, where as the fleshy leaves will make a pretty appearance; it may be propagated by laying down the branches, and also by cuttings, but both very seldom put out roots the same year, and many of them will not; in that the best way is to procure the seeds from Italy, for those plants which come from seeds, grow much larger than those which are propagated the other way.

The twenty-ninth sort grows naturally in Cambric, and several of the islands in the Archipelago. This hath a perennial root, which sends up several erect branching stalks about two feet high, which are furnished with very narrow pointed leaves, rising close to the stalks, which are hoary. The flowers come out singly on the side of the stalks, being very close to them, having scarcely any foot-stalks; these are of a very pale blue colour, and spread round about to the bottom. It flowers in June and July, but rarely produces any seeds in England.

This sort is propagated in the same manner as the twenty-fifth, and the plants require the same treatment. This plant must have a dry soil and a warm situation, otherwise it will not live through the winter in the open air in England. As the stalks of this sort decay in autumn, so at the surface of the ground about their roots is covered with some old rottens bark, it will preserve them in the hardest frosts.

The twenty-tenth sort is also in vogue. This is called *Salsola*, and *Salicaria*; it grows naturally on the sea-beaches in many parts of England, but cannot be long preserved in gardens. This hath many small, white, stringy roots, which spread wide, and send out several weak trailing branches, which twine about the neighbouring plants like the common nightshade, and are furnished with kidney-shaped leaves about the size of those of the lesser Celadine, standing upon long foot-stalks, and are placed in clusters of three or four together. The flowers are produced on the side of the branches in each joint. These are shaped like those of the first sort, and are of a reddish purple colour; they appear in July, and are succeeded by round capsules, having three cells, each containing one black seed, every part of the plant abounding with a milky juice. This is esteemed a good medicine to purge off watry humours, and is given in drops.

The thirtieth sort grows naturally in the island of Crete. This is a perennial plant, having thick fleshy roots, which spread far in the ground, and shaded with a milky juice, which rises two or three inches above the surface, and from thence sends a reddest substance, which is equal to the last sort. From the root several thick woody bearing branches

which twigt about each other, or the neighbouring plants, like the common Bindweed. Thefe are garnifhed with heart-fhaped leaves, which are foft to the touch, like thofe of the Marfh Mallow. The flowers are produced at the joints on the fide of the ftalks, feveral (landing together on the fame foot-ftalk, they are white, and fhaped like thofe of the common great Bindweed. Thefe are fucceeded by round capfules, having three cells, which contain two feeds in each. The roots of this plant, which is the only part ufed in medicine, are brought to us from India. It is titled Turpethum, or Turbith in the (hops.

This plant is tender, fo will not live in the open air in England; it is propagated by feeds, which muft be fown on a hot-bed; and when the plants are fit to remove, they fhould be each planted in a feparate pot, and plunged into a hot-bed of tanners bark, and fcreened from the fun till they have taken frefh root, and afterward muft be treated in the fame manner as hath been directed for the eighth fort.

The thirty-firft fort is the Jalap which is ufed in medicine. This grows naturally at Haleppo, in the Spanifh Weft-Indies, fituated between La Vera Cruz and Mexico. The root of this plant hath been long ufed in medicine, but it was not certainly known, what plant it was produced from. The old title of this was Mechoacana nigra, but father Plumier afferted that it was the root of one fpecies of Marvel of Peru; from whence Tournefort was induced to conftitute a genus from that plant, under the title of Jalapa. But Mr. Ray, from better information, put it among the Convolvuli, and titled it Convolvulus Americanus, Jalapium di&us. This was by the late Dr. Houftoun certainly afcertained, who brought fome of the roots of this plant from the Spanifh Weft-Indies to Jamaica, where he planted them, with a defign of cultivating the plants in that ifland, where he obferved them to thrive, during his abode there: but foon after he left the country, the perfon to whose care he committed them, was fo carclefs as to fuffer hogs to root them out of the ground, and deftroy them; fo that there was no remains of them left, when he returned there; nor have I heard of this plant being introduced into any of the Britifh iflands fince.

A few years paff I received a few of the feeds of this plant, which fucceeded in the Chelfea garden, where the plants throve very well, but did not produce any flowers. This hath a large root of an oval form, which is full of a milky juice * from which come out many herbaceous triangular twining ftalks, rifing eight or ten feet, garniied with variable leaves, fome of them being heart-fhaped, others angular, and fome oblong and pointed. They are fmooth, and ftand upon long foot-ftalks; and from a drawing of the plant, made by a Spaniard in the country, where it grows naturally, who gave it to Dr. Houfton, and is now in my poffeffion, the flowers are fhaped like thofe of the common Great Bindweed, each foot-ftalk fupporting one flower. But as it is only a pencil drawing, fo the colour is not expreffed, therefore I can give no farther account of it. The feeds of this are covered wkh very white down like cotton.

As this plant is a native of a warm country, fo it will not thrive in England, unlefs it is preferved in a warm ftove *, therefore the feeds muft be fown on a hot-bed, and the plants put into pots, and plunged into a hot-bed of tanners bark, and treated in the fame manner as the eighth fort *, with this difference only, that as this hath large, flefhy, fucculent roots, fo they fhould have but little water given them, efpecially in winter, left it caufe them to rot. They fhould be planted in light fandy earth not too rich, for the fame reafon, and the plants fhould always remain in the bark-ftove.

The root of Jalap is efteemed an excellent cathartic medicine, purging ferous watery humours efpecially, and is of fingular fervice in dropfies, and for rheumatic diforders. But the quantity of the root which is ufed in medicine, is not fufficient to render the in-

trodu&ion of this plant into the Britifh colonies, & matter of great concern. But fince the diftillers and brewers have found put its ufe for exciting a fermentation, the confumpti&n of it is now fo great, as that it would become a national benefit, if it were produced in the Britifh iflands* which might be foon effected, were die inhabitants of thofe iflands a little more attentive to their own, and the public benefit.

CONYZA. Lin. Gen. Plant. 854. Tourn. Inft. R. H. 454. tab. 259. [of KooWJ, Gr. becaufe the leaves, being hung up, drive away gnats and fleas, as Diofcorides fays:] Flea-bane.

The CHARACTERS are,

It hath a compound flower wade up of many hermaphrodite florets which compofe the dijk, and female half floret?* which are ranged round the border* and form the rays \ the hermaphrodite florets ate funnel-fhaped^ and cut into five parts at the brim* which fpread open* thefe have each five fhort hairy ftamina, terminated by cylindrical fummits-y in the bottom of each floret is fituated a germtn fupporting a flender flyle* crowned by a bifid ftigma. The female half florets or rays, are funnel-fhaped* and cut into three parts at the top * thefe have a germen, with a flender flyle* terminated by two flender ftigmas* but have noftamina. All thefe are included in a common fcafy empalement* which is oblong and fquare* the fcales are pointed* and the outer ones fpread open. The hermaphrodite and female florets* are each fucceeded by one oblong feed* crowned with down* fitting upon a plain receptacle, and are included in the empalement.*

This genus of plants is ranged in the fecond fe&ion of Linnaeus's nineteenth clafs, intitled Syngenefia Polygamia fuperflua. The plants of this feftion have hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. CONYZA (*Squarrofa*) foliis lanceolatis acutis, caule annuo corymbjofo. Hort. Cliff. 405. *Flea-bane with pointed fpear-Jhaped leaves* an annual ftulk* and flowers growing in roundifh bunches.* Conyza major vulgaris. C. B. P. 265. *Common greater Flea-bane.*

The first fort grows naturally upon dry places in several part, 1 England, fo is seldom allowed a place in gardens. This is a biennial plant, which decays the first year • the ferfi arc ripe; it hath (even) large, oblong, pointed leaves, growing near the ground, which are hairy; between these the stalks come out, which rise two feet and a half high, dividing upward into several branches, garnished with small lieroblonginvei,

standing alternate •, at the ends of the stalks the flowers are produced in round bunches, which are of a ditty yellow colour; the first are succeeded by oblong feeds, crowned with down, it flowerj in July, and the feeds ripen in autumn. If the feeds are permitted to scatter, the plants will come up the following spring, and require no other care but to keep them clear from weeds.

The second fort grows naturally on the mountains in Italy, and is preserved in botanic gardens for the sake of variety. This, is a biennial root but an annual stalk. It grows from a thick fibrous root arile many upright Polkj, garnished with oblong oval leaves, which are rough, and embrace the stalks with their base; the leaves have appendages running along the stalk, from one to the other, whereby the stalk is winged. The upper part of the stalks divide into many smaller branches, garnished with leaves of the first kind as the other, but smaller, tending alternately the branches and main stalks, are reeminated by yellow flowers growing in round bunches; these are succeeded by oblong feeds, crowned with down. It flowers in July, and the feeds ripen in autumn. This is a tender plant, and will not bear much frost. It is sown in a hot-bed, and when the plants are fit to be transplanted, they must be sown in a rich soil. The third fort grows naturally in Crete. The first is a short fleshy stalk, which in this country seldom rises more than six inches high, dividing into several branches, which are chiefly garnished with oval, woolly, very white leaves (from the branches arise the flower-stalks, which are woolly, about nine inches high, garnished with small, oval, white leaves, placed innumerable. The flowers are produced at the sides, and end of the stalk, singly but not in other times two, and sometimes three flowers. It is sown in the open field, and sometimes three flowers. It is sown in the open field, and sometimes three flowers. It is sown in the open field, and sometimes three flowers.

The third fort grows naturally in Crete. The first is a short fleshy stalk, which in this country seldom rises more than six inches high, dividing into several branches, which are chiefly garnished with oval, woolly, very white leaves (from the branches arise the flower-stalks, which are woolly, about nine inches high, garnished with small, oval, white leaves, placed innumerable. The flowers are produced at the sides, and end of the stalk, singly but not in other times two, and sometimes three flowers. It is sown in the open field, and sometimes three flowers. It is sown in the open field, and sometimes three flowers. It is sown in the open field, and sometimes three flowers.

be shaded in the winter, and they have been planted a fortnight, the glass should be raised on one side to admit air to the cuttings, and when they have taken root, they should be exposed to the open air. In autumn they should be carefully taken up, and dried in the sun, and then they may be preserved under a frame in the winter, and the others should be planted in a warm border of dry peat, where they will endure the cold of our ordinary winters very well, and continue many years. This is preferred in gardens, more for the beauty of its flowers than its fruit, which have not much to recommend them.

The fourth fort grows naturally in Jamaica, from whence it was sent me by the late Or. Henslow. This is titled by Sir Hans Sloane Virga aurea major. It is a biennial plant, which rises to the height of six feet, and is divided into several branches, which are garnished with rough leaves four inches long, flipped like the point of a halbert. The flowers are produced in small round bunches, at the extremity of the branches, they are yellow, and stand close together. These are sown in a hot-bed, and when the plants are fit to be transplanted, they must be sown in a rich soil.

pot filled with light fandy earth, and phirigfd into a hot-bed, obfcrving to fcren liem from tite fun rill they have uken new root-, then they mult lave free air admitted to titem tvzry day, in proportion to the warmth of the kilon; they mull aitt be frequently watered in warm wcuher, but rJity fhould not have it in too great plenty. As the plum advance in ilringth, l> they itfuit have a greater fruit: of air •, and if the lesion is warm, they nmy be expofed to the open air for a. few weeks in the lie.it of lummer, provided they are plnced in a warm fitu.-tion j but if the nights prove cold, or much wet fliould iall, they mult viu removed into flicker: if tofc plants are placed in a moderate iluvc in winter, they will thrive benxr lian in greater heat, and in fummer ticy ftould nave a Urge uiare of air. With th!> iii:uu;:cment l htw bad the plants Mower well in July, though they have nm perfected feeds here.

The fifth fort riles with a woody (folk (en or twelve frei high, dividing into many brandies, whole b-irk Is covered with a brown down v thde are garnittied with oblong oval leaves, which uv green on their upper fide, W o f an Alhcolouroti tlier under, placed •taroMB, on Jhorr foor-ftilks. The i lower, ant produced ai the end of the branches, upun long brandling foot-Mks, in loofc fpikes range!

They are whiic, and are focceeded by long fa crowned with down. This plant grows Li Veri Cruz in New Spain, from whence Dr Houi- IOUn fent me the feed*. It is a tender plant, lo mini be created in the fame manner as iurb been directed

for Ebc former fort.

The finth fort grows naturally at La Vera Cruz in New Spain. This harh a. perennial roor, from which arile fcrcral upright talks three feet liigh, farnittied with long narrow leave*, (awed on their edges, placed alternate, and have appendages "Which run along cbc ilalk from one to the other, forming a border or winp to die Jtidkj. The flowers are produced at the end of the fWks in round lumenes, they ate ftnall, and of a purple colour, and arc fucceded by oblong fiat Jeeds, crowiwU with down. Thus is propagated by i«di, twhicb mult be lown upon a

hot-bed in the fpr<g, and the plants mult afterward be tranblanied into pots, and plunged into a finCh luii-bed, oocirving to tin-en them from the fun till tin-y hive taken frcihroot-, after which they mult have a large fhare •fair, and about Mid-fommer they may be placed in the open *ir in a fheltered fhade n, vlicic thej nmy remun tiL the end of September, when dw>- ihould be removed into the ; >vc, and during tie winter kept in a Temperate degree of warmth. The lectind yeir thefe plants will Bower, but they du net perfect feeds in England. The ieventh fen wss few me from La Vera Crus by the late Dr Houftaun, wiw found it growing there naturally. This hath * itiong woody tern, wiikh rile, to the hd"ht of fourteen or fatten fret, covered in Alh-tobured bark, and is divided upward into many ligneous braoclics, garnilhed with fuear. Jhaprd leaves Ibnding alternate, on ihon foot-ftalks. Theft branches are txxiem

of wh K fiowen, tilting upon loiii foot-ftalks, A'c'c' r al £ t)cm beitiH jyoied on tic fame »oi-iblk. Tliclc an; njt ftitecled by. feeds in England, to that the feeds mult be proture<l fmm abroad, and thole mult be lown on a l>tf-bed, and the plants at- trd treated in the lime manner as the fourth (bit.

The eighth fort po**s mrrally at \& Vera Cru^i fruii whence it \ was fent me by the late Dr. Houltoun, this is an annual plant, which grows in low moist places, where the water floods in winter, it hath an herbaceous branching ftalk, which rifes about one foot high, garnilhed at each joint with one oval leaf, fitting clofe to the branches; thefe are flow: on ihrir edges, and covered with a white hairy down. The flowers are produced from the fide of the branches on flender foot-ftalks, each for the moft part fullain- ing three flowers, which are white, and are focceeded

by ch*Ty feeds, crownid witi down : the whole plant is viicous, and will flick to the lingers of thot who handle it.

The leeds of this plant niufl IK (own on a hot-bed in the fpring, and when the pl) are fit to be move fjicy Ihuuid U¹ cadi tnu planted into a feparat - pot, and plunged into a fhallow hot-bed, and t. Jled in the 6mc manner as tiw other tender forts, but niuji have a "ak" fhare of a^r in warm weather, and frequently rerrtdid with water, in July tie/e ptinu will rtower, and if tic aiiuun, grows favulUrable, thej will j ceu their &ei!sj (^plam or two of thL iun may be fcyedfw die lake of variety, but there u little l eany in it.

The ninth fort grow* naturally in Jamaica, from whence the lewis were lent me hy the latc Dr. I toul-touii; this riles with a fhubby ftalk fix or feven feet liigh, •ftanding in a many Itgacotu lirani have a fmothy bark, and I gftniftied with (pear-leaned leaves, fitting clofe to the brattchc4; they arc b rry, and of t L: r colour iib> their under lide, and arc ed alternate. The flowers come out from the

C of the branches, generally in loufe fpikei, which grow fucculent, and hand on the upper fide of the ftalk, but fometimes they are •Tie out (ngle, fitting dole between the leaf and bandit Uicfe are of a pale [i. rple colour. Kd are liicceeded by d a % (ixds, frowned with a tit.

This fort is propagated by feedi, whit' h mult be obtained from the country where it grows aaturatlJE, for it tbih nur produce feeds in England, though a bu flowered levtral years in the C. This is propagated by feeds in the fame manner as the fifth ibrt, Mid the jibnti nuut U- treated in the fame way. h will flower the fecond yr. it, but ^ U'ih mat ripea feeJi in England.

The tenth fort grow* naturally at La Vera. Cruz, from whence it was lent me by the i. e Uv. Villum Houf. toun; this hath a perennial r'jot, and an annual (talk. It grows about three feet i high; the kaves arc : on tour : o five inches l"5g, and one and a half broad in die i . and are tough like thole of C. unfrey. The ftalks are terminated by branching flower-ftalks, cadi l oon-ftalk fullainng feveral yellow flowers, not much unlik

• ibtL This is propagated by feeds in the fame manner as the fifth ibrt, Mid the jibnti nuut U- treated in the fame way. h will flower the fecond yr. it, but ^ U'ih mat ripea feeJi in England.

The eleventii ibrt wai fnt me li-oui La Vera Crui by the Lite Dr Moufioum thi iuii a dimling thrubby Mk which rife fourteen or fixteen feet high, and divider into many branches, garnilhed with leaves ftbout the fite of thofe of tije lky-tree, and full ai diick in their texture, having nny deep t rale nerves, running from the "midrib to the fides-, they are of J pak-green colour. The flowers art produced in long f.-tkcJ, ranged on the upper fide of i e fpike ody, which come out from tisc iide of the branches pointed upward; thefe are large and white, and arc fucceded by rUt dark-coloured I eeds, crowned with down.

This plant make, a One appearance in the ftovc when it flowers, and at it retain!; its lean all the year, fo in the vf inter fcagan it aliordi an agree j; le variety among other tender plants. The culture of this plant is the fame as hath been directed for the -;Juth fort, fo need not be repeated.

The twelfth fort was fnt me fion Canliagena in New •pain, whei it grows naturally, by the l. cMr. Roben Millur, lu foon; this rife with a fhubby ftalk fix or feven feet high, dividing into feveral ligneous branches, garnilhed with oval, fmothy entire leaves, having three longitudinal veins, placed alternate, clofe to the branches. The flowers are produced in fhort clear fpikes at thp end iif the branches; thefe are white, and are fucced i l-d fi; iiiiis fan is tender, fo mult be treated in the fame manner as the feventh, and will abide f. -;J.Tal yeait wth tiw r management.

'the thirteenth fort grows natically in the feme country as the laft mentioned^ and was fent me by, the fame gentleman; this rifes with a fhrubby ftalk eight, or ten feet High, dividing into many long (lender branches,' garnifhed with fpear-ftaped leaves,' three inches long, and three quarters of an inch broad in the middle, ending in acute points; the fmaller branches are fet with very narrow, oblong, pointed leaves, which grow clofe to the ftalks; and at each joint is produced one pretty large white flower, with a*purple empalement; thefe flowers come out the whole length of the fmall branches, fitting clofe to the bafe of the leaves, fo that the plants make a pretty appearance in flower. This may be propagated in the fame way as the fourth, and with that management it hath flowered very well, but it doth not produce feeds in England.

The fourteenth fort was fent me from Carthagen a by the before-mentioned gentleman, who found it growing there in great plenty. This hath a ftrong woody ftem, rifing ten or twelve feet high, divided upward into many fhort ligneous branches, whofe joints are very clofe to each other. The leaves come out alternate on every fide the branches, to which they fit very clofe; they are fsmooth, one inch long, and half an inch broad, ending in acute points, having three longitudinal veins. The flowers are white, and produced in fhort clofe fpikes, which come out from the fide of the branches, and are fucceeded by oblong flat feeds, crowned with down.

This is a tender plant, fo requires the fame treatment as the fourth fort, with which it hath flowered very well, but hath not produced feeds in England.

The fifteenth fort rifes with a fhrubby ftem to the height of fix or feven feet, dividing into feveral branches, which have a dark brown bark, and are dofely garnifhed with oval, fpear-ftaped, fsmooth leaves, having three longitudinal veins, ftanding on fhort foot-ftalks, placed alternate on every fide the branches. The flowers are produced on long naked foot-ftalks, which extend five or fix inches beyond the end of the branches; thefe are purple, and form a-kind of round bunch: the empalement of the flower is compofed of fhort chaffy feales.

This grows naturally at Campeachy, from whence the feeds were fent me by Mr. Robert Millar. It is a tender plant, fo muft be treated in the fame way as is directed for the fourth fort, with which it hath flowered, but hath not produced feeds in this country.

The fixteenth fort grows naturally at Campeachy, from whence I received the feeds; this rifes with a fhrubby ftalk to the height of ten or twelve feet, fending out many ftrong ligneous branches, covered tyith a dark-coloured bark, garnifhed with oblong, oval, blunt leaves, fawed on their edges, and half embrace the ftalks with their bafe: the flowers are purple, growing in round bunches at the end of the branches, and are fucceeded by flat feeds, crowned with down.

This is alfo a tender plant, and requires the fame treatment as the fourth fort, with which it hath flowered, but doth not produce feeds in England.

If the feeds of thefe plants are fown in autumn foon after they are ripe, there is no danger of their mif-carrying; but as thefe are moft of them brought from abroad, they do not arrive here in good time, fo the plants rarely come iip the firft year; therefore the feeds fhould be fown in pots, that they may be preferred through the winter, and the following fpring the plants will come up.

The fevenceenth fort grows naturally in Jamaica; this rifes with a fhrubby branching ftalk about four or five feet high. The lower branches and ftalk are garnifhed with fpear-ftaped leaves about four inches long, and one broad in the middle; they are fawed on their edges, and have fhort foot-ftalks; the leaves on the upper branches are much narrower, and end in acute points.. The flowers are purple, and are produced in round bunches at the end of the branches, and are fucceeded by downy feeds like the other fpe-

cies. This is tender, and requires the fame culture As the fourth fort.

The feventeenth fort grows naturally in China: this is a¹ biennial plant, which perifhes foon after the feeds are ripe. The ftalks are hairy, rifing about two feet high,¹ garnifhed with oblong oval leaves, which are entire, rough on their upper fide, but have many ftrong pale hairs on their under, placed alternately on the branches. The flowers are purple, coming out from the fide of the branches in oblong fpikes.

This fort is propagated by feeds, which fhould be fown in pots in the autumn, if they can be procured at that feafon; but the pots fhould be placed in a garden-frame in winter, to prevent the feeds fuffering by-cold and wet. If the feeds are fown in the fpring, the plants rarely come up the fame year, therefore it will be proper to fcreen this in winter *, when this is obferved, the plants will rife the following fpring. When the plants are fit to remove, they fhould be each planted in a feparate pot, and placed into a very moderate hot-bed, where they muft be fcreened from the fun until they have taken root *, after which they fhould be gradually hardened to bear the open air, into which they fhould be removed the beginning of June, placing them in a fheltered fituation, where the fecond feafon they will flower, and if the fummer is good, they will ripen their feeds.

CONSERVATORY. See GREEN-HOUSE.

CONVAL LILY. See CONVALLARIA.

CO PAIFERA, the balfam of Capevi.

The CHARACTERS are,

// hath no empalement; the flower confifis of five leaves+ which expands in form of a Rose; it hath ten jbertftamina crowned by hngfummitis. The pointal is fixed in the center of the flower* which afterward becomes a pod, in which are contained one or two feeds* which are furred with a pulp of a yellow colour.*

We know but one fort of this tree, which is, * CoPAIFERA(Q^ftifi/tf)foliis pinnatis. *The balfam of Capevi.*

This tree grows near a village called Ayapel, in the province of Antiochi, in the Spanifh Weft-Indies; this is about ten days journey from Carthagen a. There are great numbers of thefe trees in the woods about this village, which grow to the height of fifty or fixty feet. Some of thefe trees do not yield any of the balfam, thofe which do are diftinguifhed by a ridge which runs along their trunk* *, the trees are wounded in their center, and they place calabafh fhells, or fome other veffels to the wounded part to receive the balfam, which will all flow out in a fhort time. One of thefe trees will yield five or fix gallons of the balfam * but though thefe trees will thrive well after being tapped, yet they never afford any more balfam.

As this balfam is ufed in medicine, it deferves our application to procure the trees, and cultivate them in fome of the Ehglifh colonies of America; for as the Englifh are poffeffed of lands in fo many different latitudes, they might cultivate moft kinds of trees and plants from the different parts of the world, which are ufeful in medicine, dyeing, or for any other purpofe of life.

The feeds of this tree were brought from the country of their growth by Mr. Robert Millar, furgeon/ who fowed a part of them in Jamaica, which he informed me had fucceeded very well; fo that we may hope to have thefe trees propagated in great plenty in a few years, in fome of the Englifh colonies, if the flothfulnefs of the inhabitants doth not fuffer them to perifh, as they have the Cinhamon-tree, and fome other ufeful plants, which have been carried thither by curious perfons.

There arc not at prefent any of thefe trees in Europe, that I can learn * for thofe feeds which Mr. Millar fent over to England, were all deftroyed by infe&s in their paffage, To that not one fucceeded in the feveral places where they were fown j but could frefh feeds be procured, the plants might be raifed in England, and preferred very >vell ; for the country of their growth is much more tempe* rate than tpany others, from whence we have be..

furnished with a great variety of plants, which flourish very well in the fives, and some of them arrive to a great degree of perfection.

after which, those which are planted with forked roots require no other treatment but to keep them clear from weeds; and as they advance in height, they should be supported by sticks, otherwise they will in summer often break down, and those which were placed in a nursery-bed, when they have obtained proper strength, should be taken up and transplanted with balls of earth to their roots, where they are designed to stand for flowering.

CORIANDRUM. Lin. Gen. Plant. 318.

Link. R. H. 116, tab. 169. (of Coriandrum, or Coriaria, a tick; so called, either because it has the form of a tick, or, as others say, because it drives away all kinds of insects, and is therefore preserved, but in botanic gardens for the sake of variety.)

The CHARACTER is,

... with an axillary flower, the axillary axillary leaf but few rays, the axillary we have here a stem-leaved one, the proper ray is divided into five parts, the rays of the principal umbelliferous flower which form the disk, have five small hairs (single petals, which are reflexed, but those of the rays have five unequal points of the same form, they have each five fimbriae, the grooves which is situated under the flower, supports two lobes, enclosed by small rounded segments; it is green afterward becomes a spherical fruit, divided into four parts, each having a hemispherical convex part.

This genus of plants is ranged in the second section of Linnaeus's fifth class, entitled "the flower having five stamens and two fruitles."

THE SPECIES ARE,

1. Coriandrum (Skriww) frufflitnu globofw. Hort. Clijt loo. Csw frw*. Coriandrum inijus. C. H. P. i; 3. Major Coriander.

2. Coriandrum (T. glaberrimum) frufflitnu d. lynnij, Hort. Clijt 103. Coriander with small fruit. Coriandrum minus villosissimum. C. H. P. 158.

The first of these species is the most common kind, which is cultivated in the European gardens and fields for the seeds, which are used in tiK'didne. The second kind is less common than the first, and is found but in botanic gardens in their parts of Europe. These plants grow naturally in the south of France, Spain, and Italy; but the first is more long cultivated in the gardens and fields, though at present there is not near so much of it down in England as was wont to be.

These plants are easily raised from their seeds in the autumn, in an open foilation, on a bed of ootnl fish earth. When the plants are come up, they should be horcl out to about four inches distance every way, clearing them from weeds; by which management these plants will grow strong, and produce a greater quantity of good seeds. The first sort was formerly cultivated in the gardens as a salad herb, and in the East Indies is still much cultivated; for the plant is of great use in most of their compound dishes, as a culinary herb, and the seeds are also much esteemed for the like purposes. The second sort will rise easily in summer, if they are sown in the autumn, but dmtewhich are sown in the spring rarely succeed, or M ICJII da not come up till the filluwin...

CORIARIA. Lin. Gen. Plant. 318. Nidd. Ad. Rep. 1711. Myrtle-leaved sumach, &c.

The CHARACTER is,

... with an axillary flower, the axillary axillary leaf but few rays, the axillary we have here a stem-leaved one, the proper ray is divided into five parts, the rays of the principal umbelliferous flower which form the disk, have five small hairs (single petals, which are reflexed, but those of the rays have five unequal points of the same form, they have each five fimbriae, the grooves which is situated under the flower, supports two lobes, enclosed by small rounded segments; it is green afterward becomes a spherical fruit, divided into four parts, each having a hemispherical convex part.

the four quarters of petals, and in the center are placed fist jviatals, which tsar, I & a berry, including five hairy-pointed seeds.

This is ringed in da ninth section of Linnaeus's town f-fecood class, entitled Dianca Di auirii, (the plants having uS' and hermaphrodite flowers of different roots.

The SPECIES ARE,

1. Coriaria (Myrtifolia) foliis ovato obtusis. Here Upl. 200. Myrtle-leaved sumach, with white oval larjn. Coriaria vulgaris Linn. Nidd. A. t. j 11.

2. Coriaria (Femina) vulgaris Linn. Hort. Clijt. Female Myrtle-leaved sumach.

The first with male flowers has been the most common in England, the other having been very rarely raised in our gardens; a few years past, when some planter was raised from seeds, which came from Italy, in the Chelsea garden, where the plants so raised have since been proved of the hermaphrodite sort, and have produced great quantities of seeds, which have grown, though there is not one plant of the male loci at present in the garden; but these with male flowers, occasioned my writing about them. These grow wild in great plenty about Montpellier in France, where it is used for tanning of leather in its seed, from this use, has been named by the French icoriariorum, i. t. J. sicut sumach.

These plants seldom grow more than three or four feet high, and as they creep at the root, they send forth many stems, whereby they form a thicket, so they may be planted to fill up vacancies in wildernesses, but they are improper for small gardens, where they will take up too much room; and as there is no great beauty in the flowers, they are only raised for variety.

It is strange that Monsieur Nidd, who lived upon the place where these grow so plenty, who confirmed this genus, in the Memoires of the Academy at Paris, has taken no notice of their being of two different kinds in different plants.

It may be propagated plentifully from the seeds, which are produced from the creeping roots in great abundance; these should be sown in March, and planted into a nursery, to form good roots, where they may continue one or two years, and then must be removed to the places where they are to remain.

This plant delights in a loamy soil which is not too stiff, and which is not too cold. It may here dicker from the north and cold winds, when it will flourish the cold of our ordinary winters very well, and will flower better than if it were preserved in pots and transplanted in the winter, as is usually done by some gardeners.

CORIKDUM. See CAROTHEDUM. CORIS. Lin. Gen. i. tab. 218. roun. Ir.; 652. tab. 213. We have no English name for this plant.

THE CHARACTER is,

... with a pedicel, the pedicel is of the leaf, with a pedicel leaf, but divided at the top, where it is divided into five unequal parts, the proper ray is divided into five parts, the rays of the principal umbelliferous flower which form the disk, have five small hairs (single petals, which are reflexed, but those of the rays have five unequal points of the same form, they have each five fimbriae, the grooves which is situated under the flower, supports two lobes, enclosed by small rounded segments; it is green afterward becomes a spherical fruit, divided into four parts, each having a hemispherical convex part.

This genus of plants is ranged in the first section of Linnæus's fifth class, entitled Pentandria Monogamia, the flower having five stamens and one style.

We have but one SPECIES of this plant, viz.

Coris (Mongolica). Hort. Clijt. 61. Coris crucea maxima. C. B. P. 160. The mongolic Coris.

There are two other varieties of this plant, one is a red, and the other a white flower, but these are only accidental varieties arising from the same seeds.

These plants grow wild about Montpellier, and many other parts of the south of France, and also in Italy; they seldom grow above six inches high, and

spread near the surface of the ground like heath; and in June, when they are full of flowers, they make a very pretty appearance.

They may be propagated by sowing their seeds in the spring, on a bed of fresh earth; and when the plants are about an inch high, they should be transplanted, some of them into pots filled with fresh light earth, that they may be sheltered in winter; and the others into a warm border, where they will endure the cold of our ordinary winters very well, but in severe frost they are generally destroyed; for which reason, it will be proper to have some plants of each sort in pots, which may be put under a common hot-bed frame in winter, where they may be covered in frosty weather; but when it is mild, they should have a great share of free air: these plants sometimes produce ripe seeds in England; but as they do not constantly perfect their seeds, it will be proper to increase them from slips and cuttings, which will take root, if planted about the end of August on a very gentle hot-bed, and shaded from the sun and duly watered.

CORISPERMUM. Lin. Gen. Plant. 12. Juss. Aft. R. S. 1712. Tickseed.

The CHARACTERS are,

The flower hath no empatement, it hath two compressed incurved petals, which fit and opposite and are equal; it hath one, two, or three stamens, which are shorter than the petals, terminated by single summits, with a compressed germen, supporting two hairy styles, crowned by acute stigmas. The germen afterward becomes one oval compressed seed, with an acute border.

This genus of plants is ranged in the second section of Linnæus's first class, entitled Monandria Digynia, the flower having one stamen and two styles.

The SPECIES are,

- x. CORISPERMUM (*Hylophilium*) floribus lateralibus Hort. Upfal. 2. *Tickseed with flowers on the side of the stalks.* Corispermum Hylophilium. Juss. Aft. R. S. 1712. *Hylophil-leaved Tickseed.*
2. CORISPERMUM (*Squarrosum*) species squarrosus. Hort. Upfal. 3. *Tickseed with rough spikes.* Rhagrostis foliis arundinaceis. Buxb. Cent. 3-p. 30. *Rhagrostis with heath-like leaves.*

These plants are preserved in botanic gardens for the sake of variety; but as they have no beauty, are seldom cultivated in other gardens.

The first sort is an annual plant, which, if suffered to scatter its seeds, the ground will be plentifully stocked with the plants, which will require no other care but to prevent the weeds from over-growing them.

The second will not grow but in marshy places, where there is standing water; over the surface of which this plant will soon extend, when once it is established.

As we have the English name to this genus, I have given it the Greek name of Tickseed, which corresponds with the Greek name.

COR K-T REE. See QUERCUS.

COR N-F LAG. See GLADIOLUS.

CORNICULATE PLANTS [Plantæ Corniculatæ,] are such, as after each flower, produce many horned seed-pods, called Siliquæ,

COR N-M A R I G O L D. See CHRYSANTHEMUM.

CORN-SAL LAD. See VALERIANA.

CORNUS. Lin. Gen. Plant. 139. Tourn. Inf. 641. tab. 410. [so called, of Cornu, Lat. a horn; because its wood, or the shell of its fruit, is hard as a horn.] The Cornelian Cherry.

The CHARACTERS are,

It hath many flowers included in one common four-leaved involucre, which is coloured. The flowers have each a small empatement, sitting on the germen, which is indented in four parts. They have four plain petals, which are smaller than the leaves of the involucre, and four erect stamens, which are longer than the petals, terminated by roundish summits. The round germen situated between the empatement, supports a slender style, crowned by an oblong stigma. The germen afterward becomes an oval, roundish berry, inclosing a nut, with two cells, having an oblong kernel.

This genus of plants is ranged in the first section of Linnæus's fourth class, entitled Tetrandria Monogynia, the flowers having four stamens and but one style.

The SPECIES are,

1. CORNUS (*Sanguinea*) arborea, cymis nudis. It. Westgoth. Jyn. Sp. Plant. 117. *Dogwood-tree with naked shoots.* Cornus femina. C. B. P. 447. *Female Dogwood, and the Virga Sanguinea.* Matth. .
2. CORNUS (*MGS*) arborea, umbellis involucre sequantibus. Hort. Cliff. 38. *Tree Dogwood with umbels equal to the involucre.* Cornus hortensis mas. C. B. P. 447. *Male Cornel, or Cornelian Cherry-tree.*
3. CORNUS (*Florida*) arborea, involucre maximo, foliis obverse cordatis. Hort. Cliff. 38. *Tree Dogwood with a very large involucre, and obverse heart-shaped leaves.* Cornus mas, Virginiana, flocculis. in corymbo digestis, a perianthio tetrapetalo albo radiatum cindlis. Pluk. Aim. 120.

6. CORNUS (*Candidissima*) arborea foliis lanceolatis, acutis, glabris, umbellis involucre minoribus, baccis ovatis. *Tree Dogwood with smooth, spear-shaped, pointed leaves, umbels smaller than the involucre, and oval berries.* Cornus femina candidissima foliis Americana; Pluk. Aim. 120.
7. CORNUS (*Tartarica*) arborea foliis oblongo ovatis, nervosis, inferne albis, floribus corymbosis terminalibus. *Tree Dogwood with oblong, oval, veined leaves, white on their under side, and flowers growing in a corymbus at the end of the branches.* Cornus fylvestris fructu albo. Amman. Ruth. *Wild Dogwood with a white fruit.*
8. CORNUS (*Suecica*) herbacea ramis binis. Fl. Lapp. 55. *Herbaceous Dogwood with double branches.* Cornus pumila herbacea, chamaepericlymenum dicta. Hort. Elth. 108. *Low herbaceous Dogwood, called Dwarf Honey-suckle.*

The first of these trees is very common in the hedges in divers parts of England, and is seldom preserved in gardens. The fruit of this plant is often brought into the markets, and sold for Buckthorn berries, from which it may be easily distinguished, if the berries are opened to observe how many stones there are in each; which in this fruit is but one, but in the Buckthorn four, and they may be easily distinguished by rubbing the juice of the berries on paper, that of the Buckthorn will stain the paper green, whereas the juice of this stains it purple. This tree is called Virga Sanguinea, from the young shoots being of a fine red colour. There is a variety of this tree with variegated leaves, which is preserved in the nurseries, but is not much esteemed.

The second sort is very common in the English gardens, where it was formerly propagated for its fruit, which was by some people prized to make tart. It is also used in medicine as an astringent and cooler: there is also an officinal preparation of this fruit, called Rob de Cornis. Of this there are two or three varieties, which differ only in the colour of their fruit, but that with the red fruit is the most common in England.

As the fruit of this tree is not at present much esteemed, the nursery-men about London propagate it as one of the sorts which is commonly sold as a flowering shrub, and is by some people valued for coming forward early to flowers for if the season is mild, the

ITS will appieir by the beginning i February; and though tltre is no great beittcy in the flowers, yet, as they are generally produced in ylemy, at a iMfhn when few other flowers appear upon trees, i ftiv plants of them may be admitted for variety. The fruit of this tree is fdtioin ripe before September. The tree will grow eighteen or twenty feet high, and make a Sarge lit

The third fort is an Amerkan, from whence the feeds have been brought to England: this is found in all •urdicm parts of Amenta, as are allb the fourth, fifth, and i jxth forts, being natives of the woods in Virginia, New England, Maryland, and Carolina. Thec arc all of them very hardy, and thrive well in the open air in England, fo are cultivated by the nurfery-men near London, to acid to the variety of their hardy trees: thefe grow to the fame height with our common female Dogberry, and make a much better appearance. The (hoots of the fifth fort are of a beaulitnl ivd colour in winter-, and in fummcr the leaves being large, of a whitilth colour on their under fide, and the bunches of white flowers growing at the extremity of every branch, render; this Ihrub valuable i and in autumn, when the large bunches of blue berries Me ripe, they make a line appearance.

Tiic third fort ii now very common in the nurseries, where it is known by the name of VirginiaDogwwxi. This fort is of 'nuch humbler growth than either of the former, feldom rifing above feven or eight feel high, but is [jene rally well gamified with leaves, which are larger than either of the oilier forts. This does not flower Jo plentifully as the other forts, nor have I yecfeen anyof chefc (hrubs, which have produced berriic in England, though they are as tardy as the -nher.

There is a variety of this with a m) involucreum or cover to the Bowers, which adds to the beauty of the plant; this was found wild in Virginia by Mr. Ba* nillcr, and afterward by Mr. Careftiy. This and the former fort arc great ornaments to the woods in A-mtrica, firft by their early flowering in the fpring before the green leaves appear; and in the winter they are alib beautiful when the berries arc rijic, which hang upon the Ihrubs tili the fpring.

The eighth fort grows upon Cheviot-hills in Northumberland, and alfo upon the Alps, and other mountainous places in the northern countries, but ii very difficult to prriirve in gardens i the only method is, to remove die plants from the places oi their natural growth, with good balls of earth to their roots, and plant them in a moift (hady fittuation, where they are not annoyed by the roots of other plants. In fuch a fittuation they may be preferred two or three years, but it rarely happen* that they will continue much longer. This is a low herbaceous plant; whofe ftalks decay in the auum.i

All the forts of Dogwood may be propagated by dietr feeds, which, if fown in autumn foon after they are ripe, will molt of diem come up the following t'pring; but if the feeds are not fown in autumn, they will lie a year in the ground before the plants will appear, and when the year proves dry, die>'will fomenmes remain two yetra in thr ground; chasfore the place mould not be difturbed, where thefe feeds art fown, under two yeau, if the planes (lunik) not come up fcontr. Wlrcn the plants are come up, they fhould be duly watered in dry weather, and kept clean from w«ck\ and die autumn following they may be renwved, and plinted in beds in the nurfery, where they may remain twoyeara, by which time they will be fit to tranfplant where they arc to remain for good. They art; alfo propagated by fuckers, and laying down the brandies. Mofl of the farts produce plenty of Tuckers, efpccially when they ire plants! on moill light foil, which may be taken offrom the old lu a mtaaa, and pkated into > nurfery for y or two, and then may be t ran fp I anted into the f ari; to remain; but ihofc plant* in p fuckers, rarely have fogoott roof is twfc which are propagated by layer;

being mvidi more inclinable to (hooi out fuckers; whereby they will fill the ground round them with cheir frivwn, they are not near fo valuable Its draft planu which are railed from layers.

CORNUTIA. Plum, Nov. Gen. ij. Lin. Gen. Plant. 684. Agnanthus. !Vaill. Aft. R. 17*3. We have 110 Englifh name for [his pliant. It is fo called from Cornutus, a ptylicctn of l'>ria, whopublished a hiftory of Canada /••

The firft Ion is an humble flinib, which feldom ntes nt> • thun two or three feet liigit, with a ligneous Jung Ililk, garniW clofly with winged li being generally compel: MI ut vniM ; [or lobes) terminated by an odd one; thieft ur'ow at their bafe, and broad at the top, • are roundilh and indcnied, they are of a kx-

green colour, am) continue nil the year. The I arc produKil on Illemicr foot iilks from thewingsof the tnvcS| on tlic upper part of the branches, feveral Itiinding togethi-T in a roundfil bunch ^ they are of the butterfly, or Pea-bloom kind, and of a bright ytluw colour, having a very ftrong odour, which to ibmc perfon is agreeable, buc u> ucliers the contrary. This flowers in April and May, and die feeds ripen in Aiiguft.

This plant is propagated by lowing tht feed* in iht fpring, either upon a gentle hot-bed, or on a warm border of light frHi C2nh, and when the plants arc come up about two inches high, they Ihould be trai>f-planted either into pots, or a bed of good rich earth, at about four or five inches diltante every way, where they may remain until they have obtiintJ ftrngth enough to pSant out for gtiod ; which fhould be eitha into pots filled with gbod frlh cinh, 01 ft warm li wiled border; in which, if the winter it not too fevere, thty will abide v'ry well, provided they are in a dry foil.

The fecond fort is a lhrub of the feme fae wil the firft, from which it differs in the numba of small leaves (or lobts) on each midrib ; thtfe having nine or eieven, ind are of 1 iilver cultiur, but the flowers and pods are the fame. It flowers It the fame time, and requires [fie fame treatment as the former.

The third fort b a lhrubby pkht, rifing four or five: fta high \ the Halks are flirubby g,milhed with winged leaves, compoVJ of many small oval lobes along tltit midrib by pairs, and ending 'n an odd one. The flower* Itand upon long foot-fcdk^, which arife from the fi'.le of the biancbett they are yellow, and grow togetiipr in dole bunches. This flowtrs in winter and fpring, anJ the feeds are ripe in Auguft.

Tiiti is it perennial lhrubby plane, which it propagated J> l<di; ihry may be foiv n on a bed of light earth in April, and when the pluits arc fit (ouatiJplam, I t> them fhould be planted in a warm border, clot to a warm wall or pale, to which tlic branches fhould lie trained-, obferving to lhfuk lhaiifrom the lun tit' they hav« taken frlli rouE, and alib 10 n-irelh them with water when they requax it Afiei thej arc wdl rooted, they will require no other culture but to keep I them dean from weeds, and falen ihrir brjn,hes to the wall i the next year they will Sower, ami if they are on l dry foil «ad in a warm fittuation, they will continue many yesn. Sonic of Hi mi Id bs JIUL into jxir% that they iniy bt removed into lhelctr in winter •, where, if they ire not too tenderly treated, they will Sower gitnl purr cif that feafon ; but thdc will rarely produce feeds, whereas thofe in tht full ground generally do, [irovided they arc covered with mats in Trolly WCthcr.

Tlic fourth fort is nearly like the firft, but hath fewer pinns: on each midrib. The flowers are larger, and have little fecnt. Tht penis and feeds are much larger, and die plants arc not quite fo hardy, i his flowers in May and June, but rarely perfCSi feeds in England; it requires the lame treatment as the lirft, but in winter the plants ihouJ be ttcltered, oierwife hard frjtb will tcllroy them.

The fifth fort is a low trailing plant with fbrubb faltw, which fpread near the ground, gamimed with winged leaves, compofrd of many pair of finwll lube jilacel along (he midrib, terminated by an odd theft are wA, puid of a bright grrn; the H> find upon long fuot-fhlks in t-tofe bunches, they arc yellow, and withovii (lowers in Ma arid the feeds ripen in autumn. This h p<>pagat< by Iteds in the fame manner as die third, and require* the fame triMtricit.

The fifth fort dies down mry winter, but riicia^ in the fuccceding fpring; tlic (alkn of ihii rift to l height of five or fix fete, where they have fuj ; oierwife they trail on rje ground, and are ^arnifhed with winged leases, com poled of leveral oblong linall pinnjc, wWdi arc funiftimes placid by pairs, n d at other times are alternate, endag in a fmgle one, they

C O R

of a tcep gred. The (lower; come out on long B Jks from the wings of *tivi* leaves, many trowing t'g*ilicr ui roundbunches; (hey *tac* variable trown a deep to a l'gl" purple, mixed with white, and arc fuctieded by (lender puds from iwo to thii:e inches long, Chmding creft Tins plant flowers in June, July, and Augutt, anil the (teds ripen in autumn. Trie mots of this plant creep very far under triHind, bj which the plant increafes greatly; which, *when perniticid to remain tonremoved for two or three years, will fpread anil ovrbe.tr what plants grow nr.ir It, for which reafon the roots fhould be confiiifd, and it (limikl be planted at .1 diftance from an)- other plants; it will j*row in almoft any foil and fitintion, but thrives bell in a warm funny expofure, in which the Bowers wll .ilfa be much fairer, and in greater quantifies. This pbnt was formerly cultivated to (eed cattle.

The (ivehth fort hath an herbaceous (talk, wliich rilis two feet high, g-mifhed with winged leaves, compofed of Hit pair of final! leaves, plactti along the midrib, which is terminated by an odd one; thec are larger than thofc of the fixth furt, nnd. broader at III; top. The toot-ftalks of the flowers come out from the fide of the ilalks, bur they arc Blotter than thijt'c of the lixth fort, and fulhtin fmaller hcstils or flowers, which are fuceceeded by five taper jointed [Kids, nvar two inches long.

Tfia is III annual plant, which grows naturally In the-Ardiipelago, from whence Tuurnefort fenc the feeds to the royal garden ai Paris. The feeds of this fort fhould be (own on & bed of light earth in the fpring, where the plants arc defigned to remain, and v.tan (he plants conn: up, they fhould he thirinci! where they lire too dof, and afterward kept dean from weeds, which is all the culture they will require. In June they will flower, and the feeds ripen in autumn.

The cidirh fort -was difcovered by Dr. Tournefort in the Levant, from whence lie lent the feeds to the royal garden at Paris -, this hath a perennial root, ami an annual [talk, which riles upward of two feet high, Handing erect. The leaves arc compofid of live 01 fix pair of l'mall oWong leaves, ringed, alotg JLL-midrib, which is terminated by an odd one. The foot-ftalk of *dtr* flowers are trrang, and upward tit fix inches in length, fuppomng Targe biiiKhci of yellow flowers, which arc Juceceeded oy (bon thick pods about an inch long. This (lowers in June and July, and in warm leafons the fecdi will ripen in autumn; there b a variety ui" this with Urge white flowers.

This fort is propagated by feeds, which fhould be finwn on a warm reorder of light earth in the Ijwmg; and when the plants come up, they muft be catctiity cleaned from weeds j when they are fit to remove, they mould be tr.inf]>lant<l inco a warm border, where they are to remain, Ihadinj them from tl. till they have taken firth root, after which they will jitre no farther cart in [timmrr, bit to keep [Jiem in from weeds; and in autumn, when the ilalks are dec • H, if the furface of the "round is l • covered with fame ohl tin to keep out the trait, it will be a fit-cure method to pre&rve tht- roots. The (econd year the plants will llower, nnd, if the fame care is taken in winter, the roots may bt continued ib the year.

The nintli fort grown naturally in Spain; this rife from two to tour fret high, having many (lender ligneous brandies, gamilhed with narrow fj<car-fliapttl leaves, which arc lbmerimes trifoiiate, and at odier times have five loliesciji each foot-ftalk; the fIowtrs ftand upon pretty long twit-Halks whirri a>n. out from the wings of the (talk, and art eolkifteii in (hiali bunt; they are of a bright .How colour, and appear for fix or II^cn months together, but have not been fuceceeded by feeds

boeatycb
This is propagated by fmls in the fame manner as the firft fort, and fame of the **planes fhmild** be planted in pots thit they may be ihettcTed under a common.

C D R

franic in winteh braufe in hard frolls the plants are often **defttoyed** i but in **mild** weather they mould. **be** ixpulkl t'j the ait, orlwrwife tlity will draw up weak.

The tenth Jort was difwvered by father Plumier in America. I received the feeds of this plant from Carthajjena, which were feat me by my late ingenious friend Dr. William Houftoun •, this huth a IIeodes, hairy, twining (talk, of a brown colour, twifting round any of the fhubs which iland near it, whereby it rifee eight or ten feet high, and u gamified with winged leaves, for the molt pan ton>o:ld of tive ovai lobes, one inch lung, ana li.iii' an inch broad, nt' a deep gTein. The flowers come out by pairs at each joint, itanding on very Ihon lparate toot-llalki ~~trick~~, they are large, and of a pale yellowi thefe are fuceceeded by taper jointed podis, more than three indies long, which arc rove red with lhort, lbf, white, hairy down, and itand erect. This plant is prnpri-Eated by feeds, wliich fhould be. ibwn early in the Spring On a moderate hot-bed ; and when the plants are come op, they fhould be each tran (planted into a halfpenny pot filled with frcii rich earth, and plunged into a hot-bod of tanners bark, obltTving tu fhadc. them until they have taken root; after winch time they fhould have air and water in projjortion to the warmth of the fecon, and when they have filled thefe pfiti with theirroots, they fhould be fhifted into pots of a larger fize, and plunged bio tie hot-bed again, where [hey mud remain until autumn, when they fhould be removed into the ltove, and plunged into the can. Tflicie plants muft be conltntly kept in the bark-Jlove, and placed among plants which require a moderate heat-, where they will thrive and flower, and fhould be fupported by tall flicks, round which they will twine Bl Hop* do ; for if they have nor thib fupport, they Wilt raift round other planta and fpoil them. Thefc are very pi-opet pluntt tu place again It in epalier on the back part of the nmongit other climbing plants, where they will makt an ngrrcable vancy.

If die plants are carefully managed in the winter; they may be prelcrrved two or three years, and will annually flower in July, and fometimes they will produce upc feeds in England.

This genus of plants is ranked in the first section of Linnæus's first class, intitled Monocotylia Monogynia, the flower having but one stamen and one style. We have but one Species of this genus, viz.

COSTUS (Arebirus). Hort. Cliff. 1. Costus Arabicus, C. B. P. 16. jfrabim Osfiui.

Thj* hal.li a Bcflj jtiinted root like that of Ginger, which propugates under the surface of the earth; from which arise many round, taper, hollow stalks, garnish'd with oblong smooth leaves, embracing the stalks like those of a Reed; these stalks rise to the height of two feet high, & at the center, the stalks are parted into two, which is near two inches long, the thick net; of a narrow, and blunt at the top, composed of several leafy scales, out of which the flowered combs arise; these have but one thin white sepal, which is of short duration, seldom continuing longer than one day before it falls, and is never succeeded by seeds in this country. The time of its flowering is very uncertain, for sometimes it flowers late in the autumn, and at other times it has flowered in summer. It is not common to any part of England, it grows naturally in most parts of India. This is propagated by parting of the roots, which are cut into small pieces in the spring, before the roots put out new italics. The roots must not be divided too small, because that will prevent their flowering. They should be planted in pots, filled with light kitchen-garden earth, and plunged into the tan-bed in tin: irove, where they mouki comfortably in the sun, and may be treated in the same manner. The Ginger, which is fully treated of under the article AMOV.

The roots of this plant were formerly imported from India, and were much used in medicine; but of late years they have not been regarded, the roots of Ginger being generally substituted: for the

The first sort grows naturally in Spain, Italy, and the Archipelago; this is an annual plant, which rises with a branching black half a foot high, garnished with leaves which are finely divided like those of Chamomile. The flowers are produced singly at the end of the branches, which are very like those of naked Chai, but the heads rise higher in the middle like a pyramid. This flower in May, June, and the seeds ripen in August. If the seeds of this plant are permitted to [carter, the plant will come up in the spring, and require no other care but to keep them clean from weeds, and thin the young plants when they are too close.

The second sort grows naturally in the Ope of Good Iujuk, from whence I have received the seeds; this is an annual plant, which grows out many bunching stalks from the root, which are like a bond, and are garnished with very fine flowers, which are produced singly upon long foot-stalks, arising from the side of the branches; these have a narrow border of white nyi, which is a pale yellow disk. It flowers in June and July, and the seeds ripen in August. This plant may be sown on a moderate hot-bed in the spring, and when the plants have obtained strength, they may be transplanted into a worm bank, where they will ripen their seeds very well.

The third sort is an annual plant, which grows out in the middle of the stalks about six inches long, garnished with succulent leaves, in shape like those of Buckhorn Plantain. The flowers grow from the divisions of the stalks upon short weak foot-stalks, being distinct in rays, they are of a sulphur colour, and appear about the same time with the former. If the seeds of this sort are sown on a warm border where the plants are required, they will require no other culture but to keep them clean from weeds. The flowers of the two last sorts stand erect, and appear, but so soon as the flowers are in, and their colour changes, the foot-stalks become succulent, and the flowers change colour, but when the seeds are ripe, the foot-stalks become

fiff, and the heath (land creft for the winds to difperfe die feclt's.

The fifth fort, which is that ufed in medicine, grows upon old walls and buildings in divers parts of England, particularly in Shropshire and Hereford; in both which counties it greatly abounds upon old buildings, and on rocky places, but is not often found near London, nor when cultivated in gardens. This hath many round fucculent leaves, whole alki arc n!.

surface of the leaves are huUow in the middle, where the foot-ftalks are joined on the tower tide, as to rclembk" i r. vel, from whence the plant was called Navelwort. From between the leaves arife the foot-ftalks 0 the flowers, which in fome places grow near three feet high, and in others not more than fix inches, their lower part being garnifhed with leaves, and their upper part with flowers, which ftand clofe to the fide of the branches, and grow erect; they are of a whitifh yellow colour, and appear in June. It requires a dry rubbing foil, and to have a th.viy au-

ate flattered on walls and old buildings as Qxo as it is ripe, or if the feeds are j mmi when once the plants are eftablifhed upon an old wall or building, they will fix their roots, and maintain their place better than when cultivated with more care. The fecond fort grows naturally in Siberia, from whence it was brought to the imperial garden at Peterburgh. This was feft me by Dr. Amman, the late profeflor of botany in that garden. It is a low plant. in fhape like the Houfleck, but the leaves are longer, and terminate in foft fpuces. The flower-ftalks rife about four inches high, and fupport four or five whitifh flowers, which are cut at the brim into five parts. Thefe appear in April, and are fometimes fucceeded by feeds in England. This (an K-quires it very fturdy fiteuation, for if it is expofed to the fun in Wimmer, the plants will foon die, I- is propagated by offsets like the Houfleck, indreqt

The third fort grows naturally in the Levant. This hath a fibrous root, from which it produces a fingle upright fucculent ftalk, garnifhed with oblong, thick, fucculent leaves, placed alternate, which are fawed at their edges. The upper part of the ftalk is garnifhed with purple flowers, growing in a loofe fpike, two or three being joined on the fame foot-ftalk, which is very fhort. The flowers appear in June, and feed ripen in autumn. It is a biennial plant, which decays foon after the feeds are ripe. If' thi- let it down upon a wall, it will thrive better than in the ground, and be lefs liable to fuffer b froft; (a ihat h the feeds fatten themselves in fuch fiteuations, the plants thrive better than when they are cultivated • il.

The fourth fort grows naturally at the Cape of Good HOJK. This hath a thick fucculent ftalk, which rarely rife above a fpan high, dividing into many branches, garnifhed with fhort, thick, fucculent leaves, which are very convex on their under fide, but plain on their upper, and more than half an inch long, and of a purifh colour spotted over with white veins, and fit clofe to the branches: the foot-ftalks of the flower rife from the top of the branches, >> are fix inches long, naked, and fupport two or fix flowers, which come out alternate from the fide, ftanding very clofe to the ftalks; they are tubular, and cut into five parts as a fin; [op; thec an; greenifh, with purple tips. It flowers in June and July, but never produces feeds in England.

The fifth fort grows naturally upon dry gravelly fites at the Cape of Good Hope. It hath a thick fucculent ftalk, which by age becomes ligneous, and rife three or four feet high, tending into crooked branches, which are irregular, garnifhed with thick, fleshy, fucculent leaves about two inches long, and near so wide toward the top; they are narrow at their bafe, and rounded at the top, of a frefh green colour, with purple edge, which is frequently irregularly indented. The flowers grow upon thick fucculent foot-ftalks, which arife from the end of the branches, and are near a foot long, naked, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

the ftalks, and fupporting eight or ten flowers, growing in an irregular circle at the top; thefe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ftamens and fyft being longer than

thaii the tube of the flower, hanging downward. This fort flowers in July* Auguft, and September, but doth not ripen feeds in England.

The futth fort is alfo a native of the Cape of Good Hope. This hath a fhort, thick, fucculent ftalk, which rarely rife more than afoot high, branching out on every fide, fo as to fpread over the pots in which they are planted: they become woody by age, and are clofely garnifhed with thick round leaves, of a grayifh colour, with purple borders, plain on their upper fide, but convex on their under, and very flefhy, of an herbaceous colour within, and full of moifture. This fort hath not flowered in England, fo far as I can learn, for I have kept plants of it which were tv/enty years old, but never attempted to flower. It is undoubtedly a different fort from thp former, although they have been fuppofed to be the fame by fome writers.

The feventh fort is fomewhat like the fixth, but the ftalks rife higher, the leaves are much larger, and flaped more like thofe of the fifth, but are fotted on their upper fide with ^{^reat number^} of dark green fots -, they have a deep border of purple on their edges, and fit clofe to the branches. This hath not as yet flowered in England. This is alfo a native of ^{^Ethiopia.}

The eighth fort hath been of late years introduced into the gardens in Holland, from the Cape of Good Hope, where it grows naturally, and was fent me by Dr. Adrian Van Royen, late profefibr of botany at Leyden. This rife with a fucculent ftalk near three feet high, which divides into many branches, growing erect, garnifhed with oval fucculent leaves, placed oppofite-, they are of a lively green, and end in points, and half embrace the ftalks with their bafe. This fort hath not as yet produced any flowers in England.

The ninth fort grows on rocky places at the Cape of Good Hope, from whence it was firft brought to the gardens in Holland, and hath fince been fpread into moil parts of Europe, where there are curious perfons who preferve exotic plants in their gardens: this hath a fhort, greenifh, fucculent ftalk, which feldom rife more than a fpan high, dividing into feveral irregular branches, garnifhed with thick fucculent leaves four inches long, and half an inch broad, and as much in thicknefs, having a broad concave furrow on their upper fide, running almoft their whole length, and are convex on their under fide, of a bright green, with a purple tip. The foot-ftalks of the flowers are produced at the end of the branches, and rife near a foot high, having here and there an oblong pointed leaf, growing on their fide. The flowers ftand upon fhort foot-ftalks, which branch out from the principal fte'm; thefe are yellow, having pretty long tubes, which are cut at the top into five parts, and are reflexed backward. The flowers of this fort hang downward, and the ftamina are longer than the tube of the flower 5 the reflexed parts of the petal are tipped with purple. Dr. Linnaeus has fuppofed this to be the fame with the fifth fort, but whoever has feen both plants, cannot doubt of their being diftindt fpecies.

The tenth fort grows naturally in the warm parts of Africa, ib is much more tender than either of the other forts: this rife with an upright ftem about a foot high, which is jointed and fucculent, garnifhed with broad leaves, which are deeply cut on their edges; they are of a grayifh colour, placed oppofite, and almoft embrace the ftalks with their bafe. The foot-ftalks of die flowers arife from the end of the branches, which are about fix inches long, fuffaining feven or eight fmall flowers of a deep yellow colour, which are divided into four parts almoft to the bottom. The ftamina of thefe flowers are not longer than the fhort tube. This flowers at different feafons of the year, but never produces any feeds in England. This fort requires a warm ftove to preferve it through the winter in England, nor fhould it be expofed abroad in fummer; for if it receives much wet, the ftalks are

vety fubjeft to rot *, fo that it Qiould conftantly ~~remain~~ either in the ftoves, or in fummer fhould be placed in an airy glafs-cafe with other tender fucculent plants* where they may have free air in warm weather, and be fcreened from cold and wet 5 but in autumn they muft be removed into the ftove, where they fhould be kept in a moderate temperature of warmth: this is propagated by [#]cuttings, which fhould be taken off in fummer, and planted into fmall pots, and plunged into a moderate hot-bed, and when they have taken root, they fhould be removed into the ftove: This plant mult have but little water, efppecially in winter.

The African kinds are all of them propagated by planting cuttings in any of the fummer months, which fhould be laid in a dry place for a fortnight or three weeks after they are taken from the plant, before they are planted; for thefe abound with juice through every part of the plant, which will certainly rot the cuttings, if they are not fuffered to lie out of the ground, that the wounded part may heal over, and the great redundancy of fap evaporate. The foil in which thefe plants thrive beft, is one third frefh light earth from a pafure, one third fand, and the other third part lime-rubbifh and rotten tan, in equal quantities; thefe fhould be well mixed, and laid in a heap fix or eight months before it is ufed, turning it over five or fix times, that the parts may the better incorporate; and before it is ufed, it will be proper to pafs it through a fcreen, to feparate the large ftones, clods, &c. therefrom.

Having prepared the earth, and your cuttings being in a fie order for planting, you mult fill as many half-penny pots with earth as you have cuttings to plant; then put one cutting in the middle of each pot about two or three inches deep or more, according to their ftrength; then give them a little water to iettle the earth clofe about them, and fet the pots in a warm fhady place for about a week, to prepare the cuttings for putting forth roots; after which they fhould be plunged into a moderate hot-bed of tanners bark, which will greatly facilitate their rooting; but obferve to give them air, by raifing the glaffes at all times when the weather yill permit, as alfo to fhiae the glaffes in the heat of the day.

In about fix weeks or two months time after planting, thefe cuttings will be rooted, when you muft begin to expofe them to the open air by degrees, firft drawing the pots out of the tan, and fetting them on the top, then raife the glaffes very high in the day-time j and in about a week after remove the pots into a green-houfe, and there harden them for another week *, after which they may be expofed to the open air in a well defended place, obferving not to fee them into a place too much expofed to me fun, until they have been inured to the open air for fome time. In this place the plants may remain until the beginning of Ofober, at whiel^time you fhould remove them into the confervatory, placing them as near the windows as poffible at firft, letting them have as much free opep air as the feafon will permit, by keeping the windows open whenever the weather is good; and now you muft begin to abate your waterings, giving it to them fparingly; but you fhould not fuffer their leaves to fhrink for want of rpoifture, which is another extreme fome people run into for want of a little obfervation *, for then they are fuffered to fhrink for want of fufficient moifture to keep their veffels diftended, they are rendered incapable of difcharging this moifture whenever they receive it again. The tenth fort fhould be placed in a moderate ftove in winter, nor muft it be fet abroad till Midfummer, for it is much tenderer than any of the others.

The beft method to treat moft of thefe plants is, to place them in an open, airy, dry glafs-cafe, among Ficoideffes and African Houfleeks, where they n ay enjoy as much of the fun-fhine as poffible, and hav:a free, dry, open air; for if thefe are placed in a common green-houfe among fhrubby plants, which pe, • ffire freely, it will fill the houfe with a damp air, which

which these succulent plants are apt to imbibe, and thereby becoming too replete with moisture, often call their leaves, and many times their branches also decay, and the whole plant perishes.

CRAMBE. Lin. Gen. Plant. 739. Tourn; Inf. R: H. 211. tab. 100. [KppCii, Gr^A Sea Cabbage.

The CHARACTERS are,

The empalement of the flower is composed of four oval concave leaves which spread open. The flower hath four petals placed in form of a cross* which are large* oblong* and spread open, it hath six stamina* two of which are the length of the empalement* the other four are longer and bifid at their points \ thef\$ are terminated by single fimmits* which branch into threads on their outside. The petals have honey glands on their inside* which are longer than the stamina. It hath an oblong germen* but no style* crowned by a thick stigma. The germen afterward becomes a round dry capsule* with one cell* inclosing one round seed.* This genus of plants is ranged in the second section of Linnaeus's fifteenth class, entitled Tetradynamia filiquosa, the flower having four long and two short stamina, and the seeds growing in pods.

The SPECIES are,

1. CRAMBE (*Maritima*) foliis cauleque glabris. Fl. Suec. 570. *Sea Cabbage with smooth stalks and leaves.* Crambe maritima brassicae folio. Tourn. Inf. 211.
2. CRAMBE (*Suedica*) foliis profunde laciniatis, caule erecto, ramofo. *Sea Cabbage with leaves deeply cut* and an upright branching stalk.*
3. CRAMBE (*Orientalis*) foliis scabris, caule glabro. Lin. Sp. Plant. 671. *Sea Cabbage with rough leaves and a smooth stalk.* Crambe foliis & foliolis alternatim pinatifidis. Prod. Leyd. 330.
4. CRAMBE (*Hispánica*) foliis cauleque scabris. Hort. Upfal. 193. *Sea Cabbage with rough stalks and leaves.* Rapistrum maximum rotundifolium monopermum. Corn. Canad. 147.

The first sort sends out many broad smooth leaves, which are deeply jagged on their sides in obtuse segments, and are of a grayish colour, spreading near the ground; between these arise a thick smooth foot-stalk about one foot high, which spreads out into many branches, which have at each joint one leaf of the same form as those below, but much less; these foot-stalks subdivide again into many smaller, which are garnished with white flowers, growing in a loose obtuse spike, composed of four concave petals, placed in form of a cross, these are succeeded by round dry seed-vessels about the size of large Pease, having a single seed in each. It flowers in June, and the seeds ripen in autumn. The roots of this sort creep under ground, whereby it propagates very fast.

The seeds of the second sort were sent me from Peterburgh for the first sort, from which it differs greatly. This hath a perennial root, which sends out several oblong, smooth, pointed leaves, irregularly cut on their sides into acute segments almost to the midrib, these are very smooth, and of a sea-green colour: between these arise the stalk, which grows three feet high, garnished below by oblong pointed leaves, which are acutely indented on their edges. The stalks branch out into many smaller, and these subdivide again into less, which are garnished with loose spikes of white flowers like those of the first sort, which are succeeded by seeds of the same form. This differs greatly from the first in the shape of its leaves, which are longer, ending in points, and the segments do the same, whereas those of the other are blunt, and not half so deeply cut. The stalks rise more than twice the height of the first, branch out more, and the branches grow more erect; and these differences are constant, where the plants of both sorts grow in the same soil.

The third sort grows naturally in the East. This hath a biennial root, from which arise many leaves in the spring, that are alternately divided to the middle and these divisions are again alternately cut on

their edges into many points, so that they have the appearance of winged leaves, and are of a grayish colour. The stalks rise about two feet high, and divide into many branches, which are terminated by loose panicles of small white flowers, placed in form of a cross, which are succeeded by small round capsules, each containing a single seed. This flowers in June, and the seeds ripen in autumn, soon after which the roots decay.

The fourth sort is an annual plant, which grows naturally in Spain and Italy. This rises with a very branching stalk near three feet high, garnished with roundish heart-shaped leaves, indented on their edges, standing upon long foot-stalks; the branches subdivide into many slender ones, which end in long loose spikes of small white flowers, which are succeeded by small, round, dry seed-vessels, which contain a single seed. The leaves and stalks of this sort are rough. It flowers in June, and the seeds ripen in autumn.

The first species is found wild upon sea-shores in divers parts of England, but particularly in Suffex and Dorsetshire in great plenty, where the inhabitants gather it in the spring to eat, preferring it to any of the Cabbage kind; as it generally grows upon the gravelly shore, where the tide overflows it, the inhabitants observe where the gravel is thrust up by the floods of this plant, and open the gravel, and cut the floods before they come out, and are exposed to the open air, whereby the floods appear as if they were blanched; and when they are cut so young, they are very tender and sweet; but if they are suffered to grow till they are green, they become tough and bitter. This plant may be propagated in a garden, by sowing the seed soon after it is ripe, in a sandy or gravelly soil, where it will thrive exceedingly, and increase greatly by its creeping roots, which will soon overpread a large spot of ground, if encouraged, but the heads will not be fit to cut until the plants have had one year's growth: and in order to have it good, the bed in which the plants grow, should, at Michaelmas, be covered over with sand or gravel about four or five inches thick, which will allow a proper depth for the stalks to be cut before they appear above ground, and if this is repeated every autumn, in the same manner as is practised in earthing of Asparagus-beds, the plants will require no other culture. This may be cut for use in April and May, while it is young; but if die stalks are suffered to remain, they will produce fine regular heads of white flowers, which appear very handsome, and will perfect their seeds, by which they may be propagated.

The other sorts are only preserved in curious gardens of plants for variety, but are not of any use or beauty. The perennial sorts may be propagated in the same manner as the first.

C R A N E - B I L L. See GERANIUM.

CRANIOLARIA. Lin. Gen. Plant. 670. Martynia. Houft. Gen.

The CHARACTERS are,

The flower hath a permanent empalement composed of four joint narrow leaves which spread open* with a large swollen head* which is cut longitudinally on the side. The flower hath one petal* which is unequal* having a very long narrow tube* whose brim is divided into two lips, the upper being roundish and entire* but the under is divided into three parts* the middle segment being the largest. It hath four stamina, two of which are the length of the tube* and two are shorter & these are terminated by single fimmits; at the bottom of the tube is situated an oval germen* Supporting a slender style* crowned by an obtuse thick stigma. The germen afterward becomes an oval leathery fruit* pointed at both ends* opening with two valves* inclosing a depressed woody nut* pointed at both ends* and recurved* having two or three furrows* so as to resemble a skull* opening in two parts.*

This genus of plants is ranged in the second section of Linnaeus's fourteenth class, entitled Didynamia Angholperma, the flowers having two long and

two (hort (lamina, and the feeds being included in 1 csppile.

Gen. 27, The firft **fer** is nwd in the neighbourhood of Carthagem in New Spain, by the lite Dr. William Houftuan, who fent the feeds to England. This a an **tnmu!** plant, which rifes widi a branching (talk about two feet high -, the branches come out oppotUe, which are hairy and vifcous j the leaves silo ire placed appofisc, ujron very long foor-ftalks -, thdc arc of different fhape*. Fomi? of them arc divided into five lobes, others into three, and fome art- slmoft heart-fhap«l, endin™ in acute points; they arc hoiry and damn. The jwen are produced from the llde-, and ilfo at the^nd of the brandies, landing on fhort foot-^LJdks, having an inflated (heath or *covet*, out of whid the tube of the flower nifes, which is feven or eight inch.* long, and very (lender; but at the lop is divided into two lips, the under being large, divided into three broad legments, the middle being larger than tiie other two -, the upper lip is t&odqilb and entire: the fiowers are focceeded by oblong fmiit, having a thick dry fldn, which opens it-nghways, in-clofing s hard furrowed nut, with two recurved horns. This is an enniwl plant, whofe feediirniift befo*n on a hot-bed in^hefpring-, and when the plants arc fit to remove, they (hould Be racli planted in a feparatefsmall pot; filled witi light freih eanh, antl plunge'l tnroa moderate hot-bed^ carefully fhading them from the fun till they have taken new root; after which they flould have free air admitted to them in jiroportion to the warmth of the feaibn, to prevent thrir drawing up wck, and afterward; **netted** in the fame manner as Other tender exotic plants, being too lender to thrive in the open air in England; fo that V

grown too large to remain timlrr the frames, they fhouM ll-removed into the bark-dove, and plunged into the tan-bed, where ihry will flower in Julv, and with good management they often perfrA tficir feeds in aurumrt. But the feeds of thu plant (honkl remain on till they drop, othiTwile they will not grow, for the outer covers of thefe feeds (plit open and drop offlike thofe of the AlnKrnd, before the feeds ate fully ripened.

The fecond fort grows naturally >t the Havannah, and^ in foiiic of the 01 her iHands in America. This rifes with 1 fhnbfiy ftalk to tlic height of ten or twelve tVcr, dividing upward into a tew branches, which arc girittihed wii li fpi -shaped leaves, jut on their ciigei; and thefe ire (*oil* and hairy. Thi.- Roweni arcproduct] from (lie Jkteoi^ rhcli/ inches, growing feveral together on the fame foot-ft Ik; they are fliapeti like thnfi of the *Poplove*, of a r.Tecnilh yd-low cokmr, with brown spots oil the inBdej the flowers hairc a fwslling nibe, whkh is recurvi, and the brim is (lighly ividctj into five unequal fegments, T hie appear in July, but are not fceceeded by fruds in England.

This fort is propagated by feeds, -hkb mtift be procured from the countries where it grows naturally, and (hould be fown on a hot-bed in the fpring, when the plants arc fit to remove, they fhould be each planted into a feparate fmall pot, filled with light kitchen garden eardi, and plunged into a freih hot bed, where they muft be fhaded from the fun till they have taken frith root; then they n. muft have air admitted to them, according to the warmth of the fealbn, until frrequentl; watered during the heat of fummer. In autumn they muft be removed into the bark-frve, and plunged into the tan-bed. During the feafon, the plants fhould not have much wa-

ter, and m>y be treated in the fame manner at other rrnder plant-) from thofe ••••• The plants ftdom flower in Eogknd till the ittir year; and as they do not produce feeds lure, it is wjh difficulty the fort b prderved **St** the European garden.; at there is no other method of propagating the planti but by feeds.

C R A S S U L A . nillcn. H<irt. Elih. 114. Lin. Gen. Plant. 351. Leffir Orpine, or Live-ever. Thii name was formerly applied to the Anacampfaos, or Orpine.

- ii. CRASSULA (*Portulacaria*) foliis obovatfe, oppofitis, caule arboreo. Lin. Sp. 406, *Leffer Orpine with obverfe oval leaves placed oppofite, and a tree-like ftalk*. Craffula portulacae facie arborefcens. Hort. Elth. 120. tab. 90.

The firft fort hath a round reddifh ftalk, which is jointed, rifing about three feet high, which divides upward into many irregular branches, garnifhed with oblong plain leaves placed oppofite, having a griftly border, fet with fmall filver hairs, and clofely embrace the (talks with their bafe. The flowers are produced at the end of the branches in clofe umbels, fitting very clofe to the end of the branches, thefe are funnel-ftaped, having Qretty long tubes cut at the top into five parts, which fpread open *, they are of a fine fcarlet colour, and ftand ered *, the ufual time of their flowering is July or Auguft. This is propagated by cuttings during any of the fummer months -, thefe fhould be cut off about a fortnight before they are planted, and laid in a dry place that the wounded part may heal over; then they fhould be each planted in a fmall pot filled with light fandy earth, and plunged into a moderate hot-bed, giving them but little water. In about fix weeks thefe will have put out roots and begin to grow, when they fhould have a large fhare of air admitted to them, and muft be gradually inured to bear the open air, into which they fhould be removed, placing them in a flickered fituation, where they may remain till autumn; when they muft be removed into a dry airy glafs-cafe, where they may enjoy the fun as much as poffible, and be fcreened from the wet and cold. In warm dry weather, during the fummer months while they are abroad, thefe plants fhould be gently watered two or three times a week-, but in winter they fhould have very little water, left it rot their ftems. Thefe plants require no artificial heat in winter, but they muft be fecured from froft and wet.

The fecond fort will rife with an upright ftalk ten or twelve feet high, if it is not broken or injured, but it requires fupport for the (talks being tender, and the leaves very weighty, they are very fubjeft to break, efppecially if they are expofed to the wind. The leaves of this plant are about three inches long; they are hollowed on the upper fide, and have a convex ridge on their lower, and are placed oppofite, furrounding the ftalks with their bafe *, thefe alternately crofs each other-, they are very thick, fucculent, and of a pale green colour, ending in acute points; at the top of the ftalk the flowers are produced in large clufters; they are of a whitifh herbaceous colour, having fhort tubes, which are cut into five parts at the brim, fpreading open. The ftalk which fuftains the flowers is pretty thick and fucculent, generally turning firft downward, and then upward again, almoft in the form of a fyphon. It flowers in July, but doth not produce feeds here. This fort is propagated by cuttings in the fame manner as the firft, and the plants require the fame treatment.

The third fort rifes with a weak fucculent ftalk about two feet high, fending out many irregular branches, garnifhed with oblong, oval, thick leaves, plain on their upper fide, but convex below, of a deep green -, their borders are fet with a few filvery hairs. The ftalk which fupports the flowers rifes from the top of the branches, and is from four to fix inches long, putting out feveral fide branches, which grow eredfc; thefe are terminated by large clufters of Snail greenifh flowers, which appear in June and July. This is propagated by cuttings in the fame manner as the two former, but being pretty hardy, fhould not be fo tenderly treated *, for if the cuttings of this are planted in a border of light earth, they will put out roots, and may afterward be taken up and potted, to be flickered in winter.

The fifth fort hath a very weak fucculent ftalk, which rifes about a foot and a half high, dividing upward into fmall branches, garnifhed with thin rough leaves which are flat, near two inches long, and a quarter broad at their bafe, gradually narrowing to a point 5

thefe ire fough, placed oppofite, and embrace th* ftalks with their bafe. The flowers come out in final* clufters at the end of the branches; they are fmall, and of an herbaceous colour, fo make no figure; they appear in June and July. This may be propagated by cuttings, which may be treated in the fame manner as the fourth fort.

The fixth fort never rifes with a italk, but the leaves come out clofe to the ground, forming a fort of head j they are taper, fucculent, ending in points, and frequently put out roots; out of the center of thefe arife the flower-ftalk, which grow about fix inches high, branching into two or three (hoots upward, each being terminated by clufters of greenifh flowers, which pake no great appearance. It flowers in May, and fometimes again in the latter part of fummer. This is propagated by taking off the heads, or fide offsets, which fhould be laid to dry three or four days before they are planted; then they may be treated in the fame manner as the other hardier forts before-mentioned.

The feventh fort hath been lately introduced to the gardens in Holland, from the Cape of Good Hope 5 it was fent me by Dr. Adrian Van Royen, late profefibr of botany at Leyden. This hath very flender ftalks, which are full of joints, fo trail upon the ground, unlefs they are fupported, clofely garnifhed with thick, fucculent, heart-ftaped leaves, placed oppofite, which are clofely joined at their bafe, fo that the ftalks run through them; they are of a grayifh colour-, the ftalks are divided, and grow about eight or nine inches long, and are terminated by clufters of fmall white flowers, fitting very clofe to the top of the ftalks \ thefe appear in the fpring, and alfo again in the latter part of fummer. It is propagated by cuttings in the fame manner as the other hardier forts* and may be treated in the fame way.

The eighth fort was fent me from Leyden, by the gentleman before-mentioned \ this rifes with a fhubby ftalk four or five feet high, dividing into many branches, which at firft are taper and fucculent, but by age becomes ligneous; they are garnifhed with very flender, taper, fucculent leaves, which arc near three inches long, and are flaccid, generally turning downward, efppecially in winter, when they are in the houfe; but as it hath not as yet flowered here, I can give no further defcription of it. This is equally hardy with the former forts, and takes eafily from cuttings, fo may be treated in the fame way as the former.

The ninth fort is a low plant, with the appearance of Houfleeek, Having open fpreading heads very like thofe of fome forts of Houfleeek, which grow on the ends of very flender trailing ftalks, which are produced in plenty on every fide the parent plant, in like manner as the childing Marigold. The flower-ftalks arife from the center of thefe heads, which are naked, about four inches long, and are terminated by clofe clufters of herbaceous flowers, which appear in different feafons of the year. This plant propagates very fall by the fide heads, which come out from the parent plant, which frequently put out roots as they trail on the ground, fo may be taken off and potted, during any of the fummer months j this is equally hardy with the former forts, fo the plants may be treated in the fame way.

The tenth fort hath very flender, trailing, fucculent ftalks, of a reddifh colour, which put out roots at the joints as they lie upon the ground. The ftalks and leaves of this fort have the appearance of Purflane, but trail upon the ground like Chickweed. The flowers are produced in fmall clufters at the end of the branches *, thefe are white, with a bluff of purple at their brim *, they appear in fummer at different times, and are often fucceded by feeds, which grow eafily. This fort is eafily propagated by its trailing branches, and the plants require the fame treatment as the other hardy forts, but unlefs they are often renewed will decay.

The eleventh fort rifes with a very thick, ftrong, fucculent ftalk to the height of three or four feet, fending out branches

branches on every fide, fo.is to form i kind of pyramid, the lower branches beine extended to a great length, and the other diroinilhinij gradualj) (to he top; ihcficareof i red or a purplih colour, and very fucculent; they ire garnilhed with roundilh fucculent leaves very like thofe of Purllane, from whence the gardeners have titled it the [urflane-ttw. This fort hath not flowered in England, though it lias been many ytars in the gardens, 1b that we are no: Cure if it is properly ranged in thlis genus; bise from the outward appearance it fecms to be nearly allied to form- of the otW fpecics, on which account Dr. Dillenius tuts placed^ here.

It is propagated with great;... [ings, which may be planted during any of the fummer months; but du-ic (houd be bit! to dry for (ami: diys before they are planted, that ihc wounded pan may be healed over, otherwife they will rot. This fortii foine- what tenderer than the four fwjtj lalt mentioned, lii mull be placed in a warm glafi-Mfi: in winter, where it may enjoy the full fun, and fhmiM have very little wtgr during that le.ilbn. In lumnier the plants fhould be placed abroad in a ihrltered fituation, 3HU in warm weather will require to be refVethd with water twice a work i but as the fhks are very fucculent, too much wet at any leafon is very hurtful to rhdi; plants.

All the hardy forts of Crafula may be treated in the fame way as the Ficoides, and othi: hardier ki; > of fucculent plinu, with this difference only, not to give them fo much water; but the firft, fecond, and eleventh fora require to be placed in A warm dry gW> C&e in winter, and muft not be fo longeirpofcd abroiul in the fummer as the other fpecics, nor fhould liave much water, cpecialty itt the winter.

Thetc flant5 -ire preferred in nioll curiou gardens for the fake of variety, which confifmorein the outward appearance of their plants, ih-ia in the beauty oillicir flowers, except the lirl (on, whofe flowers art of a beautiful fearlct, and grow in clofc bunche at the end of the tranche* j (a that when frveril of the branches arc garnilhed with dowers at the lame rimr, they mike a fine appearance, nnt! tholi flowers continueir in beaut) a long rime ; but thic (lowers of the other Tom arc fmall, and mad of them arc of an htr- baccons colour, lbrnikc nofigure.

Pr. DMleiniB, who firft etablilhird this genus, and feparawd the fpeciw from Cotyledon, fo which many of them had been joined by former bntanifts, made their difference to cotifill in the flupc of the flower; fo that all tht forts with long rubulous flowers of one leaf, he placed under the genu of Cotyledon, and thofe whole flowers hare five petals, he pticed under this: genus of Crafula : but Dr. Unnira makes tht 1 r difference ro confit in thr number of their fbniin.!, fo that all thofe whnfc flowers have but five Etamin, he ranges under tht title of Craffitb, and thofe which have ten (lamina, he puts under that of Cori ledon ; fo that by his fyftem they are removed to a great diftance from each other, and the firft forr here nientiojied is brought from Cotyledon, with whole characters in every other rcfpecl. it agrees, and is pbccd here.

... they may be treated in the fame manner as the Hawth, but they fhould

... they may be treated in the fame manner as the Hawth, but they fhould

should by no means be headed or cut down; when these plants are upon a poor chalky soil, they make great progress, and the wood is very white and hard, so has been often used for making cogs for mills, and many other purposes where hard tough timber is wanted.

It may also be propagated by layers in the same manner as the Lime-tree and Elm, but these should be laid in the young wood; but they are two years before they have sufficient roots to transplant. I have also raised a few plants from cuttings, which were planted in autumn, in a shady border, but there was not more than one eighth part of the cuttings which succeeded; therefore I would recommend the raising them from seeds, for the trees so raised grow much larger and firmer than those which are raised either from layers or cuttings.

The tree will take by grafting, or budding it upon Pear-stocks very well, and Pears will take by grafting upon these trees, so that there is a nearer affinity between the Crataegus and Pear, than there is between either of these and the Medlar; for although both these will sometimes take upon the Medlar, yet neither of them thrive so well, or last so long, when grafted, or budded upon those stocks, as they do upon each other; therefore Tournefort, who has joined the Crataegus in his section, with the Pear and Quince, has come nearer to the natural division of their genera, than those who have joined the Crataegus to the Medlar.

There is another species of this tree which grows naturally about Verona, from whence I have received dried samples of it, but they were without flower and fruit, and came over by the same title as the former; for as there is no other growing in that neighbourhood, they have supposed it to be the common fort; but if that is the Aria of Theophrastus, those trees which grow in England are not, for the leaves of the fort from Verona are spear-shaped, and above an inch long, and not so broad by an inch as those of the English, and the nerves on the under side of the leaves are purplish, the leaves terminating in acute points, so that I make no doubt of its being a different species; but as I have not seen the growing tree, I would not enumerate it till I had been better informed.

The second fort grows naturally in many parts of England, and is chiefly found upon strong soils; it formerly grew in great plenty in Cane-Wood, near Hampstead; and lately there was some young trees growing in Bishop Wood, near the same place; but in many parts of Hertfordshire there are large trees now growing: this rises to the height of forty or fifty feet, with a large trunk, spreading at the top into many branches, so as to form a large head. The young branches are covered with a purplish bark, marked with white spots, and are garnished with leaves placed alternately, standing on pretty long foot-stalks; these are cut into many acute angles, like those of the Maple-tree; they are near four inches long, and three broad in the middle, having several smaller indentures toward the top, of a bright green on their upper side, but a little woolly on their under. The flowers are produced in large bunches toward the end of the branches, they are white, and shaped like those of the Pear-tree, but smaller, and stand upon longer foot-stalks; these appear in May, and are succeeded by roundish compressed fruit, which are shaped like large Haws, and ripen late in autumn, when they are brown; and if kept till they are soft, in the same way as Medlars, they have an agreeable acid flavour. The fruit of this tree is annually sold in the London markets in autumn.

The wood of this tree is hard, and very white, and is very useful for many purposes; but particularly so to the millwrights. It may be propagated in the same way as the former fort, but requires a strong soil.

The third fort grows naturally upon mount Baldus, from whence I received it, and on other mountainous

parts of Italy; this rises with a woody trunk about twenty feet high, dividing into many branches, which are covered with a purplish spotted bark, and closely garnished with oblong sawed leaves, standing alternate, on very short foot-stalks; they are about three inches long, and one and a half broad, in the broadest part, lessening toward both ends; they are flightly sawed on their edges, and of a deep green on both sides. The flowers are produced at the end of the branches in small bunches, which have rarely more than four or five flowers in each; they are white, and much smaller than those of the former forts; these are succeeded by fruit about the size of the common Haw, which is of a dark brown colour when ripe. It flowers in May, and the fruit ripens in autumn.

The fourth fort is a native of North America, but has been many years cultivated in the English gardens, where it is known by the title of Cockspur Haw. Of this there are two species, one of which has no spines on the branches; but the other has strong thorns which are curved downwards, greatly resembling the spur of a cock, from whence it had this appellation: in other respects both forts agree in the form of their leaves, their flowers and fruit. However, Dr. Linnaeus has been ill informed of the two forts by Kalm, who went to America, and is now professor at Abo in Sweden; for the doctor has added the appellation of Cockspur to the fifth fort here mentioned, which has long been known in England by the title of Virginia L'Azarole.

The fourth fort rises to the height of near twenty feet in England, where the trunk becomes large, and divides into many strong branches, so as to form a large head; the leaves are large, oval, and deeply sawed on their edges, so as almost to divide them into lobes, which are placed without order; the flowers come out from the side of the branches in clusters, they are large, composed of five petals, which spread open, and are succeeded by pretty large Pear-shaped fruit of a scarlet colour. It flowers in May, and the fruit ripens in September.

The fifth fort is generally known by the title of Virginia L'Azarole; this rises with a strong stem to the height of fifteen feet or more, sending out many irregular branches covered with a light brown bark, and have a few thorns on their sides; the leaves have short foot-stalks, they are narrow at their base, but widen upward so as to become almost of an oval figure, of a lucid green on their upper side, and pretty deeply sawed on their edges; the flowers are white, pretty large, and composed of five petals which expand; these are succeeded by large fruit of a scarlet colour; it flowers the end of May, and the fruit ripens in September.

The sixth fort grows naturally in North America; this rises with a strong stem to the height of ten or twelve feet, sending out many strong irregular branches, which, while young, is covered with a bright brown bark, but that on the older branches is of a lighter colour; the leaves are oval, spear-shaped, flightly sawed on their edges, of a bright green on their upper side, but paler on their under; sometimes they are placed by pairs, at others three or four come out from the same joint; the flowers are produced in large clusters toward the end of the branches, forming a sort of corymbus, and are succeeded by roundish fruit of a middling size, and a deep red colour. As the branches of this fort shoot very strong, and are generally interwoven with each other, being armed with very long strong thorns, it is very proper for outward fences round gardens or fields.

The seventh fort grows naturally in Italy and the Levant, where the fruit is served up to table with their desert, this hath a strong stem rising twenty feet high, having many strong irregular branches, covered with a light-coloured bark; the leaves are in shape somewhat like those of the common Hawthorn, but they are much larger, have broader lobes, and are of a paler colour; the flowers come out in small clusters from the side of the branches, which are in

Ihape like thofe of the common H.iwthorn, but aiv much larger; as is alfo die fruit, which when fully ripe has an agreeable acid tafa, for which it is citcicirs J by the inii-ibkants of the countries where it grows MDOJ . . .

The **••** fort is the common Hawthorn, which is generally ptir.ee J for fences In molt parts of England, therefore being univerfally known to the inhabitants, it requires no dclcripuon: there are two or three varieties of this fort, which differ in the fixe of their leaves and ths ftrength of their lliooocs; however, thofe with the {mallei I leaves :ire generally preferred for hedges, as tfeir branches always grow dofti together; the method of raifing the plants, and pi them for hedgn, being fully trciid of under the article of Hr.DGEs, I nctd not repeat here.

The ninth fort grows rimirally in North America, thti has a flender thubby (talk, riling about fix or feven feet high, fending out many irregular branches, aimed with lona (lender thorns, and garnifind with fliori, oval, wetfge-lhaped leaves, which are : on their edges, and are woolly on their under fide ; die flowers art final!, proceeding from the fide of rlie branc!

Sometimes fingle, and at other tiines Lvu or three upon the fame foot-ftalk, having large leafy cmpalcms, and are ficceded by finall roundifh fruit, with a large leafy umbilicus which WM before the cmpalement of the flower : thr Howers appear the beginning of June, and the fruit ripens very late in the autumn.

Tins fort may be propagated in the fame manner as the firft, but rctjuirei a ttrong deep foil, otherwife it •will not thrive. It is very Lardy in rct;c& to cold, but at prefer. is very rare in England.

All lie forts of Haws may be propagawd by fteds, which should be : -3vfa m autumn, in the fame manner a; hath been directed for the firft fort; but as thefe IJ-c.b .ire frequently brought from America, and do not arr:c lie-e till fpring, thie fruit may be buried in the ground til! the autumn following, when they msy be taken up and lbwn in drills, being careful to coivr ths m fo as to prevent the birds from defraying them. In the fpring following the pl.inti will come up, which flould be moderat i. . .irered twoor three times a week, it lie Ipring fiiuuld prove dry; during the fummer, they moil be keijt clean from weeds, which it tuffcrea to grow, will fon owrb;... the plants auld ticirroy them. The following fpring ! the plants flould be planted out before they begin to (boot, into a nurfeiy-bi el, where they n ly gruw two years to get ilrngth, when tht-y may be tranfplantL-d where • they are to remain. I; thefe plants are planted m a I: • in light i ail, their root? will extend to aeondderable tiltaiice, and put up many Ill ocs, which may be taken off in the Ipring, and thereby may be increased; this will ilib t.ike if grafted on the Pear, and if the young branches ire laid down, they will take root, fo tht c. plants may be propagatetj either way.

The other Iorts of Hawthorn are generally planted among flowering fhubs of the fame growth, where they add to the variety.

The first sort grows naturally at the Cape of Good Hope, from whence it was brought to the gardens in Holland, and hath since been spread into most of the curious gardens in Europe. The root of this plant is composed of many thick fleshy fibres, diverging from the same head, which strike deep into the ground, and put out many smaller fibres, which are white and fleshy* from the same head arises a cluster of leaves surrounding each other with their base, so as to form a kind of herbaceous stalk, about three inches high, from which the leaves spread only two ways; appearing flat the other two. The flower-stalk arises by the side of these leaves, which is round, hollow, & is near three feet high, terminated by a large head of flowers, included in a kind of sheath, which splits into two parts, and is reflexed. The flowers stand each upon a foot-stalk about one inch long*, they are tubulous, have but one petal, which is cut almost to the bottom, into six oblong blunt segments, which are waved on their edges; in the center is situated an oval three-cornered germen, supporting a long style, which is attended by six stamina, two of the same length, two somewhat shorter, and the two which rest upon the lower segments are the shortest. The flowers are of a bright blue colour, and grow in large umbels, so make a fine appearance. They begin to flower in September, and frequently continue in beauty till spring, which renders them more valuable.

This plant is propagated by offsets, which come out from the side of the old plants, and may be taken off the latter end of June, at which time these plants are in their greatest state of rest, when the plants should be turned out of the pots, and the earth carefully cleared away from the roots, that the fibres of the offsets may be better distinguished, which should be separated from those of the old roots, being careful not to break their heads. But where they adhere so closely to the old plant, as not to be so separated, they must be cut off with a knife, taking great care not to wound or break the roots of either the offsets or the parent plant. When these are parted, they should be planted each into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation, where they may enjoy the morning sun, giving them a little water twice a week, if the weather proves dry but they must not have too much wet, especially at this season, when they are almost inactive; for as the roots are fleshy and succulent, they are apt to rot with great moisture. In about five weeks time the offsets will have put out new roots, when the pots may be removed to a more sunny situation, and then they may have a little more water, which will strengthen

their flowering, but it must not be given them too liberally for the reasons before given. In September they will put out their flower-stalks, and toward the end of that month the flowers will begin to open, when, if the weather should not be good, they should be removed under shelter, to prevent the flowers from being injured by frost or too much wet; but they should have as much free air as possible, otherwise the flowers will be pale-coloured and weak. Toward the end of October they should be removed into the green-house, and placed where they may enjoy as much free air as possible, and not be over-hung by other plants; and during the winter, they may have a little water once a week or oftener in mild weather, but in frost they should be kept dry. This plant only requires protection from frost and moisture, so should not have any artificial warmth in winter, and must be placed in the open air in summer.

The second sort hath large bulbous roots, which send out many large fleshy fibres, having bulbs formed at their ends; the leaves are near three feet long, hollow on their upper side, and closely fold over each other at their base, spreading out on every side; the outer leaves generally turn downward at the top; they are of a deep green, obtuse at their points, with a ridge on their under side. The flower-stalk arises on one side the leaves, which is thick, succulent* hollow in the middle, and a little compressed on two sides; this grows two feet high or more, and is of the same colour with the leaves, and are terminated by large umbels of flowers, with a sheath or cover, which splits lengthways, and reflexed back to the stalk, where it dries and remains*, the tubes of the flowers are narrow, near four inches long, and the upper part is deeply cut into six long segments, which are reflexed back almost to the tube, in the center arises the style, attended by six long stamina, which stand out beyond the petal, and is terminated by oblong protruded summits of a yellow colour. After the flowers are past, the germen, which is situated at the bottom of the tube, becomes a large, roundish, three-cornered capsule, having three cells, two of which are generally abortive, and the third hath one or two irregular bulbs, which if planted produce young plants.

The third sort hath broader leaves than the second, which are plain, and not hollowed on their upper side, but they are shorter and of a lighter green*, these embrace each other at their base; by the side of these arises the flower-stalk, which is compressed and hollow, rising about two feet high, and terminated by large umbels of white flowers, like those of the former sort, but the segments of the petal are broader and not so much reflexed.

The fourth sort hath roots like those of the second sort*, the leaves of this are narrower at their base, and are stained with purple on their under side; the flower-stalks are purple, and grow to the same height as those of the second; the flowers are in shape like them, but the tube is purple, and the segments have a purple stripe running through them*, the stamina also are purple, which renders this more beautiful than either of the other sorts; and these differences are constant in all the plants which rise from seeds, so there can be no doubt of its being a distinct sort.

These three sorts grow naturally in both Indies, so are very tender, therefore must be kept in a warm stove, otherwise they will not thrive in England; they are easily propagated by offsets, which the roots put out in plenty; or by the bulbs which succeed the flowers, and ripen perfectly here. These must be planted in pots filled with rich earth, and if plunged into the tan-bed in the stove, the plants will make greater progress and flower oftener, than when they are placed on shelves; though in the latter way they will succeed very well, provided they are kept in a good temperature of heat. The roots should be transplanted in the spring, and all the offsets taken off, otherwise they will fill the pots and starve the old plants: they must be frequently refreshed with

but it must not be given them too plentifully* especially in winter. These sorts flower at every season of the year, which renders them more valuable; for where there are many plants, there will be almost a perpetual succession of flowers, which emit a very agreeable odour.

CRITHMUM. Lin. Gen. Plant. 303; Tourn. Inf.; 11. H. 317. tab. 169. Samphire.

The CHARACTERS are,

It is a plant with an umbelliferous flower 5 the great umbel is hemispherical, and composed of many smaller of the same figure, the involucrum of the general umbel is composed of several spear-shaped leaves*, those of the particular umbels have very narrow leaves the length of the umbel & the general umbel is uniform; the flowers have five oval inflexed petals* which are almost equal they have five stamina the length of the petals* which are terminated by roundish summits. The germen is situated under the flower, supporting two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes an oval compressed fruit, - dividing into two parts, each having one compressed, elliptical, furrowed seed.*

This genus of plants is ranged in the second section of Linnaeus's fifth class, entitled Pentandria Digynia, the flowers having five (lamina and two styles).

The SPECIES are,

1. **CRITHMUM** (*Maritimum*) foliolis lanceolatis carnosis. Hort. Cliff. 98. Samphire with spear-shaped fleshy leaves. Crithmum five Feniculum maritimum minus. C. B. P. 288. Samphire.

2. **CRITHMUM** (*Pyrenaicum*) foliolis lateralibus bis trifidis. Hort. Cliff. 98. Samphire whose smaller leaves on their sides are doubly trifid. Apium Pyrenaicum thapifacae facie. Tourn. Inf. 305.

The first sort grows upon the rocks by the sea-side, in many parts of England. This hath a root composed of many strong fibres, which penetrate deep into the crevices of the rocks, sending up several fleshy succulent stalks, which rise about two feet high, garnished with winged leaves, which are composed of three or five divisions, each of which hath three or five small, thick, succulent leaves near half an inch long; the foot-stalks of the leaves embrace the stalks at their base. The flowers are produced in circular umbels at the top of the stalks*, these are of a yellow colour, composed of five petals, which are near equal in size, and are afterward succeeded by seeds somewhat like those of Fennel, but are larger. This herb is pickled, and esteemed very comfortable to the stomach, and is very agreeable to the palate; it provokes urine gently, removes the obstructions of the viscera, and creates an appetite; it is commonly used for sauce*, it is gathered on the rocks where it grows naturally, but the people who supply the markets with it, seldom bring the right herb, but instead of it they bring a species of After, which is called golden Samphire, but hath a very different flavour from the true, nor has it any of its virtues. This grows in greater plenty, and upon the plain ground which is overflowed by the salt water; whereas, the true Samphire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at. It flowers in July, and the seeds ripen in autumn.

This plant is with difficulty propagated in gardens, nor will it grow so vigorous with any culture, as it does upon rocks; but if the plants are planted on a moist gravelly soil, they will thrive tolerably well, and may be preserved some years. It may be propagated either by seeds or parting the roots.

The second sort is by Tournefort ranged in his genus of Apium. This grows naturally on the Pyrenean mountains. It is a biennial plant, which doth not flower till the second year, and perishes soon after the seeds are ripe. There are two or three sorts of this plant, which differ in their outer appearance, but I am not certain of their being distinct species. One of these is titled by Mr. Ray, Apium montanum five pteris album. This is of humbler growth than the other; the small leaves are broader, and not so much cut on their edges, and we of a paler green:

these plants are preserved in a few gardens for the sake of variety; they are propagated by seeds, which should be sown in the autumn where they are designed to remain, and will require no other culture but to keep them clean from weeds* and thin them where they are too dense.

CRISTA PAVONIS. See POINCIA*A.

CROCUS. Lin. Gen. Plant. 53. Tourn. Inf. R. H.; 350. tab; 183, 184. [isfo called of the youth Crocus, who (as the poets feign) loved Smilax with so violent a passion, that, by reason of impatience, he WAS turned into a flower of his name.] Saffron;

The CHARACTERS are,

It hath spathe or sheath of one leaf. the flower hath one petal, which is deeply cut into six oblong segments^ which are equal. It hath three stamina which are shorter than the petal, terminated by arrow-pointed summits. The roundish germen is situated at the bottom of the tube supporting a slender style, crowned by three twisted stigmas, which are jawed. The germen afterward becomes a roundish fruit, with three cells, filled with roundish seeds.

This genus of plants is ranged in the first section of Linnaeus's third class, entitled Triandria Monogynia, the flower having three stamina and one style.

The SPECIES are,

1. **CROCUS** (*Sativus*) spathe univalvi radicali, corolla tubo longissimo. Lin. Sp. Plant. 36. Saffron with a spathe near the root, having one valve, and a long tube to the flower. Crocus fativus. C. B. P. 65. Cultivated Saffron.

2. **CROCUS** (*Autumnalis*) spathe univalvi pedunculate,* corolla tubo brevissimo. Saffron with a spathe on the foot-stalk, having one valve, and a very short tube to the flower. Crocus juncifolius autumnalis, spire jenagno purpurascete. Boerh. Ind. alt. 2. 120.

3. **CROCUS** (*Vernus*) spathe bivalvi radicali, floris left filibus. Crocus with a bivalve spathe near the flowers fitting close to the ground. Crocus: lius, flavo flore varius. C. B. P. 66. £ Bihop's Crocus.

4. **CROCUS** (*Biflora*) spathe biflora corolla brevissimo. Crocus with two flowers in each spathe, having very narrow tubes. Crocus vernus, striatus, vylgnris. Par. Bat. Ordinary, spring, striped Crocus.

There are a much greater variety of these flowers than are here enumerated -, but as most, if not all of them are only femal variations, I thought it would be needless to particularize them here, especially as there are frequently new varieties obtained from seeds. Those which are here enumerated, I think must be allowed to be specifically different, since they have many distinguishing characters, which are sufficient to determine the specific difference in plants.

The first sort is the plant which produces the Saffron; which is a well known drug; this hath a roundish bulbous root as large as a small Nutmeg, which is a little compressed at the bottom, and is covered with a coarse, brown, netted skin; from the bottom of this bulb is sent out many long fibres, which strike pretty deep into the ground; from the upper part of the root come out the flowers, which, together with the young leaves, whose tops just appear, are closely wrapped about by a thin spathe or sheath, which parts within the ground, and opens on one side. The tube of the flower is very long, arising immediately from the bulb, without any foot-stalk, and at the top is divided into six oval obtuse segments, which are equal, of a purple blue colour. In the bottom of the tube is situated a roundish germen, supporting a slender style, which is not more than half the length of the petal, crowned with three oblong golden stigmas (which is the Saffron) these spread alunder each way. The style is attended by three stamina, whose bases are inserted in the tube of the petal, and rise to the height of the style, where they are terminated by arrow-pointed summits. This plant flowers in Q&ber, and the leaves keep growing all the winter, but it never produces any seed* here.

The fecond fort grow) natuially on the Alps stru l Idveiiian mountains: this haili ;i final ler bulbous root than the firft, which is more comprcItt by the flowers appear about the fame feifon with tht former, bur they rite with a (horc foot-Italkj having 3 floiit fpattia or (heath juft below the flower, which covers it before it expands. The tube of the flower • very iliort, tlit petal being divided xlmoft to the bottom, and tie fegments terminate in acute points; the Ihmina and ftyle are fiiorr, and tlic leaves oi' tlic plant arc very narrow. The flower is of a d « p blue; but there is a variety of this with a (ky blut Bower, which is liippofed to have been produced by leech. flr. Linnxus has fuppoieil thefc, and alto all the varieties of the Spring Crocus, to be but one (nedes, but there can be no doubt, of thclb being Jiftinfnt from thole of the Spring.

The third fort hou i a pretty large, comprefled, bulbous root, covered with a light, brown, netted Ban, from which, arife four or five leaves, like thofeof the the other Vernal Crocuies, of a purpiifh colour on their lower parts; from between thcle come out one or two flowers of a deep yellow colour, fitting clofr between the young leaves, never rifing above two inches high; thefe have an agreeable odour; the outer Jcgments of the petal arc marked with three black ftreaks or ilripes running lengthways from the bottom to the top of the feemenr; thde arc narrower than the inner fegmcnc. From the double arrangement of thefe fegmenrs -fame have called it s double flower. Thefe frgments have dark purple bottoms, and the tube of the flower hath is many purple a-, there are fegments in the petal. Out of the center of the tutic arifes a (lender ftylc, crowned by a gokctn ftigma, which ts broad and flat, and is attended by three (lender (lamina of the lame length, termiruieil by yellow III mm its, After the flower is pill:, thrgrer-IV ~ "••' of the ground, and fivefa to a nwtnd- •d feed-vefli-L, which opens in three i with rundifti brown feeds. This •; Lrocufcsin the fpring.

The fourth fort rill-s with a few very narrow leaves, which are, together wkh the flower-buds, dofdy wrapped round by a fpathaor lheaiah, out of which arw two flowers, one of which hi'h a longer tube than the other, but ihefc arc wry (lender, tnd do not rile much above the fpatvi; there the petal enlargei, and a divided into fa obtufc fegment.*, which are of equal fac; they are of a dirty white on their outside, with three or four purple Urines in e>th -, the jniidc of the petal is of * purer wliite; tie B omms and Iryle Fie nearly the fame as thofe a/ the former fort. This is one of the earlicft fores which Bowers

*The method of cultivating Saffron being somewhat curious, I thought it not improper to insert in this place an abstract of it, as it was presented to the Royal Society by Dr. James Douglas.

As Saffron grows at present most plentifully in Cambridgehire, and has grown formerly in several other counties of England, the method of culture does not, I believe, vary much in any of them, and therefore I judge it sufficient to set down here the observations which I employed proper persons, indifferent seasons, to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron-Walden and Cambridge, in a circle about ten miles diameter.

In that county Saffron has been cultivated, and therefore it may be reasonably expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where else.

I shall begin with the choice and preparation of the ground. The greatest part of the tract already mentioned is an open level country, with few inclosures; and the custom there is* as in most other places, to crop two years, and let the land be fallow the third. Saffron is generally planted upon fallow ground, and, all other things being alike, they prefer that which has borne Barley the year before.

The Saffron grounds are seldom above three acres, or less than one; and in choosing, the principal thing they have regard to is, that they be well exposed, the soil not poor, nor a very stiff clay, but a temperate dry mould, such as commonly lies upon chalk, and is of an Hazel colour; though if every thing else answers, the colour of the mould is pretty much neglected.

The ground being made choice of, about Lady-Day, or the beginning of April, it must be carefully ploughed, the furrows being drawn much closer together, and deeper, if the soil will allow it, than is done for any kind of corn; and accordingly, the charge is greater.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre, and having spread it with great care, they plough it in as before. The most rotten dung is the best; and the farmers, who have the convenience of making it, spare no pains to make it good, being sure of a proportionable price for it. About Midsummer they plough a third time, and between every fifteen feet and an half, or pole in breadth, they leave a broad furrow or trench, which serves both as a boundary to the several parcels, when there are several proprietors to one inclosure, and to throw the weeds in at the proper season.

To this head likewise belongs the fencing of the grounds, because most commonly, though not always, that is done before they plant. The fences consist of what they call dead hedges, or hurdles, to keep out not only cattle of all sorts, but especially hares, which would otherwise feed on the Saffron leaves during the winter.

About the weather we need not only observe, that the hottest summers are certainly the best, and therefore, if there be gentle showers from time to time, they can hardly miss of a plentiful crop, if the extreme cold, snow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of Saffron is, planting, or setting the roots; the only instrument used for which is a narrow spade, commonly termed a *spade* (hovel).

The time of planting is commonly in the month of July, a little sooner or later, according as the weather answers. The method is this: one man with his spade (hovel) raises between three and four inches of earth, and throws it before him about six or more inches, wipers, generally women, following with heads, place them in the farthest edge of the trench he makes, at three inches distance from each other, or thereabouts; as soon as the digger or spitter has gone once the breadth of the ridge, he begins again at the

other side, and digging as before, covers the roots last set, and makes the same room for the setters to place a new row, at the same distance from the first, that they are from one another. Thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave some part of the first stratum of earth untouched, to lie under the roots, and, in setting, to place the roots directly upon their bottom.

What sort of roots are to be preferred (shall be) hewn under the fourth head, but it must be observed in this place, that formerly, when roots were very dear, they did not plant them so thick as they do now; and that they have always some regard to the size of the roots, placing the largest at a greater distance than the small ones.

The quantity of roots planted in an acre, is generally about 16 quarters, or 128 bushels, which, according to the distances left between them, as before assigned, and supposing all to be an inch in diameter one with another, ought to amount to 392,040 in number.

From the time that the roots are planted, till about the beginning of September, or sometimes later, there is no more labour about them; but as they then begin to (pire, and are ready to (hew themselves above ground (which is known by digging a few out of the earth,) the ground must be carefully pared with a (harp hoe, and the weeds, &c. raked into the furrows, otherwise they would hinder the growth of the plants,

In some time after appear the Saffron flowers, and this leads us to the third branch of our present method. The flowers are gathered as well before as after they are full blown, and the most proper time for this is early in the morning. The owners of the Saffron get together a sufficient number of hands, who place themselves in different parts of the field, who pull off the whole flowers, and throw them handful by handful into a basket, and so continue 'till all the flowers are gathered, which happens commonly about ten or eleven o'clock.

Having then carried home all they have got, they immediately spread them upon a large table, and fall to picking out the filamenta styli, or chives, and together with them a pretty long proportion of the styli itself, or string to which they are joined; the rest of the flower they throw away as useless. The next morning they return into the field again, whether it be wet or dry weather, and so on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank (that it may be moved from place to place) supported by four flint legs; the outside consists of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches square at the bottom on the inside, and twenty-two inches at top, which is likewise equal to the perpendicular height of it. On the fore-side is left a hole about eight inches square, and four inches above the plank, through which the fire is put in 5 over all the rest laths are laid pretty thick, close to one another, and nailed to the frame already mentioned, and then are plastered over on both sides, as are also the planks at bottom very thick, to serve for a hearth. Over the mouth, or widest part, goes a hair cloth, fixed to the sides of the kiln, and likewise to two rollers, or moveable pieces of wood, which are turned by wedges or screws, in order to stretch the cloth. Instead of the hair cloth, many people now use a net-work, or iron wire, with which it is observed that the Saffron dries sooner, and with less quantity of fuel; but the difficulty in preserving the Saffron from burning, makes the hair cloth be preferred by the nicest judges in drying.

The kiln is placed in a light part of the house, and they begin by laying five or six sheets of white paper on the hair cloth, upon which they spread the wet Saffron between two and three inches thick \ this they

cover with other sheets of paper, and over these lay a coarse blanket five or six times doubled, or, instead thereof, a canvas pillow filled with straw; and after the fire has been lighted for some time, the whole is covered with a board, having a large weight upon it. At first they give it a pretty strong heat, to make the chives sweat (as their expression is;) and in this, if they do not use a great deal of care, they are in danger of scorching, and of spoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the Saffron off from that which lies next it, railing at the same time the edges of the cake with a knife; then laying on the paper again, they slide in another board between the hair cloth and upper papers, and turn both papers and Saffron upside-down, afterwards covering them as above.

The same heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it, then they cover it, and lay on the weight as before. If nothing happens amidst during these first two hours, they reckon the danger to be over; for they have nothing more to do but to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, there are required full twenty-four hours.

In drying the larger plump chives they use nothing more, but towards the latter end of the crop, when these come to be smaller, they sprinkle the cake with a little small beer, to make it sweat as it ought; and they begin now to think, that using two linen cloths next the cake, instead of the two innermost papers, may be of some advantage in drying, but this practice is followed as yet but by few.

Their fire may be made of any kind of fuel, but that which smokes the least is best, and charcoal, for that reason, is preferred to any other.

The quantity of Saffron a first crop will produce, is very uncertain; sometimes five or six pounds of wet chives are got from one rood, sometimes not above one or two, and sometimes not enough to make it worth while to gather and dry it; but this is always to be observed, that about five pounds of wet Saffron go to make one pound of dry, for the first three weeks of the crop, and six pounds during the last week; and when the heads are planted very thick, two pounds of dried Saffron may, at a medium, be allowed to an acre for the first crop, and twenty-four pounds for the two remaining, the third being considerably larger than the second.

In order to obtain these, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the same manner as before set down, without the addition of any thing new, except that they let cattle into the fields, after the leaves are decayed, to feed upon the weeds, or, perhaps, mow them for the same use.

About the Midsummer after the third crop is gathered, the roots must be all taken up and transplanted; the management requisite for which, is the fourth thing to be treated of. To take up the Saffron heads, or break up the ground (as the term is,) they sometimes plough it, sometimes use a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over, during all which time of ploughing, or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads as they are turned up.

They are next to be carried to the house in sacks, and there cleaned and rased, this labour consists in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucra, and excrescences, and thus they become fit to be planted in new ground immediately, or to be kept for some time without danger of spoiling.

The quantity of roots taken up, in proportion to those which were planted, is uncertain; but at a medium, it may be said, that allowing for all the accidents which happened to them in the ground, and in

breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are sure to choose for their own use the largest, plumpest, and fattest roots, but do least of all approve the longest pointed ones, which they call spickets, or pickards, for very small, found, or flat roots, are sometimes observed to flower well.

This is the whole culture of Saffron in the county above-mentioned, and we have only now to consider the charges and profits which may be supposed, one year with another, to attend that branch of agriculture; and of these I have drawn up the following computation for one acre of ground, according to the price of labour in this country.

	l.	s.	d.
Rent for three years	—	—	—
Ploughing for three years.	—	0	18
Dunging	—	—	—
Hedging	—	—	—
Spitting and fetting the heads	—	—	—
Weeding or paring the ground	—	1	4
Gathering and picking the flowers	—	6	10
Drying the flowers	—	—	—
Instruments of labour for three years,	—	—	—
with the kiln, about	—	0	10
Ploughing the ground once, and har-	—	—	—
rowing twice	—	0	12
Gathering the Saffron heads	—	—	—
Raising the heads	—	—	—
		23	12
		0	0

Total charge 23 12 0

This calculation is made upon supposition, that an acre of ground yields twenty-six pounds of nett Saffron in three years, which I stated only as a mean quantity between the greatest and the least, and therefore the price of Saffron must be judged accordingly, which I think cannot be done better than by fixing it at 30 shillings per pound since in very plentiful years it is sold at twenty, and is sometimes worth between three and four pounds 5 at this rate, twenty-six pounds of Saffron are worth thirty-nine pounds, and the nett profits of an acre of ground producing Saffron, will, in three years, amount to fifteen pounds, thirteen shillings, or about five pounds four shillings yearly.

This, I say, may be reckoned the nett profit of an acre of Saffron, supposing that all the labour were to be hired for ready money; but as the planter and family do a considerable part of the work themselves, some of this expence is saved; that is, by planting Saffron, he may not only reasonably expect to clear about five pounds yearly per acre, but also to maintain himself and family for some part of each year; and it is upon this supposition only, that the result of other computations can be said to have any tolerable degree of exactness, but the calculations themselves are undoubtedly very inaccurate.

I have said nothing here concerning the charge in buying, or profits in selling, the Saffron heads, because, in many large tracts of ground, these most at length balance one another, while the quantity of ground planted yearly continues the same, which has been pretty much the case for several years past.

Dr. Patrick Blair, designing to treat concerning the Crocus, in his sixth Decad of his Pharmaco-Botanologia, did, in the year 1725, send me the following queries:

1. After what manner the species are propagated?
2. Whether the tap-root springs first, or the bulb?
3. At what season the leaves spring forth?

To these queries I sent him the following answer:

1. As to the propagation of the species.

This is only by the roots or offsets, which the old roots produce in great plenty, for I never saw any thing like a seed, or a seed-vessel produced, though I have let stand great quantities of flowers purposely to try.

2. As to the query, Whether the tap-root springs first, and the bulb be afterwards formed?

As food as the roots begin to (hoot upwards, there arc commonly two or three large uproots lent forth from the fide of the old root, which will run down riglic two inches and halt or more, into the ground at the place where thefe bulbs firft come out from the old one, will be formed « bulb ibmctimes (rough not always, as you wil) hear prefently :) and rhistap root decays. The bulb will increafe in its hignefs, tiil at laft it quite fijlli tiV, and is then left entire, which commonly happens in April, when the greti begins ro decay j bui many times thefe tap er « r rotry roots never produce any bulbs, but always retain the fame figure, and forever after, I believe are barren ; for I planted a parcel of thefe carrotry root four years ago in a little bed, where they have ever lince remained, but have not produced one fingi* flower, notwithstanding they have produced a plentiful offspring of the fame carmnty roots. And the people about Saffron "Waklen are well apprifed of this birrenntls, and therefore ihrow mntj all Juch roots wvhen they make a new plantation \ bu, as ihis change of the root is not peculiar to the Sat' (Von only, permit me to digrefi a little, to give you fome account at" this matter.

In the parifh of Fulham, near London, (the gardeners ufed K> drive (great trade in the jonquil, or Narciffu juncifolius, flore multiplici, it which place the great quantity of thofe roots was riefed for fale, as perhaps was in any part of England, and turned co as great account for die matter, as any crop they could employ dieir ground in, till of late years, that molt of dieir roots have turned carrotty, and (b proved barren, or have produced only Gnglc Howen ; Lo that the gardeners being hereby difheartened, hjuv thrown them out entirely, neglecting co cultivate them, fatisfying themfelves with this reafoiij that their ground was tired wtili diem.

But to return to the- Crocus. Befides thofe roots already mentioned, there will be three or four final] bulbs formed upon the upper part tit" the root, and fome underneath, whkh from the firft appearance aflume the round Jhape of its parent root, and luvtno tap-root belonging to them : thiofe on the upper part of the root rarely emit fa much u a fibre, but receive their nourilhment immediately from the old root; but thofe on the under fide lend out many fibres all around, by which they draw their noiriilhment from the ground; thefe being parted from tl root much fooner than the other, Hand in need of fit organs for receiving their nourittiment.

I have fometimes taken up fome, through the middle of which hath been a root of the Gramen caninuro, or Couch Grafs, which fame people have imagined bid ilength enough to forte its way through the Crocus root) but the truth is, the root of the Graff clofely adhering to the old root of the Crocii

at the place where the young roots were emitted, theft young roots being quick of growth, inclofed the root of the Grafs, and thus I have ten feveral roots run through each other in the lame manner.

But befidej theft offsets mentioned, directly upon the upper part of the root is otic large mot formed, of equal bignels with the old one, and this b the time that the root ii Radix gemina, as Tturncfort calls it • for they .ire not To at any other Eeafat, Old therefore I think, it a very improper appellation; for when tjw new roots arc perfectly formed, the old ones, with their coats, fall off and die, and leave the new roots all fingie. This has occafioned feveral poeijle to doubt of what Toumefort had raid of the roots, till I took uji lame plants at that fenfon, and with them the two roots of Mjual bignck, i. e. the old at the bottom, and the new one at the top.

Dr. Blair alio happening, in viewing a root, to be furpriced with a different appearance from what he had fren before or heard of, lent me another letter.

The manner of the root was thus ; from the upper part of the bulb, where it fends forth all the i within a common tunide, at the exit there was »n appendix about an inch ind a half long, about [be graff*.

nefs of a large turkey or goofe-quill, cylicvJricid and blunt, without die iealt "radical libra, by which it might rective the nou: *thromat*, *th* uoth or polifhttl, anilbluilhin tic furfac, cunfitting of Jeveral circular lines, when cut tranfverfy; white, with a hard greenifli center like a Carrof, when it hurl) pulhed toirh the floweriig-Item, mil unli • the *thromas* of of lomc running root, fuch as the Mints b;: *low ground*, only the extremity defended obliquely, inleid of ascending, to fend torth leaves to produce anew pjant; and what is moll remarkdLik, tiis did not happen to one or two plants, but to die whole bundle, which were- above iwei *thromat* > <, differing in nalhing but majus and minus-, the bulb feemed ac *the* tamo tune to be pined and ciaciuted, though, ttt, *thromat* large radical fibrci like thofe of a Leak.

I having receivni this account *fitWa* htm by letter, fent him the following aniv...

I received yours in anfwer to my Lilt, with tic figure of die roots of fome feti of Crocm Autuinns: you have taken out of the ground ; I have found a figure in I kodonseus which coirHjwnd^; will; ii, and itiolb rooni are, no new riling with the Saffron gar, *thromas*, who always throw thicm away when they make ireih *thromas*.

Your figure does not agree with my tep-rev *thromas*, as you will lee by dv *thromas* taken as juft from the lito as I iould. In mLie you will find the bulb : *thromas* Tideways, which I Jllil lind to be conlUnc in all the roots I frfw wramiitfd, whiich have been a gnai rminy, and makes me fufpect thefe up-n *thromas* occifiofled by the accidental txilkion of lix roots in ptanung, which may retard the alctiding fsp, thu towering-ftctn being thereby turned into a crooked liguie, and the tap-roots are full of longitudinal veil, *thromas* of a con filterable diinenfion, fo that the greater att rafting power of die Jap being hereby ilivrsced dnwards, the fiowar-fitna may be quite defti^ per nouriffment.

The method you propofe to remeJ ency, will not do, for I have remove *thromas* ur thdt roots at the feafon wlien the up-rooti were forming, and this alone ddroyeti thrm all i lu lliit I am jilLr- iuadt-d, the cutting; them off entirely will kill them.

The method I uicd with ilio Jo;iqi:ls was, to lay fome tiles Jult under the roow, to pitvmt their running downwards, but this has not a *thromas* *thromas* I think it poffible wholly to recover them ; *thromas* al- terarjon is not only in the, root and Dower, bu, *thromas* in the leaf and blade, which beibre was fruitulou, but after this alteration in the root, becomes a pjwb cated leaf, and if it ev<r blolloms after, i<: iowera aic large and tingle, whidi before wenc imall and doubles but the Saffron, after the change of its roots, produces a final narrow blade, lelduin half the lengtk of thofc in a natural ftate.

Lifon this Dr. Blair formed this condution:

Thefe additional obiervations plainly iliciv, diat nrlicr tiie carrotry *mat*, nor the blafted taji-root, may call it, are merely icckkntal, ur what ma) be called lufus naturae but certain dileafes inddenc tu fuch roots ; for were they accidental, they would not haw the fame appearances to diftercut perfoii in different loils and climates, nor would Jo many taken up together have luch a referenblance LO each otL I have twice obferved.

minated by Jingle fummits, and an oblong reflexed germen, supporting a Jingle Jiyle, crowned by an obtuse stigma. The germen afterward becomes a Jhort turgid pod with one cell, opening with two valves, and filled with kidney-Jhaped feeds.

This genus of plants is ranged in the third fe&ion of Linnaeus's feventeenth clafs, intitled Diadelphia Dendandria the flowers of this clafs and feftion having ten ftamina joined in two bodies.

The SPECIES are,

1. CROTOLARIA (*Verrucofo*) foliis fimplicibus ovatis, ftipulis lunatis declinatis ramis tetragonis. Flor. Zeyl. 277. *Crotolaria* with Jingle oval leaves, tunated declining ftipuU, and four-cornered branches. *Crotolaria* Afatica folio fingulari verrucofo, floribus cseruleis. H. L. 199.
 2. CROTOLARIA (*Pilofa*) foliis fimplicibus lanceolatis pilofis, petiolis decurrentibus. *Crotolaria* with Jingle, hairy, fpear-Jhaped leaves, and running foot-Jialks. *Crotolaria* Americana, caule alato foliis pilofis, floribus in thyro luteis. Martyn. Cent. 43.
 - 3* CROTOLARIA (*Sagittalis*) foliis fimplicibus lanceolatis ftipulis folitariis decurrentibus bidentatis. Hort. Cliff. 357. *Crotolaria* with Jingle fpear-Jhaped leaves, and Jingle ftipuU indented. *Crotolaria* hirtuta minor Americana herbacea, caule ad fumum fagittato. H. L. 202.
 - 4- CROTOLARIA (*Fruticofa*) foliis fimplicibus, lineari-lanceolatis hirtutis, petiolis decurrentibus, caule fruticofa. *Crotolaria* with Jingle, narrow, fpear-Jhaped leaves, which are hairy, running foot-ftalks, and Jhrubby ftalk. *Crotolaria* frutefcens hirtuta, flore luteo, ramulis alatis, foliis mucronatis. Houft. MSS.
 5. CROTOLARIA (*Juncea*) foliis fimplicibus lanceolatis, petiolatis caule ftriato. Hort. Cliff. 357. *Crotolaria* with Jingle fpear-Jhaped leaves having foot-ftalks. *Crotolaria* Benghalenfis foliis geniftae hirtutis. Pluk. Aim.
 6. CROTOLARIA (*Perfoliata*) foliis perfoliatis cordato-ovatis. Lir[^] Sp. Plant. 1005. *Crotolaria* with oval heart-Jhaped leaves perforated by the ftalks. *Crotolaria* perfoliata folio. Hort. Elth. 122. tab. 102.
 7. CROTOLARIA (*Retufa*) foliis fimplicibus, oblongis cuneiformibus retufis. Flor. Zeyl. 276. *Crotolaria* with Jingle, oblong, wedge-Jhaped leaves, reflexed at the top. *Crotolaria* Afatica, floribus luteis, folio fingularo cordiformi. H. L. 200.
 8. CROTOLARIA (*Villofa*) foliis fimplicibus ovatis villofis, petiolis fimpliciffimis, ramis teretibus. Hort. Cliff. 357. *Crotolaria* with Jingle, oval, hairy leaves, Jingle pedicles and taper branches. *Crotolaria* arborefcens Africana, Styrcis folio. H. L. 170.
 9. CROTOLARIA (*Jngulata*) foliis ovatis feffilibus, ramulis angulatis hirtutis, floribus lateralibus fimpliGiffimis. *Crotolaria* with oval leaves Jitting clofe to the tranches, which are angular, baity, and Jingle flowers proceeding from the fides of the branches.
 - *o. CROTOLARIA (*Labumifolia*) foliis ternatis ovatis acuminatis, ftipulis nullis, leguminibus pedicellatis. Flor. Zeyl. 278. *Crotolaria* with oval, trifoliolate, pointed leaves, no ftipula, and foot-ftalks to the pods. *Crotolaria* Afatica frutefcens, floribus luteis amphis tnfu-Uata. H. L. 196.
 - H. CROTOLARIA (*Alba*) foliis ternis lanceolato-ovatis, caule laevi herbaceo, racemo terminali. Hort. Cliff. 499. *Crotolaria* with oval, fpear-Jhaped, ternate leaves, finooth herbaceous ftalks, which are terminated by loofe fpikes of flowers. *Anonis* Caroliniana perennis non Ipinofa, foliorum marginibus integris, floribus in thyro candidis. Martyn. Cent. 44.
- The firft fort grows naturally in India. This is an annual plant, which hath an herbaceous four-cornered ftalk, rifing about two feet high, dividing into three or four branches; thefe have allo four acute angles, and are garnifhed with oval warted leaves, of a pale green colour, ftanding on very fhort foot-ftalks -, the flowers are produced in fpikes at the end of the branches, which are of the butterfly fhape, and of a light blue colour, fucceeded by fhort turgid pods, which inclofe one row of kidney-Jhaped

feeds. It flotteft in July and Auguft, and the feeds ripen in autumn.

This plant is propagated by feeds, which muft be fown upon a hdt-bed in the fpring, and when the plants are come up an inch high, they fhould be tranfplanted to another hot-bed to bring them forward, obferving to fhade them from the fun till they have taken new root -, after which they fhould have free air admitted to them in proportion to the warmth of the feafon, to prevent their being drawn up weak. When the plants have acquired ftrength in this bed, they fhould be carefully taken up, with balls of earth to their roots, and each planted in a feparate pot, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, carefully fhading them till they are rooted again j then they muft be treated in the fame manner as other tender exotic plants, giving them proper air and water in warm weather j when the plants are grown fo tall as to nearly reach the glaffes of the hot-bed, the pots may be removed into an airy glafs-cafe, or ftove, where they may be fcreened from inclement weather, and have proper air in hot weather *, with this treatment the plants will flower in July, and continue to produce frefh fpikes of flowers till the end of Auguft; and thofe fpikes of flowers which appear early in the feafon, will be fucceeded by ripe feeds in September, foon after which the plants will decay.

The fecond fort grows naturally at La Vera Cruz in New Spain, from whence the feeds were fent me by the late Dr. Houftoun -, this rifes with a coffpreffed winged ftalk near three feet high, putting out feveral fide branches, garnifhed with fpear-Jhaped leaves near three inches long, and one broad, covered with foft hairs, and fit clofe to the branches* alternately; from the foot-ftalks of each there runs a border or leafy wing, along both fides of the branches; the flowers are produced in loofe fpikes at the end of the branches, which are of a pale yellow colour, the ftandard being ftretchedout a confiderable length beyond the wings. Thefe are fucceeded by fhort turgid pods, which, when ripe, are of a deep blue colour, having one row of fmall kidney-Jhaped feeds, which are of a greenifh brown colour. This flowers and feeds about the fame time with the former, and requires the fame treatment.

The third fort was fent me from South Carolina by the late Dr. Dale, and alfo from Jamaica by Dr* Houftoun, fo that it grows naturally in feveral parts of America; this is an annual plant, which rifes with a (lender ftalk a foot and a half high, dividing into three or four fpreading branches, garnifhed with oblong oval leaves fitting clofe. The upper part of the branches have two leafy borders or Wings, running from one leaf to the other, but the lower part of the branches have none; the foot-ftalks of the flowers arife from the fide of the ftalk, thofe from the lower part of the branches are above a foot long, the upper are about fix inches, they are very flender, and iuftain one or two pale yellow flowers at their tops, which are not more than half fo large as the former fort, and are fucceeded by very fhort turgid pods, in which are inclofed three or four fmooth kidney-Jhaped feeds. This fort requires the fame culture as the two former, and flowers at the fame feafon.

The fourth fort grows naturally in Jamaica, from whence the feeds were fent me by the late Dr. Houftoun 5 this rifes with a fhubby taper ftalk near four feet high* fending out many fide branches which are very flender, ligneous, and covered with a light brown bark, garnifhed with very narrow fpear-Jhaped leaves, which are hairy, fitting clofe to the branches; the younger fhoots have a leafy border or wing on two fides, but the old branches have none; the flowers are produced near the end of the branches, three or four growing alternate on a loofe fpike; they are of a dirty yellow, and fmall; the pods which fucceeded them are about an inch long, very turgid, and of a dark blue when ripe. This fort is propagated by feed, which ihould be fown cm a hot-bed, and the plants

treated in the time manner as thole before *, but in autumn they should be placed in the (love, where they will live through the winter, and flower early the following summer, so will perfect their seeds very well.

The seeds of the fifth fort were brought me from the estate of Malabar, which succeeded in the Chelfa garden. This sifes with an angular stalk near four feet high, dividing upward into three or four branches garnished with narrow pinnate leaves, placed alternately on very short foot-stalks; they are pretty distinctly covered with soft silvery hair. The flowers are produced at the end of the branches, in loose spikes, they are large, and of a deep yellow colour, and the style stands out beyond the standard. The stems are succeeded by large kidney-shaped seeds.

This plant is annual in England, but by the lower part of the stalk growing woody, it appears to be of longer duration in the country where it naturally grows; though it will not live through the winter here, for if the plants are placed in a stove, the heat is too great for them, and in a green-house they are very subject to mouldiness in damp weather. I have sown the seeds of this in the full ground, where the plants have grown upward of three feet high, and have flowered very well, but no pods were formed on them, and when they have been treated tenderly, the pods have grown much larger, and produced a greater number of flowers, but these have produced few seeds. The only way which I could ever obtain seeds, was by raising the plants in pots upon hot-beds, and the beginning of July, turning them out of the pots into the full ground on a very warm border under a wall, in which situation they flowered very well, and some few pods of seeds were ripened. The sixth fort was sent me by the late Dr. Dale from South Carolina, who had the seeds lent him from the country, at a great distance from the English settlement. By the description lent me with the seeds, it grows with a shrubby stalk four or five feet high, but the plants which were raised here, perished at the approach of winter, so that they only flowered, without producing any pods. The leaves of this are round, and covered with a tight brown bark, garnished with smooth, oval, heart-shaped leaves, which are about ten inches long, and near three broad, forming the stalk in such a manner, as if it were run through the middle of the leaves. The flowers grow singly fitting close to the bottom of each leaf, toward the upper part of the branches; they are of a pale yellow colour, and appear here in August but as the plants did not produce any pods, so I can give no account of them. This is one of the most angular plants of the gentian family I have yet seen.

The seventh fort rife* with an herbaceous stalk near three feet high, dividing upward into several branches garnished with oblong leaves, which are narrow at their base, but gradually widen to the top, where they are rounded and indented in the middle in the shape of a heart; they are of a pale green, and smooth. The flowers are produced in spikes at the end of the branches, they are pretty large, and of a yellow colour, and appear here in July, and the seeds ripen in autumn, provided the plants are brought forward in the spring, and afterward treated in the same manner as has been directed for the first fort. This grows naturally in the island of Ceylon, and is an annual plant, perishing soon after it produces seed. I received the seeds of this from J. L. i. » rv

The eighth fort was sent me by the late Dr. Boerhaave, and is of a yellow colour.

This plant grows naturally at the Cape of Good Hope, from whence I received the seeds. It rises with a shrubby stalk about five feet high, dividing into several branches, garnished with roundish leaves, fitting close to the stem, they are of a hoary grey colour, and at the top of the branches are taper and imooth, the down is produced at the end of the brine leaves; they are about the size of those of the first fort, and of a fine blue colour.

This plant flowers in June and July, and in warm countries will ripen its seeds in autumn. It is propagated by seeds, which must be sown upon a good hot-bed in the spring, and when the plants are fit to remove, must be each transplanted into a small half-penny pot, and plunged into a hot-bed of rannen bari, and after must be treated in the same manner; they have been directed for the fourth time, that the plants should be in a moderate (love in winter, others if they cannot be preserved in England; the seeds sown in the spring will flower, and with proper care their seeds will ripen.

The ninth fort was sent me from Campradi, where the plant grows naturally, this rises with a stem upright five feet high, dividing upward into several hairy branches, which grow garnished with oval kidney-shaped leaves, of a pale green colour, the flowers are produced singly from the side of the branches, which are of a light yellow, and are succeeded by short kidney-shaped pods, having one row of kidney-shaped seeds. It flowers in July and August, and with the same treatment as hath been directed for the first fort, will produce seeds in autumn. This is an annual plant, which sown after the seeds are ripe.

The tenth fort grown naturally in India; this rises with a shrubby stalk four or five feet high, dividing into many branches, garnished with smooth oval leaves ending in points, the flowers are large, yellow, and produced in large bunches from the side of the branches; they appear in July, August, and September, but I have seen many pods produced here. However, when the plants are in flower, they make a fine appearance.

It is easily raised by cutting, during the summer months, if the cutting is planted in a moderate hot-bed, being careful to shade it till they have taken root, and to water them with water: during the months of July, August, and September, the plants may be exposed to the open air in a sheltered situation, where they will produce many flowers, but in the autumn they should be placed in a temperate stove, to preserve them in winter.

The eleventh fort grows naturally in Virginia and Carolina, from both these countries I have received the seeds; there are two varieties of this species, one with a white, and the other a blue flower; but the seeds of one will produce both varieties as I have more than once experienced. The root is perennial, sending up every spring a number of leaves, in proportion to the size of the root; the foot-stalks of the leaves are smooth, rising two feet high, dividing upward into three or five branches, garnished with smooth leaves, whose lobes are: mil, five-lobed, and entire; the foot-stalks of the flowers arise immediately from the root, and advance rather higher than the leaves, being terminated by a three-lobed butterfly-shaped flower; the flowers, near a foot in length in one variety they are white, and in the other deep blue: these are succeeded by large kidney-shaped seeds of a black colour when ripe, having one row of kidney-shaped seeds. It flowers in June, and the seeds ripen in autumn.

It is propagated by seeds, which should be sown in a moderate hot-bed in the spring when the plants are fit to remove, they should be gradually inured to the open air; in the autumn they should be placed in a moderate frame, or covered with mats in winter to shelter them; but the following spring they should be transplanted into the open ground, where, if the soil is dry, and the situation sheltered, they will live in many years producing flowers in autumn.

A* molt of rlic/i plants are annual, fa they require to be brought forward in the spring, otherwnc the funimen are too Diort for them to perfect fruits; fo that uncliei they arc carefully managed, they will not flower well here* forin general, die liimncrs in this country we not very favourable for tliclt; tender pliii . to England, and fold in the druggifts Ihops by the name of Tournfole.

The fecond fort grows naturally at La Vera Cruz in New Spain, from whence the feeds were fent me by the late Dr. Houftoun; this is an annual plant, which rifes about a foot high; it hath an angular ftalk ^ the branches are naked from their divifions to the top, where they are garnifhed with a few oval fpear-flaped leaves, which are fawed on their edges; they are an inch and a half long, and three quarters of an inch broad, ftanding on fbot-ftalks one inch long. The flowers are produced in clofe fhort fpikes at the end of the branches, thole on the upper part being male, and the lower female; they are white, and the male foon falls away, but the female are fucceeded by roundifh capfules, having three lobes; thefe grow in clofe clutters, they have three cells, each containing one roundifh feed. It flowers in July, and the feeds ripen in autumn.

The third fort was difcovered by the late Dr. Houftoun at La Vera Cruz, from whence he fent me the feeds; this is alib an annual plant, which grows naturally in low marfhy grounds, where it hath a very different appearance from what it puts on when fown upon dry land; thofe of the watery places have broad flat ftalks, and leaves three inches long, which are fcarce a quarter of an inch broad; thefe are rough, and but little indented on their edges; but thofe plants upon dry ground have oval leaves three inches long, and upwards of two inches broad, which are fawed on their edges. The flowers are produced at the wings of the leaves, in fhort loofe fpikes, having four or five herbaceous male flowers at the top of each, and three or four female flowers at the bottom, which are fucceeded by roundifh capfules with three lobes, covered with a prickly hufk; thefe have three cells, each inclofing a fingle feed. It flowers and feeds about the fame time as the former.

The fourth fort was difcovered by the fame gentleman, at the fame place as the former; this is an annual plant, which rifes with a taper herbaceous ftalk a foot aqff a half high, dividing into feveral branches, garnifhed with fmooth leaves, ftanding upon very long foot-ftalks, and are for the moft part placed oppofite, as are alfo the branches; the lower leaves are divided deeply into five oblong fegments or lobes, and the upper into three, which are (lightly fawed on their edges, ending in acute points. The flowers are produced in loofe fpikes at the end of the branches, thofe on the upper part being male, and the lower female, they are of an herbaceous colour; the female flowers are fucceeded by oblong capfules, having three lobes, which open in three parts, having three cells, each containing one oblong feed. This flowers and feeds at the fame time as the former forts.

The fifth fort was found growing naturally at the Havannah, by the late Dr. Houftouri, who fent me the feeds -, this is an annual plant, which rarely grows more than fix inches high, dividing into two or three branches *, the lower part of thefe are garnifhed at each joint with four leaves placed in form of a crofs, two of which are three inches long, and one inch broad near their bafe, ending in acute points; thefe ftand oppofite, and the other two leaves between thefe are about two inches long, and a quarter of an inch broad; they are of a light green on their upper fide, and of a gray or Afh-colour on their under. The flowers are produced in long loofe fpikes at the top of the ftalks, two or three of thefe fpikes arifing from the fame joint; the upper part of thefe fpikes have male, and the lower female flowers, of an herbaceous colour; the female flowers are fucceeded by round capfules with three cells, each containing one roundifh feed. This flowers and feeds about the fame time *with the former forts.

The fixth fort was difcovered by the late Dr. Houftoun in the ifland of Jamaica, where it grows naturally. It rifes with a fhubby ftalk to the height of feven or eight feet, which is covered with an Alt-

coloured bark, and divides into many (lender branches upward; fome of thefe branches are terminated by five or fix fmaller, which arife from the fame joint; thefe are naked below, but toward their upper part they are garnifhed with fmooth fpear-flaped leaves, about two inches and a half long, and three quarters of an inch broad, ftanding on pretty long foot-ftalks without order; the flowers are produced in fhort fpikes at the end of the branches, in the fame manner as the former; they are of an herbaceous colour, and incloied in large green empalcments.

The feventh fort was fent me from Jamaica, by Mr. Robert Millar *, this rifes with a fhubby ftalk feven or eight feet high, fending out many irregular branches, covered with an Afh-coloured bark, and garnifhed with heart-flaped leaves, near four inches long, and two inches broad in their wideft part, ending in acute points; they are of a light green on their upper fide, but woolly on their under, ftanding on flender foot-ftalks without any order, fometime fingle, and at others, two or three arife from the fame joint. The flowers are produced in fhort fpikes from the fide of the branches; they are of a whitifh green colour, and the female flowers are fucceeded by capfules, having three cells, each including a fingle feed.

The eighth fort grows naturally in Jamaica, from whence the feeds were fent me by the late Dr. Houftoun; this rifes with a fhubby ftalk about fix or feven feet high, fending out many fide branches, which are covered with a fmooth bark, of a yellowifh white colour, garnifhed very clofely with narrow ftiff leaves near three inches long, and about one eighth of an inch broad, of a light green on thsir upper fid? » but their under fide is the fame colour as ile bark -, the midrib is furrowed on their upper fide, and very prominent on the lower; the upper pare of ths branches divide into four or five fmaller, which arife from the fame joint, and are nearly equal in their length, and between thefe arife a long loofe fpike of whitifh green flowers. The whole plant hath an aromatic odour when rubbed. The feeds grow in roundifh capfules having three cells, each including a fingle feed.

The ninth fort grows naturally in Jamaica, from whence it was fent me by the late Dr. Houftoun; this rifes with a fhubby ftalk fix or feven feet high, dividing upward into feveral branches, which are covered with a yellowifh down, garnifhed with long heart-flaped leaves, ending in acute points; thefe are two inches and a half long, and one broad in their wideft part, ftanding on long foot-ftalks, covered on both fides with a woolly down of the fame colour as the branches. The flowers are produced on long clofe fpikes at the end of the branches; the male flowers, which are fituated on the upper part of the fpikes, have white flowers of one leaf, divided into five parts almoft to the bottom, and have five taper ftamina, fituated in the bottom. The female flowers on the lower part of the fpikes, have large woolly empalements, and are fucceeded by round capfules with three cells, each including a fingle feed.

The tenth fort rifes with a fhubby ftalk near four feet high, dividing into many fmaller branches, which have a filvery bark, and are garnifhed with fmall heart-flaped leaves, about three quarters of an inch long, and half as broad at their bafe, ending in acute points; thefe are woolly on both fides, but their under fide is filvery, their upper fide of a yellowifh green. The flowers are produced in fhort fpikes at the end of the branches, which are fmall, white, and have woolly empalements. The female flowers on the lower part of the fpikes are fucceeded by roundifh capfules with three cells, each containing one feed.

All thefe plants except the firft, are natives of warm countries, fo will not thrive in England, unlefs they are tenderly treated. They are all propagated by feeds; thofe which are annual perfeft their feeds in England *

England; but the flirubby forts very rarely irrive to
 the pi-icction, fo their feeds muft be procured from
 (the countries where they naturally grow. The feeds
 muft be lbwn on a hot-bed early in the fprinfr, and
 when the plants art fit to remove, they flould be
 each tr.m (plained into a fmaUpot, and plunged into
 a moderate hot-bed of tanners bark, where they
 lould be jhailed from the fun till they have taken
 freth roor; rhtn they triult have air itimitt(1 to liem
 daily, in proportion to (be warmth of the lea&n;
 they muft allo be frequently re&fshed with u-nt-r,
 particularly tin- bcond, third, and fourth forts. • nich
 yil! often require water, but the others hould have
 it more lparingly. After the plants art grown too
 utl to remain in the frames, d they flould be removed,
 i into the ftovc, or a glids-cafc, where there is
 a hotbed of tanners bark, into which the pets (houkl
 ^ plunged, and there the annual forts will flower
 ^d per&t their feeds; but the lhrublij- kindl moft
 « removed into the b,irk-ftovc in the autumn, anf
 during the winter fealbn tlity lhouJl have but little
 water-, and the ltovc flould IK kept in a good tern-
 pen arc of hear, otherwife they will not live through
 thr winter in England.

As thefe plants retain their leaves all the ywr, fo
 they niatc A pretty variety in winter, wien they are
 intermixed with other plants, whofe leaves ire of dif-
 ferent form* and cutoitr-i from dtclr.

The firft fort grows naturally in France, Germany, and Italy, in fhady places, and is feldom kept in gardens, unlefs for the fake of variety ^ it fends out many climbing ftalks, which grow four or five feet high where they meet with fupport, otherwife they trail on the ground; thefe ftalks fend out fide branches oppofite, at each joint; the leaves are like thofe of Chickweed, and are placed oppofite. The flowers come out fingle at the end of the branches, which have large inflated empalements; they confift of five petals, which are white, cut at the brim into feveral narrow fegments, and are placed at a diftance from each other; they are fucceeded by oval berries, which, when ripe, are black and full of juice, inclofing feveral flat fhining feeds. It flowers in June, and the feeds ripen in autumn. This hath a perennial creeping root, whereby it is apt to multiply too faft in gardens. It delights in {hade, and will thrive in almoft any foil.

The fecond fort grows naturally in mod parts of England, where it is generally called Spatling Poppy. This ftands in the catalogue of medicinal plants,

under die title of Behen album; the roots of it are fometimes ufed, and are accounted cordial, cephalic, and alexipharmic. It hath a perennial root, which ftrikes deep into the ground, fo that they are not eafily deftroyed by the plough, therefore it is frequently feen growing in bunches among corn. It is a rambling weed, fo is feldom cultivated.

The third fort grows naturally on the Alps; this differs from the former, in having much longer and narrower leaves, and the ftalks being more divided and fpreading, nor do the roots creep under ground like that. Thefe differences are confiant, for I have fown it above thirty years, and never found it vary.

The fourth fort grows naturally in Sweden, and fome other northern countries, where it paffes for the common fort; but although it is there fo, yet is very different from the fecond here mentioned, which is the fort that grows common in moft other parts of Europe. The ftalks of this are much larger, the leaves longer and more pointed *, the empalement of the flower is curioufly veined like net-work, of a purplifh colour, whereas that of our common fort is plain. Thefe differences are lafting, when the plants are cultivated in a garden.

The fifth fort was difcovered by Tournefort in the Levant, who fent the feeds to the royal garden at Paris. This puts out many oval, thick, fucculent leaves near the ground, out of the middle of which, arifes an upright ftalk about fifteen inches high, the lower part of which is garnifhed with leaves of the feme form and confidence as thofe at bottom, but are fmaller; thefe are placed oppofite *, the upper part of the ftalk divides into two fmaller, on which ftand a few fmall herbaceous flowers at each joint. It flowers in June, and fometimes ripens feeds in autumn. The plant is biennial, generally perifling when it has produced feeds; but unlefs it is fown upon a very dry rubbifh, and in a warm fituation, the plants will not live through the winter in England *, for when they are in good ground, they grow large, and are fo replete with moifture, as to be affected by the firft froft in the autumn; but where they have grown upoa an old wall, I have known them efcape, when all thofe were killed which grew in the ground.

The fixth fort grows naturally upon the cliffs near Dover. This hath a perennial root, from which arifes a fingle ftalk about a foot and a half high, garnifhed with long narrow leaves placed oppofite; the flowers are produced from the fide of the ftalks, each foot-ftalk fuftaining three flowers-, the foot-ftalks come out by pairs oppofite, the empalement of the flower is long and ftriped, the flowers are of a pale red. Thefe appear in June, and the feeds ripen in autumn.

The feventh fort grows naturally in Virginia, and feveral other parts of North America. This hath a perennial root, from which arife two or three flender upright ftalks about a foot high, their lower part being garnifhed with four leaves at each joint, placed in form of a crofs; thefe are fmooth, of a deep greeHf about an inch and a half long, and half an inch broad near their bafe, terminating in acute points; the joints of the upper part of the ftalk are garnifhed with white fringed flowers, Handing fingle upon prett/ long foot-ftalks, which come out by pairs oppofi ^ The flowers appear in June, and in warm feafons xbf/ feeds will ripen in England.

The eighth fort grows naturally in Spain and Itaty* This is a perennial plant, which rifes with an uprig ^ branching ftalk a foot and a half high, garnifhed with very narrow leaves placed oppofite; the upp < part of the ftalk is very branching; fome of thef branches are long, and others fhort; the flowers ftan < upon long naked foot-ftalks, each fupporting three or four flowers, which have long tubes, with ihrip ^ empalements; the petals are large, and deeply & * vided at the top; they are of a pale bluifh color ^ Thefe flowers are clofed all day, but when the W * leaves them, they expand, and then they have a very agreeable fcent. This fort may be propagated 9/

may be thereby separated from each other to a greater distance; then give them a little water (if the weather be dry) to fettle the earth about them* which you must afterwards repeat as often as you (shall find it necessary, 'till being careful to keep the ground clear from weeds.

When your Cauliflowers are quite drawn off the ground from between the Cucumbers, you must hoe and clean the ground, drawing the earth up round each hole in form of a basin, the better to contain the water when it is given them; you must also lay out the plants in exact order as they are to run and extend, so that they may not interfere with each other; then lay a little earth between the plants left, pressing it down gently with your hand, the better to spread them each way, giving them a little water to fettle the earth about them, repeating it as often as the season (shall require, and observing to keep the ground clean from weeds. The plants thus managed, will begin to produce fruit toward the latter end of July, when you may either gather them young for pickling, or suffer them to grow for large fruit. The quantity of holes necessary for a family, is about fifty or sixty * for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expence of pickling, without keeping them too long in the house, for you cannot expect to gather more than two hundred at each time from fifty holes -, but this may be done twice a week during the whole season, which commonly lasts five weeks; but that from fifty holes you may reasonably expect to gather about two thousand in the season, which, if they are taken small, will not be too many for a private family. And if so many are not wanted, they may be left to grow to a proper size for eating.

CUCUMIS AGRESTIS. See MOMORDICA.
 CUCURBITA. Lin. Gen. Plant. 968. Tourn Inf. R. H. 107. [so called from Curvata, Lot. bended, because the fruit of this plant generally bends,] the Gourd.

The CHARACTERS are,
It hath male and female flowers in the same plant. The flowers have a bell-shaped empalement of one leaf whose borders are terminated by five bristles-, the flowers are bell-shaped, adhering to the empalement and are of one petal, which is veined and rough divided at the top into five parts. The male flowers have three stamens, which are comelated at their extremity\ but are distinct at their base, where they adhere to the empalement; these are terminated by linear funiculi running up and down. The female flowers have a large germen, situated under the flower* supporting a conical trifid style, crowned by a large trifid stigma. The germen afterward becomes a large fleshy fruit, having three soft membranaceous cells which are distinct, inclosing two rows of seeds which are bordered.*

This genus of plants is ranged in the tenth section of Linnaeus's twenty-first class, intitled Monoecia Syngenesia, the plants having male and female flowers on the same plant, and the stamens of the male flowers being conned.

The SPECIES are,

1. CUCURBITA (*Lagenaria*) foliis cordatis denticulatis tomentosis basi subtus biglandulosis; pomis lignosis. Lin. Sp. 1434. *Gourd with heart-shaped, indented, woolly leaves, having two glands at their base, and a ligneous shell to the fruit.* Cucurbita longa, folio molli, flore albo. J. B. 2. 221. *Commonly called the Long Gourd.*
- * CUCURBITA (*Pepo*) foliis lobatis, pomis lsevibus. Lin. Sp. Plant. 1010. *Gourd with lobed leaves and a smooth fruit.* Cucurbita major rotunda, flore luteo, folio aspero. C. B. P. 213. *Commonly called Pumpum, or Pumpkin.*
3. CUCURBITA (*Verrucosa*) foliis lobatis, pomis nodoverrucosis. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, and a varied knobby fruit.* Cucurbita verrucosa. J. B. 2. 222. *Warted Gourd.*
4. Cucurbita (*Melopepo*) foliis lobatis, caule erecto, pomis depressis-nodosis. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, an erect stalk, and a depressed knotty fruit.* Metopepe clypeiformis. C. B. P. 312. *Commonly called Squish.*

5. CUCURBITA (*stignofus*) foliis lobatis asperis, flore luteo, pomis lignosis. *Gourd with rough-lobed leaves* a yellow flower, and fruit having a hard shell-, commonly called Calabash.*

The first sort is sometimes propagated in the English gardens by way of curiosity, but the fruit is very rarely eaten here * though, if they are gathered when they are young, while their (kins are tender, and boiled, they have an agreeable flavour. In the eastern countries these fruit are very commonly cultivated and sold in the markets for the table, and are a great part of the food of the common people, from June to October. These fruit are also eaten in both the Indies, where the plants are cultivated as culinary, and in those countries, where the heat of their summers is too great for many of our common vegetables, these may be a very good substitute.

This sort doth not vary like most of the others, but always produces the same shaped fruit. The plants of this extend to a great length, if the season proves warm and favourable, and will then produce ripe fruit-, but in cold summers, the fruit seldom grows to half its usual size. I have measured some of these fruit when growing, which were six feet long, and a foot and a half round -, the plants were near twenty feet in length: the stalks of this, and also the leaves, are covered with a fine soft hairy down -, the flowers are large, white, and stand upon long foot-stalks, being reflexed at their brim *, the fruit is generally incurved and crooked, and when ripe, is of a pale yellow colour. The rind of this fruit becomes hard, so that if the seeds and pulp are taken out, and the shell dried, it will contain water; and in those countries where they are much cultivated, are used for many purposes.

The second sort, which is commonly known by the title of Pumpkin, is frequently cultivated by the country people in England, who plant them upon their dunghills, where the plants run over them, and spread to a great distance; when the seasons are favourable, they will produce plenty of large fruit: these they usually suffer to grow to maturity, then they cut open a hole on one side, and take the seeds out of the pulp as clean as possible, after which they fill the shell with Apples sliced, which they mix with the pulp of the fruit, and some add a little sugar and spice to it; then bake it in an oven, and eat it in the same manner as baked Apples; but this is a strong food, and only fit for those who labour hard, and can easily digest it.

These may be propagated by sowing their seeds in April, on a hot-bed; and when the plants come up, they should be transplanted on another moderate bed, where they should be brought up hardily, and have a great deal of air to strengthen them; and when they have got four or five leaves, they should be transplanted into holes made upon an old dunghill, or some such place, allowing them a great deal of room to run, for some of the sorts will spread to a great distance. I have measured a single plant, which had run upwards of forty feet from the hole, and had produced a great number of side branches; so that if the plant had been encouraged, and all the side branches permitted to remain, I dare say it would have fairly overspread twenty rods of ground which, to some people, may seem like a romance, yet I can affirm it to be fact. But what is this to the account printed in the Transactions of the Royal Society, which was communicated to them by Paul Dudley, Esq; from New England, wherein mention is made of a single plant of this kind, which, without any culture, spread over a large spot of ground, and from which plant were gathered two hundred and sixty fruits each, one with another, as big as a half peck.

There are several varieties of this fruit, which differ in their form and size *, but as these are annually varying from seeds, so I have omitted the mentioning them, for they seldom continue to produce the same kinds of fruit three years together.

The third fort is very common in most parts of America, where it is cultivated as a culinary fruit; of this fort there are alfo several varieties* which differ in their form and fize *, some of these are flat, others round * some are shaped like a bottle, and others are oblong, their outer cover or rind being white when ripe, and covered with large protuberances or warts. The fruit are commonly gathered when they are half grown, and boiled by the inhabitants of America to eat as a sauce with their meat; but in England they are only cultivated by way of curiosity, few persons having a relish for them here, where they have a great variety of better esculent plants at that season, when these are fit for use. These may be propagated in the same manner as the second fort.

The fourth fort is alio very common in North America, where it is cultivated for the same purposes as the third. This very often grows with a strong, bulky, erect stalk, without putting out runners from the side, as the other forts, but frequently varies; for after it has been cultivated a few years in the same garden, the plants will become trailing like the others, and extend their branches to as great distance *, and yet I have known when part of the feeds, taken out from the same fruit have been sown in another garden, at a considerable distance, the fruit have been the same, and the plants have grown erect, when those which were sown in the same garden, have produced trailing plants with larger fruit of a different shape.

The fruit of the fifth fort hath a hard shell when ripe like the first, which may be dried and preserved many years: these are of very different forms and fize; some are shaped like a Pear, and are no bigger than a large Catherine Pear; some are as large as quart bottles, and almost of the same form; others are round and shaped like an Orange, and are of the same fize and colour, but these are very variable; for I have cultivated most of the forts near forty years, and have not been able, with all possible care, to preserve the varieties longer than two or three years in the same garden, without procuring fresh feeds from some distant place. Whether these changes are brought about by the admixture of the farina with each other, or from what cause I cannot say, because I have frequently planted them at as great distance from each other as I possibly could in the same garden, and yet the effect has been the same as when near.

The first fort requires to be treated more tenderly than the others, in order to procure ripe fruit 5 to the feeds should be sown upon a moderate hot-bed in April, and the plants afterward planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward; but they must not be tenderly treated, for if they have not a large share of free air admitted to them every day, they will draw up weak. When the plants are grown too large to be continued in the pots, there should be holes dug where they are designed to grow, and three or four barrows full of hot dung put into each *, these should be covered with earth, into which the plants must be planted, and covered with hand-glasses till they run out.

There are some people who plant these plants by the sides of arbours, over which they train the vines j so that in a short time they will cover the whole arbour, and afford a strong shade, and upon some of these arbours I have km the longest fruit. There are others who plant them near walls, pales, or hedges, to which they fatten the Vines, and train them to a great height: the Orange-shaped Gourd is the fort which is most commonly so planted for the ornament of its fruit, which has a pretty effect, especially when seen at some distance. All the forts require a large supply of water in dry weather.

These plants requiring so much room to spread, and their fruit being very little valued in England, hath occasioned their not being cultivated amongst us *, we having so many plants, roots, or fruits, which are

greatly preferable to those for kitchen uses: but in some parts of America, where provisions are not in so great plenty, or so great variety, these fruits may be very acceptable.

G U I E T E See C&ESCENTIA.

C U L M I F E R D U S P L A N T S [so called of Culmus, Lat. straw or haulm.] are such as have a smooth jointed stalk, usually hollow, and at each joint wrapped about with single, narrow, sharp-pointed leaves; and their feeds are contained in chaffy hulks, as Wheat, Barley, &c.

C U M I N O I D E S. See LAGOECIA;

C U M I N U M. Lin. Gen. Plant. 313. Mor. Umb. Köpwi, Gr. Cumin.

The CHARACTERS are,

It hath an umbelliferous flower; the general umbel is composed of many, which are divided into four parts; their involucre is longer than the umbel The great umbel is uniform \ the flowers have five unequal petals, whose borders are inflexed, and five single stamina, terminated by slender filaments. It hath a large germen situated under the flower \ supporting two small styles, crowned by single stigmas. The germen afterward becomes an oval striated fruity composed of two oval feeds, which are convex and furrowed on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, intitled Pentandria Digynia, the flower having five stamina and two styles.

We have but one SPECIES of this genus, viz.

CUMINUM (*Cuminum*.) Lin. Mat. Med. 139. Cumin: Cuminum femine longiore; C.B. P. 146. Cumin with a longer feed.

This plant is annual, perishing soon after the feeds are ripe 5 it seldom rises more than nine or ten inches high, in the warm countries where it is cultivated; but I have never seen it grow more than three or four inches high in England* where I have sometimes had the plants come so far as to flower very well, but never to produce feeds. The leaves of this plant are divided into long narrow segments like those of Fennel, but much smaller; they are of a deep green, and generally turn backward at their extremity; the flowers grow in small umbels at the top of the stalks; these are composed of five unequal petals, which are of a pale bluish colour, and are succeeded by long, channelled, aromatic feeds.

The feeds of this plant is the only part used in medicine; these are ranged among the greater hot feeds; they consist of very warm distilling parts, and are esteemed good to expel wind out of the stomach and bowels, so they are frequently put into clysters for that purpose, and are sometimes given in powder; and outwardly applied, they are of great service to ease the pains of the breast or side.

This plant is propagated for sale in the island of Malta, where it is called Cumino aigro, i. e. *hot Cumin*. But Anise, which they also propagate in no less quantity, they call Cumino duke, i. e. *sweet Cumin*. So that many of the old botanists were mistaken, when they made two species of Cumin, viz. acre and dulce.

If the feeds of this plant are sown in small pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed to bring up the plants, and these after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preserving the balls of earth to their roots, and afterward kept clean from weeds, the plants will flower pretty well, and by thus, bringing of the plants forward in the spring, they may perfect their feeds in very warm seasons.

C U N I L A. See SIDERITIS.

C U N O N I A. Buttn. Cun. tab. 1. Antholyza. Lin. Gen. Plant. 56.

The CHARACTERS are,

The flowers grow alternate in an imbricated spike, each having spatula orbicath, composed of two spear-shaped concave leaves \ the flower hath one ringent petal, having a short slender tube, which is dilated at the chaps, and compressed on the sides \ the upper lip is arched, and

Jretched

stretched out a conjiderabk length beyond the ale or wings, and is rounded at the top: it hath thne long flender ftamina which arefituated in the upper lip, terminated by oblong fiat fummits^ which are fastened in their middle and lie profrtrate. It bath a flender fstyle, which isfhorter than the ftamina, crowned by three cylindrical ftigmas which jdn the fummits, and an included in the upper lip. ^be germen, which is Jituated below the flower? becomes &n oblong capfide with three cells, filled with compreffed feeds.*

This genus of plants is ranged in the first feftion of Linnaeus's third clafs, intitkd Triandria Monogynia, the flowers having three ftamina and one fstyle, but he has joined it to the Antholyza, making it only a fpecies of that genus-, whereas by the form and charadters of the flower, it fhould be feperated from that, there being full as great difference between the flowers of this and thofe of the Antholyza, as is between thofe and the Gladiolus •, for the flowers of Cunonia have no carina or under lip, but thofe of the Antholyza have, in which one of the ftamina is included, which is feperated from the other two, which are fituated in the upper lip; but in this all three are of equal length, and fituated in the hollow of the upper lip. The two wings of this are fhort, whereas thofe of Antholyza are long, fo that I think they fhould be feperated. •

We have but one SPECIES of this genus at prefent in the Englifh gardens, which is

CUNONIA (*Antbofyza*) floribus feffilibus, fpaxis maximis. **Buttn. Cun, 21r. tab. i. Cunonia with flowers fitting clofe to the ftalk, and very large fpath* or fheaths. Dr. Linnaeus titles it Antholyza ftaminibus omnibus adfcendentibus. Sp. Plant. 37. Antholyza with all the ftamina afcending.**

There is a plant of this kind figured in Cornutus's book of Canada plants, under the title of Gladiolus iEthiopicus, flore Coccineo, p. 78. but by his figure and defcription, it appears to be a different Ipecies from this, his flowers having much fmaller (pathae or iheaths, nor does the ftalks of his rife near fo high as this j there are alfo fome other differences between them.

The feeds of this plant I received from the Cape of Good Hope, where it grows naturally, which fucceeded fo well in the Chelfea garden, as to produce a great number of plants, which flowered well the third feafon after they appeared, and have continued to produce flowers, and perfed their feeds every year fince.

This hath a compreffed bulbous root, fomewhat like that of Corn Flag, covered with a brown fkin 5 from this arife feveral narrow fword-ihaped leaves, about nine inches long, and a quarter of jn inch broad in the middle, terminating in acute points ^ thefe have one longitudinal midrib which is prominent, and two longitudinal veins running parallel on each fide-, they are of a fea-green colour, and appear in autumn, growing in length all the winter-, in fpring theftalk arifes from between the leaves, which is round, ftrong, and jointed; at each joint is fituated a fingle leaf, which almoft embraces the ftalk for near three inches from the bafe, then by the curvature of the ftalk it is feperated, Handing ereft: the ftalks rife near a foot and a half high, which is generally curved two oppofite ways •, * the upper part of the ftalk is terminated by a loofe fpike of flowers, coming out of large fpathic or fheaths, compofed of two oblong concave leaves, terminating in acute points: thefe are at their first appearance placed imbricatim over each other, but as the ftalk increafes in length, fo thefe are feperated -, from between thefe two leaves comes out the flower, each having a flender Saffron-coloured tube near half an inch long, which is then enlarged where the petal is divided, and the upper fegment is extended two inches in length, being arched over the ftamina and fstyle. This is narrow as far as to the extent of the wings, but above them is enlarged and fpread open half an inch in length, and is concave, covering the fummits and fti^mas

which are extended to that length; the two wings arc alfo narrow at their bafe, but are enlarged upward in the fame manner, ending in concave obtufe points, which are compreffed together, and cover the ftamina and fstyle. This flower is of a beautiful fof: fcarlet colour, fo makes a fine appearance, about the latter end of April or beginning of May, which is the feafon of its flowering. After the flowers decay, the germen becomes an oval fmooth capfule, opening in three cells, which are filled with flat bordered feeds.

This plant is too tender to thrive in the open air in England, fo the roots muft be planted in pots filled with light earth, and may remain in the open air till Oftober, when they muft be removed into fhelter, either into an airy glafs-cafe., or place! under a hot-bed frame, where the leaves will keep growing all winter, and in the ipring the ftalks arife and flower. During the winter fcaibn, the plants will require a little water wlien the weather is mild, once a week, but it muft not be given in great quantities, efpecially in cold weather •, in the fpring they fhould be watered oftener; and when the flowers are paf, the pots fhould be removed into the open air to perfect their feeds, which will ripen the latter end of June, foon after which the ftalks will decay to the root, which will remain inafive till September. When the ftalks are decayed, the roots may be taken out of the ground, and kept in a dry room till the end of Auguft, when they fhould be planted again.

This plant is eafily propagated by offsets, which it fends out in great plenty, or by fowing of the feeds, which fhould be fown in pots about the middle of Auguft, and placed in a fituation where they may enjoy the morning fun, and in dry weather fhould be gently watered 5 in September the pots may be removed to a warmer fituation, and in Oftober they muft be placed under a frame, where they may be protected from froft and hard rains, but in mild weather enjoy the free air. The plants will appear in Odober, and continue growing all the winter, and in June their leaves will decay 5 then they may be taken up, and four or five roots may be planted in each pot, till they have grown another year, when they may be each put into a feperate pot* Thefe feedling plants muft be fheltered in the fame manner as the old roots in winter, and the third year they will flower.

CUPRESSUS. Lin. Gen. Plant. 958. Tourn. Inft. R. H. 587. tab. 358. Cyprefs [takes its name either of κυπ, to bring forth, and ψιδρα*, becaufe it produces equal branches on both fides •, or of Cyparifius, a certain infant whom the poets feign to have been transformed into a Cyprefs-tree.] The Cyprefs-tree,

The CHARACTERS are,

// bath male and female flowers growing at diftances on the fame plant\ the male flowers are formed into oval katkins, in which the flowers are placed thinly', among feveralroundi/b fcales, each having a fingle flower. Thefe have no petals nor ftamina, but have four fummits which adhere to the bottom of the fcales. The female flowers are formed in a roundifh cone, each containing eight or ten flowers\ the fcales of the cones are oppofitte, each having a fingle flower* thefe have no petals; the germen isfcarce vifible, but under eaehfeale there are many punctures orfpots, and a concave truncated apex inftead of a fyle \ this afterward becomes a globular cone, opening in angular target-Jhaped fcales, under which are fituated angular feeds.

This genus of plants is ranged in the ninth feftion of Linnaeus's twenty-first clafs, intitkd Monoecia Monadelphia-, the plants of this feftion have male and female flowers on the fame plant, and the male flowers are joined in one bdoy.

The SPECIES are,

thereby. The best season for removing them is in the beginning of April, when the drying easterly winds of March are over, and, if possible, choose a cloudy day, when it is inclinable to rain * and in taking them out of the feed-bed, preserve the roots as entire as possible, and, if you can, a ball of earth to each plant. The soil in which these trees should be planted (as I before said) should be, for the two first sorts, a warm sand or gravel, which, when you have prepared, by carefully digging and cleaning from all noxious weeds, you must lay level. Then draw the lines where the trees are to be planted at three feet asunder, and plant the trees at eighteen inches distance in the rows, observing to clove the earth well to their roots, as also to lay a little mulch upon the surface of the ground about their stems; and water them well to settle the earth to their roots, which should be repeated twice a week, until the plants have taken their root.

These plants may remain in the nursery three or four years, according to the progress they make, or till your ground is ready where they are to be planted: but if you intend to let them remain longer, you should take up every other tree in the rows, and transplant out; for otherwise their roots will be matted together, so that it will render it difficult to transplant them, as also endanger the future growth of the trees. The plants should by no means be let stand too long in the nursery before they are transplanted out for good, because the roots do not mat together so closely as those of many other sorts of Evergreen Trees, whereby they may be taken up with good balls of earth to their roots; but the roots of the Cypress are apt to extend out in length, so it is one of the most difficult trees to remove when grown large; therefore most curious persons choose to plant the young plants into small pots, when they first take them out of the feed-bed, and to train them up in pots two or three years, until they are fit to plant out where they are to stand for good, and, by this management, they are secure of all the plants; for these may be shaken out of the pots at any time of the year without danger, and planted with their whole ball of earth, which is likewise a great advantage. When they are planted out for good (if they are designed for timber) they should be planted about twelve or fourteen feet distance every way, and be very careful in removing those in the full ground, not to shake the earth from their roots; to prevent which, you should open the ground about each tree, cutting off all long roots, then working under the ball of earth, cut the downright roots off; and after having pared off all the earth from the upper part of the ball, as also reduced the bulk of it, so that its weight may not be too great for the fibres to support, they may be carried upon a handbarrow by two persons to the place where they are to be planted; but if they are to be carried to a distant place, they should either be put into baskets, or their roots closely matted up. When they are planted, you must settle the earth close to their roots as before, laying a little mulch upon the surface of the ground about their stems, to prevent the sun and wind from entering the earth to dry their fibres; and water them well, to settle the ground to their roots, which must also be repeated, if the weather proves dry, until they have taken root, after which time they will require little more care than to keep them clear from weeds.

The first, which is the most common sort in England, seldom produces good seeds in this country; it is therefore the best way to have the cones brought over entire from the fourth parts of France and Italy, where they ripen perfectly well, and take the seeds out just before you sow them, for they will keep much better in the cones than if they are taken out. The method to get the seeds out is to expose the cones to a gentle heat, which will cause them to open, and easily emit their seeds.

The second sort grows naturally in the Levant, and from thence it has been formerly brought to Italy, but

at present this is pretty rare in England; yet what has passed under this title here, is only a variety of the common sort, whose branches grow much looser, and not so upright as the first; but the cones taken from these trees, and the seeds sown, have frequently produced plants of both varieties; but the true spreading Cypress extends its branches horizontally from the first year, and continues to extend them to a great length as the plants advance, and the plants raised from the seeds do not vary, so that it is certainly a distinct species. This grows to be a large timber tree in the Levant, and in Italy there are some of a considerable size.

The Virginian kind may also be propagated in as great plenty, for the cones of this may be easily procured from Carolina or Virginia, in both which places they grow in great abundance; and the seeds will rise as easily as any of the other sorts, and the plants are equally as hardy: these have been formerly kept in pots, and housed in winter, with which management they have not succeeded so well as they have done in England, since people have planted them into the full ground, and where they have had a moist soil, I have observed them to thrive best, which is since confirmed by Mr. Cateby, in his Natural History of Carolina; where he says, that this tree grows in places where the water commonly covers the surface of the ground three or four feet, so that it may be a very great improvement to our boggy soils. This tree, casting its leaves in winter, does not so well suit plantations of Evergreens at that season; though, in summer, when there is the greatest pleasure in walking among plantations of trees, it hath so much the appearance of an Evergreen, as to pass for such. It may also be propagated by cuttings, which should be planted in a bed of moist earth in the spring before they begin to shoot.

The third sort is at present pretty rare in the English gardens, though of late years there have been many plants raised here; but this sort is not quite so hardy, I fear, as the common Cypress, for the plants are frequently killed, or greatly injured in severe winters; and in the hard frost in 1740, there was a large tree of this kind entirely killed in the gardens of his Grace the Duke of Richmond, at Goodwood in Suffex, which had been growing there several years and in the year 1762, many large trees were killed. There are great plenty of these trees growing at a place called Bufaco, near Coimbra in Portugal, where this tree is called the Cedar of Bufaco, and there it grows to be a timber tree, so that from thence the seeds may be easily procured.

This tree grows naturally at Goa, from whence it was first brought to Portugal, where it has succeeded, and been propagated; formerly there were some trees of this sort growing in the Bishop of London's garden at Fulham, where it passed under the title of Cedar of Goa, by which it was sent from thence to the Leyden garden with that name.

The fifth sort is a native of North America, where it grows to a considerable height, and affords an useful timber to the inhabitants for many purposes. This sort is extremely worth cultivating in England; for as it grows in a much colder country, there is no danger of its thriving well in the open air in England, and being an Evergreen of regular growth, will add to the variety of wilderness quarters, or other plantations of Evergreen Trees.

This sort is propagated by seeds, which should be sown in the spring in boxes or tubs filled with light freestone earth, and placed where they may enjoy the morning sun till eleven or twelve o'clock. In dry weather they should be duly watered, and constantly kept clear from weeds. In this situation they may remain till Michaelmas, when they should be removed to a warmer place; for the plants seldom appear till the following spring, so that it will be proper to place the boxes or tubs near a south wall, pale, or hedge, during the winter season, lest, by being too much shaded, the wet of the winter season should rot

CUP

the seeds. In the spring following, if these seeds or berries are placed on a moderate hot-bed, it will bring up the plants very soon, and greatly forward their growth; but as the spring advances, they should be shifted to heat the open air by degrees; and in May they may be taken out of the hot-bed, and placed in a sheltered situation, where they may enjoy the morning sun, being careful to keep them clear from weeds, and always water them duly in dry weather. The following winter it will be proper to remove the LAK near a south wall or park, for the plants being very young, are sometimes milder than they will be afterwards. Toward the latter end of March, or the beginning of April, just before the plants begin to (boot, they should be carefuly taken up (and the boxes) and having prepared a bed or two (with a fertile soil) to receive the plants, raised up fresh earth in a forked ULTit-¹¹ (not, the plants should be punted therein in rows about eighteen inches apart; and about a foot distance plant from plant into the rows. This work should be done in cloudy weather, when there is rain; for in dry weather, when castly winds commonly blow at this time, it will be very Ja nacrous to transplant these plants, so that it had better be deferred a fortnight: if there is an iteration of the snr, rfn hazard the pbuii. When the plants are planted, they (houk to be watned to fettle the earth to their roots; and when the lurt;tt« til' the ground ftiouM be covered iv h match, to prevent the sun and wind from penetrating to the roots of the plants; for nothing is more injiriuii to these plants, than to Live [their fibres dried when they are Lran'plnted; therefore the plants should not be taken cut of the tibi till you are ready to place them in the ground, for they will not be likely to Le out of the ground any time without great danger.

The branches of this tree are gamiOwd with flat evergreen leaves, resembling those of the Arbor Vita; and the cone; lire no Jarger than the berries of the Juniper, from which they are not easily distinguished at a little distance; but upon elderly viewing, they are peritfe cones, having many celklike thiolc of die common Cvprcis. li ilicfc iiecs arc plaiuct in a moist jTJonij loil, they make very great progrds, and in Luch IV: bit for timber; but however thb tree may Kitcoed for timber, yet it will be a great ornament to large plantations of evergreen trees, especially in ruth places when there is naturally a proper soil for them; because, in such situations, there are not many sorts of Evergreen Treu which thrive well, especially in cold places, and by increasing the number of lbro of tilLfc Evergreen, we add to the beauty of utir gajxkns and plannrom.

The third fort (ends forth its branches nmoll horizontally, so that they extend to a reotilitfaucic.erau way, and the trees are generally furnished with branchei fitim the ground upwani; but as thefegrow without much order, the tftca have a very different appearance from all the other forts. This grows to be a Urer limber irvc in Portugal, but the largest tree which I have fren in Engtuid, has not bet I above fifteen feet high, and the fide branches of this were extended more than eight feet on every side from the stem. This fort may be propagated from feeds in the lame manner as the common Cvprcis, sod the

This should be done in me fime 'inannc' hath been directed for a difference only; that it will be proper to cover these plants during the two first winters after they are come up, especially if the soil should be severe, which might destroy them, if they are exposed to it while they are young. This fort may also be propagated by cuttings, which if planted in autumn, and covered in winter, they will strike root; but it is generally two years before they will be rooted enough to transplant, not will the plants be raised above six feet in the seedling; therefore, when the seeds can be obtained, that is the best method to propagate this tree. The American deciduous Cypress may also be propagated by cuttings, as

CUR

I have several times tried (b) that when seeds cannot be had, this method may be practised successfully. I suppose the common fan will take from cuttings. Lui this I have not experienced, in case you recommend it to practice.

These trees are very ornamental to garden, that no large garden can be compared with the 'rainy of' them; and it is to these trees that the Italian villas owe a great share of their beauty, for there is no tree so proper to place near buildings, the pyramidal upright form of their branches affords a picturesque appearance, and offsets the view or the bulkiness of the dark green of their leaves in the contrast with the whiteness of the buildings; that, wherever there are temples or other buildings erected in the vicinity, the tree is proper to place near them as a relief. In all the landscapes of Italian villas, we see many Cypress-trees represented, which have a very agreeable effect in the picture; and the trees, when they are disposed in a garden, afford a noble and agreeable prospect.

The leaves of the sixth fort were sent from the Cape of Good Hope, where the trees grow naturally, and by the account which I received with the seeds, the colour of the tree are black when ripe. The young plants which I have raised from the seeds have look like the branches, which are usually furnished with narrow linear leaves, which are not opposite, and are alternately trifoliate; their colour is green, and of a bright green colour; they continue in verdure all the year. I lick plants being young, are too tender to thrive in the open air in England as yet, but when they have obtained more strength, it is very probable they will do well in various situations. I had two of these plants growing in the full ground, which were killed in the winter season. But those which were placed under a frame, where there was no covering of glass, and only wooden flutrics, were not injured by the cold, although the earth of the pot was frequently hard frozen.

This genus of plants is ranged in the first section of Linnaeus's first class, entitled Monandria Monogynia, the flower having one lamina and one ray.

The Species are, 1. *Curcuma* (*Ravala*) *folia* *lanca* 'Isro-ovntis, *rtervis* *lateralibus* *radicibus*. Lin. Sp. Plant. a. *Cirtiimti* *viish* *spat* *spat* *and* *hars*, *having* *very* *few* *ntreet* *en* *tbt* *filia*. *Curcuma* *radice* *rotunda* C. 8. *Txriiuruivib* » *rcuHil* *not*.

2. *CL'H* (*Lappa*) *folia* *lanccolatis* *oervis* *lafrjlibitis* *numerofissimis*. Lin. Sp. Plant. 2. *Curcuma* *offetr* *spat* *spat* *hars*, *having* *many* *lateral* *seeds*. *Curcuma* *radice* *longa*. H. L. 281. *Tamaria* *with* *a* *long* *root*. The first sort has a fleshy pointed root somewhat like the *Kor'tjin*, but it stands, which sends up several upright stems, that rise upwards of a foot high; these have one longitudinal midrib, and a few transverse nerves running from the midrib to the sides. The arc of a leaf is green colour, from between these arise the flower stalks, supporting a loose spike of flowers of a pale yellowish colour, included in several different spathe or sheaths, which drop off. The flowers are never succeeded by seeds in the garden here.

The second sort hath longfleshy roots, of a deep yellow colour, which spread under the surface of the ground like those of Ginger; they are about the thickness of a man's finger, having many round knotty circles, from which arise four or five large spear-shaped leaves, standing upon long foot-stalks; they have a thick longitudinal midrib, from which a numerous quantity of veins are extended to the sides; these leaves are of a glaucous or sea-green colour. The flowers grow in loose scaly spikes on the top of the foot-stalks, which arise from the larger knobs of the roots, and grow about a foot high; they are of a yellowish red colour, and shaped somewhat like those of the Indian Reed.

These plants grow naturally in India, from whence the roots are brought to Europe for use. They are very tender, so will not live in this country, unless they are placed in a warm stove. As they do not produce seeds in England, they are only propagated by parting their roots: the best time for removing and parting these roots is in the spring, before they put out new leaves; for the leaves of these plants decay in autumn, and the roots remain inactive till the spring, when they put out fresh leaves. The roots should be planted in rich kitchen-garden earth, and the pots should be constantly kept plunged in a bark-bed in the stove. In the summer season, when the plants are in a growing state, they will require to be frequently refreshed with water, but it should not be given to them in large quantities; they should also have a large share of air admitted to them in warm weather. When the leaves are decayed, they should have very little wet, and must be kept in a warm temperature of air, otherwise they will perish. These plants usually flower in August, but it is only the strong roots which flower, so they must not be parted into small roots, where the flowers are desired.

CURRAN-TREE. See RIBES,

CURURU. See PAULLINIA.

CUSPIDATED PLANTS [so called, of cusps, Lat. the point of a spear] are such plants, the leaves of which are pointed like a spear.

CUSTARD-APPLE. See ANNONA.

CYANELLA. Rozen.

The CHARACTERS are,

The flower has no empalement; it hath six oblong concave, spreading petals, which join at their base, the three lower bending downward with six short spreading stamens, terminated by oblong erebbed summits, and a three-cornered obtuse germen, supporting a slender style the length of the stamens having an acute stigma. The germen afterward becomes a roundish capsule, having three furrows with three cells, inclosing many oblong seeds.

This genus of plants is ranged in the first section of Linnaeus's sixth class, intitled Hexandria Monogynia, the flower having six stamens and one style.

We know but one SPECIES of this genus, viz.

CYANELLA (*Capensis*). Lin. Sp. 443. Cape Cyanelle.

This plant grows naturally at the Cape of Good Hope. The root is shaped like those of the Spring Crocus; the leaves are long, narrow, and have a fulcus on their upper side; the foot-stalk of the flower arises immediately from the root, supporting one flower with six petals, of a fine blue colour, which appears in May, but the flowers have not been succeeded by seeds as yet in England.

It is too tender to thrive in the full ground in this country, therefore the roots should be planted in pots filled with light earth; and in winter must be placed in a frame, and treated in the same manner as is directed for Ixia, with which the plant will thrive and produce flowers annually.

CYANUS. See CENTAURIA.

CYCAS, the Sago-tree.

There are several small plants of this sort in the English gardens, but from these no changers of the tree can be drawn; nor are there any just accounts of these to be met with in the several authors who have figured and described the tree.

We know but one SPECIES of it at present viz: CYCAS (*Circinalis*) frondibus pinnatis circinalibus, foliis linearibus planis. Lin. Sp. 1658. *Sago-tree with full branches whose wings are placed circularly and the small leaves are plain.* Arbor Zagoë Amboinensis. Seb. Thef. 1. p. 39.

This tree has been ranged in the tribe of Palms, to which it has great affinity, especially by its buter appearance the branches and trunk having the same structure;

This tree requires to be plunged into tanners bark in a stove, which should be kept up full to temperate heat in winter; but in summer should be much warmer, when it should be frequently refreshed with water during hot weather, but in autumn and winter it should be given sparingly.

Most of the plants of this kind now in the English gardens, have been communicated to the possessors by Richard Warner; Esq; of Woodford; in Essex, who received a tree off this sort, which was brought from India by the late Captain Hutchenfon; but his ship being attacked by the French near home, the head of the tree was shot off but the stem being preserved, put out several heads, which being taken off, produced so many plants.

CYCLAMEN. Lin. Gen. Plant. 184. Toiirn. Inft. R. H. 154. tab. 68. Cyclamen; in French, *Pain de Pourceau*. [Κύκλαμ'ον], of Κύκλας Gr. a circle, because the root of this plant is orbicular; it is called Sowbread, because the root is round like a loaf, and the fowls eat it]. Sowbread.

The CHARACTERS are,

The flower hath a roundish permanent tinpament of one leaf divided into five parts at the top. It hath one petal with a globular tube which is much larger than the empalement, the upper part is divided into five large segments, which are reflexed it hath five small stamens situated within the tube of the petal, terminated by acute summits, which are connected in the neck of the tube. It hath a roundish germen, supporting a slender style, which is longer than the stamens, and crowned by an obtuse stigma. The germen afterward becomes a globular fruit with one cell opening in five parts at the top, inclosing many oval angular seeds.

This genus of plants is ranged in the first section of Linnaeus's fifth class, intitled Pentandria Monogynia, the flower having five stamens and one style.

The SPECIES are,

1. CYCLAMEN (*Europium*) foliis hastato-cordatis dngulatis. *Cyclamen with spear-pointed heart-shaped leaves which are angular.* Cyclamen hederæ folio. C; B. P. 306. *Sowbread with an Ivy leaf.*
2. CYCLAMEN (*Purpurascens*) foliis orbiculato-cordatis; inferne purpurascens. *Cyclamen with round heart-shaped leaves, purple on their under side.* Cyclamen orbiculato folio inferne purpurascens. C. B. P. 308. *Round-leaved Sowbread with a purple under side.*
3. CYCLAMEN (*Perficum*) foliis cordatis ferratis. *Cyclamen with sawedbeart-shaped leaves; or Perfian Cyclamen;*

6. CYCLAMEN (*Com*) foliis orbiculatis planis, jtediculis brevibus floribus minoribus. *Sowbread with orbicular plain leaves, shorter foot-stalks and smaller flowers.* Cyclamen Hyemale, orbiculatis foliis inferne rubentibus, purpurascens flore Coum Herbariorum. H. R. Pan

The first sort is the most common in the English gardens. This grows naturally in Austria, Italy, and other parts of Europe, so will thrive in the open air in England, and is never killed by the frost. It hath a large, orbicular, compressed root, from which arise a great number of angular heart-shaped leaves, upon

Tingle foot-ftalka, which are six or seven inches long, the leaves are marked with black in their middle, the BOWOT appear before the leaves, rising immediately from the root, with long fine foot-Harks; they appear in August and September, and come after the leaves come out, continue glowing all the winter and luring till May, when they become dried up. After the flowers are fallen, the root-twifts up like a icrow, inclosing the germen in the crinr, and Uj down dole to the surface of the ground between the leaves, which serve as a pruic&ton to the teed. This germen becomes a round Pefhy fred-vefcl with one tell, in doting fevErd angular feeds. The feeds ripen in June, and ihouM be lbv'n in August. There are two varieties of this, one with a white anil the other with a purple flower, which appear at the lime timr.

The second fort flowers in itiravn: isit¹. is at prfent very rare in England; the leaves of this fort are hr^r, orbicular, and heart-shaped at their bnfc, and of a purple colour on their under fide -, the leaves and Bowers of this come up from the root at the same time; the flowers are of a purple colour, and their bottoms are of a deep red. It Benrn law in the autumn, and requires protection from the froit in winter.

The third fort hath (riff hwri-shaped leaves which are tawci on their edges-, they have frong fldhy foot-lhklj near six inches long, of a purple colour, as are alib the veins of the leaves on their under fide, but the tipper fide is marbled with white. The flowers rise with finglc foot-ftalks from the root -T these are pure white with a bright purple bottom; the petals are divided into nine segments to the bottom, which are twisted and reflexed backward like the other fort. This flowers in March and April, and the feeds ripen in August.

The fourth loir is commonly called the Pcrfvn Cyclamen. This hath large, angular, heart-shaped leaves, whose edges are entire; they are veined and marbled with white on the upper fide, and stand upon pretty long foot-iULks; the flowera are large, of a pale purple colour, with a bright red or purple bottom. These appear in March and April, and the feeds ripen in August.

The fifth fort hath a (mat! irregular root not larger than 3 Nutmeg; the leaves are orbicular and (trull - the flowers are of a Hem colour, Imaill, and have purple bottomj. They appear to the autumn, but rarely produce feeds in England.

The sixth fort is not so tender as the four first mentioned, so may be planted in warm borders, where, if they are covered in hard froit, they will thrive in flower very well. This hath plain orbicular leaves, which have florcerand weaker foot-ftilks than either of the other; their under fides are very red in the beginning of winter, but that colour goes off in the spring; their upper fides are smooth, of a tucl-green; wd Ipreid open flat; wlvreas the other fons w^{kaN} are not, and are ed at their bale. The flowm are of a very bright purple colour, and appear in the middle of winter, at a time when there are foil other flowers, which renders the pbnu more valuable. The fee* of the fort ripen in the end of June.

There are several other varieties of this plant, -which chiefly dirJI-r in the colour of thtir Bo*ers, : articu- hub amor the Persian kind, or ^ c h t n e r; is one with an enl¹ white flower, which smells very sweet. ^"t a these are accidental variations, I have not enumerated them here, those which are here mentioned being undou¹ly distinct species; for I have many y^{care} pr.i; noted them from seeds, and have not found I tiem var¹, nor have I heard that any other person has observed either of them alter farther than varying of their colours. Though Dr. Linnæus supposes them but one species, it is well known at the last list will endure the greatest froit in the open air, whereas all the Persian sorts are tender, and require shelter in winter.

All the forts are propagated by se;ji*, **whkh** (hoolt

be down soon: in<er they are ripe, in 12:cie\$ or pots filled with light kitchn-girdi: earth, covered with a linen sand, and covered about half an inch deep, pbit in them where they may have only the nt of fine sun till the beginning of September, when they may be removed to « warmer expo lure. Those of the first fort may be plunged into the ground dole to a fourth wall, a pale, or Kead hedge, in October, where, if it should be very severe in winter, it will > proper to cover them either with mars or l'eide haulm, but in common winters they will not require any covering. The pots or tubs in which the l'crfan kind' are sown, should then be placed in a warm room, where they may be protected from frost and sun rains, but in mild weather the glass may be taken off every day > «djnii frefu aii ro them, the first fort will come up about Christmas, if the feeds were sown in August, and their leaves will continue green till May; and diof of the PerEun kinds will come up early in the spring, and continue green till June, when they will begin to decay; if they should be removed to an east aspect, where they will have only the moon's sun, in which situation they may remain till the middle of August -, during which time they should have very little water, for then the roots are in an inactive state, and the mud will rot them. The pots and tubs in which the rht7 are sown, must be constantly kept clean from «w¹, for if the weeds are permitted to grow, their roots will decay; single with tholbofuie Cyclamen-, that in pulling out the < m b, the other roots will be drawn out with them. In the beginning of October, liwre should be some fresh earth spread over the tubs or pots, which should be removed again into the shade, in the same manner as before-, and the following summer they must be managed also in the same manner till their leaves decay, when they should be carefully taken up, and thoir of the first fort placed in a warm border at three or four inches distance, but the other 1-orts must be planted till xns to be dickered in winter. The third, fourth, one! tilth forts, are more impatient of cold and wet than the other three; they must constantly be preclerved in a K>T hilt! cartli, and housed in winter, but should be placed near the glasses, where they may enjoy so much free open air as possible, when the weather will permit 5 for if they are crowded under other plants, and are kept too dole, they are very liable to mould. They nor should they have much water in winter, which is all very injurious to them, but when they want water, it should be given them sparingly. In summer the plants may be exposed to the open air, when their green leaves will decay; at which time you should remove them to a place, where they may have the morning sun until eleven o'clock: but during the time that the roots are delittut. of leaves, they should have very little water given them, because at that season they are not capable of discharging the moisture. This is all the proper season to transplant the roots, or to fresh earth them; and as the autumn comes on, when the heat decreases, they may be removed into a jilace* more exposed to the sun, where they may remain until October before they need be housed.

Toward Christmas, if the roots are in good health, the plants will begin to flower, and continue producing fresh flowers till the middle of February, and thde will flourish, excited by the Pertinn ibtts, which continue till May; but if you intend to have any feeds, you must let the pots be placed so as to receive a great share of fresh air, for if their flowers are drawn up in the house, they seldom produce any feeds. These feeds are ripe about July, when they should be immediately lbwn in pots or tubs of good light unclamped earth, which should be sheltered in winter under a frame, and exposed in summer in the same manner; if sowed for the older roots, observing to move them into pots at a wider distance when they are 3 years old, and so from time to time, as their roots increase in bulk, you must give them mot*

room; and in all but four or five years more they will begin to flower, tttion you (hould let each root hiv a fepir:il(; ... which at first may he fmall, but wlu: the roots a c growa larger, they mutt be put into hrger pots.

The v forts have been planted under wirtY wills ir the full ground, when: in mild winters the have doni- very well, but in fever: frofi all ik- roots have been destroyed, therefore, whew ver thole rooti art planed in an open border, there lliould ht r amon non-bed frames placed over them in winter, that ii bad weather t • y may be covered to protc; • them from froft: ai where they arc thus managed, die plants will produce more flowers, which wijl in much fairer than what are produced from ilir root: in the pots, and funi thcIi there may always be goo expected: theidwe filch periqns who are curious in flowers, mould have 3 border framed over on pur pofe for rhelt-, the Gurniey and BeDwtoni Lilies, with fume other of the curious bulbou; roored flow i in which border there may be many o curious flowers c toward, to more advantage thai in any other method now pr.ictifed.

Apocynum scandens foliis cordatis asperis, floribus amplis patulis luteis. Houft. MSS. The first and second sorts grow naturally about Montpellier, these have perennial creeping roots, but annual stalks, which decay to the root every autumn, and rise afresh in the spring; these stalks twist themselves like Hops, round whatever plants are near them, and rise to the height of six or eight feet; the first of these is garnished with oblong, heart-shaped, smooth leaves, ending in acute points, and are placed by pairs opposite on long foot-stalks, the flowers come out in small bunches from the wings of the leaves* they are of a dirty white colour, and divided into five acute segments, which spread open in form of a star. These appear in June and July, but are not succeeded by any seed-vesicles in England, which may be occasioned by their roots creeping so far under ground; for most of those plants which propagate themselves so much by their roots, become barren of seeds, especially if their roots have full liberty to extend.

The second sort differs from the first in the shape of its leaves, which are broader and rounder at their base. The roots of this sort are very thick, running deep into the ground, and extend themselves far on every side; so that where this plant hath got possession of the ground it is not easily extirpated, for every piece of the root will shoot, which may happen to be left in the ground. Both these plants abound with a milky juice like the Spurge, which issues out wherever they are broken, and this milky juice when concreted, has been frequently used for scammony.

These plants propagate too fast by their creeping roots when they are admitted into gardens, so few people care to have them: the roots may be transplanted any time after their stalks decay, till they begin to shoot in the spring.

The third sort grows naturally in Carolina, from whence the seeds were brought to England; this is a perennial plant with twining hairy stalks, which, if supported, will rise six or seven feet high; the lower part of the stalks are covered with a thick fungous bark, somewhat like cork, which is full of fissures; these stalks are tender, and garnished at each joint with two oblong, heart-shaped, pointed leaves, hanging on long hairy foot-stalks. The flowers are produced in small bunches at the wings of the leaves, these are star-shaped and green when they first appear, but afterward fade to a worn-out purple colour. They appear in July and August, but are not succeeded by seeds in England.

This plant will live in the open air in England, if it is planted in a dry soil and warm situation. It may be propagated by laying down some of the young shoots about Midsummer, which, if they are now and then refreshed with water, will put out roots, so may be transplanted in the autumn, where they are designed to remain. The roots of this plant should

be covered in winter with some rotten tan to keep clear the frost, otherwise in severe winters they are liable to be destroyed.

The fourth sort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houftoun, this rises with a twining stalk to the height of twenty feet or upward, provided it hath support; the lower part of the stalks are covered with a thick fungous bark, full of fissures, which gape open, the leaves are oblong and smooth, and placed by pairs opposite, hanging on long foot-stalks: the flowers are produced from the wings of the leaves in small bunches, they are star-shaped, and are of a yellowish green colour, but are not succeeded by pods in England.

This sort is tender, so will not thrive in this country unless it is placed in a warm stove, and requires the same treatment as other tender plants from the same country; and as it abounds with a milky juice, so the plants must have little water in winter. This may be propagated by laying down of the young shoots, which in three or four months will put out roots, and may then be transplanted into pots filled with light sandy earth, and plunged into the tan-bed in the bark-stove, where the plants should continue all the year.

The fifth sort grows naturally in Syria, this is a perennial plant, which rises with slender upright stalks about three feet high, garnished with broad, smooth, heart-shaped leaves ending in points, placed opposite; the flowers come out from the wings of the leaves in small bunches, (landing on branching foot-stalks, these are small and white, greatly resembling those of the common white *Aclepias*, or Swallow-wort, and are succeeded by oblong, taper pods, filled with flat seeds crowned with down, but these rarely ripen in this country.

It is propagated by parting of the root; the best time for doing of this or transplanting of the roots, is in the spring, before they shoot: this requires a warm situation, otherwise it will not live abroad in England.

The sixth sort grows naturally at La Vera Cruz in New Spain, from whence the seeds were sent me by the late Dr. Houftoun; this hath a shrubby twining stalk, which twists about whatever prop is near it* and rises to the height of twenty feet or upward 5 the stalks are very slender, and are armed with small stinging hairs, and garnished with broad heart-shaped leaves, which end in acute points; these are placed by pairs at each joint, which are far distant, and have slender foot-stalks; they are covered with rough hairs on their under side; the flowers are produced in small clusters, fitting close to the side of the stalks; they are pretty large, yellow, and star-shaped, spreading open to the bottom; they are succeeded by long swelling pods, filled with flat seeds lying imbricately, which are crowned with long down.

This sort is tender, so requires the same treatment as the fourth, and is propagated the same way.

CYNARA. Lin. Gen. Plant. 835. *Cinara*. Tourn. Inf. R. H. 44*- tab. 254. *Artichoke*, in French *Artichaut*.

The CHARACTERS are,
// hath a compound flower, made up of many hermaphrodite florets, which are included in one common scaly empalement, which is swollen in the bottom. The florets are tubulous, equal, and uniform, divided at the top into five narrow segments. These have five short hairy stamina, terminated by cylindrical summits, which have five indentures at the bottom of each situated an ovalgermen, supporting an oblong style, crowned by an oblong indented stigma. The germen afterward becomes a single, oblong, compressed, four-cornered seed, crowned with long hairy down.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia aequalis; the plants of this class and section have only hermaphrodite florets which are fruitful.

The first fort grows naturally by the side of hedges and foot-ways in many parts of England, so is seldom admitted into gardens, the roots of this fort are used in medicine, which are gathered by the herb-folks in the fields. The leaves of this plant have a strong odour, like that of mice in a trap. It flowers in June, and the feeds ripen in autumn.

The second fort grows naturally on the Apennine mountains, the leaves of this fort are much larger, the petal of the flower is shorter, and the plants grow taller than those of the first, and come earlier to flower in the spring; this is equally hardy as the common fort, and where the feeds are permitted to scatter, there will be plenty of the plants arise without care.

The third fort grows naturally in Andalusia, I received the feeds of this from Gibraltar; this hath a tall branching stalk, garnished with oblong woolly leaves, which embrace the stalk with their base. The flowers are produced in loose spikes, which come out from the side of the stalk, and are from six to eight inches long, the flowers are thinly placed on one side; these are blue, striped with red, and appear in June. The feeds ripen in autumn, soon after which the root decays.

The fourth fort grows naturally in Spain, and also in the island of Crete; I received this from Gibraltar, with those of the former; this rises with an upright stalk little more than a foot high, garnished with long, narrow, silvery leaves, having no foot-stalks. The flowers are produced from the side, and at the top of the stalks, which are but thinly dispersed on the side, but at the top of the stalk are in small clutters; they are of a deep purple colour, and much longer than the empalement, these are succeeded by four broad buckler-shaped feeds, which are rough. It flowers in June, and the feeds ripen in autumn, soon after which the roots generally perish.

The fifth fort grows naturally in Virginia, and in other northern parts of America; this rises with an upright branching stalk near four feet high. The stalks and leaves are covered with rough hairs, the branches are spread out on every side, and are but thinly garnished with leaves, from three to near four inches in length, and little more than one inch broad in the middle, gradually lessening to both ends* they embrace the stalks with their base, and are placed alternate; the flowers grow scatteringly toward the end of the branches; these are small and white, they appear in June, and are succeeded by four small feeds, which ripen in autumn, and then the plants decay.

The sixth fort grows naturally in Portugal, where it was first distinguished from the seventh by Dr. Tournefort. The seventh fort had been long before that cultivated in the gardens for ornament, by the title of Venus Navelwort, but of late years that has been almost lost; and the sixth fort is now generally preferred in the English gardens, and the feeds are sold by the seedsmen under that title, and is a much larger plant than the other, so makes a better appearance. The leaves of the sixth fort are broad at their base, and are gradually narrowed to the end; they are (lightly covered with hairs. The stalks grow nine or ten inches high, and divide into many branches, each being terminated by a long loose spike of white flowers, standing on separate short-stalks, which are suc-

ceeded by four umbilicated feeds, from whence it had the title of Navelwort.

The seventh fort seldom rises more than five or six inches high; the stalks do not branch near so much as those of the sixth. The leaves are very narrow and long, of a grayish colour, and smooth. The flowers grow in loose panicles at the end of the branches; these are white, but smaller than those of the other fort, and are succeeded by feeds of the same form. This plant was formerly titled *Linum Umbilicatum*, i. e. *umbilicated Flax*, from the leaves having some appearance of Flax, and the feeds having a hollow like a navel.

These are both annual plants, and have been commonly sown in gardens, with other low annual flowers, to adorn the borders of the flower-garden, but these should be sown in autumn, for those which are sown in the spring often fail, especially in dry seasons, and the autumnal plants always grow much larger than those which arise from the spring sowing, and come to flower earlier in the year. The feeds should be sown where the plants are designed to remain, for they do not bear transplanting, unless it is performed while they are young. The plants require no other culture but to be thinned where they are too close, and kept clean from weeds. They flower in June and July, and the autumnal plants come a month earlier; their feeds ripen in autumn.

The eighth fort is a low perennial plant, which grows naturally in the woods of Spain and Portugal, where it usually flowers about Christmas, this hath trailing branches, which put out roots from their joints, whereby it propagates very fast. The leaves are heart-shaped, of a bright green colour, and stand upon long (tender foot-stalks. The flowers grow in loose panicles, which arise from the divisions of the stalk; they are shaped like those of Borage, but are smaller, and of a lively blue colour; they appear in March and April, and in a cool shady situation continue great part of May, but are rarely succeeded by feeds, but the plants propagate themselves so fast by their trailing branches, as to render the cultivation of them by feeds unnecessary. It delights in a moist cool situation.

CYPERUS, Cyperus Grafs.

There are about twenty species of this genus known, some of which grow naturally in England, but the far greatest number are natives of America, where they grow in moist equal places; and as there are not above two or three species which are preferred in gardens, so it will be to little purpose to enumerate the others.

The SPECIES are,

1. CYPERUS (*Longus*) culmo triquetro folio, umbella folio supra decomposita, pedunculis nudis, spicis alternis. Prod. Leyd. 50. *Cyperus with a three-cornered stalk* an umbel with many leaves, alternate spikes on naked foot-stalks. Long-rooted Cyperus of the hops.*

2. CYPERUS (*Rotundus*) culmo triquetro subnudo, umbella decomposita, spicis alternis linearibus. Flor. Zeyl. 36. *Cyperus with a three-cornered naked stalk, a decomposed umbel, and linear spikes placed alternate Round-rooted Cyperus of the hops.*

The first fort grows naturally in France and Italy* from whence the plant was brought for medicinal use, but at present it is very seldom used in England. The roots of this fort are composed of many strong fleshy fibres which root deep in the ground, sending up every spring a great number of grassy three-cornered leaves near two feet long, the flower-stalks are triangular, nearly of the same length, supporting an umbel at the top, having many narrow triangular leaves under it, the spikes of the umbel are like those of some sorts of grass, but the feeds rarely ripen in England; so the plant is here propagated by dividing the root in the spring, and if planted in a warm situation, will thrive here in the open air.

The second fort is tenderer than the first, so the round compressed roots should be planted in pots, and sheltered in winter.

CYPRIPEDIUM. Lin. Gen. Plant. 906. Calceolus. Tourn. Inf. R. H. 436. tab. 249. Ladies Slipper, in French, *Sabot*.

The CHARACTERS are,

It hath a firm spadix. The germen sits under the flower which is covered with a spathe or sheath. The flowers have four or five narrow spear-shaped petals, which expand. The nectarium, which is situated between the petals, is swollen and hollow, in shape of a shoe, or slipper. It hath two short stamens which sit upon the point, and are terminated by erect summits, which join to the upper lip of the nectarium below the flower is fixed a slender contorted germen, supporting a short style, adhering to the upper lip of the nectarium, crowned by an obsolete stigma. The germen afterward becomes an oval blunt pod with three corners, having three furrows, three valves, and one cell, which is filled with small seeds.

This genus of plants is ranged in the first section of Linnaeus's twentieth class, intitled Gynandria Diandria, the plants of this class and section have two stamens fixed to the style.

The SPECIES are,

1. **CYPRIPEDIUM** (*Calceolus*) radice fibrosa, foliis ovato-lanceolatis caulinis. Aft. Upfal. 1740. Ladies Slipper with fibrous roots, the leaves on the stalks oval and spear-shaped. Calceolus Marise. Ger. 3 59. Our Lady's Slipper.
2. **CYPRIPEDIUM** (*Bulbosum*) seapo unifloro, foliis oblongis glabris petalis angustis acuminatis. Ladies Slipper with one flower in a sheath, oblong smooth leaves, and very narrow pointed petals. Calceolus Mariae luteus. Mor. H. R. Blof. Yellow Ladies Slipper.
3. **CYPRIPEDIUM** (*Hirfutum*) foliis oblongo-ovatis venosis hirsutis, flore maximo. Ladies Slipper with oblong, oval, veined leaves, which are hairy, and a very large flower. Calceolus flore majore. Tourn. Inf. R. H. 437. Ladies Slipper with a larger flower.

The first sort grows naturally in some shady woods in the north of England. I found it in the park of Borrough-Hall, in Lancashire, the seat of the late Robert Fenwick, Esq; It hath a root composed of many fleshy fibres, from which arise, in the spring, two, three, or more stalks, in proportion to the strength of the root; these grow nine or ten inches high, and are garnished with oval spear-shaped leaves, having a few longitudinal veins, in the bottom of one of the upper leaves is enclosed the flower-bud, which is supported by a slender foot-stalk, which generally turns a little bud on one side. The flower hath four dark purple petals, placed in form of a cross, which spread wide open. In the center is situated the large hollow nectarium, almost as large as a bird's egg, shaped like a wooden shoe, of a pale yellowish colour, with a few broken streaks; the opening is covered with two ears; the upper one is tender, white, and spotted with purple, the lower is thick, and of an herbaceous colour. The flowers appear about the end of May, and the stalks decay early in autumn.

The second sort grows naturally in Virginia, and other parts of North America, this hath longer and smoother leaves than the former. The two side petals of the flower are long, narrow, and terminate in acute points, and are wreathed, or undulated on their sides. The nectarium is oblong, and narrower than in the first sort, and is yellow, spotted with brownish red. The stalks rise near a foot and a half high.

The third sort grows naturally in America, where the inhabitants call it Mo'ccasin Flower; this rises a foot and a half high. The leaves are of an oblong oval form, and are deeply veined. The flower is large, of a reddish brown colour, marked with a few purple veins. This sort flowers in the end of May.

All these sorts are with difficulty preserved in gardens; they must be planted in a loamy soil, and in a situation where they may have the morning sun only. They must be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots should be seldom removed, for transplanting them prevents their flowering.

CYSTICAPNOS. See **FUMARIA**.

CYTISUS Q-G E N I S T A. See **SPARTIUM**.

CYTISUS. Lin. Gen. Plant. 785. Tourn. Iri & R. H. 647. tab. 416. [so called from Cythos, an island in the Archipelago* where it grew in great plenty.] Bale-tree Trefoil, in French, *Citise*.

The CHARACTERS are,

It hath a butterfly flower, with a short bell-shaped empalement of one leaf, divided in two lips? the upper being bifid and acute, the under indented in three parts. The standard of the flower is rising, oval, and reflexed on the sides. The wings are obtuse, erect, and the length of the standard. The keel is bellied and acute. It hath ten stamens, nine joined, and one standing separate, terminated by rising summits. It hath an oblong germen, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes an oblong blunt pod, narrow at their base, filled with kidney-shaped flattened seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, from the flowers having ten stamens divided into two bodies.

The SPECIES are,

1. **CYTISUS** (*Laburnum*) foliis oblongo-ovatis, racemis brevioribus pendulis, caule arboreo. *Cytifus* with oblong oval leaves, short spikes of flowers hanging downward, and a tree-like stalk. *Cytifus* Alpinus latifolius, flore racemoso pendulo. Tourn. Inf. R. H. 648. Commonly called *Laburnum*.
2. **CYTISUS** (*Alpinus*) foliis ovato-lanceolatis, racemis longioribus pendulis, caule fruticoso. *Cytifus* with oval spear-shaped leaves, long pendulous bunches of flowers, and a shrubby stalk. *Cytifus* Alpinus angustifolius, flore racemoso pendulo longiore. Tourn. Inf. R. H. 648. Commonly called *long-spiked Laburnum*.
3. **CYTISUS** (*Nigricans*) racemis simplicibus erectis, foliis ovato-oblongis. Hort. Cliff. 354. *Cytifus* with single erect bunches of flowers, and oval oblong leaves. *Cytifus* glaber nigricans. C. B. P. 390. *Black smooth Cytifus*.
4. **CYTISUS** (*Sejjilibus*) racemis erectis, calycibus bractea triplici auctis, foliis floralibus feffilibus. Lin. Sp. Plant. 739. *Cytifus* with erect bunches of flowers, three lamina under the empalement, and the leaves on the lowest branches sitting close. *Cytifus* glabris, foliis subrotundis, pediculis brevissimis. C. B. P. 390. Commonly called by the gardeners, *Cytifus fecundus* Cluffi.
5. **CYTISUS** (*Hirfutis*) pedunculis simplicibus lateralibus, calycibus hirsutis trifidis ventricoso-oblongis. Hort. Upfal. 211. *Cytifus* with single foot-stalks on the side of the branches, trifid hairy empalements, oblong and bellied. *Cytifus* incanus filiqua longiore. C. B. P. 390. Commonly called *hairy*, or *Evergreen Cytifus* of Naples.
6. **CYTISUS** (*Jrgenteus*) floribus feffilibus, foliis tomentosis, caulibus herbaceis. Lin. Sp. Plant. 740. *Cytifus* with flowers sitting close to the branches, woolly leaves, and an herbaceous stalk. *Cytifus* humilis argenteus angustifolius. Tourn. Inf. 648.
7. **CYTISUS** (*Supinus*) floribus umbellatis terminalibus, ramis decumbentibus, foliolis ovatis. Lin. Sp. 1042. *Low Cytifus* with umbellated flowers terminating the branches, which are trailing, and oval leaves. *Cytifus* fupinus foliis infra & filiquis molli lanugine pubescentibus. C. B. P. 390*
8. **CYTISUS** (*Auftriacus*) floribus umbellatis terminalibus, caulibus erectis foliolis lanceolatis. Lin. Sp. 1042. *Cytifus* with umbellated flowers terminating the branches, erect stalks and spear-shaped leaves. *Cytifus* floribus capitatis, foliolis ovato-oblongis, caule fruticoso. Diff. Hort. Commonly called *Siberian Cytifus*.
9. **CYTISUS** (*Mthiopicus*) racemis lateralibus trifidis, ramis angulatis, foliolis cuneiformibus. Lin. Sp. 1042. *Cytifus* with narrow bunches of flowers proceeding from the side of the branches, which are angular, and wedge-shaped leaves. *Cytifus* iEthiopicus, subrotundis incanis minoribus foliis, floribus parris luteis. Pluk. Aim. 128.
10. **CYTISUS** (*Gracus*) foliis simplicibus lanceolato-linearibus, ramis angulatis. Lin. Sp. 1043. *Cytifus* with single, linear, spear-shaped leaves, and angular branches. *Barba Jovis linariae folio*, flore luteo parvo. Tourn. Cor. 44.

 The first sort is the • common broad-leaved Laburnum, which was formerly in great plenty in the Lanelih • nu introduced, it bag dmoft turned this out; titt uf flowen beinr much longer, they make * appearance when they are in flower, which has afforded their twinn more generally ctdtivated -, but the: firft grows to *IK* the lanjeft tree, and the wood oi' it: 11 very hard, of a fine colour, and will jiolifli ver) well. it approjclurs near to green Ebon;.. In by the French titled *Ebony of the Al|>s* and "is thr; used for many kinds of furniture •, In; in England there are few of thefe trees which have been l'ufr to ftand long enough to jr rive to any confiderable flux, for as they have been only confidered as an ornamental ire- the frequent alterations which moft of the gardens in England have • undergor. .
 In ui in iome of the' old garden in Scotland, » here they l' • ivt- been pcrmitcii to (Un.i. rers of this kind, which = re fit to con down for the ufr of the timber. I have feen two old tn ardens, which were more th : tetfrotn the ground, md thtli had been broken and abused, otherwife might lit hav been mutlg Urg- ruw \. • ajxin poor I expofed liniatiu: His Grace the Duke of Queensberry fowetlagreat qusnntity of the ii of this tree, upon the fide of the downs, at his li-at nej: Amelbury, in Wiltshire, where the Gruicion waj very mud xpofed, and the foil to Itiallow. LI titat few trees would grow there ; yet in this place : the young trees cm twelve feet I, i in four year's growth : b became a lilcl-er to the other plantations, for which urpo!< they were defigned, but the hart and rabbits are great enemies to thefe trees, by bark- g them in winter, to that where thefe trees'arc cultivated, hey (hould be fenced from th'du animals.
 Both thefe forts are eafily prup'jaiced by fectSs, • which the trees produce in great plenty. I thefe are fown upon a common bed in March, the plant will appear jly the middle or end of April, ar.ti will require no iclwr care but to be kept clean from werdj <iurinf Se foil wing fum ;cr-, anriii the plants are too choic e>geiher, they may be traufplanted ilu- .. rous following, either imu a nurery, whefe rhs; may grow a year or two to get frngth, or im the places where they are • firm i to remain: wlm thefe trees would cultivate them Tir their wood, it will be :he bet* way to low the freeds upon the fpot where they are intended to grow, becaui thefe trees tend out long, thick, flefhy •JOB to a g: out diftance, which will penetrate the jvel or i backs; and if their roots are cut or broken, it greatly retards their growth; therefore when they are not down upon the intended fpot, they fhould be tranfplanted thither young, otherwife they will not grow to near the fix, though where they are only defigned for ornament, the removing the plants twice will flop their growth, and caufe them to be more productive of flowers; but all trees intended for timber, are much better down on the ground where they are defigned to ftand, than if they are tranfplanted.
 If the freeds of thefe trees are fown in winter, the plants will rife in great plenty the following fpring, fo that a few trees will foon fupply any perfon with a fufficient number of the plants.
 Thefe trees flower in May, at which time they make a fine appearance, their branches being generally loaded with long fringes of yellow flowers, which hang down from every part. The freeds grow in long pods, which ripen in autumn. There is a variety of

both the: trees with variegated leaves, which fome pedbntve I and of cultivating; but • this is only to be flonc b cuttings or layers, for the feeds of the tie will produce plants with green leaves; the autumn's fliould be pl.mrrd :: autumn, when the l.iveibegiii ti fall, and !• plants -iitit have 11 M>or litit, b>r in good ground they are apt to become plain.
 If the first sort comes to be considered as a useful wood, which there is no reason to doubt it may be, it may be planted in large clumps in parks, where they will be very ornamental, and I am certain, from long expert see, that this tree will thrive upon many soils, and in filch ficuai and as few other trees will make any (-rogreli i [he ob, ction to fencing is the fame here, as (ur »ny other trees, for wherever paraaitM i are madi', they are not well fecurity from animsls, tit-y will not answer the defign of the planters.
 'The fecond I bet differs from the firft, in having narrower leaves, longer bunches of flowers, and the trees do not grow fo large and ftout; this difference I find is conflant from feed. There is another fort mentioned by Tournefort, with flatter bunches of flowers than either of ih', one tree of which kind I thought I had found in a garden; the bunches of the flowers upon this tree were clofe and almoft round, but I fow'd the feeds of it, and the plants proved to be O1 by the com' ion fort.
 The third fort grows naturally in Auflria, in Italy and • ain, and ;n preici it is pretty rare in the English gardens; it was formerly in fome of the curious gardens here, but had been long loft, till a few years ago, when I procured the feeds from abroad, • which I fucceeded • the Chelsea gardens, where the plants have flowered and produced ripe feeds, which have been communicated to feveral curious perfon's.
 This ftrub seldom rizes more than three or four feet high in England; it naturally puts out many lateral branches near the ground, which ftand out on every fide, to :n to farm a low (lirubby bulh, lo with dijciiliy- railed to a llrm : the branches are very tender, and teit ends are frequently kili • if the winter is irvercj thefc arc gamifhti.l with oblonge ova] U wcrs, growing by threes on each foot-ftalk; they are equal in fize, and of a dark green colour; the branches grow erect, and are terminated by spikes of yellow flowers, about four or five inches in length, ftanding upon •I; and as ill thic i en the flruu >rance ; >L Rowers in Jul; ; ure pail, am
 This is propagated by feeds, which fhould be fown upon a bn: of light earth in March, covering them about one third [] ni incli wiith mjc il.renccti IHUL. is the beginning of May the plants will appear, when they must be carefully weeded, and during the following summer ti:; y must constantly be kept clean, which is all the culture they require till autumn, when it will be v.; proper to arch the bed over with hoops, that in -rny weather the plants may be covered .l with mats, to prevent their t<nder fhoots from being killed; for as thefe young plants are apt to continue growing later in the autumn than thofe which are become woody, fo they are much more liable :ble at told therefore where there is not fome care ikcn to covet ihei, if the winter fhould prove fevere, many of the m tuncy In entirely deftroyed, and the others killed to the ground. I the fpring following, after the danger of hard froft is over, the plants fhould be carefully taken up, and planted out at the dlitkuice of one I one, row from row, and fix inches afunder in the rows; this fhould be in a fiftenced fituation, and as thefe plants do not fhoot till late in the fpring, fo they need not be tranfplanted before the end of March, or the beginning of April; and if the feafon fhould then prove warm and dry, it will be proper to give the plants fome water to fettle the earth to their roots; and if the drought continue, and the autumn is three times repeated at a week's interval time each, it will be of fervice to the plants. After they have akn new root, they will require

no farther care, but to keep them constantly dean from weeds; in this nursery the plants may remain two years, in which time they will have acquired strength enough to be transplanted where they are to remain. There is a figure of this shrub exhibited in the 117th plate of my figures of plants.

The fourth sort grows naturally in the fourth of France, in Spain and Italy, but has been long cultivated in the nursery gardens, as an ornamental flowering shrub, by the title of *Cytisus fecundus* Clusii. This rises with a woody stalk, putting out many branches which are covered with a brownish bark, and garnished by obverse oval, small leaves, growing by threes on very short foot-stalks. The flowers are produced in close short spikes at the end of the branches, (standing erect, they are of a bright yellow colour, and appear in June; these are succeeded by short broad pods, which contain one row of kidney-shaped seeds, which ripen in August. These shrubs will rise to the height of seven or eight feet, and become very bushy, they are very hardy, so will thrive in any situation, and upon almost any soil, which is not too wet. They are propagated by seeds, which may be sown upon a common bed of light earth in the spring, and kept dean from weeds the following summer, and in autumn the plants may be transplanted into a nursery in rows, one foot apart, and at six inches distance in the rows, where they may remain two years to acquire strength, and should then be removed to the places where they are designed to grow. The fifth sort hath a soft shrubby stalk, dividing into many branches, which grow erect, and frequently rise to the height of eight or ten feet; the stalks and leaves of this are very hairy, the leaves are oval, growing three upon each foot-stalk, and are placed dolely on the branches, the flowers come out from the side of the stalk, in short bunches; they are of a pale yellow, and appear in June, these are succeeded by long, narrow, hairy pods, with one row of kidney-shaped seeds, which ripen in September.

This sort, of late years, has been much cultivated in the nursery gardens near London, by the title of *Evergreen Cytisus* of Naples; but as in severe frosts these shrubs are sometimes killed, so they are not proper for every situation, therefore should only be planted on a dry soil, and in warm situations, they are also very difficult to remove, when grown to any size, for they shoot long roots deep into the ground, and when these are broken or cut, the plants seldom survive it. This may be propagated in the same manner as hath been directed for the third sort. It grows naturally in the fourth of France, in Spain and Italy. The sixth sort hath herbaceous stalks, garnished with woolly leaves; the flowers are produced sometimes single, at other times two, three, or more grow together at the end of the branches, these appear in June, and are succeeded by hairy pods.

This plant is propagated by seeds, which may be sown at the same time, and the plants should be afterward treated in the same way, as is directed for the third sort.

The seventh sort grows naturally in Sicily, Italy, and Spain, this is a perennial plant, from whose downright root proceed several weak branches which trail upon the ground, and extend to the length of eight or ten inches; these are garnished with oblong leaves, placed by threes upon pretty long foot-stalks; they are hoary on their under side, but smooth above, the flowers are collected in heads at the end of the stalks, having a cluster of leaves under them; they are of a deep yellow colour, and appear the latter end of June, and in warm seasons these are succeeded by flat woolly pods, containing one row of small kidney-shaped seeds, which ripen in September. This plant is propagated by seeds, which should be sown where the plants are to remain, and should be treated in the same manner as the sixth sort.

The eighth sort grows naturally in Tartary, from whence the seeds were sent to the Imperial garden at Peterburgh, and hath since been sent to many of the curious gardens in Europe, which have been tur-

hished with the seeds. This hath a shrubby stalk; which rises near four feet high, dividing into many branches, which when young are covered with a green bark, dolely garnished by oblong, oval, smooth leaves, which are of a hoary green colour; the flowers are produced in close heads at the end of the branches, having a cluster of leaves under them, they are of a bright yellow colour, and appear in the beginning of May; these are sometimes succeeded by short woolly pods, containing three or four small kidney-shaped seeds in each. This is propagated by seeds, which should be sown early in April, on a border of strong ground exposed to the east; for if they are sown where they have fill sun, the plants will not thrive. This requires a cold situation and a pretty strong soil, otherwise it will not thrive.

The ninth sort grows naturally about Algiers, from whence the Rev. Dr. Shaw brought the seeds, which succeeded in the Chelsea garden. This rises with a soft shrubby stalk to the height of eight or ten feet, putting out many slender branches on every side, garnished with small wedge-shaped leaves, which are indented at the top, of a dark green colour and smooth, the flowers come out frequently single from the side of the branches, these are large and of a bright yellow; they appear in June, and are sometimes succeeded by pods containing three or four kidney-shaped seeds, which ripen in autumn. This sort is too tender to live in the open air through the winter in England, therefore the plants must be created in the same way as those which are natives of the same country.

The tenth sort grows naturally in the islands of the Archipelago, it rises with a ligneous stalk six or seven feet high, sending out many angular lateral branches, garnished with single, narrow, spear-shaped leaves; the flowers are produced in short bunches from the side of the branches; they are small, yellow, and appear in July and August, but are not succeeded by seeds in England.

This is propagated by cuttings, which if planted on a bed of light earth the beginning of July, and are dolely covered with a bell or hand-glass, which should be shaded from the sun in the middle of the day, they will put out roots by the middle or end of September; when they should be carefully taken up, planting each in a separate small pot, carefully watering and shading them until they have taken new root, after which they may be exposed in a sheltered situation till the end of October, when they must be removed into shelter, for this plant is too tender to live in the open air in England.

The eleventh sort grows naturally in the islands of America, and also at the Cape of Good Hope. This rises with a weak shrubby stalk eight or ten feet high, sending out many erect side branches, which grow erect, and are garnished with spear-shaped woolly leaves, placed by threes, the middle lobe having a longer distinct foot-stalk, than the two on each side which grow close to the principal foot-stalk. The flowers come out from the side of the branches, sometimes single, at other times in clusters, they are of a deep yellow colour, and about the size of those of the common *Laburnum*; these are succeeded by hairy pods about three inches long, which are fickle-shaped, ending with a long acute point, swelling at the place where each seed is lodged, the seeds are roundish, a little inclined to a kidney-shape. These seeds are esteemed an excellent food for pigeons in America, from whence it had the title of Pigeon Pea.

This plant grows only in very warm countries, so cannot be preserved in England, unless it is placed in a warm stove. It rises easily from seeds in a hot-bed, and will grow three or four feet high the first year, provided they have a proper heat, and the second year they will produce flowers and seeds. The plants must be placed in the bark-bed in the stove, and treated in the same manner as other tender plants from the same countries: they should have but little water in winter, and in the summer should have a large share of free air admitted to them in warm weather.

Although

D A P

Although the berries of this tree are so very acrid, as to burn the mouth and throat of those who may incautiously taste them, yet the birds greedily devour them, as soon as they begin to ripen; so that unless the shrubs are covered with nets to preserve the berries* they will all be destroyed before they are fit to gather. There is of this and the former sort, some plants with variegated leaves, which some persons are fond to have in their gardens, but the plain are much more beautiful.

The third sort grows naturally in Spain, Italy, and the south of France, where it rises to the height of three or four feet, with a single stalk covered with a light-coloured bark -, the flowers come out in clusters on the sides of the stalks, which are of an herbaceous colour, so make but little appearance; they appear early in the spring, and are succeeded by final berries which are yellowish when ripe.

The fourth sort grows naturally in the south of France, from whence I received the seeds. This is a low shrubby plant, which sends out several weak stalks from the root, which grow about a foot long, and spread about irregularly, these seldom become woody in England, but are tough and stringy, covered with a light bark; the leaves are small, of an oval form, and are very soft, white, and shining like satin; these fit pretty close to the stalks; between these the flowers come out in thick clusters from the side of the stalks*, they are white, and are succeeded by roundish berries having one hard seed. This flowers here in June, but doth not produce ripe seeds.

The fifth sort grows on the mountains near Geneva, and in other parts of Italy, where it rises about three feet high -, the flowers of this come out in clusters from the side of the branches* early in the spring. The leaves are spear-shaped, ending in blunt points, and are hoary on their under side. The flowers are succeeded by small roundish berries, which turn red when ripe.

The sixth sort grows naturally on the Alps, as also upon the mountains near Verona, from whence it was sent me; this is a very humble shrub, seldom growing more than one foot high, with ligneous stalks, which put out several side branches; these are garnished with narrow spear-shaped leaves, which are placed round the stalks without order; the branches are terminated by small clusters of purple flowers which stand erect, having no foot-stalks; the tubes of these flowers are longer and narrower than those of the Mezereon, and the mouth is cut into four acute parts which are erect. These flowers emit a pleasant odour; they appear early in the spring* but do not produce seeds here.

The seventh sort grows naturally about Montpellier; this rises with a shrubby stalk about two feet high, dividing into many small branches, which are closely garnished with narrow spear-shaped leaves growing erect, ending in acute points; the ends of the branches are terminated by panicles of flowers, which are much smaller than those of the Mezereon, having swelling tubes, which are contracted at the mouth. These appear in June, but are not succeeded by seeds here.

The eighth sort grows naturally at the Cape of Good Hope; this shrub rises to the height of five or six feet, dividing upward into several branches which grow erect, and are covered with a white bark, and closely garnished with small narrow leaves, which come out on every side of the branches without order, spreading open; the tops of the branches are terminated by woolly heads, out of which the flowers come in small clusters -, they are white, having oblong tubes, which are divided into four obtuse segments at the mouth, which spread open. These plants do not produce seeds in Europe.

The ninth sort grows naturally in many islands in the West-Indies, it was sent me from Antigua. This shrub rises to the height of four or five feet, with a woody stalk, covered with a rugged bark of an Ash colour; the upper part of the branches are garnished

D A P

with leave* about the size, and the same sort those of Rosemary -, between the leaves the flowers come out in small bunches, upon foot-stalks an inch long; they have short tubes cut into four parts at the top, and are white; these are succeeded by small round berries, of a brown colour when they are ripe.

The third, fourth, and seventh sorts are hardy, so will live through the winters in England in the open air, provided they are in a dry soil and a warm situation. The fifth and sixth sorts are as hardy as the common Mezereon, so are not in danger of being hurt by frost in England; but they are all very difficult to keep in gardens, because neither of them will bear to be transplanted. I have several times raised the plants from seeds, which have succeeded well in the places where they were sown, but whenever they were removed, they certainly died, though performed at different seasons, and with the greatest care, and the same has happened to every other person who has raised any of these plants; and some of my correspondents have allured me, they have frequently attempted to remove these plants from their natural places of growth, into their gardens, and have chosen plants of all sizes, from the youngest seedlings to the oldest plants, yet have never succeeded in it; though they have used their utmost care, and have performed it at different seasons. Therefore those who are desirous to have these plants in their gardens, must procure their seeds from the countries where they naturally grow, and when they arrive, they should be immediately sown where they are designed to remain, which for the third, fourth, and seventh sorts, should be on a very warm dry border, where, if there is a foundation of lime, rubbish, or chalk, under the upper surface of the ground, the plants will thrive better and continue much longer, than in better ground; and all the culture they require, is to keep the place clean from weeds, for the less the ground is stirred near their roots, the better the plants will thrive; for they naturally grow on poor shallow land, and out of crevices in rocks; so the nearer the soil approaches to this, the more likely the plants will be to succeed.

The fifth and sixth sorts may have a cooler situation; if these are sown where they may have only the morning sun, they will thrive better than in a warmer situation, and the ground near the roots of these should not be disturbed; therefore in the choice of the situation, there should be regard had to this, not to sow them near other plants, which may require transplanting, or to have the ground dug and loosened. The seeds of these plants coming from distant countries, rarely arrive here time enough to sow in autumn, so that when they are sown in the spring, the plants do not appear till the succeeding spring; and I have sometimes had the seeds remain till the second spring in the ground, before the plants have appeared; but as this may be too long for many people to leave the ground undisturbed, so they had better put the seeds into small pots of earth, and bury them in the ground the first summer, and in autumn take them up, and sow them where they are to stand; by this method, the seeds will be forwarded to vegetate the following spring.

The fifth sort is a beautiful sweet shrub, so deserves a place in gardens, as much as any of those we cultivate for ornament. The first and second sorts are sometimes used in medicine as was before observed, but being of a very caustic nature, are seldom prescribed; but if proper trials were with caution made, it is not doubted but they may be found very efficacious in many stubborn disorders, for some very ignorant quacks have performed great cures with these plants. The seventh sort produces the Granatida of the shops.

The eighth sort grows naturally at the Cape of Good Hope, so will not live abroad in winter in England, but requires a good green-house to preserve it. This plant is very difficult to keep or propagate in gardens.

The ninth fort will not thrive in England, unless it is preserved in the bark-frove; this plant will not bear transplanting, for I raised several from feeds which thrive pretty well while they continued in the pot where they were sown, but when they were transplanted, they all decayed.

D A T I S C A. Lin. Gen. Plant. 1003. Cannabina. Tourn. Cor. 52. Bastard Hemp.

The CHARACTERS are,

// is male and female in different plants \ the male flowers have an empalement composed of five narrow acute leaves -, these have no petals, and scarce any visible stamina, but have ten stamens which are much longer than the empalement. The female flowers have no petals, but the empalements are the same as the male, having an oblong perisperm germen, supporting three styles, crowned by single stigmas; the empalement afterward becomes an oblong triangular capsule, opening with three valves, having one cell filled with small seeds, adhering to the three sides of the capsule.

This genus of plants is ranged in the tenth section of Linnæus's twenty-second class, entitled Dodecandria, from the male and female flowers growing in separate plants, and the male flowers having ten (lamina.

The SPECIES are,

1. DATISCA (*Cannabina*) caule laevi. Lin. Sp. Plant. 1037. *Datisca* with a smooth stalk. Cannabina Cretica florifera & fructifera. Tourn. Cor. 52.

2. DATISCA (*Hirta*) caule hirsuto. Lin. Sp. Plant. 1037. *Datisca* with a rough stalk.

The first fort grows naturally in Crete, and some other eastern countries. This hath a perennial root, from which arise several herbaceous stalks, about four feet high, garnished with winged leaves placed alternately, each being composed of three pair of lobes, terminated by an odd one; these are two inches long and half an inch broad, ending in acute points, and are deeply fawed on their edges, of a light green. The flowers, come out in long loose spikes from the upper part of the stalks at the wings of the leaves, but having no petals, make but a poor appearance. The stamens of the male flowers being pretty long, and of a bright yellow colour, are the only visible parts of the flowers to be discerned at any distance.

The flowers on the female plants are succeeded by oblong three-cornered capsules, filled with small seeds, which adhere to the three valves. The plants flower in June, and the seeds ripen in September. The stalks decay in autumn and new arise in spring. This fort may be propagated by parting the roots, which should be performed in autumn when the stalks decay, (which is the best time to transplant the roots), but they must not be parted too small they may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds.

It may also be propagated by seeds, but these should be taken from such plants as grew in the neighbourhood of male plants, otherwise they will not succeed -, and if the seeds are not sown in autumn, they seldom grow the first year. The seedling plants when they rise, will require no other care but to keep them clean from weeds till autumn, when they may be transplanted where they are to grow.

The second fort grows naturally in Canada, and other parts of North America. This differs from the former, in having hairy stalks, which grow taller the leaves are larger, and do not stand so near each other upon the stalks. It is equally hardy with the first fort, and may be propagated in the same manner, but should have a more shady situation and a moist soil.

D A T U R A. Lin. Gen. Plant. 218. Stramonium. Tourn. Inf. R. H. 118. Thorn Apple.

The CHARACTERS are,

The flower is of one petal which is funnel-shaped, having a long cylindrical tube, spreading open at the top, which in some species is pentagonal, each angle being pointed; the empalement of the flower is permanent, swelling in the middle five-cornered) and tubulous \ the flower hath

five stamina, which are as long as the empalement, terminated by oblong compressed stamens; // hath an oval germen, supporting an upright style, crowned by a thick obtuse stigma. The germen afterward becomes an oval capsule, divided into four cells by a cross intermediate partition, which are filled with kidney-shaped seeds adhering to the partition:

This genus of plants is ranged in the first section of Linnæus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. DATURA (*Stramonium*) pericarpis spinosis erectis ovatis, foliis ovatis glabris. Hort. Cliff. 55. *Datura* with an oval erect fruit having a prickly cover. Stramonium, fructu spinoso rotundo, flore albo simpliciter. Tourn. Inf. R. H. 118. Thorn Apple with a round prickly fruit, and a single white flower.

2. DATURA (*Tatula*) pericarpis spinosis erectis ovatis, foliis cordatis glabris dentatis. Lin. Sp. 256. *Datura* with an erect oval fruit with a prickly cover, and smooth, heart-shaped, indented leaves. Stramonium fructu spinoso oblongo, flore violaceo. Tourn. Inf. R. H. 119. Thorn Apple with an oblong prickly fruit, and a violet-coloured flower.

3. DATURA (*Mete*) pericarpis spinosis nutantibus globosis, foliis cordatis subintegris pubescentibus. Hort. Cliff. 55. *Datura* with a globular nodding fruit having a prickly cover, and heart-shaped, entire, hairy leaves. *Datura alba*. Rump. 5. p. 242.

4. DATURA (*Ferox*) pericarpis spinosis erectis ovatis, spinis supremis maximis convergentibus. Amoen. Acad. 3. p. 403. *Datura* with an oval erect fruit, whose upper spines are largest, and converge together. Stramonium ferox. Bocc. 50. Rough Thorn Apple.

5. DATURA (*Inoxia*) pericarpis spinosis innoxii ovatis pro-pendentibus, foliis cordatis pubescentibus. *Datura* with an oval hanging fruit, whose cover is beset with barbed spines, and heart-shaped hairy leaves. Stramonium folio hyocyami, flore toto candido, fructu pro-pendente rotundo, spinis innoxii ornato. Boerh. Ind. alt. 1.

6. DATURA (*Fastuosa*) pericarpis tuberculosis nutantibus globosis, foliis hecivibus. Lin. Sp. 256. *Datura* with a globular nodding fruit, whose cover is set with tubercles and soft leaves. Stramonium Egyptianum flore pleno, intus albo, foris violaceo. Tourn. Inf. 119. Egyptian Thorn Apple with a double flower, white on the inside, and violet-coloured on the outside.

7. DATURA (*Arborea*) pericarpis inermibus nutantibus, caule arboreo. Lin. Sp. Plant. 179. *Datura* with a nodding fruit having an unarmed cover, and a tree-like stalk. Stramonium arboreum, oblongo & integro folio, fructu tevi, vulgo. Flori pondio. Feuil. tab. 46. The first fort here enumerated is the most common Thorn Apple in Europe, and was probably first introduced from Italy or Spain, where it naturally grows; but it is now become so common about London, and near other great towns in England, as to appear like a native plant, for there are few gardens or dunghills without this plant in summer, though it is only near such places, where the plants may have been cultivated first in the gardens, and wherever any of these plants are permitted to feed, they will furnish a supply of the plants for some years to come, as their produce a vast quantity of seeds, some of which will lie years in the ground, and when they are turned up to the air will vegetate.

This fort seldom grows much more than two feet high, dividing into many strong irregular branches which are hollow, garnished with large smooth leaves divided into irregular angles, and emit a foetid odour. The flowers come out first from the forks or divisions of the branches, and afterward near the extremities of the branches they have long swelling tubes, which are dilated at the top into large pentagonal brims, each angle ending in a long point or ligula, these stand in long, green, five-cornered empalements, and are succeeded by large roundish feed-vessels, covered with strong thorns, divided by four furrows, to which adhere the partitions, which separate the four cells, filled with black kidney-shaped seeds. It flowers in July, August, and September, and the seeds ripen

D A T

in autumn, which, if permitted to scatter, will fill the ground about them with plants the following years. There was formerly a cooling ointment made with the leaves of this plant and hogs lard, which was greatly esteemed for burns and scalds.

There is a variety (if not a distinct species of this) which grows naturally in North America the plants of this grow more than twice the size of the former; the leaves are smoother, and of a lucid green, but the flowers and fruit are of the same form as those of the other, so may be deemed a distinct species, especially as the difference continues in the plants propagated in England.

The second sort grows naturally in most parts of America, for I have frequently received the seeds of it from the islands in the West-Indies, and also from all the northern parts of America. This rises with a purple stem to the height of four or five feet, dividing into many strong branches, garnished with leaves shaped somewhat like those of the former sort, but larger, and have a greater number of angles and lacinae on their edges, the flowers have longer and narrower tubes, and are of a purple colour; the fruit is also longer, and these differences are permanent. This is equally hardy with the former, and if the seeds are permitted to scatter, the plants will become troublesome weeds. The third sort hath a strong stem, which rises three feet high, and divides into many woolly branches, the leaves of this sort are almost entire, having only two or three slight indentures on their edges; the flowers have long tubes, which extend beyond the bifid empalement, then they spread out very broad, where the brim is divided into ten obtuse angles, they are of a pure white above, but the tubes have a tinge of green within. These are succeeded by roundish fruit, closely covered with thorns, and are divided into four cells as the other, but the seeds of this are of a light brown colour when ripe.

This plant is not so hardy as the others, so the seeds must be sown upon a gentle hot-bed in the spring, and the plants must be afterward treated in the same manner as the Marvel of Peru, and other of the hardier kinds of annual plants, and may be transplanted into the full ground the latter end of May. They will flower in July, and the seeds will ripen in autumn.

There is a variety of this with double flowers, but unless the plants of this are placed in a glass-case, they will not produce seeds in this country.

The fourth sort is of humbler growth, seldom rising more than a foot and a half high, spreading out into many branches, which are garnished with leaves somewhat like those of the first sort, but are smaller, and stand upon longer foot-stalks; the flowers are like those of the first sort, but smaller; the fruit is round, and armed with very strong sharp thorns, the upper being large, and converge toward each other. The seeds of this are black when ripe.

This sort is too tender to be sown in the full ground in England, so the plants should be raised on a hot-bed, and afterward transplanted into borders as the former sort.

The fifth sort grows naturally at La Vera Cruz, from whence I received the seeds. This rises with a purple stem three or four feet high, dividing into several strong branches, garnished with oblong heart-shaped leaves. The stalks, branches, and leaves of this sort are covered with soft hairs; the flowers come out at the division of the stalks and branches, Handing credit; they are large, white, and are succeeded by oval fruit, covered with long, soft, innocent spines, opening in four cells, which are full of brown seeds. This plant is annual, and should be first raised on a moderate hot-bed, then may be transplanted into open borders, where it will flower and perfect its seeds in the autumn. If these seeds are permitted to scatter, the plants will rise the following spring, and if the summer proves warm, they will flower and often perfect their seeds.

The sixth sort grows naturally in Egypt, and also in India. This rises with a fine polished purple (talk four

D A U

feet high, dividing into several branches, which are garnished with large, smooth, sinuated leaves, standing upon pretty long foot-stalks. *The flowers are produced at the divisions of the branches, these have large swelling tubes, which expand very broad at the top, their brims being divided into ten angles, each ending with a long slender point. The flowers are of a beautiful purple on their outside, and a fatty white within; some of these are single, others have two or three flowers standing one within another, and some are double, having four or five petals within each other of equal length, so as to appear a full flower at the brim, they have an agreeable odour as first, but if long left to, become less agreeable, and are narcotic. If these plants are brought forward upon a hot-bed in the spring, and in June planted out on a warm border of rich earth, they will flower very finely in July and August, but unless they are covered with glasses, the seeds seldom ripen well in England. The fruit of this sort is round, and grows nodding downward; the seed-vessel is thick and fleshy, as are also the intermediate partitions which divide the cells. The outside of the fruit is covered with blunt protuberances, and the seeds are of a bright brown colour when ripe.

The seventh sort was sent me from La Vera Cruz by the late Dr. Houftoun, who found it growing there naturally. This rises with a woody stalk to the height of twelve or fourteen feet, dividing into several branches, which are garnished with oblique leaves six inches long, and two inches and a half broad in their broadest part, growing narrower at each end; they are oblique to the foot-stalk, which stands nearer to one side than the other, they are downy, and stand upon long foot-stalks. The flowers come out at the division of the branches; these have a loose tubular empalement near four inches long, which opens at the top on one side like a path or (heath, within the empalement; the tube of the flower is narrow, but immediately above it swells very large for near six inches in length, then spreads open at the brim, where it is divided into five angles, which terminate in very long points; they are white, with some longitudinal stripes, of a pale yellow on their outside; these are succeeded by round smooth capsules, filled with kidney-shaped seeds.

This tree is one of the greatest ornaments to the gardens in Chili, where the inhabitants propagate it with great care. When the flowers are fully blown, they make a fine appearance, and a single tree will perfume the air of a large garden.

This plant is tender, so requires to be kept in a stove in England. The seeds of this must be procured from the places where the trees naturally grow; they should be perfectly ripe when gathered, and carefully put up, so as that the vermin cannot get to them, for they will destroy them. Most of the seeds which were sent over by Dr. Houftoun, were devoured in their passage by insects, so that but few plants were raised. There were two or three of them raised in the gardens of the late Lord Petre, and two in the Chelsea garden; one of which came so far as to flower, but perished without producing seeds, so that at present I believe there is not any of the plants in England.

D A U C U S. Lin.Gen.Plant. 296. Tourn. Inft. R.H. 307. tab. 161. [Jay's, which some derive of foiiu, Gr. to burn, of its (harp and fiery power, or fervent taste.) The Carrot.

The CHARACTERS are,

// bath an umbelliferous flower, the principal umbel is composed of a great number of small ones called rays, which are short, and in clusters. The involucre of the principal umbel is composed of many narrow leaves, having winged points, these are scarce so long as the umbel, those of the rays are shorter and simple. The flowers have five beart-shaped petals which turn inward, those which compose the rays are unequal in size, but those of the disk are nearly so, these have each five hairy stamina, terminated by roundish summits. The germen sits under the flower, support-

supporting two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes a finally roundish, striated fruit, dividing in two parts, each having a single seed, convex and furrowed on one side, and plain on the other. This genus of plants is ranged in the second section of Linnaeus's fifth class, entitled Pentandria Digynia, the flower having five stamina and two styles.

The SPECIES are,

1. DAUCUS (*Sylvestris*) feminibus hispida, radice tenuiore fervido. Carrot with a prickly feed, and slender hot root. Daucus vulgaris. Clus. Hist. 2. p. 198. Common wild Carrot.
2. DAUCUS (*Carota*) feminibus hispida, radice carnofo esculento. Carrot with a prickly feed, and a fleshy eatable root. Daucus fativus, radice aurantii colons. Tourn. Inf. R. H. 307.
3. DAUCUS (*Gingidium*) radiis involucri planis, laciniis recurvis. Prod. Leyd. 97. Carrot with plain rays to the involucre, and recurved jags. Daucus montanus lucidus. Tourn. Inf. 307. ~~Shing root & wild carrot.~~
4. DAUCUS (*Hispidus*) caule hispido, segmentis foliorum latioribus. Carrot with a prickly stalk, and broader segments to the leaves. Pastinaca Oenanthes folio. Bocc. Rar. PL 75. Parsnep with a Water Dropwort leaf.
5. DAUCUS (*Creticus*) radiis involucri pinnatifidis, umbellis duplo longioribus, foliis acutis. Carrot with wing-pointed rays to the involucre, which are twice the length of the umbel, and acute leaves. Daucus tenuifolius Creticus, radiis umbellae longioribus. Tourn. Inf. R. H. 308. Narrow-leaved Carrot of Crete, with rays longer than the umbel.
6. DAUCUS (*Mauritanicus*) feminibus hispida, flosculo centrali sterili carnofo, receptaculo communi hemisphaerico. Lin. Sp. 348. Carrot with bipid feeds, the central flower barren, and the common receptacle hemispherical. Daucus Hispanicus, umbella magna. Tourn. Inf. 308.
7. DAUCUS (*Vifnaga*) feminibus nudis. Hort. Cliff. 89. Carrot having naked feeds. Gingidium umbella oblonga. C. B. P. 151. Gingidium with an oblong umbel
8. DAUCUS (*Muricatus*) feminibus aculeatus. Lin. Sp. 349. Carrot with prickly feeds. Caulis major Daucoides Tingitana. Mor. Hist. 3. p. 308.

The first sort is the common wild Carrot, which grows by the side of fields, and in pasture grounds in many parts of England. The plants of this sort do not differ greatly in appearance from the Garden Carrot, which has led some persons into an opinion of their being the same plant; but those who have attempted to cultivate the wild sort, are fully convinced of their being distinct plants. I have tried to cultivate the wild sort for many years, but could never get the feeds which were sown in the spring to grow. Soon which I sowed the feeds in autumn, part of which have come up well; these plants I cultivated in the same manner as the Garden Carrot, but could not improve the roots in the least, for they continued to be small, stinky, and of a hot biting taste; and this has been always the case, wherever the plants have been sown, therefore there can be no doubt of their being different plants. The feeds of this sort are used in medicine, and are esteemed good to bring away gravel: it is an excellent diuretic, but instead of these feeds, the (hops are usually supplied with old feeds of the Garden Carrot, when they have lost their vegetative quality, then the feedmen sell them to the druggists for medicinal use; but certainly all feeds which are too old to grow, can have little virtue remaining in them.

There are several varieties of the Garden Carrots, which differ in the colour of their roots, and these variations may be continued, where there is proper care taken not to mix the different sorts together in the same garden; but the Orange Carrot is generally esteemed in London, where the yellow and the white Carrots are seldom cultivated.

The dark red, or purple Carrot, I take to be a distinct sort from either of these; but as it is much tenderer, I have not had an opportunity of seeing it in the flower, for the roots were all destroyed by the tint

frosts in autumn. The feeds of this sort were sent me from Aleppo, which succeeded very well; the roots were not so large as those of the other sorts of Carrots, and were of a purple colour, very like that of a deep-coloured Radish; they were very tender and sweet; the leaves were finer cut than those of the common Carrot, and were less hairy.

The second sort is commonly cultivated in gardens for the kitchen, and the different varieties of it are, in some places, esteemed* though in London, the Orange Carrot is preferred to all the other.

They are propagated at two or three different seasons, or sometimes oftener, where people are fond of young Carrots, whenever they can be procured. The first season for sowing the feeds is soon after Christmas, if the weather is open, which should be in warm borders, near walls, pales, or hedges, but they should not be sown immediately close thereto; but a border of Lettuce, or other young fallad herbs, of about a foot wide, should be next the wall, &c. for if the Carrots were sown close to the wall, they would draw up weak, without making any tolerable roots.

These delight in a warm sandy soil which is light, and should be dug pretty deep, that the roots may the better run down; for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral roots, especially where the ground is too much dunged the same year that the feeds are sown, which will also occasion their being worm-eaten; it is therefore the better method to dung the ground intended for Carrots the year before they are sown, that it may be consumed, and mixed with the earth; but in such places where there has not been ground so prepared the year before, and there may be a necessity for dunging it the same year as the Carrots are sown, the dung should be well rotted which is laid upon it, and should be thinly spread over the ground; and in the digging of it into the ground, great care should be taken to disperse it all through the ground, and not to bury it in heaps, for that will flop the roots of the Carrots in their downright growth, and cause them to be short and forky. Where the ground is inclinable to bind, there cannot be too much care taken to break and divide the parts, therefore in digging the land for Carrots, there should never be large spots taken, but they must be very thin, and the clods well broken; which, if not attended to by the matter, is seldom properly performed by workmen, who are too apt to hurry over their work, if they are not well observed.

The ground when dug should be laid level and even, otherwise when the feeds are sown and the ground is raked over, part of the feeds will be buried too deep, and others will be in danger of being drawn up into heaps; so the plants will come up in bunches, and other parts of the ground be naked, which should always be carefully avoided.

The feeds have a great quantity of small forked hairs upon their borders, by which they closely adhere, so that they are difficult to sow even, so as not to come up in patches; you should therefore rub it well through both hands, whereby the feed will be separated before it is sown; then you should choose a calm day to sow it in, for if the wind blows, it will be impossible to sow it equal, for the feeds being very light, will be blown into heaps. When the feed is sown, you should tread the ground pretty close with your feet, that it may be buried, and then rake the ground level.

When the plants are come up and have got four leaves, you should hoe the ground with a small hoe about three inches wide, cutting down all young weeds, and separating the plants to four inches distance each way, that they may get strength; and in about a month or five weeks after, when the weeds begin to grow again, you should hoe the ground over a second time, in which you should be careful not to leave two Carrots close to each other, as also to separate them to a greater distance, cutting down all weeds, and (lightly stirring the surface of the ground in every

place, the better to prevent young weeds from springing, as also to facilitate the growth of the young Carrots.

In about a month or five weeks after, you must hoe them a third time, when you must clear the weeds as before; and now you should cut out the Carrots to the distance they are to remain, which must be proportioned to the size you intend to have them grow. If they are to be drawn while young, five or six inches asunder will be sufficient, but if they are to grow large before they are pulled up, they should be left eight or ten inches distant every way; you must also keep them clear from weeds, which, if suffered to grow amongst the Carrots, will greatly prejudice them.

The second season for sowing these feeds is in February, on warm banks, situated near the shelter of a wall, pale, or hedge; but those which are intended for the open large quarters, should not be sown before the beginning of March, nor should you sow any later than the end of the same month, for those which are sown in April or May, will run up to seed before their roots have any bulk, especially if the weather should prove hot and dry.

In July you may sow again for an autumnal crop, and at the end of August you may sow some to stand the winter; by which method you will have early Carrots in March, before the spring sowing will be fit to draw; but these are seldom so well tailed, and are often very tough and sticky. However, as young Carrots are generally expected early in the spring, most people sow some at this season, but these should be sown upon warm borders and dry land, otherwise they are seldom good. If the winter should prove very severe, it will be proper to cover the young Carrots with Pease-haulm, the haulm of Asparagus, or some such light covering, to prevent the frost from penetrating into the ground, which often destroys the Carrots, where this care is wanting: but if in very hard winters the Carrots should be all destroyed which were sown in autumn, there should be a hot-bed made early in the spring to sow some, which will be fit for use long before any that are sown in the full ground; but these beds should be earthed fifteen or sixteen inches deep, that the roots may have a proper depth of soil to run down. If these beds are lined with no dung twice, at such times when the heat of the beds decline, it will greatly forward the growth of the Carrots, but there would be great care taken not to draw the plants up too weak; these may be allowed to grow clove together than those sown in the full ground, because they will be drawn for use very young. Many people mix several other sorts of feeds, as Leek, Onion, Parsnep, Radish, &c. amongst their Carrots; and others plant Beans, &c. but, in my opinion, neither of these methods are good; for, if there is a full crop of any one of these plants, there can be no room for any thing else amongst them, so that what is got by one is lost by another, and besides, it is not only more tightly, but better, for the plants of each kind to be sown separate; and also by this means your ground will be clear, when the crop is gone, to sow or plant any thing else; but when three or four kinds are mixed together, the ground is seldom at liberty before the succeeding spring: besides, where Beans, or any other tall-growing plants are planted amongst the Carrots, they are apt to make them grow more in top than root; so that they will not be half so large as if sown singly, without any other plants amongst them.

The covetousness of some gardeners will not permit them to cut out their Carrots to a proper distance when they hoe them, so that by leaving them clove, they draw each other up weak: and if they are drawn while young, they never recover their strength afterward so perfectly, as to grow near the size of those which are properly thinned at the first hoeing-, therefore where the Carrots are designed to have large roots, they must never stand too clove, nor should they have any other crop mixed with them.

This root has been long cultivated in gardens for the table, but has not till of late years been cultivated in the fields for cattle, nor has it been prattified as yet but in few parts of England, it is therefore greatly to be wished, that the culture of it was extended to every part of England, where the soil is proper for the purpose; for there is scarce any root yet known, which more deserves it, being a very hearty good food for most sorts of animals. One acre of Carrots, if well planted, will fatten a greater number of sheep or bullocks, than three acres of Turneps, and the flesh of these animals will be firmer and better tailed. Horses are extremely fond of these roots, and for hogs there is not any better food. I have also known these roots cultivated for feeding of deer in parks, which has proved of excellent use in hard winters, when there has been a scarcity of other food; at which times great numbers of deer have perished for want, and those which have escaped, have been so much reduced, as not to recover their flesh the following summer; whereas, those fed with Carrots have been kept in good condition all the winter, and upon the growth of the grass in the spring, have been fat early in the season, which is an advantage, where the grass is generally backward in its growth.

There is also an advantage in the cultivation of this root beyond that of the Turnep, because the crop is not so liable to fail; for as the Carrots are sown in the spring, the plants generally come up well, and unless the months of June and July prove very bad, there is no danger of the crop succeeding; whereas Turneps are frequently destroyed by the flies at their first coming up, and in dry autumns they are attacked by caterpillars, which in a short time devour whole fields, but Carrots are not attacked by these vermin: therefore every farmer who has a flock of cattle or sheep, should always have a supply of these roots, if he has land proper for the purpose, which must be light, and of a proper depth to admit of the roots running down.

In preparing the land for Carrots, if it has not been in tillage before, it should be ploughed early in autumn, and then ploughed across again before winter, laying it up in high ridges to mellow by the frost; and if the ground is poor, there should be some rotten dung spread over it in winter, which should be ploughed in about the beginning of February, then in March, the ground should be ploughed again to receive the feeds* in the doing of which, some farmers have two ploughs, one following the other in the same furrow, so that the ground is loosened a foot and a half deep. Others have men with spades following the plough in the furrows, turning up a spit of earth from the bottom, which they lay upon the top, levelling it smooth and breaking the clods; the latter method is attended with a little more expence, but is much to be preferred to the first, because in this way the clods are more broken, and the surface of the ground is laid much even.

If the land has been in tillage before, it will require but three ploughing; the first just before winter, when it should be laid in high ridges for the reasons before given; the second cross ploughing should be in February, after which, if it is well harrowed to break the clods, it will be of great service, the last time must be in March to receive the feeds, this should be performed in the manner before mentioned. After this third ploughing, if there remain great clods of earth unbroken, it will be proper to harrow it well before the feeds are sown. One pound and a half of feeds will be sufficient for an acre of land, but as they are apt to adhere together, it renders them more difficult to sow even than most other sorts; therefore some mix a quantity of dry sand with their feeds, rubbing them well together, so as to separate the Carrot feeds from each other, which is a good method. After the feeds are sown, they must be gently harrowed in to bury them and when the plants come up, they should be hoed in the manner before directed.

But in order to preserve your Carrots for use all the winter and (spring, you (should, about the beginning of November, when the green leaves are decayed, dig them up, and lay them in sand in a dry place, where the frost cannot come to them, taking them out from time to time as you have occasion for them, reserving some of the longest and frailest roots for feed, if you intend to have any j which roots should be planted in the middle of February, in a light soil, about a foot asunder each way* observing to keep the ground clear from weeds; and about the middle of August, when you find the feeds are ripe, you must cut it off*, and carry it to a dry place, where it should be exposed to the sun and air for several days to dry *, then you may beat out the feeds, and put it up in bags, keeping it in a dry place until you use it. This feed is seldom esteemed very good after the first or second year at most, but new feed is always preferred, nor will it grow when it is more than two years old.

The third sort grows naturally about Montpellier; this hath smoother (talks than the common Carrot, the segments of the leaves are broader, and of a lucid green; the umbels of the flowers are larger, and not so regular. This is an annual plant, but it succeeds best when sown in autumn.

The fourth sort is of lower growth than either of the former; the stalks are closely covered with short prickles, the segments of the leaves are broad and obtuse, the umbels are final, and the involucre is longer than the umbel, and the leaves are trifid which compose it.

The fifth sort rises with a (tender, rough, hairy stalk upward of two feet high -, the leaves are short, and have a few finally ones intermixed, which are thinly placed, and cut into acute segments; the umbels are not so large as those of the common sort, and the involucre is twice the length of the umbel; the leaves which compose it are divided into five or seven parts, ending in acute points; the flowers are yellow.

The sixth sort hath a channelled stalk rising near three feet, which is terminated by large umbels of flowers, with a wing-pointed involucre the segments of the lower leaves are cut into obtuse segments, and are of a deep green colour.

The seventh sort is an annual plant, which grows naturally in Spain and Italy; this rises with an upright, smooth, channelled stalk three feet high, garnished with smooth leaves, which are divided into many fine narrow segments like those of Fennel; the stalks branch out upward, and each branches terminated by a large umbel, composed of a great number of small ones; the involucre is (shorter than the umbel, and each of the leaves which compose it is trifid: the foot-stalks which sustain the small umbels (or rays) are long and stiff; these are by the Spaniards used for picking their teeth, from whence the plant had the title of Vifnaga, or Pick-tooth. The feeds of this plant (should be sown in autumn, for those which are sown in the spring frequently fail, or at least remain in the ground till next year before they grow; the plants require no other culture but to keep them clean from weeds, and thit them where they are too close.

The eighth sort grows naturally about Tangier. This rises with an upright stalk above two feet high, garnished with double-winged leaves which are hairy; the stalk branches upward into several divisions, each being terminated by an umbel of white flowers, which are succeeded by prickly feeds. •

If the feeds of this sort are not sown in the autumn, the plants rarely perfect their feeds in this country; for when they are sown in the spring, and the plants come up soon after, they generally run up to feed in autumn, so that the frosts come on before they have time to ripen.

These sorts are sometimes preserved in botanic gardens for the sake of variety, but being of no use, are not cultivated in other gardens*

CAUCUS CRETICUS. See ATHAMANTA.

D ^ A YENIA; Monien

This genus of plants receives its title from Monfeigneur Le Due D'Ayen, who is a great lover and promoter of the science of botany; and has a noble garden at St. Germain, which is well stored with rare plants from many different parts of the world, and has appointed Dr. Monier, member of the Royal Academy of Sciences, the superintendent of it.

The CHARACTERS are*

// hath an empalement composed of five small oval leaves which are dry. The flower hath five petals whose points are united to a plain fleshy nectarium; the nectarium sits upon a cylindrical column which is erect, and the length of the empalement; it is bell-shaped, having five depressed lobes at the margin: it hath five short stamens inserted into the border of the nectarium, terminated by roundish summits which are joined to the border of the petals. It hath a roundish germen in the bottom of the nectarium, supporting a cylindrical style, crowned by a five-cornered obtuse stigma. The capsule hath five cells, including five oblong feeds fastened to the capsule.

This genus of plants is ranged in the fourth section of Linnaeus's twentieth class, intitled Gynandria Pentandria, the flowers having five stamens, which are fastened with the style to the nectarium.

We at present know but one SPECIES of this genus* viz.

DVAYENIA (*Puffilla*) foliis cordatis glabris. Lin. Sp. 1354.

*Uyenia with heart-shaped smooth leaves**

The feeds of this plant were sent by the younger De Jussieu from Peru to Paris, where they succeeded, and have since been communicated to many other gardens in Europe. I received the feeds from Dr. Monier, intendent of the garden of the Duke D'Ayen at St. Germain, which have for some years grown in the Chelsea garden, where the plants annually flower and perfect their feeds.

This plant, hath a weak ligneous stalk* which divides into several (tender branches, rising from nine inches to a foot high, garnished by heart-shaped smooth leaves, which are (lightly indented on their edges, (landing upon pretty long foot-stalks; they are of 2 lucid green, and end in acute points, placed alternately on the branches. At the base of each foot-stalk, from the side of the branches, come out the flowers, two, three, or four, arising from the same point, each (landing upon a separate (tender foot-stalk; they have five (tender stamens, collected into a sort of column, like the malvaceous flowers, having a five-cornered germen at the bottom, which afterward becomes a roundish five-cornered capsule, having five cells, in each of these is lodged one kidney-shaped feed. The flowers are tubulous, (spreading open at the top, where they are cut into five acute segments, each being terminated by a (tender tail; they are purple, and continue in succession on the same plants from July to the winter.

This plant is propagated by feeds, which (should be sown upon a moderate hot-bed early in the spring; and when the plants are come up, and have four leaves, they (should be transplanted on a (hot-bed to bring them forward *, part of them may be planted in small pots, and the others may be planted on the bed: those in the pots (should be plunged into a hot-bed of tanners bark *, they must be (shaded till they have taken new root, then they must have free air admitted to them everyday, in proportion to the warmth of the season *, they require to be frequently watered in warm weather, but they (should not have it in too great plenty. The plants (should continue all the summer in the hot-bed, where they must have a good (share of air -, for those which are fully exposed to the open air will not thrive, and if they are too much drawn, they do not flower well. The plants will live through the winter in a moderate dove, but as they perfect their feeds well the first year, few persons care to continue the old plants. There is a figure of this plant exhibited in the 118th plate of our figures of plants.

D A Y-LIL Y. Sec HEMEROCALLIS,

£ > ECOKTICATION, is the pulling off the out-ward bark of trees, alfo the peeling or barking of roots.

DELPHINIUM. Lin. Gen. Plant. 602. Tourn. Inft. R. H. 426. tab. 241. [AfApi* Gr. a dolphin, fo called, becaufe the flower, before it opens, re-fembles a dolphin. It is called Confolida Regalis, from its confolidating virtue. Cafpar Bauhin calls it the Royal Plant, becaufe it has its cup turned backwards, like a nobleman's badgje. Csefalpinus, «Pliny, and the poets fay, this plant is the true Hyacinth, becaufe it has the fyllable ai infcribed on its flower, which is a particle of bewailing,] Larkfpur, or Larkheel.

The CHARACTERS are,

*The flower hath no empalement; it is compofed of five unequal petals placed circularly *, the upper petal is extended at the hinder part into a tubular obtufe tail; the two fide petals are nearly of the fame fize with the upper', but the two lower are fmaller; thefe fspread open. There is a bifid neffarium fituated in the center of the petals, and is involved in the tube by the back part. The flower hath many fmall ftamina which incline to the petals, and are terminated by fmall ere&l fummits; it hath three ovalgermen, fupporting three ftyles which are as long as the ftamina, crowned by reflexed ftigmas 5 the germen afterward become fo many capfules joined together', which open croffways, each having one cell filled with angular feeds.*

This genus of plants is ranged in the third fe&ion of Linnaeus's thirteenth clafs, intitled Polyandria Trigynia, the flower having many ftamina and three ityles

The SPECIES are,

1. DELPHINIUM (*Confolida*) neftariis monophyllis, caule fubdivifo. Hort. Cliff. 217. *Larkfpur with a one-leaved neffarium and a divided ftalk.* Delphinium fegetum. Tourn. Inft. 426. *Corn Larkfpur', and the Confolida regalis arvenfis.* C. B. P. 142. *Field Royal Confound.*
2. DELPHINIUM (*Ajacia*) neftariis monophyllis, caule fimplici. *Larkfpur with a one-leaved neStarium, and an treh ftalk.* Delphinium hortenfje, flore majore & ilmplici caeruleo. Tourn. Inft. R. H. 426. *Garden Larkfpur, with a larger fingle blue flower.*
3. DELPHINIUM (*Ambiguum*) neftariis monophyllis, caule ramofo. *Larkfpur with a one-leaved netlarium and a branching ftalk.* Delphinium elatius purpuro violaceum. Suvert. Flor. *Branched Larkfpur.*
4. DELPHINIUM (*Peregrinum*) neftariis diphyllis corollis enneapetalis capfulis teretis, foliis multipartitis obtufis. Hort. Cliff. 213. *Larkfpur with a two-leaved neffarium, a flower with eleven petals and three capfules, and leaves divided into many obtufe fegments.* Delphinium latifolium, parvo flore. Tourn. Inft. R. H. 426. *Broad-leaved Larkfpur with a fmall flower.*
5. DELPHINIUM (*Elatum*) neftariis diphyllis, labellis bifidis, apice barbatis, foliis incifis, caule erefto. Hort. Upfal. 151. *Larkfpur with a two-leaved neSarium, a bifid lip bearded at the top, cut leaves, and an ereSI ftalk.* Delphinium perenne montanum villofum, aconiti folio. Tourn. Inft. 426. *Perennial hairy Mountain Larkfpur with a Monk/hood leaf commonly called the Bee Larkfpur.*
6. DELPHINIUM (Gr^^^rww)neftaris diphyllis, labellis integris, floribus fubfolitariis, foliis compofnis linean-multipartitis. Hort. Upfal. 150. *Larkfpur with a two-leaved neStarium, an entire lip, flowers growing Jingly, and compound leaves divided into many narrow parts.* Delphinium humilium anguftifolium perenne, flore azureo. Amman. *Dwarf narrow-leaved perennial Larkfpur with an azure flower.*
7. DELPHINIUM (*Americaxum*) neftariis diphyllis, labellis integris, floribus fpicatis, foliis palmatis multifidis glabris. Plate 119. *Larkfpur with a two-leaved nettarium, an entire lip, flowers growing in fpikes, and palmated, multifid, fmooth leaves, commonly called American Larkfpur.*
8. DELPHINIUM (*Staphifagria*) ne&ariis diphyllis, foliis palmatis, lobis integris. Hort. Cliff. 213. *Larkfpur with a two-leaved empalement, andpalmated leaves having*

entire lobes. Delphinium platani folio, ftaphyagga didtum. Tourn. Inft. R. H. 428. *Larkfpur with a Plane-tree leaf, called Stavefacre.*

The feveral varieties of the Garden Larkfpur are not here enumerated, as they would fwell the work beyond its intended bulk, if all thefe were diftinguifhed, therefore here are only the diftinft fpecies mentioned; and as the gardeners diftinguifh the Garden Larkfpurs into thofe which are branched, and fuch as have upright ftalks; which difference is permanent, and never alters, whatever may be afferted to the contrary by ignorant pretenders-, fo I fiall juft mention the feveral varieties which there are of each fort, commonly cultivated in the gardens of the curious. And firft of the branched Larkfpur, there are of the following colours, with fingle and double flowers.

Blue, purple, white, flefh, Alh, and Rofe colours -, and fome have flowers beautifully fpotted, with two or three of thefe different colours.

The upright or unbranched Larkfpur, produces a greater variety of colours than the branched, and the flowers are larger and fuller than thofe-, but the principal colours run nearly the fame with thofe of the other, though many of the colours are deeper, and there are more different {hades of thefe colours in the flowers of this fort.

The firft fort grows naturally on arable lands, in France, Spain, and Italy, and is fuppofed to be the fame as the Garden Larkfpur, which is a great miftake; for I have cultivated it many years in the garden, and never found it alter: the leaves of this fort are broader, and not fo much divided as thofe of the garden kind, and are placed thinner upon the ftalks; the flowers are fmaller, and grow in longer fpikes; the ftalks are not fo much branched as that fort which is called the branched, nor are they fingle like the upright, fo that I think it may be allowed to be a different fpecies.

The fecond fort hath upright ftalks, which fcarce put out any branches -, the fpikes of flowers grow eredt, and the flowers are placed very clofe together, fo that they make a fine appearance. Thefe plants flower in July and Auguft, and are very great ornaments to the borders of the flower-garden.

The branching Larkfpur, which is the third fort, comes later to flower than the upright -, this rifes with a very branching ftalk three feet high or more; the branches come out horizontally from the fide of the ftalks, but afterward turn that part on which the fpike of flowers grow, which is at the extremity upward, fo as to make an angle; the leaves are long and finely divided *, the flowers are placed thinner in the fpikes than thofe of the upright fort *, they are large, and fome of them very double and of various colours.

Thefe plants are annual, fo are every year propagated by feeds, which fhould be fown where the plants are defigned to remain, for they do not bear tranfplanting well, efpecially if they are not removed very young; thofe feeds which are fown in autumn, produce the frongeft plants and moft double flowers, and ripen their feeds better than thofe which are fown in the fpring, as they come earlier to flower; but to continue a fucceffion of thefe flowers, there fhould be fome feeds fown in the fpring. When they are fown on the borders of the flower-garden for orttament, they fhould be in patches of about a foot diameter, in the middle of the borders, at proper diftances; in each of thefe patches may be fcattered ten or a dozen feeds, covering thim over about a quarter of an inch with earth; and in the fpring the plants may be thinned, leaving about five or fix of the upright fort in each patch to ftand for flowering *, but of the branching fort, not more than three or four, becaufe thefe require room; after this the plants will require no farther care but to keep them clean from weeds, and when they begin to flower fhould be fupported by flower-fticks to prevent their being broken by wind, efpecially if they are not in a flickered fituation. If the feeds were well chofen, there will be very few ordinary

DEL

ordinary flowers among them; and if there are feeds of the different coloured flowers sown in each patch, they will make a pleasing variety: but the upright sort should never be mixed in the same patches with the branching, because they do not flower at the same time.

But in order to preserve the two sorts fine without degenerating to single or bad colours, there should be a bed of each sort sown in autumn, in some separate part of the garden, where the plants should be properly thinned, and kept clean from weeds, till they begin to show their flowers; when they should be carefully looked over every other day, to pull out all those plants, whose flowers are not very double nor of good colours; for if these are permitted to stand among the others till their farina has impregnated them, it will certainly cause them to degenerate; so that those persons who are contented with only marking their good flowers for seed, and suffer the others to stand for seed among them, will always find themselves disappointed in the goodness of their flowers the following season: therefore those who propose to have these flowers in perfection, should never gather the seeds of such as grew in the borders of the flower-garden; because there it will be almost impossible to preserve them so true, as when they are in beds at a distance from all other kinds.

When the seed-vessels turn brown, they must be carefully watched, to gather them before they open and discharge the seeds; so that those which are situated on the lower part of the stalk, will open long before those on the upper part of the stalk are ripe; for which reason the pods should from time to time be gathered as they ripen, and not suffered to stand till the stalks are pulled up, which is often practised. Those pods which are situated on the lower part of the stalks, are much preferable to such as grow near the top; for which reason those who are very curious in the choice of their seeds, crop off the upper part of the spikes of flowers, and never suffer them to stand for seeds.

r.

As these plants are very hardy, and require so little care in their culture, so they are worthy of a place in every good garden; for during their continuance in flower, there are few plants which make a better appearance; and for gathering to make flower-pots to adorn rooms, there is scarce any flower so proper; because by their upright growth and long spikes, they rise to a proper height above the pots; and when the several colours are skilfully intermixed they make a rich appearance, and continue long in beauty.

The fourth sort grows naturally in Sicily and Spain, I received the seeds of it from Gibraltar; this hath a very branching stalk, which rises about two feet high; the lower leaves are divided into many broad obtuse segments, but those which are upon the stalks are generally single; the flowers grow scattering toward the upper part of the branches, they are small, and of a deep blue colour, these are succeeded by very small seed-vessels, which are sometimes single, and at others double, and very rarely three together, as in the common sorts. This is an annual plant, whose seeds should be sown in autumn, and the plants treated as the common sort; it hath little beauty, and is only kept in some gardens for the sake of variety.

The fifth sort hath a perennial root, which sends out several upright stalks in the spring to the height of four feet, garnished with leaves which are divided into many broad segments, in form of a spreading hand; these segments are cut at their extremities into two or three acute points; the leaves are hairy, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a light blue, covered toward their hinder part with a mealy down. This flowers in July and August, and in autumn the stalks decay to the root.

The sixth sort grows naturally in Siberia, from whence the seeds were sent to the Imperial garden at Pe-

DEN

terburghi where they succeeded; and the seeds were sent me from thence by the late Dr. Anita an, who was professor of botany in that university. This hath a perennial root, which puts out two or three branching stalks every spring; these rise about a foot and a half high, and are garnished at each joint with leaves composed of many narrow segments, which terminate with several acute points; they are smooth, and of a light green colour; the flowers come out toward the upper part of the stalks singly, each standing upon a long naked foot-stalk; these are large, and of a fine azure colour; they appear the latter part of July, and are succeeded by seeds which ripen in the autumn.

The seventh sort grows naturally in America; this is a perennial plant, which rises with strong branching stalks six or seven feet high, garnished with hand-shaped leaves, which are divided into four or five broad lobes, ending with many acute points; these are smooth, and stand upon long foot-stalks; the flowers terminate the stalks, growing in long spikes; they are of a fine blue colour, with a bearded nectarium, having two lips; and of a dark colour, resembling at a small distance the body of a bee.

All the perennial Larkspurs are propagated by seeds, which, if sown in autumn, will more certainly succeed, than those which are sown in the spring; when the plants come up, they should be kept clean from weeds, and where they are too close together, part of them should be drawn out, to allow room for the others to grow till the following autumn, when they must be planted where they are to remain; the following summer they will flower, and the roots continue many years growing in magnitude, so will produce a greater number of flower-stalks.

The eighth sort is an annual plant, which grows naturally in the Levant, as also in Calabria; this rises with a strong hairy stalk about two feet high, garnished with hand-shaped hairy leaves, composed of five or seven oblong lobes, which have frequently one or two acute indentures on their sides; the flowers form a loose spike at the upper part of the stalk, each standing on a long foot-stalk; the flowers are of a pale blue or purple colour, and have a two-leaved nectarium: this is propagated by seeds, which should be sown in autumn, for those sown in the spring never grow the same year. The seeds should be sown where the plants are to remain, and require no other treatment than the common Larkspur. The common people use the powder of this seed to kill lice, from whence it has been titled Loufewort.

D E N S C A N I S. See ERYTHRONIUM.

D E N S L E O N I S. See LEONTODON.

D E N T A R I A. Lin. Gen. Plant. 726. Tourn. Lift. R. H. 225. tab. no. Toothwort; in French *Dentaire*.

The CHARACTERS are,

The empalement of the flower is composed of four oblong oval leaves, which fall off the flower hath four obtuse petals placed in form of a cross it hath six stamina, four of which are as long as the empalement, the other two are shorter these are terminated by oblong heart-shaped summits, which stand erect. In the center is situated an oblong germen, supporting a short thick style, crowned by an obtuse stigma the germen afterward becomes a long taper pod with two cells, divided by an intermediate partition, opening with two valves, including many round seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, intitled Tetradynamia Siliquosa, the flowers having four long and two short stamina, and the seeds being inclosed in long pods.

The SPECIES are,

1. PENTARIA (*Pentaphyllos*) foliis fummis digitatis. Lin. Sp. 912. *Five-leaved toothwort, whose upper leaves are hand-shaped.* Dentaria pentaphyllos, foliis mollioribus. C. B. P. 322. *Five-leaved Toothwort with soft leaves.*
2. DENTARIA (*Bulbifera*) foliis inferioribus pinnatis, fummis simplicibus. Hort. Cliff. 335. *Tooth-wort with lower leaves winged, and the upper ones single.* Dentaria

ria heptaphyllos baccifera. C. B. P. 322. *Seveir-leaved bulb-bearing Toothwort*.

- 3- DENTARIA (*Enneaphyllos*) foliis ternis ternatis. Lin. Sp. Plant. 653. *Toothwort with three-leaved trifoliate leaves*. Dentaria triphyllos. C.B. P. 322. *three-leaved toothwort**

The first fort rises with a strong stalk a foot and a half high, garnished with a leaf at each joint, composed of five lobes, which are four inches long, and near two broad in the widest part, ending in acute points, deeply fawed on their edges *, these are smooth, and stand on long foot-stalks; the flowers grow in loose spikes at the top of the stalks; they are small, of a bluish colour, and succeeded by long taper pods filled with small roundish seeds. It grows in the shady woods in the south of France and Italy.

The second fort rises with (tender stalks about a foot high; the leaves at the bottom have seven lobes, those a little above five, others but three, and at the upper part of the stalk they are single: the flowers grow in clusters at the top of the stalk *, these have four obtuse purple petals, and are succeeded by taper pods filled with roundish seeds.

The third fort rises with an upright stalk a foot high; the leaves are composed of nine lobes, three growing together, so that one leaf has three times three; the flowers grow in small bunches on the top of the stalks, and are succeeded by small taper pods filled with roundish seeds.

These plants grow on the mountains in Italy, and in the woods of Austria. The second fort is found wild in some parts of England, but particularly near Harefield, in moist shady woods, and is seldom preserved in gardens: this produces bulbs on the side of the stalks, where the leaves are set on, which, if planted, will grow and produce plants. These plants are propagated by seeds, or parting their roots 5 the seeds should be sown in autumn, soon after they are ripe, in a light sandy soil and a shady situation: in the spring the plants may be taken up where they grow too close, and transplanted out in the like soil and situation; where, after they have taken root, they will require no farther care, but to keep them clear from weeds: the second year they will produce flowers, and sometimes perfect their seeds.

The best time to transplant the roots is in October, when they should be planted in a moist soil and a shady situation; for they will not live in a dry soil, or when they are exposed to the sun.

D E W is by some defined to be a meteor bred of a thin cold vapour, or composed of the fleams and vapours of the earth; which, being exhaled by the heat of the sun, and kept suspended during his presence, do, upon his absence, convene into drops, and then fall down unto the earth again.

Others define it, a thin, light, insensible mist or rain, falling while the sun is below the horizon.

The origin and matter of dews are, without doubt, from vapour and exhalations of the earth and water, raised by the warmth of the sun and earth, &c.

There being many vapours in the air, though not always visible, hence it comes to pass, that even in dear weather great dews fall, especially in countries where it seldom rains *, for when it happens that the scattered vapours are collected and condensed together, and forced downwards, they must needs fall, and bedew the plants and grass.

The thin vesicles, of which vapours consist, being once detached from their bodies, keep rising in the air till they arrive at such a stage as is of the same specific gravity with themselves, when their rise is stopped: now, as it is the warmth or fire that dilates the parts of water, and forms those vesicles that are specifically lighter than the air, and are capable of ascending therein; so when that heat declines, or is lost, as by the approach or contiguity of any colder body, the vesicles condense, and become heavier and descend.

Therefore the sun warming the atmosphere in the day-time, by the continual influx of his rays, the va-

pours being once raised, continue their progress, and meeting with any thing to increase their gravity, till such time as they are got far beyond the reach of the reflected warmth of the earth in the middle region of the atmosphere, and there condense and form clouds.

Though some say, it is disputable whether dews ever congregate so as to form clouds, as they are only elevated by the sun; so that when that power is gone, as it is after the setting of the sun, they immediately descend; and this is more observable in very warm weather, and very hot climates.

The time for the falling of the dew is either before sun-rising, or after sun-set; that it may regularly fall at such times, it is necessary for the air to be calm, for windy or stormy weather hinders it; but when it is calm weather, and gentle breezes are felt from the west about the setting, and from the east about the rising of the sun, it is probable, that by moderately-cooling the air, they collect the vapours and precipitate them; and because the morning breezes are more general than the evening ones, for this reason the evening dews fall only here and there, but those in the morning seldom fail to be universal: or, as it may be otherwise expressed, when the sun is got below the horizon, the atmosphere cools the vapours, which have in the preceding day been raised by the warmth of the earth -, and the rays of the sun being lodged there, as soon as they are got out of the air, they begin to condense apace, and spend their flock of heat and fire on the cold moist air that they pass through.

Hence it is, that dews are more copious in the spring than other seasons, there being a greater flock of vapour in readiness, by reason there has been but a small expence thereof during the winter's cold and frost than at other times.

It is found by experience, that the dews are more copious in hotter countries than in cold, as Pliny observes of the summer nights in Africa, which he calls *Roscidæ æstatis* nodes; the reason of which seems to be this, that in the day-time the heat of the sun raises abundance of vapours out of the water; which vapours are so extremely rarefied by the same heat, that they are dispersed far and wide 5 but the cool of the night brings them together, and condenses them to that degree, that they fall to the ground, but not in such large drops as rain does -, but in colder countries, where there are frequent rains, and the vapours are less rarefied, most of them come down in rain, and but a small part turns to dew: besides, in Africa there is a great difference between the heat of the day and night, particularly in summer -, for their nights are long, and very cold *, whereas in northern countries they are little colder than the day, and much shorter than in places nearer the line.

Pliny likewise relates of Egypt, that it abounds in dews throughout all the heat of summer; for the air being there too hot to dissipate the vapours in the day-time, they never gather into clouds, and for that reason they have no rain. But it is known, in climates where the days are excessive hot, the nights are remarkably cold, so that the vapours that are raised after sun-set are readily condensed into dews: or, perhaps notable coldness may be rather the effect than the cause of the quantity of dews; for much vapour being raised by the great heat of the earth, and the flock of fire being spent on it in the day-time, the influx of such a great quantity of moisture must greatly chill the air.

The difference between dew and rain seems to be only this, that dew falls at some particular times as aforesaid, and in very small drops, so as to be seen when down, but scarce perceivable while it is falling; whereas rain falls at any time, and in grosser drops.

The reverend Dr. Hales, in his Treatise of Vegetable Statics, tells us, That in order to find out the quantity of dew that fell in the night on the 15th of August, 7 p. m. he took two glazed earthen pans, which were three inches deep, and twelve inches diameter

in surface: that he filled them with pretty moist earth, taken off the surface of the ground, and they increased in weight by the night's dew 180 grains; and decreased in weight by the evaporation of the day 1 ounce + 282 grains.

He says likewise, he set these in other broader pans to prevent any moisture from the earth (licking to the bottom of them. He adds, that the moister the earth is, the more dew falls on it in a night, and more than a double quantity of dew falls on a surface of water than there does on an equal surface of moist earth. The evaporation of a surface of water in nine hours winter's dry day, is $\frac{1}{2}$ of an inch: the evaporation of a surface of ice set in the shade during a nine hours day, was $\frac{1}{4}$.

So here are 540 grains more evaporated from the earth every 24 hours in summer than fall in dew in the night; that is, in 21 days near 26 ounces from a circular area of a foot diameter, and circles being as the squares of their diameters, 10 pounds + 2 ounces will in 21 days be evaporated from the hemisphere of 30 inches diameter, which the Sunflower's root occupies; which, with the 29 pounds drawn off by the plant in the same time, makes 39 pounds, that is, 9 pounds and $\frac{1}{2}$ out of every cubic foot of earth, the plant's roots occupying more than 4 cubic feet: but this is a much greater degree of driness than the surface of the earth ever suffers for 15 inches depth, even in the driest seasons in this country.

In a long dry season therefore, especially within the tropics, we must have recourse, for sufficient moisture to keep plants and trees alive, to the moist strata of earth, which lie next below that in which the roots are.

Now moist bodies always communicate of their moisture to more dry adjoining bodies; but this flow motion of the ascent of moisture is much accelerated by the sun's heat to considerable depths in the earth, as is probable, he says, from the twentieth experiment in the said book.

Now 180 grains of dew falling in one night on a circle of a foot diameter = 113 square inches; these 180 grains being equally spread on this surface, its

depth will be $\frac{1}{2}$ part of an inch $\frac{113}{233}$ He adds, that he found the dew in a winter night to be $\frac{1}{4}$ part of an inch; so that if we allow 151 nights for the extent of the summer dew, it will in that time arise to one inch depth: and reckoning the remaining 214 nights for the extent of the winter's dew, it will produce 2,39 inches depth, which makes the dew of the whole year amount to 3,39 inches depth.

And the quantity which evaporated in a fair summer day from the same surface, being as 1 ounce 282 grains, gives $\frac{1}{2}$ part of an inch depth for evaporation, which is four times as much as fell at night.

He says likewise, that he found by the same means, the evaporation of a winter's day to be nearly the same as in a summer's day, for the earth being in Winter more saturated with moisture, that excess of moisture answers to the excessive heat in summer.

Nic. Cruquius, N^o 381. of the Philosophical Transactions, found, that 28 inches depth evaporated in a whole year from water, i. e. $\frac{1}{2}$ of an inch each day at a mean rate: but the earth in a summer's day evaporates $\frac{1}{2}$ of an inch, so the evaporation of a surface of water is to the evaporation of a surface of earth in summer as 10: 3.

The quantity of rain and dew that falls in a year is at a medium 22 inches. The quantity of the earth's evaporation in a year is at least 9 + 4 inches; since that is the rate at which it evaporates in a summer's day: from which 9 + 4 inches are to be deducted 3,39 inches for circulating daily dew, there remains 6,2 inches, which 6,2 inches deducted from the quantity of rain that falls in a year, there remains at least 16 inches depth to replenish the earth with moisture for vegetation, and to supply the springs and rivers.

Dr. Hales proceeds to instance, in the case of a Hop-ground which he gives in the ninth experiment of his book of Vegetable Statics, that the evaporation there found, from the Hops, considered only for three months, at $\frac{1}{2}$ part of an inch each day, which will be $\frac{1}{2}$ of an inch: but before it be allowed 6,2 inches to form the surface of the ground, which added to the $\frac{1}{2}$ give 7,1 inches, which is the utmost that can be evaporated from a surface of Hop-ground in a year; so that of 22 inches depth of rain, there remain 15 inches to supply springs, which are more or less exhausted, according to the driness or wetness of the year.

Hence we find, that 22 inches depth of rain in a year is sufficient for all the purposes of nature in such flat countries as that about Teddington near Hampton Court. But in the hill countries, as in Lancashire, there falls 42 inches depth of rain water, from which, deducting 7 inches for evaporation, there remains 35 inches depth of water for the springs, benefits great supplies from much more plentiful dews than fall in plain countries; which vast stores seem to abundantly suffice to answer the great quantity of water, which is conveyed away by the springs and rivers from those hills, that we need not have recourse for supplies to the great abyss, whose surface at high water is surmounted some hundreds of feet by those vast hills from whence the longest and greatest rivers take their rise.

DIANTHERA. Lin. Gen. Plant. 37. Flon Virg. 6.

The CHARACTERS are,

The flower hath a permanent empatement of one leaf which is fabulous* and cut at the top into five equal parts* the flower is of the grinning kind* having one petal with a short tube* the upper lip is reflexed and bifid, the lower is divided into three parts* the middle being the broadest, it hath two short slender stamina adhering to the back of the petal* one of these hath a twin summit* the other is a little taller. It hath an oblong germen* supporting a slender style the length of the stamina* crowned by an obtuse stigma. The empakment afterward becomes a capsule with two cells* opening with two valves* which are alternately compressed at the top and bottom* and open with an elasticity* casting a single flat seed out of each cell*

This genus of plants is ranged in the first section of Linnaeus's second class, intitled Diandria Monogynia, the flower having two stamina and one style. This is one of the genera which, by Linnaeus's method, is separated to a great distance from their congeners; for by all their other characters they should be joined to his fourteenth class, but having only two stamina, they are put under his second.

We know but one SPECIES of this genus at present, viz.

DIANTHERA {Americana} spicis folitariis alternis. Lin. Sp. 24. Dianthera with folitary alternate spikes.

This plant grows naturally in Virginia, and other parts of North America, from whence the seeds have been sent to England, where they have succeeded. This is a low herbaceous plant with a perennial root, which sends out several weak stalks about four inches long, garnished with roundish leaves of an aromatic odour, (landing close to the stalks; they are hairy, and of a dark green colour; from the side of the stalks the flowers are produced in small spikes, placed alternately; these are in shape and colour very like those of the Clinopodium, but have only two stamina in each. It flowers the latter end of July, but rarely produces seeds in England.

This plant is very difficult to preserve in this country, for although it is hardy enough to live in the open air in England, yet it is very subject to rot in winter; and if it is placed under flicker, it is apt to draw up weak, and soon after decay, so that at present the plants are rare in this country.

The

The seventh fort is the common Sweet William, which has been long cultivated in the gardens for ornament, of which there are now great varieties which differ in the form and colour of their flowers, as also in the size and shape of their leaves; those which have narrow leaves were formerly titled Sweet Johns by the gardeners, and those with broad leaves were called Sweet Williams; there are some of both these forts with double flowers, which are very ornamental plants in gardens.

The eighth fort grows naturally in the south of France, in Spain, Italy, and in England. This is an annual plant, which rises with an upright stalk about a foot high, garnished with narrow grassy leaves, and is terminated by a small head or cluster of pale red flowers, which are included in one common scaly empalement. These have little beauty, for the plants are seldom kept in gardens.

The ninth fort is a biennial plant, which rises with an upright stalk a foot and a half high, having two long narrow leaves placed opposite at each joint, which embrace the stalk with their base; they are of a deep green colour, stiff, and end in acute points. The flowers grow in close clusters at the top of the stalks, having stiff bearded empalements; they are yellow and iron coloured intermixed on the same stalk, and frequently they are of both colours in the same head. This plant flowers in July, and the seeds ripen in autumn.

The tenth fort came originally from China, for it is titled the China Pink; the flowers of this have no scent, but there are a great variety of lively colours among them; and of late years there has been great improvements made in the double flowers of this fort, some of which are as full of petals as the double Pink, and their colours are very rich. The plants seldom grow more than eight or nine inches high, branching out on every side; the branches grow erect, and are terminated each by a single flower. These flower in July, and continue in succession, till the frost stops them; they are commonly raised every year from seeds* but the roots will continue two years in dry ground.

The eleventh fort is found growing naturally upon old walls and buildings in many parts of England, this is a single small Pink, of a sweet odour, but of a pale colour and small, for makes no appearance; and since the great improvement which has been made in these flowers by culture, this has been entirely neglected.

The twelfth fort grows naturally on the Alps. This hath round, short, blunt leaves; the stalks seldom rise more than four inches high, each being terminated by a single flower of a pale red colour. It is sometimes preferred in botanic gardens for the sake of variety, but is rarely admitted into other gardens.

The thirteenth fort grows naturally in Germany and Denmark; the leaves of this fort are like those of the narrow-leaved Sweet William; the stalk rises more than a foot high, and is terminated by a single flower, having five large petals of a pale red colour, which are cut into many long segments. The roots of this fort will live three or four years, but the second year from seeds they are in greatest beauty; therefore as the seeds ripen well in England, young plants should be annually raised.

The fourteenth fort is a very diminutive plant, having short narrow leaves growing in close heads; the stalk seldom rises six inches high, which is terminated by a single flower, of a pale red colour, for has little beauty, therefore is only kept in botanic gardens for variety.

The forts here enumerated, are such as the botanists allow to be distinct species; and all the varieties of fine flowers, which are now cultivated in the gardens of the curious, are only accidental variations which have been produced by culture; and the number of these are greatly increased annually, in many different parts of Europe; for that as new varieties are obtained, the old flowers are rejected.

The plants of this genus may be properly enough divided into three sections. The first to include all the variety of Pinks, the second all the Carnations, and the third, those of the Sweet William; for although these agree so nearly in their principal characters, as to be included under the same genus by the botanists, yet they never vary from one to the other, though they frequently change and vary in the colour of their flowers.

I shall now proceed to treat of these under their different sections, and first I shall begin with the Pink, of which there are a great variety now cultivated in the gardens; the principal of which are, the damask Pink, the white Shock, the Pheasant Eye, with double and single flowers, varying greatly in their size and colour; the common red Pink, Cob's Pink* Dobson's Pink, white Cob Pink, and Bat's Pink. The old Man's Head, and painted Lady Pink, rather belong to the Carnation.

The damask Pink is the first of the double forts in flower. This hath but a short stalk, the flower is not very large, and not so double as many others; the colour is of a pale purple, inclining to red, but is very sweet.

The next which flowers is the white Shock, which was so called from the whiteness of its flowers, and the borders of the petals being much jagged and fringed; the scent of this, is not so agreeable as of some others.

Then comes all the different kinds of Pheasant's Eye, of which there are frequently new varieties raised, which are either titled from the persons who raised them, or the place where they were raised; some of these have very large double flowers* but those which burst their pods are not so generally esteemed.

The Cob Pink comes after these to flower; the stalks of this are much taller than those of any of the former; the flowers are very double, and of a bright red colour; these have the most agreeable odour of all the forts, for merits a place in every good garden. The time of the Pinks flowering is from the latter end of May to the middle of July, and frequently that fort of Pheasant Eye, which is called Bat's Pink, will flower again in autumn.

The old Man's Head Pink* and the painted Lady, do not flower till July, coming at the same season with the Carnation, to which they are more nearly allied than the Pink. The first when it is in its proper colours, is purple and white striped and spotted, but this frequently is of one plain colour which is purple; this fort will continue flowering till the frost in autumn puts a stop to it, and the flowers having an agreeable scent, renders them valuable. The painted Lady is chiefly admired for the liveliness of its colour, for it is not so sweet, or of so long continuance as the other.

The common Pinks are propagated either by seeds, which is the way to obtain new varieties, or by making layers of them, as is practised for Carnations*, or by planting slips, which, if carefully managed, will take root very well.

If they are propagated by seeds, there should be care taken in the choice of them, and only the seeds of the best forts sowed, where the persons are curious to have the finest flowers. These seeds may be sown in the spring, and the plants afterward treated in the same manner as is hereafter directed for the Carnation; with this difference only, that as the Pinks are less tender, they may be more hardily treated. Those which are propagated by layers, must be also managed as the Carnation, for which there are full instructions hereafter given. The old Man's Head and painted Lady Pinks, are commonly propagated this way, but most of the other forts are propagated from slips.

The best time to plant the slips of Pinks is about end of July, when, if there should happen rain, it will be of great service to them, but if the weather should prove dry, they will require to be watered every other day, until they have taken root; these should

should be planted in a shady border, and the ground should be dug well, and all the clods broken, and if no rain falls, it should be well soaked with water a few hours before the slips are planted; then the slips should be taken from the plants, and all their lower leaves stripped off, and planted as soon as possible after, for if they are suffered to lie long after they are taken from the plants, they will wither and spoil; these need not be planted at a greater distance than three inches square, and the ground must be closed very hard about them; then they must be well watered, and this must be repeated as often as is found necessary, till the cuttings have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they should be transplanted to the borders of the flower-garden where they are to remain. There are some who plant the slips of Pinks later in the season than is here directed, but those plants are never so strong nor flower so well, as those which are early planted.

We shall next proceed to the culture of the Carnation; these the florists distinguish into four classes. The first they call Flakes; these are of two colours only, and their stripes are large, going quite through the leaves.

The second are called Bizarrs; these have flowers striped or variegated with three or four different colours, in irregular spots and stripes.

The third are called Piquettes; these flowers have always a white ground, and are spotted (or pounced, as they call it) with scarlet, red, purple, or other colours.

The fourth are called painted Ladies; these have their petals of a red or purple colour on the upper side, and are white underneath.

Of each of these classes there are numerous varieties, but chiefly of the Piquettes, which some years ago were chiefly in esteem with the florists, but of late years the Flakes have been in greater request than any of the other kinds. To enumerate the varieties of the chief flowers in any one of these classes, would be needless, since every country produces new flowers almost every year, so that those flowers, which, at their first raising, were greatly valued, are in two or three years become so common, as to be of little worth, especially if they are defective in any one property. Therefore (where flowers are so liable to mutability, either from the fancy of the owner, or that better kinds are yearly produced from seeds, which, with good florists, always take place of older or worse flowers, which are turned out of the garden to make room for them) it would be but superfluous in this place to give a list of their names, which are generally borrowed either from the names and titles of noblemen, or from the person's name, or place of abode, who raised it.

These flowers are propagated either from seeds (by which new flowers are obtained), or from layers, for the increase of those sorts which are worthy maintaining; but I shall first lay down the method of propagating them from seeds, which is thus:

Having obtained some good seeds, either of your own sowing, or from a friend that you can confide in, about the middle of April, prepare some pots or boxes (according to the quantity of seed you have to sow), these should be filled with fresh light earth mixed with rotten neats dung, which should be well incorporated together; then sow your seeds thereon (but not too thick) covering it about a quarter of an inch with the same light earth, placing the pots or cases so as to receive the morning sun only till eleven of the clock, observing all to refresh the earth with water as often as it may require. In about a month's time your plants will come up, and if kept clear from weeds, and duly watered, will be fit to transplant about the latter end of July; at which time you should prepare some beds (of the same sort of earth as was directed to sow them in) in an open airy situation, in which you should plant them at about three inches square, observing to water and shade them till they have taken

new root, then you must observe to keep them clear from weeds; in these beds they may remain until the end of August, by which time they will have grown so large as almost to meet each other; then prepare some more beds of the like good earth (in quantity proportionable to the flowers you have raised) in which you should plant them at six inches distance each way, and not above four rows in each bed, for the more conveniently laying such of them as may prove worthy preserving, for in these beds they should remain to flower.

The alleys between these beds should be two feet wide, that you may pass between the beds to weed and clean them. If the season should prove very dry at this time, they should not be transplanted till there is some rain, so that it may happen to be the middle, or latter end of September some years, before there may be wet enough to moisten the ground for this purpose; but if there is time enough for the plants to get good root before the frost comes on, it will be sufficient. If the winter should prove severe, the beds should be arched over with hoops, that they may be covered with mats, otherwise many of the plants may be destroyed, for the good flowers are not so hardy as the ordinary ones of this genus. There will be no other culture wanting to these, but to keep them clean from weeds, and when they shoot up their stalks to flower, they must be supported by flicks to prevent their breaking. When your flowers begin to blow, you must look over them to see which of them proffer to make good flowers, which as soon as you discover, you should lay down all the layers upon them; those which are well marked, and blow whole without breaking their pods, should be reserved to plant in borders, to furnish you with seed; and those which burst their pods, and seem to have good properties, should be planted in pots, to try what their flowers will be, when managed according to art; and it is not till the second year that you can pronounce what the value of a flower will be, which is in proportion to the goodness of its properties; but, that you may be well acquainted with what the florists call good properties, I shall here set them down.

1. The stem of the flower should be strong, and able to support the weight of the flower without hanging down.
2. The petals (or leaves) of the flower should be long, broad, and stiff, and pretty easy to expand, or (as the florists term them) should be free flowers.
3. The middle pod of the flower should not advance too high above the other petals of the flower.
4. The colours should be bright, and equally marked all over the flower.
5. The flower should be very full of leaves, so as to render it, when blown, very thick and high in the middle, and the outside perfectly round.

Having made choice of such of your flowers as promise well for the large sort, these you should mark separately for pots, and the round whole blowing flowers for borders; you should pull up all single flowers, or such as are ill-coloured, and not worth preferring, that your good flowers may have the more air and room to grow strong, these having been laid at a proper season, as soon as they have taken root (which will be some time in August) they should be taken off, and planted out, those that blow large, in pots, and the other in borders (as hath been already directed).

Of late years the whole-blowing flowers have been much more esteemed than those large flowers which burst their pods, but especially those round flowers which have broad stripes of beautiful colours, and round Rose leaves, of which kinds there have been a great variety introduced from France within these few years; but as these French flowers are extremely apt to degenerate to plain colours, and being much tenderer than those which are brought up in England, there are not such great prices given for the plants now, as have been a few years past; from the present taste for these whole-blowing Flake flowers, many

> of the old varieties, which had been turned out of the gardens of the florists many years ago, to make room for the large flowers; which were then in fashion, have been received again \$ and large prices have been paid of late for such flowers as some years ago were sold for one shilling a dozen, or less, which is a strong proof of the variableness of the fancies of the florists.

But I shall now proceed to give some directions for propagating these flowers by layers, and the necessary care to be taken in order to blow them fair and large.

The best season for laying these flowers is in June, as soon as the shoots are strong enough for that purpose, which is performed in the following manner: after having stripped off the leaves from the lower part of the shoot intended to be laid, make choice of a strong joint about the middle part of the shoot (not too near the heart of the shoot, nor in the hard part next the old plant); then with your penknife make a slit in the middle of the shoot from the joint upwards half way to the other joint, or more, according to their distance; then with your knife cut the tops of the leaves, and also cut off the swelling part of the joint where the slit is made, so that the part slit may be shaped like a tongue; for if that outward skin is left on, it would prevent their pushing out roots -, then having loosened the earth round the plant, and, if need be, raised it with fresh mould, that it may be level with the shoot intended to be laid down, left by the ground being too low, by forcing down the shoot you split it off-, then with your finger make a hollow place in the earth, just where the shoot is to come, and with your thumb and finger bend the shoot gently into the earth, observing to keep the top as upright as possible, that the slit may be open; and being provided with forked sticks for that purpose, thrust one of them into the ground, so that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the flank of the layer with the same sort of earth, giving it a gentle watering to settle the earth about it, observing to repeat the same as often as is necessary, in order to promote their rooting. In about five or six weeks after this, the layers will have taken root sufficient to be transplanted *, against which time you should be provided with proper earth for them, which may be composed after the following manner:

Make choice of some good up-land pasture, or a common that is of a hazel earth, or light sandy loam; dig from the surface of this your earth about eight inches deep, taking all the turf with it; let this be laid in a heap to rot and mellow for one year, turning it once a month, that it may sweeten; then mix about a third part of rotten neats dung, or for want of that, some rotten dung from a Cucumber or Melon-bed; let this be well mixed together, and if you can get it time enough before-hand, let them lie mixed six or eight months before it is used, turning it several times, the better to incorporate their parts.

Observe, that although I have mentioned this mixture as the best for these flowers, yet you must not expect to blow your flowers every year equally large in the same composition; therefore some people who are extremely fond of having their flowers succeed well, alter their compositions every year in this manner, viz. one year they mix the fresh earth with neats dung, which is cold; the next year with rotten horse dung, which is of a warmer nature, adding thereto some white sea sand to make the earth lighter.

But, for my part, I should rather advise the planting two or three layers of each of the best kinds in a bed of fresh earth not over dunged, which plants should only be suffered to blow their flowers, that you may be sure they are right in their kind and colours; and when you are satisfied in that particular, cut off the flower-stems, and do not suffer them to spend the roots in blowing, by which means you will strengthen your layers. And it is for a these beds I would make

choice of some of the best plants for the next year's blowing, always observing to have a succession of them yearly, by which means you may have every year fine flowers, provided the season proves favourable: for it is not reasonable to suppose, that the layers taken from such roots as have been exhausted in producing large flowers, and have been forced by art to the utmost of their natural strength, should be able to produce flowers equally as large as their mother root did the year before, or as such layers as are fresh from a poorer soil, and in greater health can do. But this being premised, let us proceed to the planting of these layers, which (as I said before) should be done in August, or the beginning of September.

The common method used by most florists is to plant their layers at this season, two in each pot (the size of which pots are about nine inches over in the clear at the top); in these pots they are to remain for bloom; and therefore, in the spring of the year, they take off as much of the earth from the surface of the pots as they can, without disturbing their roots, filling the pots up again with the same good fresh earth as the pots were before filled with. But there is some difficulty in flickering a great quantity of these flowers in winter, when they are planted in such large pots, which in most winters they will require, more or less; my method therefore is, to put them singly into halfpenny pots in autumn, and in the middle or latter end of October, to set these pots into a bed of old tanners bark, which has lost its heat, and cover them with a common frame (such as is used for railing Cucumbers and Melons) -, and in two of these frames, which contain six lights, may be set a hundred and fifty of these pots: in these frames you may give them as much free air as you please, by taking off the lights every day when the weather is mild, and putting them on only in bad weather and great rains; and if the winter should prove severe, it is only the covering the glasses with mats, straw, or Pease-haulm, so as to keep out the frost, which will effectually preserve your plants in the utmost vigour. In the middle or latter end of February, if the season is good, you must transplant these layers into pots for their bloom (the size of which should be about eight inches over at the top in the clear); in the doing of which, observe to put some potsherds or oyster shells over the holes in the bottoms of the pots, to keep the earth from flopping them, which would detain the water in the pots to the great prejudice of the flowers: then fill these pots about halfway with the same good compost as was before directed, and shake the plants out of the small pots with all the earth about the roots; then with your hands take off some of the earth round the outside of the ball, and from the surface taking off the fibres of the roots on the outside of the ball of earth *, then put one good plant exactly in the middle of each pot, so that it may stand well as to the height, i. e. not so low as to bury the leaves of the plant with earth, nor so high, that the flank may be above the rim of the pot; then fill the pot up with the earth before-mentioned, doing it gently to the plant with your hands, giving it a little water, if the weather is dry, to settle the earth about it; then place these pots in a situation where they may be defended from the north wind, observing to give them gentle waterings, as the season may require.

In this place they may remain till the middle or latter end of April, when you should prepare a stage of boards to set the pots upon, which should be boarded as to have little cisterns of water round each pot, to prevent the insects from getting to your flowers in their bloom, which, if they are suffered to do, will mar all your labour, by destroying all your flowers in a short time; the chief and most mischievous insect in this case is, the earwig, which will gnaw off all the lower parts of the petals of the flowers (which are very sweet) and thereby cause the whole flower to fall to pieces *, but since the making one of these stages is somewhat expensive, and not very easy to be under-

D I A

... which I shall describe a very simple one, which I have found to be the best, which answers the purpose full as well as the belt and most commonly our can do: first, prepare some common Hat pans, about fourteen or fifteen inches over, and three inches deep; place twelve two and two opposite to each other, at about two feet distance, and at every eight feet lengthways, two of these pans; in each of these wheel a Hower-jot, which should be about six inches over at the top, Upright-down, and lay a flat piece of timber, about two feet and a half long, and three inches thick, close from pot to pot, till you have finished the whole length of your stage-, then lay your planks lengthways upon these timbers, which will hold two rows of planVii for the free pots which were ordered for the Carnations-, and when you have lit your pots upon the stage, fill the flat pans with water, always observing, as it decreases in the pans, to replenish it, which will effectually guard your flowers against insects; for they do not care to swim over water, but that if by tick or any other contrivance, the passage from the ground to the llice, on which the pot is placed, in $I < f$ a measure of water three or

four inches broad, and as much in depth, it will effectually prevent these vermin from getting to the flowers.

This stage should be placed in a situation open to the sun, but defended from the west winds, 10 which these stages must not be covered, lest the pots should be blown down by the violence of that wind, which is often very troublesome at this season when these flowers blow; indeed they should be defended by trees at some distance, from the winds of every point-, but rather they should not be [at the] towers, nor by any means placed near walls, or tall buildings, for in such situations the flowers will draw up too weak. About this time, viz. the middle of April, your layers will begin to shoot up for flower; you must therefore be provided with some quart deal (licks, about four feet and a half long, which should be thicker toward the bottom, and planed off taper at the top; these should be carefully stuck into the pots near as possible to the plant, without injuring it; then with a slender piece of bawling mat, ratten the spittle neck thick to prevent it from being broken; this you must often repeat. As the spindle advances in height, and also observe to pull off all the side spindles; they are produced, and never let more than two remain upon one root, nor above one, if you intend to blow exceeding large. Toward the beginning of June your Mowers will have attained their greatest height, and their pods will begin to swell, and the earliest begin to open on one side; you must therefore observe to let it open in two other places at $\langle \text{jua! ang!} \rangle$; this must be done so soon as you see the JOJ break, otherwise your plants will run on one side, and be in a state of time; recovering, (as to make a complete recovery, and in a few days after the Rowen begin to open, you must cover them with glasses white) are made for that purpose; the soil must be in manner;

Upon the top of the glass, exactly in the center, is a tin collar, or socket, about three fourths of an inch square, for the brass stick to come through-, to this socket are soldered eight slips of lead of different distances, which are about six inches square; these are spread open at the bottom about four inches square, into three slips of lead of different lengths, which are soldered to the bottom of the glass, which, when they are fixed in, the bottom of the glass has eight angles, with the socket in the middle, and spread open at the bottom about seven inches wide.

When your flowers are open, enough to cover with these glasses, you must make a hole through your socket, exactly to the height of the under part of the pod, through which you should put a piece of small wire about six inches long, making a ring at

D I A

one end of the wire to contain the pod, into which ring you should fix the stem of the flower; then cut off all the strings of bats, and thrust the stem of the flower into the hole from the back, as may give convenient position for the flower to expand without injury to the socket to which distance you may fix it, by turning your wire so as not to draw back through the hole; then make another hole through the back, at a convenient distance above the flower, through which you should put a piece of wire, an inch and a half long, which is to hinder the plants from falling down upon the Sowers; and be sure to observe, that the glass is not placed so high as to admit the sun and rain under them to the flowers, nor so low as to scorch their leaves with the heat. At this time all, or a few days after, as you judge necessary, you should cut the roots of the plants, or some of them, into small pieces, and about the middle of it about three fourths of an inch diameter, for the bottom of the flower to be stuck through; then place the plants about them, to support the pods.

This collar should be placed with inside the calyx of the flower, and should be fixed thereby, then proceed from day to day what progress your flowers make, and if one side comes out fitter than the other, you should turn it about, and shift the other side towards the sun, and all if the weather proves very hot, you should shade the glass in the heat of the day with Cabbage leaves, to prevent their being (torched, or forced out too soon; and when the middle pod begins to rise, you should take out the calyx thereof with a pair of nippers made for that purpose; but this should not be done too soon, lest the middle part of the flower (should advance) high above the sides, which will greatly diminish the beauty of it; you should also observe whether there are more leaves in the flower, than can properly be expanded for want of room, in which case you should cut some of the lowermost or most useless leaves to prevent the swelling of the pods at the time; and when the flowers are fully blown, you cut them off with a pair of nippers, and put on a fine paper collar of stiff paper, which should be cut to the size of the fire of the flower, that it may be put to their full width, but not to be taken off till the flower is in any part; when this is put on, you must draw out the widest leaves to form the outside of the flower, which although they should be in the middle (as it often happens,) yet by removing the other leaves they may be drawn down, and the next longest leaves upon them remain, that the whole flower may appear equally globular without any hollow parts. In the doing of this, some florists are so curious as to render an indifferent flower very handsome; and on this depends, in the case of the large flowers, the kind of the arid to produce large line flowers.

During the flowering season, particular care should be taken not to let them suffer for want of moisture, which should by no means be wanting (spring water; nor Jo I approve of compound waters but as are enriched with various sorts of dung-, and the best and most natural water is that of a fine (soft river-, next to dam pond water, or (landing water, but if you have no other than (firing water, it should be exposed to the sun and air two days before it is used, I think it will give the flowers the canker and spoil them.

The direction here given are chiefly for the management of those large flowers, which require the greatest care; It is ill of the florists, to have them in perfection; but as of late years there have not been so much in esteem as formerly, and those Sowers which do not break (their petals, and are termed whole flowers, have now the preference. These are generally planted in pots, and are sown in the same way as the large flowers, but do not require so much trouble to blow them; all that is necessary to be done is to be for them to fall on their flints and to Sower-sticks to prevent their being

noemg broken, md to take off the pa. which pro-

The farther care is to keep them clean from weeds
nil n. end of May, at which time they may be
transplanted to the places bere they MX dt-igtnd to
remain for flowering, when they may be taken up
with large balls of earth to their roots, fo as to •-irtcly
their removal, efpecially if it iap] . . . to rain
at th.it time.

As theft pUntjd do not grow large, fo when they art
planted onlj in the borders of the flower-garden,
they do not make •• fo vance, as whic icthy
are planted by them lei ves in heda; or if they are
planted

planted in small clumps, of six or eight roots in each, where the flowers being of different colours, let off each other to advantage.[^]

Those who are curious in these flowers, take particular care in having their feeds, for they never permit any single flowers to (land among their double, but pull them up as soon as they (hew their flowers, and also draw out all those which are not of lively good colours; where this is observed, the flowers may be kept in great perfection % but where persons have trusty friends, who live at some distance, with whom they can exchange feeds once in two or three years, it is much better for to do, than to continue sowing feeds in the same place many years in succession, and this holds true in most sorts of feeds: but the great difficulty is to meet with an honest person of equal (kill, who will be as careful in the choice of his plants for feed, as if he was to sow them himself.

D I A P E N S I A. See SANICULA.

D I C T A M N U S. Lin. Gen. Plant. 468. Fraxinella. Tourn. Inf. R. H. 430. tab. 243. White Dittany, or Fraxinella; in French, *Fraxinelle*. This plant was titled Fraxinella, from Fraxinus the A(h-tree, the leaves of this having some resemblance in their form, to those of the A(h-tree, so it was called Little Afh. But as this plant has been long mentioned under the title of *Dicamnus albus*, i. e. *White Dittany* in the dispensaries, so Dr. Linnaeus has adapted that title to this genus.

The CHARACTERS are,

The empalement of the flower is composed of five small oblong leaves, ending in points. The flower hath five oblong petals which are unequal two of them turning upward, two are oblique on the sides* and one turns downward. It hath ten rising stamens* which are as long as the petals* which are situated between the two side petals -, they are not equal in length* and are terminated by obtuse four-cornered summits standing erect. In the center is situated a five-cornered germen* supporting a port incurved style* crowned by an acute stigma; the germen afterward becomes a capsule with five cells* each having a compressed margin* which spreads open at their exterior parts* but join together at their inner* opening with two valves* and inckling several roundish* hard* shining seeds.*

This genus of plants is ranged in the first section of Linnæus's tenth class, intitled Decandria Monogynia, the flower having ten stamens and one style.

We have but one distinct SPECIES of this genus, viz.

D I C T A M N U S (*Albus*). Hort. Cliff. 161. Fraxinella. Clus. Hist. 99. and the *Dicamnus albus*, vulgo Fraxinella. C. B. P. 222. *White Dittany* commonly called Fraxinella*. There are three varieties of this plant, one with a pale red flower striped with purple, another with a white flower, and one with (horter (pikes of flowers; but as I have observed them to vary when propagated by seeds, so I esteem them only femal varieties. This is a very ornamental plant for gardens, and as it requires very little culture, so deserves a place in all good gardens. It hath a perennial root, which strikes deep into the ground, and the head annually increases in size; these send up many (stalks, which rise from two to three feet high, garnished with winged leaves placed alternate, composed of three or four pair of oblong lobes, terminated by an odd one: they are smooth and stiff, fitting close to the midrib, which hath a longitudinal furrow on the upper side *, the lobes (or small leaves) placed on each side the midrib, are oblique, but those which terminate the leaf have their sides equal. The flowers are produced in a long pyramidal loose spike or thyrse) on the top of the (stalk, which is nine or ten inches long; the flowers of one sort is white, and of the other they are of a pale red, marked with red or purple (stripes. The whole plant when gently rubbed, emits an odour like that of Lemon peel, but when bruised has something of a balsamic scent. It flowers the latter end of May, and in June, and the seeds ripen in September.

These plants are propagated by seeds, which* if sown

in the autumn soon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the spring, the feeds seldom succeed -, or if they do grow, it is the following spring before the plants appear, so that a whole year is lost. When the plants come up, they must be constantly kept clean from weeds; and in the autumn when their leaves decay, the roots should be carefully taken up, and planted in beds at six inches distance every way; these beds may be four feet broad, and the paths between them two, that there may be room enough to pass between the beds to weed them. In these beds the plants may (land two years, during which time they must be constantly kept clean from weeds; and if they thrive well, they will be strong enough to flower* so in the autumn they (should be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more stems of flowers in proportion to the size of the roots. All the culture these require, is to be kept clean from weeds, and the ground about them dug every winter. The roots of this plant are used in medicine, and esteemed cordial and cephalic, refilling putrefaction and poison, and are useful in malignant and pettilential distempers, as also in epilepsies.

D I C T A M N U S C R E T I C U S. See OtiGANUM. D I E R V I L L A. Tourn. R. Par. 1706. Lonicera. Lin. Gen. Plant. 210.

The title of this genus was given it by Dr* Tournefort, after Mr. Dierville, a surgeon, who brought this plant from Acadia.

The CHARACTERS are,

The empalement of the flower is cut into five parts almost to the bottom *, the flower is of one leaf* having a tube at the bottom* but is cut into five parts at the top* and has the appearance of a lip flower; it hath five stamens* which are terminated by oblong summits* which are equal with the style. At the bottom of the flower is situated an oval germen fixed to the empalement* supporting afterward a style equal with the stamens* crowned by an obtuse stigma \ the germen afterward becomes a pyramidal berry* divided into four cells* which contain small round seeds.*

This genus of plants is ranged in the fourth section of Tournefort's third class, which includes the plants with a tubulous anomalous flower of one leaf. It is ranged by Dr. Linnaeus under his genus of Lonicera, in the first section of his fifth class, intitled Pentandria Monogynia, the flower having five stamens and one style.

We know but one SPECIES of this genus at present, viz.

D I E R V I L L A (*Lonicera*) *Acadiensis fruticosa, flore luteo*. Act. R. Par. 1706. *Shrubby Dierville of Acadia with a yellow flower*. This is the *Lonicera racemis terminalibus foliis ferratis*. Lin. Sp. Plant. 275. *Lonicera with bunches of flowers terminating the branches, and fawed leaves*.

This plant grows naturally in the northern parts of America, from whence it was brought to Europe, and is now propagated in the gardens for sale. It hath woody roots which spread far in the ground, and put out (shoots at a distance from the principal (stalk, whereby it multiplies greatly: the (stalks are ligneous, and seldom rise more than a foot and a half high; these are garnished with oblong heart-shaped leaves, ending in acute points -, they are very (lightly fawed on their edges, and are placed opposite, fitting close to the (stalks: the upper part of the (stalks are garnished with flowers, which usually come out from the side of the (stalk at the fitting on of the leaves, and also at the top of the (stalks; there are two or three flowers sustained upon each shoot-stalk: they are of a pale yellow, and being small, make no great appearance. These come out in May, and if the season proves moist and cold, they frequently flower again in August.

It is easily propagated by suckers, which it sends out in plenty, and loves a moist soil and (shady situation, where die cold will never injure it.

DtfGIT ALIS. Lin. Gen. Plant. 676. foun. Inft. R. H. 164. tab. 73. Raii Meth. Plant. 89. Foxglove in French, *Digitale*.

The CHARACTERS are,

*It hath a permanent empalement, which is cut into five parts -, the flower is bell-Jhaped, of one petal, with a large open tube, whose bafe is cylindrical and contracted, but the brim is divided into four parts flightly; the upper lipfpreading and indented at the top, the lower is larger. It hath four ftamina, which are infertedin the bafe of the petal, two being longer than the other, which are terminated by bipartite acuminated fummits *, the flower being paf, the germen fwells to an oval capfule, having two cells fitting on the empalement, inclofing many fmall angular feeds.*

This genus of plants is ranged in the fecond fe&ion of Linneus's fourteenth c&afs, intituled *Didynamia Angiofermia*, the flower having two long and two fhorter ftamina, and the feeds being included in a capfule.

The SPECIES are,

1. DIGITALIS (*Purpurea*) calycinis foliolis ovatis acttis, corollis obtufis, labio fuperiore integro. Hort. Upfal. 178. *Foxglove whose fmall leaves of the empalement are oval and acute, the petals obtufe, and the upper lip entire. Digitalis purpurea folio afpero. C. B. P. 243. Purple Foxglove with a rough leaf, or common Foxglove.*
2. DIGITALIS (*Thagi*) foliis decurrentibus. Lin. Sp. 867. *Foxglove with running leaves. Digitalis Hispanica purpurea minor. Tourn. Inft. 165. Leffer Spanijh purple Foxglove.*
3. DIGITALIS (*Lutea*) calycinis foliolis lanceolatis corollis acutis labio fuperiore bifido. Hort. Upfal. 178. *Foxglove with fpear-Jhaped leaves to the empalement, an acute petal, whose upper lip is bifid. Digitalis minor lutea, parvo flore. C. B. P. 244. Leffer yellow Foxglove with a fmall flower.*
4. DIGITALIS (*Magno flore*) foliolis calycinis linearibus, corollis acutis, labio fuperiore integro, foliis lanceolatis. *Foxglove with long narrow leaves to the empalement, an acute petal, whose upper lip is entire, and fpear-Jhaped leaves. Digitalis lutea, magno flore. C. B. P. 244. TeUow Foxglove with a larger flower.*
5. DIGITALIS (*Ferruginea*) calycinis foliolis ovatis obtufis, corollae labio inferiore longitudine floris. Lin. Sp. Plant. 622. *Foxglove with oval blunt leaves to the empalement, and the lower lip of the petal as long as the flower. Digitalis angustifolia, flore ferrugineo. C. B. P. 244. Narrow-leaved Foxglove with an iron-coloured flower.*
6. DIGITALIS (*Canarienfis*) calycinis foliolis lanceolatis, corollis bilabiatis acutis, caule fruticofa. Lin. Sp. Plant. 622. *Foxglove with fpear-Jhaped leaves to the empalement, an acute petal with two lips, and a Jhrubby ftalk. Digitalis acanthoides Canarienfis frutescens, flore aureo. Hort. Amfi. 2. p 105. Shrubby Canary Foxglove like Bearjbreech, with a golden flower.*
7. DIGITALIS (*Orientalis*) calycinis foliolis acutis, foliis ovato-lanceolatis nervofis. *Foxglove with acute leaves to the empalement, and oval, fpear-Jhaped, veined leaves. Digitalis lutea non ramofa, fcorzonrae folio. Buxb. Cent. 25. Tellow unbranched Foxglove with a leaflike Scorzonera.*

The firft fort grows naturally by the fide of hedges in fhady woods in mod parts of England, fo is rarely cultivated in gardens. This is a biennial plant, which the firft year produces a great tuft of long rough leaves which are hairy; the fecond year it fhoots up a ftrong herbaceous ftalk, which rifes from three to four feet high, garnifhed with leaves of the fame form as the lower, but they gradually leffen upward, fo thofe which are intermixed with the flowers on the top are very narrow. The flowers grow in a long loofe thyrfe, ftanding only on one fide of the ftalk; they are large, tubulous, and fhaped like a thimble, of a purple colour, with feveral white fspots oil the under lip *, thefe flowers are fucceeded by oval capfules with two cells, which are filled with dark brown feeds- It flowers in June, and the feeds ripen in autumn, if they are permitted to fcatter, the plants

will come up in the fpring, and becomie troublefome weeds; but whoever has a mind to cultivate it, fhould fow the feeds in autumn, for thofe which are fown in the fpring feldom fucceed, or at leaft lie one year in the ground before they grow. This plant ftands in the lift of medicinal fimples of the differifaries, and there is an ointment made of the flowers, and May-butter^ which has been in good efteem.

There is a variety of this with a white flower, which is found growing naturally in fome parts of England* which differs from this only in the colour of the flower and leaves; but this difference is permanent* for I have cultivated it more than thirty years in the garden, and have never found it vary.

The fecond fort grows naturally in Spain, from whence I received the feeds; this plant feldom rifes much more than a foot and a half high; the lower leaves are ten inches long, and three broad in the middle; they are foft, woolly, and roughly veined on their under fide; the (talks are garnifhed with leaves of the fame fhape, but fmall; the upper part of the ftalk hath a fhort thyrfe of purple flowers like thofe of the common fort, but they are fmall, and the fegments of the petal are acute. This plant retains its difference when cultivated in gardens.

The third fort hath very long obtufe leaves near the root; the ftalk is fmall, and rifes from two to three feet high, the lower part being pretty clofely garnifhed with fmooth leaves, about three inches long and one broad, ending in obtufe points: the upper part of the ftalk, for ten inches in length, is adorned with fmall yellow flowers, which are clofely ranged on one fide of the ftalk, having afew very fmall acute leaves placed between them, which are fituated on the oppofite fide of the ftalk; the upper lip of the flower is entire, and the petal is obtufe. It flowers in June, and the feeds ripen in autumn.

The fourth fort hath long fmooth-veined leaves at the bottom; the ftalk is ftrong, and rifes two feet and a half high, garnifhed with leaves which are five inches long, one and a half broad, ending in acute points; thefe have many longitudinal veins, and are lightly fawed on their edges; the upper part of the ftalk is adorned with large yellow flowers, nearly of the fize of thofe of the common fort, the brim having acute points, and the upper lip entire. This flowers and ripens its feeds about the fame time as the former.

The fifth fort hath narrow fmooth leaves, which are entire; the ftalk rifes near fix feet high, and puts out fome (ender branches from the fide toward the bottom; the lower part of the (talks is garnifhed with very narrow fmall leaves, three inches long, and one third of an inch broad; the flowers terminate! the ftalk, growing in a very long fpike, with very few leaves between them, and thofe very fmall; the empalement is divided into four obtufe parts, the lower lip extending much longer than the upper. The flowers are of an iron colour, and appear in June.

The fixth fort grows naturally in the Canary Iflands; from whence the feeds were firft brought to England 9 and many of the plants were raifed in the bifhop of London's gardens at Fulham, part of which were lent to the -royal gardens at Hampton Court, and foma were fent over to the gardens in Holland: thofe which were fent to Hampton Court, were preferred there a few years, but by the ignorance of the gardeners, to whose care thofe gardens were committed, this, with many other valuable plants, were foon deftroyed.

This plant hath a fhubby ftalk which rifes to the height of five or fix feet, dividing into feveral branches, garnifhed with rough fpear-fhaped leaves, near five inches long, and two broad in the middle* gradually decreasing to both ends, having a few fhort ferratures on their edges; thefe are placed alternately on the branches 5 each of thefe branches is terminated by a loofe fpike of flowers, about four inches in length; the empalement of thefe is cut into five acute feg-

D I O

ments nlmoll to the bottom; the upper lip is long and enure, this is arched, and immediLely under it lie an fl... ftyle are fituatcd; the town lp b obtvik-, and indented at the top; there are two scure legmeits on the fide, which compote the chaps of the flower; there are two of the flam inn longer than the other\ theie arc crowned with roundilh Summits, In the bottom oi' the flower is tituated the germen, fiipportin^ t iknder flyle, enmed by an oval figm.i; the germen afterward becomes M ov.il capfulc, filled with finall angular feeds.

Tiui plant begins to fltwer in May, and there is generally a luccellion rfflowers On III- lime plane, ill' die winter puts a flop to them, which renders the plant more valuable. It is propagated by feeds, which ihould be Town in pots filled with light earth, in the autumn, luon after the feeds are ripti thefe pou flouU! be plunged into an old bed oi' tanners b.irk, whole heat is gone, and in mild weather the glaHis ihould be drawn off to admit thu -At; but in hard rains and froft they ma& be kept on, to prated th- feeds from . ii frequently dettroy* than Jiere ...: in die spring the plants will coin.. foould enjoy the free air in mild

her, but mult be prute&cd from the cold. When thec art- large ex- *igh to trLinlphnt, they (lioum IX: each planted into a lparare fmal pot filled with light rarf, and {Jaf cd under the frame til) they linvc uken new root, tJien they would be gradually inured To the open ; During the fummer fealbn the plants Ihould remain abroad in a lhelterel fiuation, but in the winter they rouft be placed in a greenhoulc, for tiny wili not live abroad tn i-jiglaml; they muft not be kept too warm and clofc. in the houfe, for they only want pfoctefion from the froft; therefor in mild weather, they Ihould have free air contantly admitted to them, and they require frequent wateiiora, but they Ihould not have it in too great plenty in winter.

The ieventh fort grows naturally in Tartary, from whence ilii- lctds were lent to the imperial garden at Pcterburgh, and from thence I received them. This plant hath many oval fpcar-fliafed leaves, which are imooth, irifing from ihe root •, between thefe arife the flalk, which grows about a foot high, and is garnifhed below with linooth fpcar-lhaped leaves, from four to five inches long, and one and a half broad in the middle, lcfieini gradually at both ends ; thefehave no foot-ftajks, bat tiieir bale embraces the llalks half ruund ; the upper part of the ilalk is adorned by a fhort Uxjfe Jpikc of' yellow flowers, winch arc almoft as large au thole of the great yellow lbrt before-mentioned, but they are (hotter. This flowera in Majr ontlu feeds ripen in autumn.

All thrfe lons Ihould be lawn in the autumn j for if the feeds are iown in the fpring, they commonly fail, or at ltilt lie a wh'lc year in the ground brfor they vegewte. Tilt plants are biennial (except the fevent:?) Uy perifh foon after the feeds

arc ripe. DIOSCORGA. Plum. Nov. GCJI. 9. tab. 26. Lin. Gen. Plum. 995.

The firft lbrt grows naturally in moft of the ijiintfa in die Weft India. I received the feeds of this fair from Jamaica, where the law Dr. l-loufoun found ic growing plentifully; This haili (lender clinibin; (talks, which fix themfelves to any fuupport near them, and rili: to the height of eighteen or twenty f«r, garnifhed with heart-Uiiiped leaves, ending with ucuviv jKjints, having five longitudinal veins, which arife from the foot-ftalks, which diverge toward the fides, hut meet again at the point of the kai'cs. They ftand l... long foot-lts lks, from the bafe of which sruc the branching fpikts ut' flowers, which arc rni.ili, and hnc no beauty; the female flowers air (ucoecodeci by three-cornered oblong capliile-:, having three cells, e^ch containing two con: [reiTcd feeds.

The fecond lbrt differs from the firftin the fhape of their leaves, thefe hiving two round ear 5 at their bafe, but the middle extends 10 an acute point, tike that of an halberc. The butjehej of flowew are longer, and are loofer piaccd than thofe of the former fort.

The third lbrt hath broad, round, heart-ill fped leaves, which end in acute points j thefe have many longitudi- nal veins which arife tiom the foot-!; il verge to the (iic, bur afterward join at the point of ihc leaf i tilt flowers come out on lon^ looie things, Handing on (hor: foot-flatk jnt arc

fucccedcd by three-cornered obloi capfules, with three cells; liaving comprelTfd bor... The fourth forthaih triant; trhftrh trail upon the ground and extend to a yrai length; rhefe frequently put out tnofs (rom the joitiK as they lie upon rlie ground, wiiLTby the plants are multi- plied. The roots of this plant art eaten in many parts of both Indies, where the plants ar* much cut-

llic fifth fan grows naturally in Virginia, and in other parts of North America. This harf .l imooth flalk which climbs on l... pl.int*, and tifes five or fix feet high, ; r... whidi are plat 1: they ace covered widi In.ill uuir5, and have leveral longitudinal veins. The liim-rs come out from the fide of the l! in the ne manner as the other ljrts, but have no beauty. Tiiefe plants are pfcncd in fcmc curioui bo- lirdem for the fake of variety; bu: •• they have no beauty, there are few perfons who will allow tWin a place, and l lally as moft of die lbrts require a good fare them through the and.

The (c pteiti may be propagated by living their brandies imo the ground, which in about throe months will lit out r/fj's, mil may then be taken from [the old plants, and planted LnttfjemniK pots, which Iliou Id be plunged into tin; can-bed in the (rove; during the winter thefe plums (hould have but little water given them; but in fummer, when they arc growing vigorously, they flroud be watered three or four times a week, inl tn warm westlier the gblfcs (hotfkt be opened to admit a Urge ihare of few air. Tixefe planti rarely flower in lingland, but ivhen the feeds are fan from America, (he? mould be immediately in pou, anil plunged inti> a hot-bed, where, if the ietds are Jciv.it early in the fpring, the plant; will come tip the [imc ical'un; bin when they arc (own late, the feeds often remain in the ground (ill the following fpring before they vegetate i thereto- when the plants do not come up the firft feafbn, the pen (hould be ferwntd from the (roll the fill) wint, and put into a nen hot-bed in the fpring,

witich'wiu bring up mi punts," h lite ittos-wtre-giJui. The fourth fon is mutli cultivated by the inhabitants of the illands in America, and is of great ule to them ibr feeding of their negroes-, and the white people make puddings of their roots, when ground to a tort of flour. This pknt is fuppoi to have "em brought from the Eoft to the Weft Indie;, for it has * been dtfeovrredtogrow wild in any pan of America, but in the illand oi' Ceylon, <nd tm the coiflr of M abar, it grows in die woods, and tiicre arc in thiofc places a fir< variety of

This fort, which isdtieRy cultivated in theWeft Indies, has a root as big as a man's leg, of an irregular form, and of a dirty brown colour on the oucfide, bur when cut, arc white and nit-ally within. The ftalks of this plant arc triangular and win^ the leaves are heart-liiapai like thole of Arum. J uf ten or twelve fti-t, when : lliirubs, to which they fatten themlefwa, otherwili: they trail upon rfeegine

This plant is propsgaced by cutting of the re. into pieces, obferving to prefervc an eye or bud to etch, as is praftifed in planting of Potatoes; each a' their being planted will grow, and produce three or four large roots. In America they arc commonly (it or tight months in the ground before the roots an: taken up for ufc. The roots are roaled or boiled, and eaien by the inhabitants, and foinetimw are made into bread.

In fomc curious gardens this plant w preferved for die Ske of litka, but ir is fo tender as nut to lue in Endand, unifs it is placed i « »enn ftove. &i thefe roots art frequently brought frum America, who- ever hath an intimation to prelVrve the- plan?, may cut them in the manrr before defenbed, aad plant each piece ir. a por filled with ftefh earth, and plunged into .hoc-bed of tanners bark, <d rire than tele water until they IW>t, left they fixwlc rot. Whh this management I have had the foouu ten fwt high, hut the roots have not grown to any great fire with me. This plant will not thrive in the open ait m the warm ft time of LIC year, lb mult conftitny TM k c P: in the bifk-ftovc.

Thrl'e plants grow naturally at the Caj>e of CIOIXI J lope, Ifom whence ik: fctds were fent to Europe, w litre

where some of the species have been long preferred in the gardens of the curious. There have been some other species in the English gardens than are here enumerated, but these are all that are at present to be found here.

The second sort frequently ripens its seeds in England but if the seeds are not down soon after they are ripe, they rarely grow, or they commonly lie a whole year in the ground.

DIOSPYROS. Lin. Gen. Plant. 1027. Guaiacana. Tourn. Inft. R. H. 600. tab. 371. The Indian Date Plum.

The CHARACTERS are,

It hath hermaphrodite and female flowers on the same plant, and male flowers on separate plants; the hermaphrodite flowers have a large obtuse permanent empakment of one leaf which is divided into four parts, the flower hath one petal which is shaped like a pitcher, and cut at the brim into four segments, which spread open; it hath eight short briefly stamina firmly joined to the empakment, terminated by oblong summits which have no farina. In the center is situated a roundish germen, supporting a single quadrifid style, crowned by an obtuse bifid stigma, the germen afterward becomes a large globular berry with many cells, each including one oblong, compressed, hard seed. The male flowers have a one-leaved empakment, cut into small acute segments the petal is thick and four-cornered, cut into four obtuse segments which turn backward y they have eight short stamina, terminated by long, acute, twin summits, but have no germen.

This genus of plants is ranged in the second section of Linnæus's twenty-third class, intitled Polygamia Dioecia. The plants of this class and section have hermaphrodite and female flowers growing on the same plant, and the male on separate plants.

The SPECIES are,

1. **DIOSPYROS** (*Lotus*) folibrum paginis difcoloribus. Lin. Sp. Plant. 1057. *Diospyros with the surface of the leaves of two colours.* Guaiacana. J. B. 2. 138. The Indian Date Plum.
2. **DIOSPYROS** (*Virginiana*) foliorum paginis concoloribus. Lin. Sp. Plant. 1057. *Diospyros with the surface of the leaves of one colour.* Guaiacana Virginiana Pifhamin di&ta. Boerh. Ind. alt. 2. The Pijhamin or Perfimon, and by some Pitcurno* Plum.

The first sort is supposed to be a native of Africa, and was transplanted from thence into several parts of Italy, and also the fourth of France. The fruit of this tree is by some supposed to be the Lotus, which Ulysses and his companions were enchanted with. This is a tree of a middling growth in the warm parts of Europe, where there are several of them which are upward of thirty feet high but particularly in the botanic garden at Padua there is one very old tree, which has been described by some of the former botanists, under the title of Guaiacum Patavinum. This tree produces plenty of fruit every year, from the seeds of which many plants have been raised. In England there are none of these trees, but what have been raised within a few years past, in the physic garden at Chelsea; for the seeds of which I was greatly obliged to my much honoured friend, his excellency the Chevalier Rathgeb, his imperial majesty's minister at Venice, who has also supplied me with many other curious plants, trees, and fruits, from different parts of the world, where his extensive correspondence has been employed to collect whatever rare plants he could procure, and his generosity in communicating what seeds and plants he can procure to the physic garden at Chelsea, requires this public acknowledgment.

The second sort is a native of America, but particularly in Virginia and Carolina there is great plenty of these trees growing in the woods. The seeds of this sort are frequently brought to England, where the trees are now become pretty common in the nurseries about London. This rises to the height of fourteen or sixteen feet, but generally divides into many irregular trunks near the ground, so that it is very rare to see a handsome tree of this sort. This produces

plenty of fruit in England, but they never come to perfection here. In America the inhabitants prefer the fruit until it be rotten (as is practised by Medlars in England) when they are esteemed a pleasant fruit.

These are both propagated by seeds, which will come up very well in the open ground, but if they are sown upon a moderate hot-bed, the plants will come up much sooner, and make a greater progress, but in this case the seeds should be sown in pots or boxes of earth, and plunged into the hot-bed, because the plants will not bear transplanting till autumn, when the leaves fall off; so that when the plants are up, and have made some progress, they may be inured by degrees to the open air and in June they may be wholly exposed, and may remain abroad until November, when it will be proper to set the pots under a hot-bed frame to protect them from hard frosts, which, while they are very young, may kill the tops of the plants; but they must have as much free air as possible in mild weather. The following spring, before the plants begin to shoot, they should be transplanted into a nursery, in a warm situation, where they may be trained up for two years, and then removed to the places where they are designed to remain. These are both hardy enough to resist the greatest cold of this country, after the plants have acquired strength.

DIPSACUS. Lin. Gen. Plant. 107. Tourn. Inft. R. H. 466. tab. 265. [*Saxifraga*, Gr. i. e. thyrity. It is said to have taken its name by way of contrary, because it receives the dew or rain in the hollow sinus of its leaves that cohere together, by which it drives away the injuries of thirst. It is also called Labrum Veneris, from the position of its leaves, which form a sort of basin, containing a liquor that beautifies the face.] The Teazel; in French, *Chardon à Bonnetier*.

The CHARACTERS are,

It hath many florets collected in one common perianthium, which is permanent; the florets have but one petal, which is tubular, cut into four parts at the top, which are erect. They have four hairy stamina which are as long as the petal, terminated by prostrate summits; the germen is situated below the flower, supporting a slender style, crowned by a single stigma. The germen afterward becomes a column-shaped seed, inclosed in the common conical fruit, which is divided by long prickly partitions.

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flower having four stamina and one style.

The SPECIES are,

1. **DIPSACUS** (*Sylvestris*) foliis sessilibus ferratis, ariftris frutibus erectis. Teazel with fawed leaves. *Je't clofe to the stalks, and erect beards to the fruit.* *Dipsacus fylvestris.* Dod. Pemp. 735. Wild Teazel.
2. **DIPSACUS** (*Fullonum*) foliis connatis, ariftris fru&ibus recurvis. Teazel with leaves joined at their base, and the beards of the fruit recurved. *Dipsacus fativus.* Dod. Pemp* 735. Cultivated Teazel.
3. **DIPSACUS** (*Laciniatus*) foliis connatis finuatis. Lin. Sp. Plant. 97. Teazel with jagged leaves joined at their base. *Dipsacus folio laciniato.* C. B. P. 385. Teazel with lacinated leaf.
4. **DIPSACUS** (*Pilosus*) foliis petiolatis appendiculatis. Hort. Upfal. 25. Teazel with foot-stalks having appendices. *Dipsacus fylvestris, capitulo minore, feu. Virga. Pactoris minor.* C. B. P. 385. Wild Teazel with a smaller head, or smaller Shepherd's Rod.

The first of these plants is very common upon dry banks in most parts of England, and is seldom cultivated in gardens, unless for the sake of variety.

The fourth sort grows naturally in many places near London, and is rarely admitted into gardens.

The third sort grows naturally in France, and is kept in botanic gardens for the sake of variety, this differs from the wild Teazel in having the leaves deeply cut and jagged.

But it is the second sort only which is cultivated for use, which is called *Carduus Fullorum*, or *Fullonum*, being of so singular use in raising the knap upon, woollen cloth, for which purpose there are great quantities

D O D

quantities of this plant. cultivated in the wet country, this plant is propagated by sowing the seeds in March, upon a soil that has been well ploughed: about one peck: > this seed, will sow an acre; for the plant will not be so large: it is in great quantity. When the plants are come up, you must hot them in the same manner as for Turneps, cutting down all the leaves, and singling out the plants to about six or eight inches distance; and when the plants advance, and the weeds begin to grow again, you must hoe them a second time, cutting out the plants to a width of four feet, for they should be left at a distance of a foot and a half: and you should be particularly careful to clear them from weeds, especially the first year, for when the plants have reached to us to cover the surface of the ground, the weeds will not be readily grown between them. The second year after sowing, the plants will shoot up in bunches, which will be lit to cut about the beginning of August at which time they should be cut, and set up in bunches, letting them in the sun till they are dry: if not, they will be in rot to dry. The common produce is about an hundred weight of bundles or faves upon an acre which they fall to 3 good method, for the one foils the other; nor can you easily clear them from weeds, as when the second year. The common wild Teazel; but I have cultivated both the kinds more than forty years, and have never found either of them alter, it that there can be no doubt of their being distinct species.

DIRCA, Leather Wood.

The CHARACTERS are,

There is a small tree, which is double-flowered, the fruit is round, turning a red-brown color, and is much used in the country.

This genus of plants is named in the first edition of Linnaeus's eighth class, entitled *Ofandria Monogynia*, the flower having eight (lamina and one style.

We know but one species, viz. *Dirca palupis*.

Dirca (*Palupis*). Amoen. Acad. a. p. *iz. Marji Netherwind*. *Thymetaphoribusaitis* ...

This shrub is, foliis oblongis, viminibus & conice valde reuactibus. Flor. Virg. 153.

This shrub grows naturally in swamps in Virginia, Canada, and other parts of North America. It is the common wild Teazel, but in Europe it rarely is more than half so high; it sends out many articulated branches near the root, furnished with oval leaves, of a pale yellowish colour, and in moist soil the flowers come out from the sides of the branches, two or three together. The stem is of a greenish white colour, and is very early in the spring, just as the time when the leaves begin to grow; the flowers are seldom produced by seeds in our island. This shrub is very difficult to propagate in Europe, as it does not produce seeds; it can only be increased by layers or cuttings, and these are generally two years before they put out roots; for the shrubs grow naturally in very moist places, they are with us very difficult to be raised, unless they are planted in wet ground, but they are seldom injured by cold.

The first was discovered by Dr. Tournefort near Mount Ararat in Armenia, from whence he sent the seeds to the royal garden at Paris, where they succeeded, and from thence most of the curious gardens in Europe have been supplied with this plant. This plant having characters which are different from all those of Tournefort's *Illicium*, he constituted this genus, and gave it the title of *Monfieur Dodart*, member of the Royal Academy of Sciences at Paris, and phyEeua u> lstr ROYJJ Hthgnefi the Princefi of Conn.

It hath a perennial root which creeps far under the surface, and sends out many little branches from the parent plant; these have a little compound leaf, and grow a foot and a half high, sending out several side branches, garnished with long, narrow leaves placed opposite to each other, of a deep green colour, the lower part of the leaf is rather flat and broader than that above, but those on the upper part are more entire; and at these joints the flowers come out singly on each side of the stalk, being close to it; these are near an inch high, the bottom is divided into two lips above, the upper lip is hollow like a spoon, the convex side bending upward, and is divided into two parts; the lower lip is divided into three parts, the middle being the narrowest. The flower is of a deep purple colour, and appears in July, and is rarely succeeded by seeds in England. It propagates very fast by its creeping roots, so that when it is once established in a garden, it will multiply fast enough; it loves a light dry soil, and may be transplanted in autumn when the leaves decay, or in the spring before the new shoots arise.

The second sort is a biennial, or at most a triennial plant, which frequently perishes soon after the seeds are ripe. This sends out from the root several oblong leaves, which are near four inches long, narrow at the base, but increase in width upwards, where they are about an inch broad, rounded at the end, and deeply lined on the edges; between these arise the stalks, which are a foot long, and are garnished with leaves of the same form as the lower leaves, but much smaller; the upper leaves are very narrow and entire. The flowers grow in a cluster on the top of the stalks; these are very small and white, but are beset like those of the former sort. This is propagated by seeds, which should be sown in autumn soon after they are ripe, upon a border of light earth, where they are destined to remain. When the plants appear in the following spring, they must be thinned, and kept clear from weeds, which will

D O L

culture they require : the second year they will flower and feed, after which the plants usually decay, when the feeds are down in the spring, the plants never come up the same year.

D O D E C A T H E O N . See MEADIA.

D O G ' S T O O T H . See ERYTHRONIUM.

D O G - W O O D . See CORPUS.

D O L I C H O S , Kidney Bean.

The CHARACTERS are,

The ewpalement is of one leaf, Jbort, and cut into four equal segments. The flower is of the butterfly kind, having a large round vexillutn which is reflexed. The wings are oval, obtufe, and the length of the keel The keel is moon-floaped, comprejfed, and the top ascends; it hath nine stamina joined below, and a Jingle one standing separate, terminated by Jingle fummits, with a linear com prejfed germen, fupporting an afcending flyle, crowned by a bearded fligma. The germen afterward becomes a large oblong pod with two valves, containing comprejfed elliptical feeds.

This genus is diftinguifhed from Phafeolus, by the keel of the flower not being fpiral

This genus of plants is ranged in the third fe&ion of Linnaeus's feventeenth clafs, intituled Diadelphia Decandria, the flower having ten ftamina in two bodies.

The SPECIES are,

1. **D O L I C H O S** (*Lablab*) volubilis, leguminibus ovato-acinaciformibus, feminibus ovatis hilo arcuato versus alteram extremitatem. Prod. Leyd. 368. *Dolichos with a winding flalk, oval bill-Jhaped pods, and oval feeds. Phafeolus iEgyptiacus nigro femine. C. B. P. 341.*
2. **D O L I C H O S** (*Uncinatus*) volubilis, pedunculis multifloris leguminibus cylindricis hirtutis apice unguiculo fubulato hamato, caule hirtuto. Lin. Sp. 1019. *Dolichos with a winding fialk, many flowers on each foot-ftalk, cylindrical hairy pods, wbofe points are crooked and awl-jhaped.*
3. **D O L I C H O S** (*Pruriens*) volubilis, leguminibus racemosis hirtis, valvulis fubcarinatis, pedunculis ternis. Jacq. Amer. 27. *Dolichos with a winding ftalk, hairy pods growing in a racemus, ahnoft boat-Jhaped valves* and each foot-ftalk having three pods.*
4. **D O L I C H O S** (*Urens*) volubilis, leguminibus racemosis hirtis traniVerfim lamellatis, feminibus hilo cin&is. Jacq. Amer. 27. *Dolichos with a winding ftalk, hairy pods in a racemus, wbofe hairs arejtuated in tranfuerfe lamella, commonly called Cow-itch.*

There are many other fpecies of this genus, as there are alfo of Phafeolus \ but as there are few of them cultivated in the Englilh gardens, it would fwell this work to a great bulk, if they were all inferted which have come to our knowledge, as the author has cultivated more than fixty fpecies, befide many varieties. The two firft* forts here mentioned, are cultivated in warm countries for the table, but in England thefe feldom perfedt their feeds; and were they to thrive here as well as in the warm countries, they would be little efteemed, becaufe we have much better forts in our gardens already; for the fcarlet flowering Kidney Bean is preferable to all the other forts for eating, fo deferves our care to cultivate it more than any other.

The third and fourth forts are fometime preferred in botanic gardens, but especially the fourth, wbofe pods are clofely covered with flinging hairs, commonly known by the title of Cow-itch 5 but thefe are too tender to thrive in the open air in this country, fo that whoever is defirous to have the plants, fhould fow their feeds in a hot-bed in March; and when the plants are come up, they fhould be each planted in a feparate pot, and plunged into the hot-bed again, being careful to (hade them till they have taken root -, after which they muft have frefh air every day admitted to them, in proportion to the warmth of the feafon-, and when the plants are too tall to remain in the hot-bed, they fhould be removed into the bark-ftove, where, if they are allowed room to run, they will flower and perfedt their feeds.

The firft fort grows naturally in Hungary, and upon the Helvetian mountains, but is frequently preferred in the Englilh gardens. It hath thick fleihy roots, which are divided into many knots or knees, fending out ftrongflefhly fibres, which penetrate deep into the ground; and from thefe>rife in the fpring a clutter of heart-fhaped leaves, which are hairy, and (land upon foot-ftalks; between thefe arife the flower-ftalks, which are channelled and hairy, growing near three feet high, putting out one or two fmaller ftalks from the fide, which grow eredt, and are garnifhed with one or two heart-fhaped leaves, clofely embracing the ftalks with their bafe 5 each ftalk is terminated by one large yellow flower, compofed of about twenty-four rays or female florets, which are about an inch long, plain, and indented in three parts at the top. In the center is jtuated a great number of hermaphrodite florets, which compofe the difk-, thefe are tubulofus, and (lightly cut at the top into five parts. The flowers appear in May, and are fucceeded by feeds which ripen in July; thefe are crowned by a hairy down, which ferves to convey them to a diftance.

This plant multiplies very faft by its fpreading roots, and if the feeds are permitted to fatter, they will produce plants wherever they happen to fall, fo that it becomes a weed where it is once eftablifhed i it lover, a moid foil and a fhady fituation.

The fecond fort hath oval leaves, ending in acute points; thefe are indented on their edges toward their bafe, but their upper parts are entire, the ftalks rife about two feet high \ each is terminated by a large

ycillov/

yellow Rower, like thofi; of the former fort; the stalks of • lis lbrl have two or chrc leaves, which are placed alternately, and [heir b:ii < / fits cluli; to the (b: thec are not (b hairy as the ... of the inner fort*, it ... is about the ianc timt with (har, and the feed: ripen, well in England! This ^ruws naturally in Portugal, Spain, and Italy, but u equally hardy with the firft, and multiplies lit us great plenty; the rjot is perennal.

The third fort hath longer leaves than either of the former, which are covered with a hoary down on their under fide, and ire iniemeil on their edges j the stalks are fingle, and have i lom more than one le-if vpan each; thefe grow a foot and a half hi^h, and arc terminated by a fingle flower on the top, like thiole of the former forts. This grows , naturally on the ! yrcnees and Helvetian mountains. I: delights in a moift fui) and a Dudy Ikuatiun, and propagate} in plenty, eitwh from il-eds or by parting th: roots; it il iwt* and feeds about the fame time -with [he for ncr.

The fourth fort grow:: naturally on the Alps and Pyrenean mountains', this huh a perennii, root, the il-aves nre like of the lefier Daify, but ! nger, and not fo broad. The lower g: i us upon a naked ioot-fhik, which is nt-ir a foot long; the rooti feldom fend out more thin one Ihlk; the rays of the Bower arc white, and \ ery like th: • of [he common Dailj; the difk of the flow*! i* ydlow, which w coi: pofed of hi. naparoline Bowers.

This plant is puct-iv i in botanic catiifns for the lake of variety, but the Bowers make little better appearance than thofe of the common Fiefd Daily, only they (laud upon ninth oiler foot-ftalks. It muft have a duddy tu: ition and a muift foil, otherwife it n-i-i nw thrive, in this country; it is propagated by yirring of the roots, for the ieedo do not ripen well in England. I recei-ed this from Verona, near which pmtic it grows nai.

The roots • the fort have been fomtimes ufed in medicine, fone having commended it, mnexpelier of diepol then reckon it w be a poi&n, and affirm liiai it will defroy wolves and t!^" .

The first sort grows naturally on the Alps, and other mountainous parts of Europe; it is a very low plant, which arises from small heads, and from thence it sends out many short, narrow, and very hairy; from each of these heads come out a naked flower, which is an inch and a half high, terminated by some stalks of yellow flowers, having four oblong petals placed in form of a cross; when they fade they are succeeded by four roundish pods, which are compressed, and include three or four roundish seeds. In March, and the seeds ripen the beginning of June. This plant is easily propagated by parting of the heads; the best time for doing of this is in autumn, because it throws up its stems very early in the spring. It should have a moist soil and a shady situation, where it will thrive and flower annually. It requires no other culture but to keep it clear from weeds. The second sort is an annual plant, which grows usually upon walls and dry banks in many parts of England, it is never cultivated in gardens. This grows in April, and the seeds ripen in May.

Tiii third t>t groMs namrilly on the Alps, an rri'untainou parts of Eurj;:-. This is a low pent- .mt, wficiti fclJom riw niwi than two. ICJCS it J-ai n lhrubby ftalk, which divkjes into many small heads like the first sort. The leaves; iv feme of them are winged, reiving dve (hrt narrow lobes, placed on a stubb, iithers have but three. The flowers come out in eufsters, Cttn? cleic to this Ic^ve;. They are of a bright purple colour, and appr early m tits Ipring. Tins is a perennial plant, which may be propagated by parting of the heads in the fall; ltc ntajuor as the fifth, anJ requires the fame cmtoknt.

The bori li fort grows naturally in ftajy woods in many pans of Europe, and h but li-klom kept in gardens, unlch for the take of varu. It is an innui! plant, riling with an uprigiit branching ftalk about ten inches high, g3mi[hed with hi-: shaped in-tailed leaves, which embrace t! e stalks with their r infc Tiic ftalks arc tennatcd by looc Ipikcs of wliite I. wliiit appear the beginning of May, in June the feeds rip'it, anJ the plants tcin alter tli^ay. If the feeds are permitted to fower, the plant will come up w hiiut trooi.jf. It rault liave a furry ftuitor., 3III) tk'liQbu in a. inoift foil.

The iith fort is in annusJ plant, wbkh grows in ihatly wiykli in the northern parts of Etrroj; J. This is the former fort, but the leaves are larger, rounder, and do not embrace thr (talks; they are alls hatr^i and rlie (lowers are yellow. li 1 the seeds of this are I raiitEdcea loner, the llaup will n. lintain thenil'elvc; if ihq' have alhady TUN stem.

The lixth (on rites with an upright ftalk aluut 3 IVHll hi^h, the lower pun bein; VLV clotly !:imilried by oblong liojry leaves, which art* indcncctd on their edges. The upper jiarr of rht Itij' parts out iwo or clirce (hurt I heds; hfc arc alinoll naked ofTeavc;, as if alfo the upper part of the ftalk. Ttie flowers come out loofdy on [he top of the Ihk, they ate compofed of four inail white petals placed in form of a crofs, which arc fuccceded by<)blong poJs, vjucfa arc twirled, containing three or (our roundUb comprcd feeds. It flows; and the feet! ripen in July. This grows naturally in the north of Englnui and in Wales.

This plant felenn continues more than two years, but if the feeds arc fawn in autumn in a Jh-idy border, the plants will come up in die faring; or where the frdrk arc permitted to fcauer, the pLanu will rife without any trouble.

9. DRACOCEPHALUM (*Grandiflorum*) floribus verticillatis foliis ovatis incifo-crenatis, bracteis lanceolatis integerrimis. Lin. Sp. Plant. 595. *Dragon's-Head* with flowers growing in whorls, oval leaves which are cut and crenated, and ſpear-Jhaped bractes* which are entire.

The firſt fort is a native of North America, where it grows in the woods, and by the ſides of rivers. This riſes with an upright ſtalk, which is four-cornered, near three feet high, garniſhed with ſpear-Jhaped leaves about three inches long, and half an inch broad, fitting cloſe to the ſtalk *, they are ſawed on their edges, and are placed oppoſite at each joint, ſometimes there are three leaves {landing round at the ſame place. The flowers are purple and grow in ſpikes on the top of the ſtalks, ſo make a pretty variety among other hardy plants, eſpecially in the plants are ſtrong and vigorous. This is a perennial plant, which will live in the open air, but requires a moiſt foil, or (hould be duly watered in dry weather, otherwiſe the leaves will ſhrink, and the flowers will make little appearance. This may be allowed a place in the hady borders of a garden, ſince it will not ramble, or take up much room. It flowers in July, and continues until the middle or end of Auguſt, and may be propagated by parting of the roots in autumn.

The ſecond fort is a native of the Canary Iſlands, and hath been long an inhabitant in the gardens \ it is uſually called by the gardeners *Balm of Gilead*, from

the ſtrong refinous ſcent which the leaves emit a* being rubbed This is a perennial plant, which, riſes with ſeveral ſquare ſtalks to the height of three feet or more, becoming ligneous at their lower parts, and are garniſhed with compound leaves at each joint, which are placed oppoſite *, theſe have three or five lobes, which are oblong, pointed, and ſawed on their edges. The flowers come out in ſhort thick ſpikes* on the top of the ſtalks *, they are of a pale blue colour, and are ſucceeded by feeds, which ripen very well in England. This plant continues producing flowers moſt part of ſummer; it is uſually kept in green-houſes *, but in mild winters the plants will live abroad, if they are planted in warm borders *, and thoſe plants which are kept in pots, will thrive much better when they are sheltered under a frame, than if placed in a green-houſe, where the plants are apt to draw up weak, for they ſhould have as much free air as poſſible in mild weather, and only require to be ſheltered from ſevere froſt. This may be propagated by feeds, which, if ſown in autumn, will more certainly grow, than thoſe which are ſown in the ſpring; but if theſe are ſown in pots, they muſt be ſheltered under a frame in the winter, and if the plants do not come up the ſame autumn, they will ariſe in the ſpring; but if the feeds are ſown in the full ground, it (hould be in a warm border; and in hard froſt they (hould be ſheltered, otherwiſe the young plants will be deſtroyed. The plants may alſo be propagated by cuttings; which, if planted in a ſtady border any time in ſummer, will very ſoon take root, and furniſh plenty of rooted plants.

The third fort is a native of Moldavia; this has been long preſerved in curious gardens. It is an annual plant, which riſes with branching ſtalks a foot and a half high, garniſhed with oblong leaves, which are placed oppoſite, and are deeply ſawed on their edges. The flowers come out in whorls round the ſtalks at every joint; theſe are blue, and appear in July, continuing to the middle of Auguſt, and the feeds ripen in September. The plants have a ſtrong balſamic odour, which is to ſome perſons very agreeable: the feeds ſhould be ſown in ſmall patches in the ſpring; upon the borders where they are to remain, and when the plants come up, they ſhould be thinned where they grow too near together, and kept clear fr m weeds, which is the only culture they require. Of this there is a variety with white flowers, which is pretty common in the gardens; this only differs from the other in the colour of the flowers, but yet theſe conſtantly retain their difference from feeds.

The fourth fort was diſcovered by Dr. Tournefort in the Archipelago, who ſent the feeds to the royal garden at Paris, which have ſince been communicated to many curious gardens in Europe; this riſes with upright ſtalks about a foot high, which ſeldom put out branches *, theſe are garniſhed with long narrow leaves, which are entire, placed oppoſite at each joint, where the flowers come out in whorls, almoſt the whole length of the ſtalks, theſe are of a pale blue, and appear about the ſame time as the former; this fort has very ſmall flowers, which make no great appearance, therefore is ſeldom cultivated, except in botanic gardens for the ſake of variety.

The fifth fort was diſcovered by Dr. Tournefort in the Levant, this hath hoary ſquare ſtalks, which riſe a foot and a half high, putting out two or three ſide branches, garniſhed with hoary leaves near two inches long, and half an inch broad, a little indented on their edges; they are placed oppoſite at the joints, juſt under the whorls of flowers, which fit cloſe to the ſtalk; theſe are larger than thoſe of the other ſpecies, and are of a fine blue colour, which between the hoary leaves of the plant, make a pretty appearance. It flowers and feeds about the ſame time as the former forts; this is generally treated as an annual plant, like the former forts, but the roots of this will live two years if they are in a dry foil. There is a variety of this with white flowers, the feeds of which generally produce the ſame coloured flowers.

The first fort grows, naturally in Sil... the birds... the imperial g... Jen it icterl- burgh, anil the Uw Dr. Amman, who was pi of bu'inv, lent F= d... roots coic out many fqiii- ihilks, which grow about nine inches lon... e bottgni eanulhed with oval lpear-fiuyl«J lea?» nbom two inches long, and one inch and n quarter bxo>... flanking opposit up...:1 pretty long foot- and an crtr wed on their edges. The upper part of the [talks hiiec GnaUer leaves, which fc clofe at the joints; from whence coaie out rlic flowers in whack; they jrc of a deep blue L)juir, ;md lung downward -, these appear at...:4 fitme time with the former, and the seeds ripen in aururan.

The feventh fort grows alia in Siberia, the feeds of dtu were !• •: ine with the former. It hath Square ftjks, whidi llii- a toot and .t hull bight the lower lores are very like thole of Betony, and fond, upon very long foot-iblki. The upper leaves arc foul], and I-...-ir IUlks. The flowers come out in whorh a: e--ery joint •, thefe are very innall, ami of a pate purple or blue colotr, To make little appearance, but it is preferved in tome gardens for the Cike of variety.

The eighth lbrt grows naturally in the Levant, from whence Dr. Toumefert fen: the feeds to the royl garden at Paris. This is an annual plane, which riles with a figure (talk about a foot high, fending out two /mall (kte blanches tram the lower part. The leaves arc fpcfif-fliaped, and creoaed on their filgcs -, they arc placed opjwlke, and ttand on foot-lbdks. The flowers are finall, of a purplifti colour, audcome out in whorls round th... living two munJih fmiU leaves (called bractea:; invncdiaily under them, which arc fiwtd on their edges, each lirrature ending with a long hair. This fort flowers and feeds at the fame time as the former.

All thife forts are propagated by feeds, which may be Sown either in the ipring or autumn, in the places where die plants ire to remain, and will require no other treat-...ndt than the third fan.

DRACONTIUM (Camphorosma) DRACONTIUM. LINN. ACUM. Aci... 160. Dragm with four-floped leaves. The fHI lbrt grows natural!, in most of the islands in the VVdt-Indics. This hat It (lender join Ltd I... which nut out roots at every joint, that ratten w the crntntkiof trees, wallr, or any luppott which is nor tlic^, anil thereby rile to the lieighr. of twenty- five or thirty feet. The leaves are placed nitern.itiety, (landing upon langtoot-ltalks-, they are four or ilve inches loig, and two and a half bro.ii!. Living fev- vcral ublon^ holes in each, which on the iirtt view appears as it eaten by iiiiVcis, but they are natural to the bares. The flowers are produced ar the top oi the ta&k, which always Swells IQ a larger fi-ze in that pan than in any other; tiirfc are covered with an oblong lpaiba (or hood) of a whitifb green colour, which opens longitudinally on one iwic, ;i:ci! flies the piilil, which is dofirly covered with (lowers, uf i pole yellow, inclining to white. When this plant begins to flower, it luldom advances urthcr in hciohr, l< that thefc feldom are more than feven ur eight feet high, but the leaves are much forger on thele, than thole of the plants which ramble much farther.

This plant is cafily propagated by cuttings, -which, if planted in pots filled with poor fandy earth, and plunged into a hat-bed, will loot] put out roots, if they lkid none before ; but there arc few of tin... which have not roots: the piatus arc tender, ... will not live in the open air in England, therefore the potsftoukl be placed near the null of du b >! lioule, againft which the planes will climb, and ratio their roots into the wall, and thereby luppott tie Aalks. They lliould bive but ILJie water given them in die winter, but in v.jrm weather ir muü be given chem threoor fo-... times a week, and in the... llimmr the free lir mould be admicici! to theno in plenty. The plants have no jiaritilLdjr fealun of floivcring, for they ibmciimtrs flower in aummn, and at other times in the ipring, but they do not ripen their feeds in England.

The fecond lbrt grows naturally in feveral « • the islands of America. I received roocof this from Barbu- da. TiisliDth a lai^e knobbed irrefrogal root, covered with a rugged brown (kin. The (talk i... about a foot high, is naked to the top, where it is gamiihed with a tut of leaves, which are diviJed into many parts. The llalk is fmuoth, of a purple colour, but is full of (harp protuberances oi different colour:, which llline like die body of a ferpent. The fpadii: (or ficdk) of the flower rifes HnmedLucly from the root, and is felJom more than three inches hiah, having in oblong fwelling hood at the top, v... opens lengthways, lhcwing the Shan, thick, pointed pnllil within, upon which the flowers ore clofely ranged.

This fort 's tender, So requires a warm Hove to pre- ferve it in England. The root* muft be planted in poti filled with light kitclwn-gwrcki? earth, and plunged into the tan-bed in the ftovt, where they fhould contttntly remain j in i!i- winter iliey muft IK watered vta •... but in warm weather, when the plants are in vigour, they muft be often'refreshed, but it lhiuH not be pvtm them i... great quantities i with this management the planu will flower, but their roots do not incicle here.

The third for :... naturally in the... indofCey- h>n, and i: feveral parts of India; this hath jit ob- long ihii-k root, full oi... from which arife feveral leaves, ihaped lite tholi ot i... the common Arum, but their foot-itajfes are covered with rough protubiran- ces. Tiee (talk which fupports t... is fhort, >nd in witi the like pi... and at the top a hood, or fpatha, U... four inches long, as thick as a man's linger, which opens longitudinally, and e) :pofe> thi- [?ftul, which is fa with /lowers. This it a...;der pi-iiu, and requires die fame treat:-... as the former furt.

The fourth fort hath roots like the common MIQII Arum, from which come out feveral ipost-shaped leaves, flanding each upon a feparate foot-ftalk, arting im- mediately

iteiy from die root, as ihofir of liic common A, ruoi. This liaih not yet iiowerrd in England, Ib [c.in give no further account of it. This growl naturally in Siberia, Ib requires • (bady Btuotca, and will bear the greateit cold of thh couniry.

Thhfc plants arc preserved in the gawdciu of the curious in England and Hollor-rt, mure for tlw like of variety than far beauty; for except the filli ibrt, there is not any of theni which niske mueh appearance; that indeed may be liifleted to have a place ^gaiull ilie wall of [he Hove, ovr which it will Spread, and cover die nakcdr.cl of (he Will; and the leaves reuiniina all (he fen, which arc fi) remarkably perforate J, m.'ke a fins ranee.

AQ the other fors of Dragon are sender plants, fa will not live in this country, ualcfj they are preferred in the warmft ftovs; At lever., merigM lores grow naturally in the woaA", in Jamiics, and other hot parts of America; dc climbing forts twift thieni-feives round tir trunks of trecci, iot which they fiillen their roots, whicli are limi u> with I on their joi-i-, ant! rife to the height of thirty or forty feet. In Flanders and other places, they houfe their flieep at nights in places fpreac'd with clean fand, laid about 6ve or fix inches thick, which, being laid on frelh every night, is cleared out once a week j this mixture of fand and dung makes an excellent dreffing for ftrong land, for the dung and urine of the flieep is a very rich manure, bears a confiderable price, and is an excellent manure for all ftiff cold land : and Mr. Quinteney is of opinion, that it is the greateft promoter of fruitfulness in all forts of ground.

Others recommend hogs dung as the fatteft and moft beneficial of all forts of dungs; and fay, that one load of it will go as far as two loads of other dung, fnd that it is the bed of all dungs for fruit-trees, efpecially for Pear and Apple-trees in alight foil, and a very rich dung for grafs. I have often ufed this dung to fruit-trees when it was well rotted, and have found it the moft beneficial to them of any manure. The dung of pigeons, hens, and geefe, are great improvers of meadow or corn land, the firft of thefe being the beft fuperficial improvement that can be laid on meadow or corn land: but before it is ufed, it ought to have lain abroad out of the dove-houle ibme time, that the air may have a little fweetened it, and mollified the fiery heat that is in thofe dungs.

Efpecially it is good for cold, wet, clayey lands; but it ought to be dried before it be ftrewed, becaufe it is naturally apt to clod in wet-, and it fhould be mixed with earth or fand to keep it from clinging together, that it may be itrewed thin, being naturally very hot and ftrong.

Some recommend the dung of pigeons, and alfo of other fowls, as the beft manure for Afpargus, Strawberries, or any forts of flowers; but this fhould be rotted and well mixed with the earth, before it is ufed to flowers.

Monfieur Gentil approves of pigeons dung, as being good for fuch trees whofe leaves are apt to turn yellow, if they grow in free foils that are rather cold than hot, provided the heat of it has been abated by lying two or three years in the dunghill •, but this fhould be applied in autumn, and in fmall quantities.

This being fprecd about an inch thick at the foot of a tree, whofe leaves are yellow, and being left there till March, he recommends as very ufeful in cold and moift foils.

The dung of poultry being hot and full of falts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the dung of animals which feed on herbs.

Sir Hugh Flat fays, one load of grain will enrich ground more than ten loads of common dung •, which if it be true, it is rational to fuppofe, that if fimple grain, by only infufion in the mixture of compofts, has a very good effect, it will be more powerful when it has paffed through the bodies of animals.

Human dung is a great improver of all cold four lands, and efpecially if it be mixed with other earths or dungs to give it a fermentation.

But there is not any fort of manure equal to the cleaning of London ftreets, for all ftubborn clayey foils; the parts of which will be better feparated, and in a much lefs time, with this manure, than with any other compoft whatever •, and where it can be obtained, is extremely well worth procuring, either for corn, grafs, or garden land.

D U R A N T I A. Lin. Gen. Plant. 704. Caftorea. Plum. Nov. Gen. 30. tab. 17.

The CHARACTERS are,

<The flower bath a permanent ctnpalement of one leaf, which is ereB, and cut intc five acute fegments at the tcp, and fits upon the germen-, the flower is of the ringent hind, with one petal, hewing a long tube, which opens at the top in two lifts; the upper lip is oval, ereB, and concave; the under is divided into four equal fegments, which are round. It hath four Jhort ftamina, ftiuuated in the bottom of the tube, the two middle being a little farther than the other, terminated by precfirate fummits 5 tbe germen which is fituated under the flower, fupports a long

flenderjiyle, crowned by a beaded fligma. The germen aj terward becomes a globular berry, terminated by three acut points, having one cell inclofmg four angular feeds.

This genus of plants is ranged in the fecond fection of Linnicus's fourteenth clafs, intituled Didynamia Angiofpermia, the flower having two long and two fhorter ftamina, and the feeds being included in a capfule.

The title which was firft given by father Plumier to this genus, was Caftorea, in memory of Caftor Durant, a phyfician of Rome, who publifhed a hiftory of plants in Italian, which was printed at Rome in 1585. Dr. Linnaeus has now altered the title of the genus, and inftead of the chriftian name, he has given it the furname of the fame perfon.

The SPECIES are,

1. **DURANTIA** (*Plumeiri*) fpinofa. Lin. Sp. Plant. 637. *Prickly Durantia.* Caftorea repens fpinofa. Plum. Nov. Gen. 30. *Creeping prickly Caftorea.*
2. **DURANTIA** (*Racemofa*) inermis. Lin. Sp. Plant. 6gy. *Duraitia without thorns.* Caftorea racemofa flore caeruleo, fru&u croceo. Plum. Nov. Gen. 30. *Branching Caftorea with a blue flower and Saffron-coloured fruit.*
3. **DURANTIA** (*Erecta*) caule erecto fpinofa, foliis ovatis integerrimis, floribus racemofis. *Durantia with an upright prickly ftalk, oval entire leaves, and flowers growing in long bunches.* Jafminum folio integro, obtufo, floie caeruleo racemofa, fructu flavo. Sloan. Cat. Jam. 169. *Jasmine with entire obtufe leaves, blue flowers growing in bunches, and a yellow fruit.*

The firft fort hath many trailing branches, which arc armed with hooked thorns at every joint, and arc garnifhed with oblong leaves, which are placed without order, and are (lightly fawed on their edges -, the flowers come out from the fide of the ftalks in pretty long bunches, like thofe of the common Currant •, they are of a pale bluiſh colour, and fucceeded by brown berries not unlike the fruit of the Hawthorn j thefe have one cell, and inclofe four angular feeds.

The fecond fort hath a branching woody ftalk, which rifes feven or eight feet high; the branches are garnifhed with oval fpear-flaped leaves three inches long, and one and a half broad in the middle; they are fawed on their edges, of a lucid green colour, and ftand oppofite. The flowers are produced in long bunches at the end of the branches •, thefe are bhie, and fucceeded by pretty large, round, yellow berries, which contain four angular feeds.

The third fort rifes with a ftrong woody ftem to the height of ten or twelve feet, covered with a white bark, dividing into many branches, which are armed with (harp thorns on their fide •, thefe are garnifhed with oval ftiff leaves one inch long, and three quarters broad. The flowers come out in long bunches from the end of the branches, which are blue, and are fucceeded by fmall, round, yellow berries, which contain four angular feeds. I received this from the late Dr. Houftoun, who found it growing in Jamaica.

The plants are natives of warm countries, fo they require a ftove to preferve them in England; they are propagated by feeds, which fhould be fown in fmall pots, and plunged into a hot-bed of tanners bark; and when the plants are fit to remove, they muft be planted each into a feparate fmall pot filled with light earth, and plunged into the hot-bed again, obferving to fhade them till they have taken new root, then they muft be treated in the fame manner as other plants from the fame country.

The fecond fort may be propagated by cuttings, which may be planted in any of the lummer months 5 but thefe fhould be plunged into a moderate hot-bed, and fhaded from the fun till they have taken root, then they may be treated in the lame manner as the feeding plant;: This fort is not fo tender as the other two, fo may be placed in the open air in lummer -, and if they are kept in a moderate temperature of warmth in the winter, they will thrive better than in great heat. I kept fome of the plants of this fort three winters, in a dry warm ghfs-cafe without fire;

ind they have succeeded pretty well; but the winter 1762 proving severe, caused their leaves to fall, but since they have put out again very well.

DWARF-TREES. These were formerly in much greater request than they are at present; for though they have many advantages to recommend them, yet the disadvantages attending them greatly over-balance; and since the introducing of espaliers into the English gardens, Dwarf-trees have been in little esteem for the following reasons:

1stly, The figure of a Dwarf-tree is very often so much studied, that, in order to render the foliage beautiful, little care is taken to procure fruit, which is the principal design in planting these trees.

2^dly, The branches being spread horizontally near the surface of the ground, render it very difficult to dig or clean the ground under them.

3^dly, Their taking up too much room in a garden (especially when they are grown to a considerable size) so that nothing can be sown or planted between them.

4thly, These trees spreading their branches near the ground, continually shade the surface of the earth; so that neither the sun nor air can pass freely round their roots and stems, to dissipate noxious vapours; whereby the circumambient air will be continually replete with crude rancid vapours, which, being drawn in by the fruit and leaves, will render its juices crude and unwholesome, as well as ill tasted.

It is also very difficult to get to the middle of these Dwarf-trees in the summer, when their leaves and fruit are on the branches, without beating off some of the fruit, and breaking the young shoots; whereas, the trees on an espalier can at all times be come at on each side, to tie up the new shoots, or to displace all vigorous ones, which, if left on, would rob the trees of their nourishment.

Add to this, the fruit-buds of all sorts of Peaches and Apples, and most sorts of Plumbs and Cherries, are first produced at the end of the former year's (shoot, which must be shortened in order to keep the Dwarfs to their proper figure, so that the fruit-buds are cut off, and a greater number of branches are obtained, than can be permitted to stand; so that all those sorts of fruit-trees, whose branches require to be trained at their full length, are very improper to train up as Dwarfs; and the Peaches and Nectarines which will bear amputation, are too tender to be trained so in this country.

These evils being entirely remedied by training the trees to an espalier, hath justly gained them the preference; however, if any one has a mind to have Dwarf-trees, notwithstanding what has been said, I shall lay down a few rules for their management.

If you design to have Dwarf Pear-trees, you should bud or graft them on Quince stocks; but as many sorts of Pears will not thrive if they are immediately budded or grafted on Quince stocks, so some of those sorts which will take freely, should be first budded on the Quince stocks; and when these have shot, the shoots intended to cultivate, should be budded into

chefs; for free stocks are apt to make them (shoot) vigorously, as not to be kept within bounds. These grafts or buds should be put in about four or six inches above the surface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four shoots, you should flop the end of the shoots, to force out lateral branches.

Two years after budding, these trees will be fit to transplant where they are to remain; for though many people chuse to plant trees of a greater age, yet they seldom succeed so well as young ones. The distance these trees should be planted is twenty-five or thirty feet asunder, for less will not do if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs while the trees are young, but you should not sow or plant too near their roots.

In order to train your trees regularly, you should drive stakes into the ground round the tree, to which the branches should be fattened down with liff in a horizontal position, for if they are suffered to grow perpendicularly while young, they cannot be afterwards reduced without great violence to any tolerable figure. The necessary directions to be afterwards followed are, not to suffer any branches to cross each other; and always in shortening any shoots be sure to leave the uppermost eye outwards, whereby the hollows in the middle of the tree will be better preferred; and be careful to rub off all perpendicular shoots in the middle of the trees, as soon as they are produced. The other necessary rules you will find under the article of PRUNING.

The sorts of Pears which do best in Dwarfs, are all summer and autumn fruits; for winter Pears are not worth planting in Dwarfs, they seldom bearing well, nor are ever well tasted, and commonly are very stony, because they are commonly grafted on Quince stocks.

Apples are also planted in Dwarfs, most of which are now budded or grafted on Paradise stocks; but as these are for the most part of a short duration, they are not profitable, and are fit only for small gardens as a matter of curiosity, producing fruit sooner, and in greater plenty, than when they are upon Crab or Apple stocks.

The distance these trees should be planted, if on Paradise stocks, should be six or eight feet, and upon Dutch stocks eighteen or twenty; but if on Crab stocks, twenty-five or thirty feet asunder each way. The management of these being the same with Pears, I need not repeat it.

Some persons also plant Apricots and Plumbs for Dwarfs, but these seldom succeed well, as being of a tender constitution; and those which will produce fruit on Dwarfs, are much more likely to do so when trained on an espalier, where they can be much better managed; and therefore I judge it much the better method, as being more certain, and the trees will make a better appearance.

E.

E A R

EARTH is the principal matter whereof our globe confists; the charaſter of which, according to Dr. Boerhaave, is, that it is a foſſil body, neither diſſoluble by fire, water, nor air; that it is infipid and tranſparent -, more fuſible than ſtone; ſtill friable, and containing uſually a {hare of fatneſs. There is no ſuch thing as a ſtrictly ſimple earth. Mr. Boyle ſays, that it doth not appear, that nature, any more than art, affords an elementary earth; at leaſt, ſome which appear of the ſimpleſt ſorts are found, upon examination, to have qualities not aſcribed to pure earth.

Of ſuch earths ſome are ſimple and immutable, as chalk, pumice, and rotten ſtone; others compound and fatty; of which kind are all boles, red, white, and brown; fullers earth, and divers kinds of medicinal earths, as the Cretica, Hungarica, Lemnian earth, and others.

Which earth are all reſolvable into oil, a little acid fait, &c. and a calx, which is the baſis, or the earth properly ſo called.

Sand is by naturaliſts generally ranked as a ſpecies of earth, though not very properly; in that ſand, ſtrictly ſpeaking, are a fort of cryſtals, or little tranſparent pebbles, and are calcinable *, and, by the addition of a fixed alkaline fait, fuſible and convertible into glaſs.

The fat earth is rendered fertile by the means of ſand, and becomes fit to feed and nourish vegetables, &c. for pure earth is liable to coaleſce into a hard coherent maſs, as in clay -, and earth thus embodied, and as it were glued together, would be very unfit for the nourishment of plants.

But if hard ſand, i. e. cryſtals, which are indiffoluble in water, and ſtill retain the ſame figure, be intermixed with ſuch earth, they will keep the pores of the earth open, and the earth itſelf looſe and incompaſt, and by that means give room for the juices to move, aſcend, &c. and for plants to be nourished thereby.

Thus a vegetable, being planted either in the ſand alone, or in the fat glebe and earth alone, receives no growth or increment, but is either ſtarved or ſufocated; but mix the two, and the maſs becomes fertile.

In effect, by means of ſand the earthy is rendered, in ſome meaſure, organical; pores and interfaces being hereby maintained or preſerved, ſomething analogous to veſſels is effected, by which the juices of the earth maybe conveyed, prepared, digeſted, circulated, and at length excerned and thrown off in the roots of plants.

The earth is made up of two parts; the firſt the containing part, i. e. the body, bed, or couch :^ the ſecond the part contained, and thoſe are the nitrous or fulphureous particles, or prolific falts. The firſt is a lifeleſs inanimate maſs, and is only the receptacle of the other; for the earth, conſidered ſimply, and abſtracted from the before-mentioned nitrous and prolific falts, is a lifeleſs, dead, and inanimate maſs; but by the co-operation of water, fun, and air, is put into motion, and promotes the work of vegetation: but if it were ſtript of thoſe prolific falts and ſpirituous particles, would produce no manner of plant, herb, &c. that ſhould be planted or ſown in it-

E A R

Theſe nitrous particles, or prolific ſalts, are of various and different qualities; and according as the earth is more or leſs ſtored with all or ſome of them, it is more or leſs productive; and according as it abounds with ſome of them more than others, differing from one another in contexture, it conſtitutes the different ſpecies or kinds of ſoils adapted to the propagation of different plants, the pores of whoſe roots are formed to receive, and whoſe nature is to attraſt, thoſe ſalts that are congenial to them.

Some diſtinguiſh earths into three claſſes, ſand, loam, and clay, as thoſe upon one or other of which all others do in ſome reſpects depend.

Gravel, and all the open ſoils, till the loam is come at, are of the ſandy kind.

Theſe binding earths from the loam downwards, till the ſtiffneſs of chalk may be come at, may be reckoned of the clay kind.

All theſe ſorts of earth have a little tendency to vegetation, and have their ſalts proper for it, but in a different proportion -, as a peck of clay may probably have double the quantity of ſalts in it that a peck of loam has, and a peck of loam may have fix times the quantity of ſalts that a peck of land has.

Loam. Some call the ſuperficial earth that we meet with in England by this name, without having regard to what proportion of ſand and clay it contains: others again call that earth loam, that inclines more to clay than ſand. Some by loam mean that fort of earth that equally partakes of ſand and clay, being a medium between ſand and clay, which they call mother earth; but the true definition of loam is, that fort of earth which is fat and flippery, not of ſo cloſe a texture as clay, nor too looſe and ſandy, but of a middle nature between them, and is eaſily diſſolved by froſt, and gentle or eaſy to be wrought. This is one of the beſt ſoils for moſt eſculent^o plants and roots.

This mother earth, they ſay, may be in colour either black or yellow, and of which of theſe colours ſoever it be, plants of moſt ſorts will grow in it.

Sand and clay likewiſe produce certain plants, which are natural to each of them, and conſequently will thrive better in them than in any other ſoil.

But ſand is apt to precipitate thoſe plants that are ſet in it, earlier than clay, and will cauſe them to germinate near a month ſooner than thoſe that grow in clay, and that for this reaſon, becauſe the ſalts which are in ſand, are liable to be put in motion by the leaſt approach of the warmth of the fun; but as ſand is quick in the operation, the ſalts are ſoon exhaled and ſpent.

Clay. The pores of clay are more cloſely compared together, and do not ſo eaſily give out thoſe ſalts that are contained in it; nor can the fibres of every tender plant make their way through it in queſt of their proper nutriment.

But if the parts of the clay be opened, by digging and breaking it into finall particles, and thoſe parts be kept open by a mixture of ſome ſharp ſand, or ſome other body of the like quality, the effects of its vigour will plainly appear.

Some diſtinguiſh the ſeveral temperaments of the earth either into a light, ſandy, or looſe contexture,, or into thoſe of a ſtiff clayey, or cloſe one, either *oi* which

which have their reproductive good **qualific**, and all of them, when they are in their extremes, require art to render them useful and beneficial in the production and growth of plants.

A light, sandy, or loose earth, requires a particular ligature, and should have a compote of a heavier nature, and those that are heavy, clayey, and cloudy, should have a compote of 3 more fiery sprightly nature, that will infuse into them a more heavy, lumpy, indigested clod, which would otherwise very much obstruct the production of vegetation.

A gaode should be of 1 Hickith cole, fat, pliant, oreafy to be digged-, it should be neither cold nor light it ought to have no ill smell or taste, and it should be of the Unit quality three or four feet deep for trees, which, if they have not that depth, will languish and decay after they have been planted fix years. But this depth is not required for fruit-trees, which will thrive very well if they have two feet and a half of good earth, and generally produce the most fruitful crops.

In order to know whether the earth has any quality or talk-, they direct to by a handful of it: 10 fook in water for seven or eight hours, and afterwards to strain it, and taste and smell it, by which the taste or smell will be perceived.

EARWIG

These are very troublesome (bmc vermin in a garden, especially where Cnematia are preferred; for to prevent them, they will entirely destroy them, by eating off the sweet part at the bottom of the leaves. To prevent which, small peopls have been erected, which have a basin of earth in each suppofter, which is contained kept filled with water. Set the article CAHNA-NOX.

Others holding the hollow claws of crabs and toblter upon (licks in divers parts of the garden, into which these vermin get, and by which they will destroy them; which will be of great service to you in your wall fruit, for these are great destroyers of ill loft fruits.

elephant. l. bwMnnfiru

The CHARACTERS are, There are many flowers collected together in one common large umbel, permanent, and each individual contains four or five parts, the petals are tubular, aid hermaphrodite, they have the point which is mgttt- fl, only the stem is narrow, and without any free round parts they have five very short bony filaments, terminated by cylindrical summits. In the bottom is placed a round germ, supporting a slender style, crowned by two slender stigmas; the germ after ward becomes a fleshy compressed seed covered with bristles, sitting on a placenta imbedded in the capsule.

This genus of plants is ranged in the first of Lanof Linnæus's seventeenth class, which includes the plants with tubular flowers, whose stamens are all hermaphrodite.

[C and fri] • • • • •

• • • • •

The first sort grows naturally in both the Indies, I have received it from several parts of America; this sends out many sliding rough leaves, which spread near the ground; between these in the spring arises a branching stalk, which rises more than a li gh. The side branches are short, and are generally terminated by two heads of flowers, each standing upon a short stem. The heads contain several hermaphrodite flowers, each with a corolla involurrate, composed of five oval leaves, ending in acute points. The flowers are of a pale purple colour. They appear in July, but are rarely succeeded by seeds in England; the second sort grows naturally in South Carolina; the plants of this have frequently come up in the garden, which has been sent over from thence with other plants as weeds; this hath several oval woody leaves, four inches long, and three inches broad, growing from the root, having many small, curved, running from the middle to the sides; they

E L L

spread flat on the ground, and between these arise a stiff stalk, about a foot high, which divides into several branches, each being terminated by two flowers, which are composed of five leaves; included in a four-leaved involucre; the flowers are alternately larger in size than the other. The involucrum is longer than the Boret, for they do not just appear within the involucre; the flowers make no appearance.

They ripen in July, but the seeds never ripen in this country.

The first sort bears a perennial root, but an annual stalk. If this is (planted in pots, and sheltered in the winter from frost, it may be preserved several years, and the plants will annually flower; but the second sort seldom continues longer than two years.

The second sort is propagated by seeds, which should be sown on a hot-bed in the faring; and when the plants are raised, they should be transplanted into pots filled with fresh light earth, and plunged into a hot-bed of tanners bark, observing to water and shade them until they have taken root; then they should be transplanted into a large box of fresh air in warm weather, and they will require to be frequently refreshed with water.

RLE; HAS. See RHIZAN. iius. ELLIC • lity. SUM. See GNAPHALUM. 1-LM. See UL.

ELLISIA. The CHARACTERS are, The flowers permanent, composed of five petals, erect, spreading leaves; it is of the palm, found upon the length of the cap, and has five slender filaments at top; it hath five filaments the length of the tube, terminated by small summits, and a round germ supporting a short slender style, crowned by an oblong bifid stigma; the germ after ward becomes a fleshy compressed seed with two cells, enclosing two rough seeds.

This genus of plants is ranged in the first of Linnæus's fifth class, included Pentandria Monogyma, (the flowers having five stamens and one pistil.) We know but one Species of this genus, viz. ELLISIA (Nylind.) Lin. Sp. 1561. Tree-leaved Ellisia.

This plant grows naturally in Jamaica, where it forms a bushy shrub about six or seven feet high. I have raised many of the plants from seeds, some of which are now four or five feet high, but have not as yet produced flowers. It has a thick bud at the base of the stem, from which the branches are generally enveered; the bark is thick, the leaves are exposed in the sun, and are of the same colour, but after they have been some time removed into the shade, they recover their verdure again. The leaves are placed opposite on the branches, which are about an inch and a half long, and are indented on their edges, and have a small hole in the middle of the larger leaf. The branches are generally placed opposite to the upper part of the branches, but upward they are alternated, and the ends of the branches are without thorns. As the plants have not as yet produced flowers in England, I can give no further account of them.

This plant may be propagated by cuttings, which if planted in small pots filled with light earth, and plunged into a moderate hot-bed, covering them close with a hand-glass any time in July, will put out roots in about two months. It may then be separated and put into small pots, plunging them again into the hot-bed to promote their taking new root, after which they should be gradually removed to the open air; but the beginning of October they should be removed into the dry stove, where, during the winter, they should have a moderate warm air, in which they will thrive better than in the open air.

When seeds of this plant can be procured from abroad, if they are sown in a hot-bed in the faring, and may be afterwards treated in the same way as it is directed for those raised by cutting!

EME

EMERUS: Tourn. Inf. 2, H. 650. Coronilla. Lin. Gen. Plant. 275. [this name was given it by Theophrastus, and testified by CijiiiUi;nu&.] Scorpium

The CHARACTERS are, The flower hath a very fast empolment of the leaf, & continues for parts which is permanent. 'tht jtowr is of its nature hard. The leaf of the plant is much longer than the empolment. The standard is not larger than the wings, nor which it is united. The tivirfs are three and constant. The leaf is low - JiIjpei and rjttextd. That an- un Jsain'ma in tech, site .ymkiitb fanns sparit, the most used are found. There are finished tM the fixxiard. in lit impjürxHt is Jilusti an a long fan. . . grows, preparing a 'lender fyitl, oWf . . . by a taper stigma. This is an annual plant, whose seeds itiuft b' sown upon a li]-brd in the spring, and when the plants are fit to remove, they should be each planted into a separate small pocilled with light kitchen-gurd- : cinlr, and plunged into a moderate bus-bed of tanners' bark, shading them from the sun until thq¹ luvc taken new root, then they : must be transpl; the time ni<incir as other exoric plants from those wirm countries. If theft plants are brought forward in the tpring, and kept under a deep frame in a t,r-bed, or plunged into the bark-bed in the stove, when they are grown tuo tJi to remain under common frames, they will ripen seeds m Kngland; for thole seeds which I received did not arrive here till May, and v-l ijifoc plants iluvt-nil well in Av^ufti but the nitum conn:ng on soon after, prevented their perfecting; fecd^, and that j- . . . of the feed which I received :!l the next v-ar did not grow.

EM I' i T R U M. Lin. Gen. Plant. 977. Tourn. Inf. R. H. sjy. tab. +ii. ; fpecies, of 6, in 1 HIT(, Cr, ;i' . . . or flous, because this tree grows .l fony [itact.J Black-berried I k\uh.

The CHARACTERS are, It hath male and female flowers on different plants; the male flowers have a three-pointed empolment, which is permanent; they have three stony points, which are nec- essary at their base, and three long hanging flamma which

ere hairy, terminated by Jhort two-pointed fummits, which Jlandereft. The female flowers have the fame empalement and petals as the male, but no ftamina. In the center isftuated a depreffed germen, fupporting nine reflexed fpreading ftigma. The germen afterward becomes a depreffed round berry of one cell, inclafing nine feeds placed circularly.

This genus of plants is ranged in the third fe&ion of Linnaeus's twenty-fecond clafs, which includes thofe plants whose male and female flowers grow on feparate plants, and the male flowers have three ilamina.

We have but one SPECIES of this genus in England, viz.

EMPETRUM (*Nigrum*) procumbens. Hort. Cliff. 470. *Trailing Berry-bearing Heath.* Empetrum montanum, fruftu nigro. Tourn. Inft. 5J9. *Black-berried Heath, Crow berries. Crake berries.*

This little fhrub grows wild upon the mountains of Staffbrdshire, Derbyshire, and Yorkfhire, and is feldom propagated in gardens unlefs for variety sake -, but it may be cultivated in fhady places, and will thrive very well in gardens, where the foil is (tiff. The plants fhould be procured from the places where they grow naturally, for the feeds remain a year in the ground before they vegetate, and afterward are very flow in their growth, fo they are not worth the trouble of cultivating from feeds. If the plants are planted on a moid boggy foil in autumn, they will get roots in the winter, and will require no farther care than to clear them from weeds, provided they have a moift foil, otherwife they will require to be frequently watered; for thefe low fhrubs commonly grow upon the tops of wild mountains, where the foil is generally peaty, and full of bogs. The heath cocks feed much upon the berries of this plant; fo that wherever there is plenty of thefe low fhrubs, their *re commonly many of thefe fowls to be found.

EMUSCATION, die clearing a tree of mofs, *Lat.* ENUCLEATION, a taking out the nut or kernel of any fruit, *Lat.*

ENULA CAMPANA. See INULA.

EPHEDRA. Lin. Gen. Plant. 1007. Town. Inft. 663. tab. 477. *Shrubby Horfe-Tail, vulgo.*

The CHARACTERS are,

It hath male and female flowers in different plants -, the male flowers are collected in katkins, which arefcay -, under each feale is a Jingle flower-, thefe have no petals, but feven ftamina, which are joined inform of a column, and are terminated by roundjh fummits. The female flowers have an ovalperiantbium, compofedof five ferief of leaves, which alternately tie over the divifions of the lower range; thefe have no petals, but have two oval germen fitting upon the periantbium, fupporting Jhort ftyles, crowned by Jingle ftigma. The germen afterward turn to oval berries, each having two feeds.

This genus of plants is ranged in the twelfth fection of Linnaeus's twenty-fecond clafs, intitled Diccacia Monadelphia, the plants of this clafs and fection having male flowers on different plants from the female, and their ftamina join in form of a column. *

We have but one SPECIES of this genus in England, viz.

EPHEDRA (*Distachia*) pedunculis oppofitis, amentis geminis. Hort. Cliff. 465. *Shrubby Horfe-Tail with oppofe foot-ftalks, and twin katkins.* Ephedra maritima minor. Tourn. *Lejfer Sea Horfe-Tail.*

This is a low fhrubby plant, which grows naturally upon the rocks by the fea in the fouth of France, in Spain, and Italy -; it is alfo preferved in feveral gardens for the fake of variety, but has little beauty. This hath a low (hrubby ftalk, which puts out a few ftort branches, riling about two feet high, which have many protuberant joints, at which come out feveral narrow ruffly leaves, like thofe of the Horfe-Tail, which continue green all the year, but the plants rarely flower in this country.

It may be propagated by offsets, which the plants fend forth in great plenty; for the roots creep under ground, and fend forth fuckers, which may be taken

off to transplant in the fpring. They love a pretty floift: ftrorig foil, and will endure the cold of our ordinary winters very well in the open air. Some of thefe plants were formerly preierved in pots, and were houfed in winter, but by later experience they are found to thrive better in the full ground.

E P H E M E R U M. See TRADESCANTIA.

E P I D E N D R U M: Lin. Gen. 1016. *Vanilla.*

There are near thirty fpecies of this genus, which grow naturally upon trees in Africa and both Indies; but as the plants cannot, by any art yet known, be cultivated in the ground, it would be to little purpofe the enumerating of them here; though could the plants be brought to thrive by culture, many of them produce very fine flowers of uncommon forms. I had three fpecies of them fent me from America, which were ftripped from the trees on which they grew; thefe I planted with care in pots, which were placed in a ftove, where they came fo far as to (hew their flowers, but the plants foon after periffed;

E P I G ^ A. Lin. Gert. Plant. 486. *Memecylum, Mitch.* 13. *Trailing Arbutus.*

The CHARACTERS are,

The flower hath a double empalement, which is permanent; the outer is compofed of three, and the inner of one leaf, divided at the top into five parts. The flower is of the falver Jhape, with one petal, having a cylindrical tube, which is longer than the empalement, and hairy within. The brim is cut into five parts, which fpread open. It hath ten flender ftamina the length of the tube, which are fixed to the bafe of the petal, and are terminated by oblong fummits. In the center isftuated a globular hairy germen, crowned by an obtufe quinquefid ftigma. The germen afterward becomes a depreffed, half globular, five-cornered fruit, having five cells, opening with five valves, containing feveral feeds.

This genus of plants is ranged in the firft fe&tion of Linnaeus's tenth clafs, intitled Decandria Monogynia; the flowers having ten ftamina and one ftyle.

We know but one SPECIES of this genus, viz. *

EpiGiEA. Lin. Gen. Plant. 486. *Trailing Arbutus.*

This plant grows naturally in North America, from whence it has been introduced to the Englifh gardens. It is a low plant, with a trailing (hrubby ftalk, which puts out roots at the joints, and when in a proper foil and fituation, multiplies very faft. The (talks are garnifhed with oblong rough leaves which are waved on their edges. The flowers are produced at the end of thefe branches in loofe bunches; thefe are white, and divided at the top into five acute fegments, which fpread open in form of a ftar. It flowers in July, but doth not produce fruit in England.

The plants are eafily propagated by their trailing (talks, which put out roots at the joints, fo may be cut off from the old plant, and placed in a fhady fituation and a moift foil: the beft time for this is in autumn, that the plants may be well rooted before the fpring. If the winter (hould prove very fevere, it will be proper to lay a few dried leaves, or fome fuck light covering over them, which will prevent their being injured by froft; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

E P I L O B I U M. Lin. Gen. Plant. 426. *Chamaenerion.* Tourn. R. H. 302. tab. 157. *Willow Herb, or French Willow.*

The CHARACTERS are,

The empalement of the flower is compofed of four oblong pointed leaves, which are coloured. The flower hath four bordered petals which fpread open, and eight ftamina which are alternately Jhorter, terminated by oval compreffed fummits. Below the flower isftuated a long cylindrical gennen, fupporting a flender ftyle, crowned by art obtufe quadridftigma. The germen afterward becomes a long, cylindrical, furrowed capfule with five cells, filled with oblong feeds, crownedwith down.

This genus of plants is ranged in the firft fe&ion of Linnaeus's eighth clafs, intitled OAandria Monogynia; the flower having eight ftamina and one ftyle;

The SPECIES are.

The firft lort p; . . . "I the iouih of France* and in Italy, Th'u haih a perennial rodt, from which . . . ilk* jar three fet high, garnifhed with ubloi>e w³¹ ^ v ^ whidi *K hairy, and fit dole 10 the H Jk ; they are pineal alternate, and inr four inches lojifi, an' two wood in the middle ; thec in warm weather fwcat out a clammy juice. The flowers arc produced Tingle upon pretty long ftiot- 8alk-, ibme arifing from die fide of ilie (lalk, *nd other)

thers terminate it; they are yellow, and have an agreeable odour. They flower in July, and the seeds ripen in autumn.

This plant is propagated by seeds, which, if sown in autumn, will more certainly succeed than those which are sown in the spring. When the plants come up, they should be thinned if they are too close, and kept clear from weeds till autumn, when they should be transplanted where they are to remain. They delight in a dry soil and a sunny exposure. The second year the plants will flower and perfect their seeds, but the roots will continue several years, and annually produce their seeds and feeds.

This is one of the plants preserved in the botanical garden, for the sake of variety, but are seldom admitted into gardens for pleasure. The fifth sort is a perennial plant, which grows naturally on the Alps, and may be propagated by seeds in the same manner as the first, but should have a shady situation and a moist soil.

The others are annual plants, which, if once admitted into a garden, and suffered to scatter their seeds, will become very troublesome weeds there.

The fifth sort *nk** with five stalks three feet high, garnished with narrow spear-shaped leaves, the flowers are yellow, and are produced in loose bundles from the side of the stalk toward the top; these appear in July, and in warm seasons are succeeded by seeds in August.

It may be propagated by cutting the stalk in proper lengths, which, if planted in a shady border, and duly watered, will put out roots; and the following autumn, they may be taken up and planted in the borders of the flower-garden.

The common sort grows naturally in Africa: the roots of this are five or six upright stalks near four feet high, closely garnished with linear spear-shaped leaves which are hairy; the stalks are terminated by pretty large bunches of yellow flowers, formed in a corymbus. These appear in October, and frequently continue more than two months, which renders the plant more valuable.

This is too tender to thrive in the open air in this country, it is therefore to be kept in pots; and in winter they are placed in a common frame, where they may have a large share of fresh air in mild weather, and protected from hard frosts, they will thrive better than in any other situation. It is usually propagated by cuttings, which, if planted in May, will readily put out roots, and the young plants will flower the second year following.

H. N. U. S. Lin. Gen. Hist. 689. Ageratum. Tournefort. R. H. 6. i. t. b. + 2j.

The first sort grows naturally upon the Alps... : upon mountains: this is a very low plant, whose leaves lie close to the ground, growing in close tufts; they are about half an inch long, and one eighth of an inch broad, tawed on their edges, and of a dark green, between these arises the flower-stalk, which is about two inches high, supporting a loose bunch of purple flowers, which stand erect. These appear in May, and sometimes are succeeded by ripe seeds in July.

It is propagated by parting the roots; the best time for this is in autumn, they must have a shady situation and a loamy soil without dung, for the rich earth these plants like very much.

The second sort was first discovered by the late Dr. Houfton from Linnæus, where he found it growing naturally. This sends out several trailing stems about six inches high, which are covered with small oval leaves, which are on every side; they are very white and woolly, and at the joint; just above the leaves come the flowers, fitting very close to the stalks, these are in pairs, and are enclosed by round capsules, having two stalks, inserted with final feeds: this plant has great resemblance to the distance to the Sea Cudweed.

The third sort was discovered by Dr. Houfton, in the same country with the former: this has an upright stalk, which is about two feet high, garnished with spear-shaped leaves, which are placed opposite, and toward the top of the stalk is produced two or three smaller branches, which are also opposite, which stand erect. These are also the roots, which are terminated by loose spikes of purple flowers, which are succeeded by oval stalks, filled with small seeds.

The fourth sort rises with a shaggy stalk about four feet high, dividing into several small branches, which are garnished with oval spear-shaped leaves, which are placed on their edges, they are placed alternate, and have pretty long foot-stalks. The flowers come out from the side of the stalks, five or six together, at other times two or three at a joint, which are white, and are succeeded by round seeds, which are enclosed by round seeds, which are filled with small seeds.

E R I

The fifth fort sends out many trailing smooth stalks, which branch out very much on every side; they grow about seven or eight inches long, and are garnished with small oval leaves placed opposite. The flowers come out in whorls, fitting very close to the stalks; they are white, and make but little appearance; these are succeeded by round capsules filled with small seeds.

The sixth fort sends out several trailing stalks about six inches long, which divide into many smaller branches; these are garnished with small oval leaves, standing opposite. The flowers come out singly from the side of the stalk; they are of a bright yellow, and stand on long slender foot-stalks; these are succeeded by oval seed-vessels, filled with small seeds.

The fourth fort is a perennial shrubby plant, which will continue several years, if kept in a warm stove; but the second, third, fifth, and sixth forts are annual, decaying soon after they have perfected their seeds.

These are propagated by seeds, which should be sown in pots filled with light earth, and plunged into a moderate hot-bed, where sometimes the plants will come up in five or six weeks, and at other times the seeds do not vegetate till the following spring; this happens frequently when the seeds have been kept long after they were gathered. When the plants are fit to remove, they should be each planted in a separate small pot filled with light earth, not too rich with dung, and then plunged into a hot-bed of tanners bark. When they have taken new root, they should be treated in the same way as other plants from those countries, by admitting proper air to them at all times when the weather is warm, and frequently refreshing them with water: with this management the annual forts will flower in July and August, and frequently ripen their seeds in autumn, if the plants are brought forward early in the spring, otherwise the winter will be too late before their seeds ripen.

The shrubby kind must be placed in the bark-stove in autumn, and during the winter the plants should be frequently refreshed with water, but it must not be given them in large quantities, nor too often repeated in cold weather, for moisture will then destroy them; the second year the plants will flower and perfect their seeds.

ERIOCEPHALUS. Dill. Hort. Elth. n. o. Lin. Gen. Plant. 890.

The CHARACTERS are,

It hath a radiated flower composed of female half florets which form the rays and hermaphrodite florets, which form the disk; these are included in one common scaly empalement. The hermaphrodite florets are funnel-shaped. It is cut into five parts at the brim, which spread open; these have five short hairy stamens, terminated by cylindrical funnels; they have a small naked germen, supporting a single style, crowned by a pointed stigma; these are barren. The female florets have their petals stretched out on one side like a tongue, which is divided at the end into three small lobes; these have no stamens, but an oval naked germen, with a single style, crowned by an inflexed stigma; these have one naked seed fitting on the naked plain receptacle.*

This genus of plants is ranged in the fourth section of Linnaeus's nineteenth class, which includes those plants with compound flowers, whose hermaphrodite florets are barren, and the female half florets are fruitful.

We know but one SPECIES of this genus, viz. **ERIOCEPHALUS (Africanus.)** Lin. Sp. Plant. 926. We have no proper title for this in English. *Eriocephalus sempervirens, foliis fasciculatis & digitatis.* Hort. Elth. 132. *Evergreen Eriocephalus with fingered leaves growing in bunches.*

This plant hath a shrubby stalk, which rises from four to six feet high, putting out many side branches the whole length, closely garnished with woolly leaves, which come out in clusters; some of these are taper and entire, others are divided into three or five parts, which spread open like a hand; they have a strong smell when bruised, approaching to that of

E R U

Lavender Cotton, but not quite so rank. The flowers are produced in small clusters at the extremity of the branches, standing erect; they are tubulous. The female florets which compose the rays, form a hollow, in the middle of which the hermaphrodite flowers are situated which form the disk. The border is white, with a little reddish cast on the inside, and the disk is of a purplish colour. The flowers appear in autumn, but are not succeeded by seeds in this country.

This plant is propagated by cuttings, which may be planted any time from May to the middle of August, for if they are planted later in the season, there will not be time for them to get good root before the winter; these cuttings should be planted in small pots filled with light earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun till they have taken root; these must be refreshed with water two or three times a week, but they should not have too much at each time, for much moisture is very hurtful to these plants. When the cuttings have taken root, they should be gradually inured to the open air, to prevent their shoots from being drawn up weak; afterward they should be removed into the open air, and placed in a sheltered situation, where they may remain till October, when they must be removed into an airy glass-case, that they may have as much sun as possible, and enjoy the free air in mild weather, but secured from frost and damp air, either of which will soon destroy them. During the winter they must be sparingly watered, for the reason before given; but, in the summer, when the plants are placed in the open air, they will require to be frequently refreshed with water in hot weather.

These plants retain their leaves all the year, so they add to the variety of exotics in the winter season.

ERUCA. Tonrn. Lift. R. H. 226. tab. i. n. Brastica. Lin. Gen. 734. Rocket j in French, *Roquette.*

The CHARACTERS are,

The empalement of the flower is composed of four oblong leaves, which stand erect, forming a tube. The flower hath four oblong petals, placed in form of a cross which are rounded at their ends, where they are broad, but narrow at their base, and are much longer than the empalement. It hath six stamens, four of which are a little longer than the empalement, the other two are shorter, terminated by acute segments. It hath an oblong taper germen, supporting a short style, crowned by an obtuse bifid stigma. The germen afterward becomes a taper-cornered pod with two cells, filled with roundish seeds.

This genus of plants is ranged in the second section of Linnaeus's fifteenth class, which includes the plants whose flowers have four long and two short stamens, and their seeds are contained in long pods. Dr. Linnaeus has joined the common Rocket to his genus of *Brastica*, and some of the other species he has distributed under his other genera; but as the common Rocket has been long established as an officinal plant, I chuse to continue this genus by its old title.

The SPECIES are,

The first fort grows naturally in it is an annual plant, which r n^ak ftalkj a foot and a half high, garnilhed at e h joint wich one winged leaf, c>mp •nd of fourteen • r fit- ten i> very like thole of iln- Verth, but rwrrov >tie out from d;r Me of the* on toor-lhlc- an inch long, c;>:ji fliflaining two p*le-to!- than podj it little com; l thefc, each having three or four round ! the pods twell at the place where each feed is lodged, fo that it is called a jointed pod by many. The feeds of this plant • Lind to

is (bmr. d in mtdtcir -reen ,... is used for feeding in some co-ties, but IL is not worth cultivating for th' piirpofe in Kngl.ini The feeds are the common Lentil, ikh h ml' tivttiri'. many parts of England, either u fodder

for cattle, or for the feeds, which are frequently used. The plant is an annual, and 11 cm. tall. The leaf is ovate, and is cultivated: it rises with weak stalks a foot and a half high, the leaves are at each joint, terminated by a pair of lobes, terminated by a pair of lobes, which are neighbouring plant, and 11 thereby supported; the flowers are upon stalks of a pale purple colour, three or four (landing upon a foot-stalk) these are succeeded by (hort) lint pods, containing two or three seeds, which are flat, round, a little convex in the middle. The flowers appear in May, and the seed ripens in July. The feed; of this plant are commonly sown in March, where the land is dry, but in moist ground the best time is in April. The usual quantity of seed allowed to an acre of land, is from one bull and a half to two bushels. If these are sown in drills in the same manner as Peas, they will succeed better than when they are sown in broad cast: the drills should be a foot and a half asunder, to allow room for the Dutch hoe to clean the ground between them if the weeds are permitted to grow among them, they will get above the lentils and starve them. The seeds of this will ripen in July, when the seed should be dried, and afterwards the seeds should be threshed out for use. The seeds of lentils are frequently the common food of the poorer sort of people in (some of the islands of the Archipelago, and other warm countries, when they can meet with no better fare; for these they loathe, when they have better food, from the proverb, *Diva faxj im difii gaidere ictitt*; which is applied to those who turn at those things in which they were used.

The fourth and fifth sorts are small annual Vetches, which grow naturally among the Wheat and Rye in many parts of England, but are not admitted into gardens; they are only mentioned here as weeds, which may be easily rooted out of the fields, if they are cut up when they begin to tower, and not permitted to ripen their seeds, for as they have annual roots, if they do not fatten the feeds, they may be destroyed.

This genus of plants is named in the honour of Libanus's first class, which includes those plants which have five stamens and two styles.

decay; the young roots ate rm:di belter ia remove thin the old, becaule they ar= furujibed with fibres, lbwill readily rake root: wten thec art fixed ill the ground, they (ilivild remain unrcinovytd; and if they arc kept ckaa from wenU, it is all titc culture they will require.

The fcoml fort grows naturally in fceveral pans of England, whrre it a very troublelome i*ev. for the roots run deep into the grtjund, b arc not cniily delhoyed by the plough; and they Ijntd and multiply greatly in <he ground, to the ptejudke of whnever is lbwn or pUnted oit the hutd, then. I are it is not Admitted into gardens.

The third fort makes a very pretty appearance when it is in flower, efpecially that with the blue Italks vind flowwers, for there is a variety of thijj with white flowwers and fhks | but as this (loth nut fpreid at die root, but kcrps within bounds. It. a few of die piano fhoulk be allowed a place in the pleafure-garden. This is propagated by feeds, which, if town in die autumn, will more certainly faceted than when ix is low in the fpring, for die latter commonly remains in the ground a year before they vegetate; and if the lireda are fown where the plants are to remain, diey will flower ftrongiT than thole which are trauplanted j fix as they have long downright roots, lo thieie arc commonly broken in taking out of the ground, which greatly weaken the plants. The culture they require u to thin them where they are toil near, keep them clean from weeds, and dig the ground about them every fpring before they ihoot.

The [talk* of this fort will rife from two to three feet high, the tower leaves are oval and plain *, thoft i- white fort arc of a lighter green than thoic of the blue; the upper pin of the italks of die white i ihst colour, [hole of th« blue arc of die colour i [lie flalks divide upward, win, d with leaves divided into many paints j ividi fpines; the flowers are produced in oval » at the top of the (talk, Handing upon feparak Stalk*. I ic ilovcrs come out in July, and die; Jccds ripen in September.

The fourth fort grows naturally upon the mountains of Syria, Mid allb upon die Ajjenninrj. The lower itavei of this fort are divided like the fingers of a hand, into five or fix legmtnts, which are very much cut at their extremities into many ptra, and have linall fpines \ the ftalk rifea abouL two feet high, Dm- jiih'i'l »illi fmailer and more divided leaves; die upper part of the ftalk, and allb the head; of flowers, are of [he fined amethyft colour, fo that they make a very fine appearance. This fort Bowers in July, and when the autumn proves dry, their feeds will ripen in September, but in wet fealbn the feeds never ripen, in England. This is propagated by feedi in the e nunnr as the former fen.

The fifdi fart has been fuppoied by many, to be only i variety of the fourth; but I have propagated it by cecli moie than thirty years, without iindint? I

that) nuke no doubt of its Wing a diftinct fpecies. The lower leaves of this are very much divided, and the extre- ity of the fegments form an oval or circle; the upper part is a plain leaf, which is in the middle, and

green mi rive borders. The It two feet high, garnished It i' - joints with fmaller leaves -Siieh are finely cut

the flowers terminate in: iLilk, they are of a lighr blue colour, and grow in largjr heads than either of the lbntier fort. It flower, in June and July, a«i tlic ireds ripen in autumn. This rowi iijaturally on the Alpi i it is a perennial plant, etc.; may be ptpagated by feeds in the fame manner as the rbrmer,

The fifth fort was difcovered by Sir. Tountdbn in the Levant, from whence he tent the Jccds to tlic royal garden OI Paris. This hath a perennial root, the lower leaves are regularly divided into fcvCB or nine parts to the middle, as the »r winged L. each part is a leaf, which end in deep thorns. The stalks rise to i leet lit,

findu"3 on I fide br.indicj, garni (hed with fffff) which we divided into narrowrr fcgawnts than th lower, and are texnuated by three points. The How. era te rm i ll. •, I i ti ing dole among ti ll leaves, ami ate of a fine blue, as are alii* the kava on tl: upper part of the flalks, fo they make a pretty i; pcaranee. 'I his Dowers in July, but fldom ripen feeds m Eagltnd. It is propagated in the fame manne EU the three former lores, and the plants requite die lame treatlent.

Tin: (breath fort grows naturalW i i Vir^i.nii and Carolina, where it is tilled Ratrlcfnaltc Weed, from its virtues of curing the bite of that venomoiK reptile. This bath a perennial root, from which arife fevtnl long leaves, which ure-fawed on thdr eilgrs, ending in fpines; thiclit ietma sit ciipofcd roun! die root, after the fame form of the Alue or Yucca; they are of a gray colour, » foor long or nwre, and v.e inch and 3 half broad, (tilf, and end in fiuBe*. TJIL- IUII: ib frtang, grows two feet high, dividing upward into fceveral tooi-lblks, each being terminated by an oval head of flowers, ihaped like thole of the former foirs; they arc while, wkh i Ihde csft at pale blue. This (bn Qamn in July, but unclci the ktSaa is very warm, the lit Jt will nut ripen in England.

This fort i: propagated by feeds, which, il" fown in pan and plunged into a moderate hot-bed, the plants will come up mxich luoner than thofe which ar= Sown in the full ground, whereby they will be much ftrong« before the winter. When the planes arc fie to rem lovi-, il:cy fhould be each planted in a Icpirate (mall pot, tilled with light cartii-, and if they are plunged into a moderate hot-bed, it will forward itieir taking root i then they mud be gradually inured to bear the open air, into which they may be removed toward the lir.er end of May, anil plied among odit-r hardy exotic plants. When vie plant have rilled thile pots wirh their roots, i may be fhaken out, and planted in a warm bo the oihers mny be put into larger pots, and in the autumn placed under a common frame, where diry may be expofcd to the free air in mild weather, hut Oiekered from fevert trail: the following fpring thefe may be turned out of the pots, and planted in a warm fituntion, where they will endure the colr of our ordinary winters very well; and if in levere froft they arc covered with Straw, Peas-hau'm, or any fuch light covering, it will leure them from injury.

The eighth fort grows nwundly in Spain and Intly. This puti uut ublong pluin km* frum die rod, which arc cut on their edges-, the (hks rife about foot high, and branch out into many forked dii which ire rfgiilar, and at each of thele divinions h iituataed a fmill head of flowers, litting very clole be iween the branches. Thefe have no great beauty, the plants Krc Ieldom cultivated in gardem, ex for the &kc of variety.

The ninth fort grows naturally on the mountains of Helvetia and Itly. The root is pneesjal, the lower leaves are oblong, heart-ftaped, and plain *, thr- flalks rife from two to ihrec fret high, branching out on dicir fides upward; diefe »rc garniW with ft'i'fi' i leaves, which art deeply divided, ending in many points with /harp fpines i the flowers terminate the (talks, (hey are colfc&cd into conical heads, and arc of a light blue colour, as are alfo the upper part of the (alk:.

This [owen in July, and the fcedt arc ripe in September i it ii propagated by feeds in the fame manner as d*« other loni.

The tenth fort growi naturally in th« Weft-Indies, where it u much UVLI in medicine, being accounted of great ferncc in the cure of fevers, from wki hath the appellation of Feverweed in thofe countries. The roots of this plant arc competed of many lm:ll (ibri, which Ipnradnetr the furfaee, ihr "••• leaves are fix or frven inches long : they are raw at their bafe, and enlarge upward to an inch in bread ! near the top, whiTL- they are rounded off on one fid« like a liymiur; they arc finely awed on their eight *, and are of a light green colour *, die (talk rific about a

The first fort grows naturally in South Carolina, from whence Mr. Catchy sent the seeds in the year 1714, and many of the plants were then raised in ivi-ral curious gardens. This hath a very large woody root, which seldom rises more than a foot and 2 half high, from which come out rVfli shoots every spring; these grow about two feet high, their lower part being garnished with trifoliaEr leaves, of a deep green colour, which are (haped like the point of an arrow; the upper pin of the stalks are terminated by a longi'pikcof karlet flowers, composed of five petals, the upper petal being much longer than the uhr, so that at a small distance the flowers appear to have but one petal. **L** the flower turns to a taper ... I fix inKisL lonti^ iweHMg v every part where the seeds are lodged, opening in one cell, containing five or six kidney-shaped seeds. These plants flower in England, but they never produce seeds here.

The second fort hath a thick woody stem, which rises about ten or twelve feet high in this country, but in its native country grows to twice that height, sending out many frons irregular branches, which are covered with a brown bark, garnished with trifoliolate leaves? [landing upon long foot-stalks, the middle lobe which is the largest, being much larger than the other two-, they are all heart-shaped, smooth, and of a (deep green colour-, the flowers come out at the end of the stem, in short, thick, clove spikes; they are of a deep scarlet colour, and make a fine appearance. These commonly are in beauty in May and June in this country, but are not succeeded by seeds here; but in America, where these trees grow naturally, they bear crooked pods, which contain large kidney-shaped seeds, of a reddish purple colour. The leaves of this tree decay in the spring and fall off, so that in summer they appear to have no life-, but in the autumn it puts out new leaves, which continue green all the winter. The flowers do not appear till the leaves drop, so that the branches are often naked at the time when the flowers are out.

The third fort chiefly differs from the second, in having its trunk, bark, and the twigs, of the Wave like spines, the leaves are armed with short crooked spines, and flowers being very like those of the second fort. The fourth fort has shrubby stalks, which divide into betels-; the wood is above tight at nine

feet High; these are armed in every part with crooked, black spines, the leaves are rather like those of the two last, and have a nearer resemblance of the first; the foot-stalks of the leaves are armed with the same sort of (spine, and the middle of the leaves have also spines which are much narrower than the Bowers are of a paler scarlet, and grow in looser spikes. The seeds are as large as those of the second fort, but are of a dark purple colour. This tree is generally planted in the East-Indies for a support to the Pepper plants, which twine round the stem and branches, whereby they are prevented trailing on the ground; and as the branches of this tree will put out roots and grow, they are preferable to any dead props, which in those hot countries, where there is much rain, would rot. The seeds of the fifth fort were sent me from J. S. Viera Cruz, where the plants grow naturally; and since I have received seeds of the same sort from the Cape of Good Hope, so that it is a native of both countries. The seeds of this are not half so large as those of the second or third fort, and are of a bright fender colour; the leaves are all much smaller, and have long acute points; the branches are very cloistly armed with crooked spines, as are also the stems and foot-stalks of the leaves. The flowers in very long doles (spikes, and are of a beautiful leaflet colour.

I have also raised a variety of this with paler flowers and seeds, and the plums were less than, but as I was doubtful of its being a distinct species, so I only mention it here.

The sixth fort grows in Jamaica, and some of the other islands in America, from whence I have received the seeds. The pods of this are longer, and not more than half so thick as those of the second fort; the seeds are of a bright (scarlet colour, they are longer and slenderer than those of the other two, the leaves are final and acute-pointed, and the twigs are without spines: these do not grow very large, but shoot out into branches at a little distance from the ground, which grow erect, so form a bushy shrub. The flowers come out at the end of the branches in short spikes; the stem of the flower is long, and the lites turn down over the wing; which are also longer than those of the other species, and the whole flower is more closed.

I have also received specimens of a variety of the third fort from the island of Barbuda, with very few flowers and pods; they came by the title of Beal, which is the common appellation given to it in America; but the flowers were (separated from the stalks, so that I ran in vain to see in what manner they grow, whether in long or short spikes, but the stamina of these are much longer than the petals, in which it differs from all the other, the pods are very large and eitherside, the leaves are thicker than those of the third fort; the leaves have the same appearance, and are armed with spines, as are also the stems and branches, but the plants have not as yet produced any flowers here.

A few years ago I received a few very small seeds of a Coral-tree from the Cape of Good Hope, which were of a bright scarlet colour like the plums have no spines on them, the leaves are much larger than the other forts, their stems are fringed, and have the appearance of growing to hrg: trees, but at 17 are young, so there is no determining how they may differ from the other forts.

There are two oilier (bra of Coril-tree mentioned) by Sir Hans Slawe, in his History of Jamaica: one of which is by its characters a Sphora, under which genus we shall place it; and the other will be put under Robini*, to which genus it properly belongs. These plants when they produce their flowers, are some of the greatest ornaments to the lites we yet know; for their flowers are of a fine purple colour, and are of a beautiful scarlet, so that they are a fine appearance; but it is seldom they are seen here, or in any of the other parts of Europe; yet in the

ind expofc the fecdi, which ave of a bwuittul red colour ; to that when the branches are well ltoed with them, the trtes make a good appearance, ac that tealon, whin growing among other fora. The wood of this tree n ufedy the mulical lullrument-makers for toothing of organs and virginal keys; the branches are tut into tooth -pickeri, an Jibr making of fkwers-, and foindla are made of the wood, from whence the tree wis tiileJ Spindle-tree •, but in tome coontic) it is called Dogwood.

Thelecond lort grows mturally in Aultria and Hungary ; this was very leidom feen in England till of late years, finrc I procured a from France, andl'r. on the feeds of iliijft plants great numbers have bven lince railed, to it 15 now pretty common in fveral or" the nur[erics near London -, this rifei with a frenger fcio than the fill', and grows to a larger fize. The leaves are oval jndlpcar-flhapud, about four indies li'njr, md two inches broad in ilrc middle, of a light green colour, inti entire; they are placed oppofite on the branches, with lhon foor-flalks. The flowers come out from the iide nf the branches, upon very flendet foot-rhik*, which are two inches and a half long-, theft branch out into a loofe bunch, fodiat the flowers ftand upon feparare foot-liaiti. The flowers have five petals, which al lirt are white, but afterward than^L- to a purple colour •, the cmpalctuent of the flower is divided, into five twts. It hath five (batnina, ami the frail a fce fi fce-c imcred; the fruit is much iirger thai, than of the con non lort, and the fpot-ftalks being weik, tnc fruit «lways hang down. Or. Linmcai has fupposed thefe to be Mil and fpecies, and has taken ilie cnaroAeri ut' this genus from the fecund lort, whole ilowers liarc five Itamina and five petals, and i tlrc triiit tive corners, but all thofe of the common fort whkfi I! have examined hive but four, ami thefe dtrR-rencs are permanent in thofi plants which rile from fertlij fas I haw nifcd many of both foris from fceUfj but hive never found eithc of them altei.

The third fort ; grows naturally in Virginia, Carolina, and Oler parts of North America; this rifei wrth I JhrLi! by htofo eight or ten feet, dividing into many branches, which come out oppo lire from the join' of the firft ,tn:arcgarniuSedw:tlfpear-flihPi:c leaves, which are two inches lung, and about three quarters of an iiii.li broad in the middle, emlinu in acure points ; they Me placed opjioftr, and continue greeri ill the year. The Bowers jire produced at the end of the branches, and alfo front the fides, in fmal' duller?, which are fuccceded by round capfulcs, wliich ar^ chafely armed •, rough protuberances. This Shw-n in July, • but feldom products ripe fruit in I-ngland,

As^ is an evergreen thurbj lo it mtrits a plate in every curi in the garden, and puficly lirlly in all plinta- (ions of evergreen trees and Qinj* I thercisavari ery ofthiwith vaiirgated leave*, which ij preferved in the nuricry-gardens.

The fourth lort grows naturally in Jamaica, (it) fome of the nther iflants in the Weft-Indies j this rifei with an upright woody (hilk, to the height of ten or twelve feet ; at the lop it divides into two or three fhort branches, WIUL-II art garniflied by winged leavei rriiijiofni of fix orleven pair of final I leaves ;ur I lobes, abovit two inthes lung, and one inch broatl, theft lores come oui without order, itandinz upon long foot-ftalks. The fiowcis come out in clutters from llie fide of the branches, towjrJ tl' ends; thefe are rorcededfay roundfii capfiii, having a thick brown cover, which open in th/ce cells, each containing I (ngle hard feed.

The two firft fort^ may be jro[,]int«l either by feeds, or Layers; if bj kei!^, they fhould bt (own in autumn, loon after they are ripe ; then the plants wiil cmnc ui the fpring following; but if die feed* art not down till fpring, the plants will not appear till the folknvini (pring, whereby a whole year is lo. The feeds (houki be fown upon a Biady b^ir-icr, where they will ••ceed bettrr Euo when they are marc expofed to die fun

E U P

When the plants come up, they will require no other care but to keep them clean rroin WLcdi til) the ftb- lollowing autumn, when, as loon jis thtir leave* decay, the pUnts (K in Id ue taken up and r.:;litPU*^J into * nuifery, in rows two feet diftant, and at plants one foot alundrr in the rows •, in this pbee they may remain two ycufl, and then iiii-L-y truy be removed 10 tht places where truy ai-c to remjin.

When ihtfe are propagated' by ktyen, the fOOUg fnoots Oatfuld be bid down in autumn ; and if tit which is laiii deepefl in die ground u fli, as is pteac- i jtrdrnatii)ivi-; I1 will cat.li- ilicm P3 put OUI roox much toonertan they otherwifr would do ; rhesel.iv- ca w!! /K fuScienily rooted in one year to bear rranf planting, when I they fhould be taken from ili-old plants, ind 0 re ufthc lrt Uingy. Thecuttiir rated in a . in I flmly border, will rake ro-nt, but they fhould be plnted in autumn, as foon as their leaves' begin to fall; they (hould be the ftioots of the 61M year, with a knot of the fer- mcr year at bo: cam.

The third fort, which grows naturally in North America, is ib handy u rarely to fuffer by cold in England, pnmded it is nut pi.in Led in places very much expofed. This may be propagated by laying down the youn^ branches in HK ainimn, ohfen- ing to tongue them in the fame manner u is piaAifed in layin; of Carnati jr:-; tnefc will invuaiaie good foots in one year, when the/ may be cut from the old plants, and planted in a nurfery K^r wo years to get ftrengtii; alter whil, they fhould be planted where they are dtign'd to remain.

The fourth fort ••• warmer countries; tries, in cantit beprt-i (and, untefs v. is planted in a lioveinM.iii), this is generally ftorage. Vd by icjiimft be town in pots, nud plunged into a hot-bed ; ind when the phins arc fit to remove, they fhould be each planted in a li-parate UPHH jmt, ixA plunged into the hot-bed again, being careful to liiadi: them until they have tken III . roots, after which the] muh be r-Jted in the lame way z- other tentier plant of the : at coDntric. This fct may alfo be jriropngjcd by cuttings during any of the fummer moi.

The Inf grams nanirallj- In Carol:na, from choice
 the lace Dr. DJIC itni me the feeds; ihele :ants
 tlow^ifj very IIIILU' the year after they wen raised, but
 never have flowered fince, for the rood cr<[> greatly
 in the •. ground, but never **fend up** »ny tta
 The rirlt fort yrtjwi iiatuilly by the fide of I veta
Liiddl[che in most parts of England, and is du
 only species of this genus, which . Knumi to gr.w itatu-
 rally in Europe, this is esteemed as a very good sal-
 nerary herb, ft 1:ands in the list of medicinal plants.

It is **feldora adm 1** and into gardens, because, where-
 ever it is fuS'cred tu I'rd, the ground will be well
 ffircil
 with the plants to a great distance.

The fccomd lore r'rowi nururally in tvrraJ parta of
 North America, from whence ithm [XLCV. introduced
 to die gardens in Europe; this hath a perenn • rou:,
 but an annual stalk, which rises .liou; two feet
 ani • half high . it is purpl and has many dark
 fpcu ulia: . The leaves are rough, oval and serrate-
 Inaped, having fbo

Found th? ! sink toward the bottom, but upward by
 pairs opposite at each joint. The stalks are termi-
 pandrl by ilufbrnt of purjile (lowers, grow ing in a sort
 of corymbus; these come out in July and August,
 and in wirm leafons will ripen its feed* b autumn,
 The .liird fore grons naturally in North America;
 this rises vifit in upright stalks, near four feet high,
 gnriilted with hny, narrow, fyesa-Bapt •; leaves at
 each joint; these are deeply lobed on their edges, and
 the midrib is obliet¹ Eo the toot-Ibkl ; thtv arc
 placed by four* r round the fl Ik in whorls, and are
 of a dark green »)our. The (Ulks are tanr. and
 hj' bunches of i>"tp^{ic} flp<en tike die lift, •. which
 appear at the base of the stalk. This hath a perennal root
 and an annual stalk.

The fourth sort grows naturally in Virginia and Ca-
 rolina; this hath a perennil roor, which sends out
 many twining stalks in their swift about
 any neighbouring support, and rise to the height of
 five 0 six feet, garnished at each joint with two heart-
 fliapi I leaves, which are indented on their edges, and
 terminate in RCU' points; at each joint there are two
 jjnall side branche 1 conw out, which are icrmii
 by dullers of white So ers, to th: thr (Ulti I veta
 covered with them most part of their length, but
 as the f- come pretty liie in the feafon, Ib unless the
 fommets prove w-iin, the plants do not (lower well m
 and.

There is another (these plant:s with pur, I flowers,
 ftiinit; upon longer foot fl:is, which was led me
 from Campchacy; but Lhc ii
 stalks and leaves are very
 like

like thofc of this fort, fo that I doubt whether it be a diftindt fpecies.

The fifth lbrt grows naturally in New England and Virginia, from both of the fcountia I have received die feeds i this hath a perennial root and an annual)Ulk ; il riltt with upright ftalks about a foot high ; thefe have their joints pretty near each other, where they are gimithed with roilndifh heart-fhaped leaves, fitting dole to the ftalks; they are fawed on their edg s, and arc of a light green colour. The flowers arc produced in fmafl loole panicles at the top of the (talki; they are white, and have two frudl green leaves immediately under the flowers. Thd'c (lowers appear the latter end of June, but the feeds leidom ripen in England.

TTic fuch fort grows naturally at La Vera Cruz in America, from whence the kit Dr. Houffon Cent me the feeds *, this hath a lhrubby climbing Itaik, which riles to the heighr of En ur twelve tret, rattening itfclw w any neighbouring prop for fupport, and is «wr-nifticd with heart in..; il leaves, placed oppofitc; they are abuc thrve inches long, and one nnd a hair broad, of a lucid green ; the flowers conic out in long branching panicle], wuch procecd from the ide of the Ihlks, and are terminated by a branching [muc of white flowers. This fort is tender, To will rot live in this country without artind.il heat.

The feventh fort riles with upright, ftalks three feet high, garnifhed with oval leaves at each joint, which tre placed oppofitc -, ilicy have very ftioi; fuch ftalks, and arc fawed on tScr edges; from the fides oj die ftalkj, at every joint, is produced two (ender branches, which lland erect; thefe, and the principal ftalks a(lb, we terminated by tlufters of wlite flower;; they appear in Auguft and September, and the ftalks decay in winter, but the root is jierennial. This grows naturally in Pcnfyvania, and other parts of Amctica.

The dgTith lbrt grows n.itunlry in Virginia and Philadelphia; this hath a perennial root and an annual ftalk. The ftalks rife from two tu three feet high; they are hlir. and garnifhed with rough leaves .it each joint, which are from three to five inches long, and about an inch broad at their tmlc, gradually lellining to a very ac'itc point; the • are aned at their bale, l the ftalk Item to grow through th^m ; they are of a dark green, and me covered ivitli lhort hairs. The upp.'rp.irt of the ftalk many (ender foot-fbJk , each fufaining a d'ok c.;:terof while flowers. Thcfc come eutu- July, and in warm fealons the (alk will be ^times ripen in England.

The ninth lbn crow* MEumly at La Vera Cruz, from whence the latcY*r. Houftoun frnt mcilhc feeds i this riles with an upright lblk ntar two toet high, garnilrt toward the bottom with oblong obtule leaves, •which are of a thick fublance, and crnated on their edgw i the upper j-jti of the ilalk is naked to die top, where ihe flowers come out in a thick panicle; the) arc blue, and have Tingle cmpalenients. This floweri 1st; in autumn, but never ripens feed.; here^ thr root i> biennial, and [wriiht.^ Coon after it has flowered. The tenth fort was lent n< by the late Dr. Houftoun from La V-za Cruz, Vlcrc he ibund it growing naturally • lbs hath a thick woody (ulck, which riles twelve or fourteen few high, lend ing out many branches,

wh h arc channelled, and covered with a brown bark, garnifhed with regular hestrt-maped leaves u b; n- z- ilwfc of the Millborj'-tree; they ie i ljwnl on their edges, upon foot Italic, nrrar two inches

by ?our or lwe pair of foot-ftalk... me out oppofue fiomthi" and the top is terminated by an odd one ; the fufain branching panicles of white flowers, which together form a long loole pyramidal iliyV, and make a fine HUU ; for there are no leaves intermixed with the flowers, but fo far as the ftalk reaches the ftalks are naked. This bit hai ""W" in the Charles garden, but did IOI produce fcr*.

The eleventh fon grows naturally at La Vcr.i I , from whence the late Dr. Houftoun fent it me . this rites with nuny ihrubby ftalks war five feet high, which divide into many (ender branches, whole juinu arc three or four inches afundcr; at each of thdicome out two oval leaves about three quarters of an inch long, and half an inch broad, lluniimr Dpofl long (ender foot-ftalc. , they fcvtral black ljiuts on their furfece. The hntnchj comeout horrionti), and arc icrmm.ucd by lnull bunches of white flowers, whofe empalcmnt^ ire Qngte, and compofed of feven nirror fp'ar-ihapcd teen , which re divided to the bottom.

The twelfth fort rife? with an upright round ftalk to the height of thtce feet, leading out feveral brandies toward the top, which come out regularly by pairs; they are gamithed with U. . . (placed b) piirr'i; theie are two inches and a half long, nntl about onr third of an inch brn'd, having thtce li-ij)Etrudinaj veins i they arc of a light green colour, and entire. The flowers (land upon lons foot-ft lks at the end of the branches, fomc furhmiing one, fame two, and others three or four Cower,; they are white, and appear late in nutumil. This grows naturally inCartiiiu.

The flirteentli KM . . . naturally in Maryland; this bath a perennial row and an anno.. ftalk, which riles three feet high. i' . . . along upward into many be . . . which arc clofely garnifhed with narrow fpear-i shaped leaves, wunch are rotn two to thr,e inches long, nid a quarter of an inch broad, . . . a deep green, fitting clofe to the branches; l . . . have three longitudinal veins, and their upper part ji:

ending in acute j . . . the branches arc termi-nate: by roundilh ttulUrs u; wiiite lowns, which appear in Ainruft, tad . . . ill CWtobrt and in v.:ruil tetSxa they arc fuccceded by feed*, wliich ripen here.

The fourteenth fort grows naturally in Jamaica, ami in mtit of the other illMdi in tlie We-fi-lwWi this riles with fhrubby ftalks about fix or frven feet lugh, dividing into many brinclu , which ire gamithrd with heart-ihaped leaves, ending in acute pom-dntedoniheiredgn, havingth roe lon^itudi nal veins; the upper part of the branches arc terminated by ber foot (talks, each fuffaining a iin.ill L ttltler of i flowm, included in oblong ibtly emjalcmenc of a filvery colour.

The fifteenth fort was fent rnr from J.a Vtn Crui by the late Ur. Houllonin; this riles with an T^'11 branching (talk three feet lit; . . . fending our two fide branches from every joint, aimoi; the whole length, •which are Kratintted by loole fpikt-s of red H as is alib the principal lblk. The leaves are heart-ftiancd, roitgh, indarcrcrcniteUon thnredgc:, fitting clofe to the iblkt; they are t . . . a light green, and a little hoary.

Tbe (imcenth . . . was frfon . . . Jamaica by the UteDr, J-Iouftmir . . . this lark fender rerring ftalks, which faften thcn.. . . riles eight or l . . . foot high, leading out fmall branches upward, at moft of the upper joints. The leaves on the lower part of the ftalk are heart-fhaped, ending in acute points; the upper leaves are almost triangular, they are fmooth, and of a lucid green; the upper part of the ftalks have long branching ftalks of white flowers, which are fmall, and fit clofe to the foot-italka.

The icventcenth ! . . . grows naturally in Penfvvania; this hath a per- upright H!

eight fort i: . . . or where they are fupplied with water in d: . . . weather, and are garnifhed with orti, rough, fpt.; f shaped leaves, which are a little &wed on their ed> they are placed in whelns round the ftalk 1, tomrtimr; feven, at wher pb: . . . a pair of five of thofe . . . itand si each joint •, they arc about t inches lung, and t*o inches brotd. The ft . . . are terminairtl by a Jkife Liirrmbu! 01' purple flowers, which appear in Aupylt and cottLn^c nil C . . . but are not fuccedu by leedi to . . . England. The

The eighteenth fort rises with a single, upright, green (stalk, about four feet high, garnished at each joint by four spear-shaped leaves, placed in whorls round the stalks; they are six inches long, and two inches broad in the middle, tapering to both ends, terminating in acute points; they are rough, fawned on their edges, and hand on foot-stalks, the stalk is terminated by a close corymbus of purple flowers, which appear in July, and continue till September. The root is perennial, but the stalks decay every winter; it grows naturally in North America.

The nineteenth fort grows naturally in Carolina; this hath a creeping root, which spreads and multiplies very fast. The stalks rise about two feet high; they are garnished with oval heart-shaped leaves, which have foot-stalks, and are fawned on their edges. The flowers are produced at the top of the stalks in a sort of corymbus, they are of a fine blue colour, but the roots spread so much as to cause barrenness of flowers after the first year.

All these forts may be propagated by seeds; several of them ripen their seeds in England, these should be sown in autumn as soon as they are ripe, for then the plants will come up the following spring; but if they are kept out of the ground till spring, the plants will not come up till the year after; and those seeds which are procured from America should be sown as soon as they arrive, for though they may not grow the first year, yet there will be a greater certainty of their succeeding, than when they are kept longer out of the ground.

The second, third, fifth, seventh, eighth, twelfth, thirteenth, seventeenth, eighteenth, and nineteenth forts are hardy plants, so the seeds of these may be sown in the full ground, but there must be care taken in the sowing to keep the forts separate; for as the seeds of these plants have a light down adhering to them, they are easily displaced by the least wind, so that the best way will be to sow them in drills, but these should be but shallow, for if the seeds are buried too deep they will not grow. The bed in which these are sown should not be too much exposed to the sun, but rather have an east aspect, where the morning sun only reaches it; but where it is more exposed, it should be shaded with mats in the heat of the day, and the ground should be kept pretty moist, for as these plants generally grow in moist shady situations in their native countries, they will succeed better when they have a foil and situation somewhat like that; though as we want their heat in summer, the plants will thrive here when exposed to the sun, provided they have a moist foil, or are supplied with water in dry weather.

When the young plants come up, they must be kept clean from weeds; and where they are too close, some of them should be drawn out, to give room for the others to grow; and if these are wanted, they may be planted in another bed, where, if they are shaded and watered, they will soon take root, after which they will require no farther care but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are to remain. As the roots of these plants spread out to a considerable distance, they should not be allowed less than three feet from any other plants, and some of the largest growing should be allowed four feet. If the foil in which they are planted is a soft gentle loam, they will thrive much better, and flower stronger than in light dry ground, in which, if they are not duly watered in dry summers, their leaves will shrivel, and their stalks will not grow to half their usual height.

All these forts have perennial roots, by which they may be propagated; for as some of them do not perfect their seeds in England, so that the only way of increasing the plants here; some of the forts have creeping roots, sending out offsets in great plenty, so these are easily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which there should be care

taken not to cut or injure the old plants too much, which would cause them to flower weak the following year. The best time to remove these plants is in autumn, as soon as they have done growing, that they may get fresh roots before the frost comes on; but if that should happen soon after their removal, if the surface of the ground is covered with tan, or dried leaves, to keep out the frost, it will effectually secure them; and if this is done to the old plants in very severe winters, it will always preserve them; but the nineteenth fort is the only one which I have known killed by frost: however, it may not be amiss to practise this on the young seedling plants, which have not so good roots, nor are so well established in the ground; the future culture will be only to dig the ground about them every spring, and keep them clean. The fourth fort sends out many weak twining stalks, which require support; so there should be some stakes fixed down by their roots in the spring when they begin to shoot, to which the young stalks should be led and fattened, and afterward they will naturally twine round them and rise four or five feet high if they are supplied with water, and in warm seasons they will produce plenty of white flowers in August. This fort is sometimes killed in very severe winters, if they are not covered; but if, when the stalks decay in the autumn, the ground about them is covered with some old tanners bark, it will effectually secure the roots. This fort multiplies very fast by its creeping roots, which may be parted every other year.

The sixth and sixteenth forts have twining slender stalks, which require to be supported in the like manner; but these are natives of warm countries, so they will not thrive in England, unless they are placed in a warm stove; therefore they should be planted in pots and plunged into the tan-bed in the stove, where, if they are supplied with wet in hot weather, they will thrive and produce flowers. The sixth fort hath shrubby stalks, and does not propagate by the root, so there should be layers made of the young branches, which will put out roots if they are properly supplied with water; but the sixteenth fort may be propagated by parting the roots, in the same manner as the fourth fort.

The ninth and fifteenth forts have perennial roots, but their stalks decay every winter. These are tender plants, so should be planted in pots, and kept constantly plunged in the tan-bed in the stove, where they will thrive and flower. These may be propagated by cutting off some of their young shoots about the middle of June, when they have strength, and planted into pots filled with light earth, and plunged into a moderate hot-bed, where, if they are shaded from the sun, and gently watered as they may require it, they will put out roots in six weeks, and may then be transplanted into separate pots, and treated as the old plants.

The tenth, eleventh, and fourteenth forts have shrubby stalks, which are perennial. These are natives of warm countries, so will not thrive in England out of a stove; therefore they should be planted in pots and kept plunged in the tan-bed of the stove, and treated as the former forts. These will sometimes take root from cuttings, but not very freely, so that the best way is from seeds when they can be procured. When the seeds of these tender forts can be had from their native countries, the plants raised that way are much preferable to those which are obtained by any other method, and will flower much stronger, therefore should be preferred; but as these seeds seldom grow the first year, few persons have patience enough to wait for the plants coming up. When any of these seeds are brought over, they should be sown as soon as they arrive in pots; that they may be removed at any time; the pots should be plunged into a moderate hot-bed, and the earth kept tolerably moist; the glasses should also be shaded in the heat of the day, to prevent the earth from drying; in this hot-bed the pots may remain till autumn, when, if the plants are not up, they should be plunged between

the plants in the bark-trove, and in the spring removed to a gentle hot-bed, which will bring up the plants soon after. When these are fit to remove they should be planted in separate small pots, and plunged into the hot-bed again, (having them from the sun till they have taken new root; then they should have a large share of free air admitted to them in warm weather, and frequently refreshed with water.

In the winter these plants should be more sparingly watered, especially those sorts whose stalks decay; and in the summer they should have a large share of free air admitted to them, with which management they will thrive and flower.

EUPHORBIA. Lin. Gen. Plant. 536. Euphorbium. Boerh. Ind. alt. 1. 258. Tithymalus. Tourn. Inft. R.H. 85. tab. 18. The Burning Thorny Plant.

This plant was named Euphorbia by King Juba, the father of Ptolemy, who governed both the Mauritania; whose physician was named Euphorbus, and his brother Antonius Musa is said to have healed Augustus with this plant.

The CHARACTERS are,
The flower hath a permanent empalement of one leaf, which is swelling, rough* and divided into five parts at the brim. The flower hath four or five thick truncated petals* and twelve or more stamens which are inserted in the receptacle* they are longer than the petals, and are terminated by globular summits. In the center is situated a three-cornered germen* supporting three bifid styles* crowned by obtuse stigmas. The germen afterward becomes a roundish capsule with three cells* each containing one roundish seed.

This genus of plants is ranged in the third section of Linnæus's eleventh class, which includes the plants whose flowers have twelve (lamina and three styles). To this genus he has added the Tithymalus and Tithymaloides of Tournefort and others. The difference between the Euphorbium and Tithymalus, consists more in their outward form, than in the characters of either flower or fruit, so may be properly enough joined together; but the flower of Tithymaloides being very different in its form, should be separated from them, therefore I shall place them under the title of Tithymalus; and as the number of Tithymali is very great, many of which are common weeds, I shall select only the more rare or useful kinds to enumerate here.

The SPECIES are,

1. EUPHORBIA (*Antiquorum*) aculeata triangularis fubnuda articulata, ramis patentibus. Lin. Hort. Cliff. 196. *Euphorbia with triangular jointed stalks which are naked* and have spines and spreading branches.* Euphorbium verum antiquorum. Hort. Amft. 1. p. 23. *Prickly triangular-pointed Euphorbia* with spreading branches* commonly called the true Euphorbium of the ancients.*
2. EUPHORBIA (*Canariensis*) aculeata nuda fubquadangularis, aculeis geminatis. Hort. Cliff. 196. *Euphorbia with naked stalks* which have four angles and double spines.* Euphorbium tetragonum & pentagonum spinosum Canarium. Boerh. Ind. alt. 1. 258. *Canary Euphorbium with four or five angles which have spines.*
3. EUPHORBIA (*Trigonum*) aculeata nuda triangularis articulata, ramis erectis. *Thorny-jointed triangular Euphorbia with upright naked branches.* Euphorbium trigonum & tetragonum spinosum, ramis compressis. D'Inard. Art. Par. 1720. *Prickly Euphorbium having three and four angles with compressed branches.*
4. EUPHORBIA (*Officinarum*) aculeata nuda multangularis, aculeis geminatis. Lin. Hort. Cliff. 196. *Thorny Euphorbia having many angles and spines growing by pairs.* Euphorbium cerei effigie caulibus crassioribus, spinis validioribus armatum. Hort. Houft. MSS. Upright, annual, branching Spurge of America, with leaves like fmall Bafil
- The firft fort has been generally taken for the true Euphorbium of the ancients, and as fuch hath been dire&ed for medicinal ufe, but it is from the fecond fort, that the drug now imported under that title in England is taken. Dr. Linnaeus fuppofes the fourth to be the fort which fhould be ufed, though as they are all nearly of the fame quality, it may be indifferent which of them that drug is taken from, which is the Jhpiffated juice of the plant.
- The firft fort hath a triangular, compreffed, fucculent ftalk, which is jointed, and rifes to the height of eight or ten feet, fending out many irregular twilling branches, which are for the mod part three-cornered, but have fometime only two, and at others four angles; they are compreffed, fucculent, and fspread out on every fide the ftalk, thefe have at the extremity of the branches a few fhort roundifh leaves, which foon fall off; and near thefe come out now and then a few flowers, which, have five thick whitifh petals, with a large three-cornered germen in the center thefe foon drop off without having any feeds. It grows naturally in India, from whence the plants were brought to the gardens in Holland, and have fince been communicated to moft of the curious gardens in Europe.
- The fecond fort grows naturally in the Canary Iflands, from whence I have been credibly informed, the Euphorbium which is imported in England, is now brought, and is the infpiffated juice of this plant. In its native country this grows to the height of twenty feet or more, but in England it is rarely feen more than fix or feven; nor is it of any advantage to have them fo tall here, becaufe they fend out many branches which are large and fucculent, fo render the plants too heavy to be eafily removed. This hath a very thick, green, fucculent ftalk, which has four or five large angles or corners, clofely armed with black crooked fpines, which come out by pairs at every indenture: the ftalks fend out from every fide large fucculent branches of the fame form, which extend to the diftance of two or three feet, then turn their ends upwards, fo that when the plants are well grown, they have fome refemblance to a branched chandelier thefe have no leaves, but are clofely armed with black fpines like the ftalks 5 at the end of the branches come out the flowers, which are fhaped like thofe of the firft fort.
- The third fort hath a naked three-cornered ftalk which is compreffed, fending out a great number of branches which grow ereft, and join up to the main ftalk; thefe are generally three-cornered, but fome vary to four; they are jointed and armed with fhore crooked fpines, but have no leaves, nor do the

E U P

plants produce Bowers here. TUi; grows natural!) in India.

The fourth fort puts out many stalks just above the surface of the ground, which are thick, succulent, and roundish, having tight white they are young, but as they grow old they lift their angles and become round; the branches grow distorted and irregular, first horizontal, and afterward turn upward; they are arched with small crooked spines on their angles, and on the upper part of [lit branches come out the (lowers, which are small, and of a greenish white, (bapedlike those of the fecund (bit TflugmM naturally in India.

The fifth fort grows naturally in India; this rises with a strong upright stalk five or six feet high, which hath irregular angles, and protuberances which are oblique to the angles; the lower part of the stalk is naked, the upper part is branching, and the branches are armed with crooked spines, at every protuberance, and at the top, they are garnished with small leaves of a lucid green, which are very smooth, entire, and rounded at their ends; then fall off, and the plants remain naked for some months; and then the flowers come out, which (it dole, to the branch us* and are of a greenish white colour; the leaves come out in the autumn, and fall off in the spring.

The sixth fort rises with 3 roundish, upright, succulent stalk about three feet high, putting out several branches on the side of the same form which have seven angles; or furrows, which are armed with long (single, flake (horns) which come out first flowers, of the same form with those of the other forts, and are furnished with succulent (small) fruit.

The seventh fort hath thick, roundish, succulent stalks, which are fleshy; these send out many branches* from their sides of the same form, which are interwoven and run one over another, so as to appear like a parcel of ferns coming out from the stalks, BOD whence it had the appellation of Medusa's Scap. The ends of the branches are garnished with narrow, thick, succulent leaves, which drop off, and round the upper part of the branched down. The flowers which come out these are white, and of the same form with those of the other species, but larger, and are frequently succeeded by round smooth fleshy petals with three cells, each including a (single roundish seed.

The eighth fort hath roundish stalks, which swell out like a belly in the middle, and have knobbed angles, between which come out long (pines which are frayed, these (stalks rise two feet high and put out a few branches on their side of the same form; the flowers are produced at the end of the branches, tending dole upon the angle?; they are of a greenish yellow colour, and shaped like those of the other species.

The ninth fort hath (stalks and branches very like those of the fourth, but much thicker and the spines of the stalks are finned, and those of the other double; and the ends of the branches are chiefly garnished with flowers on every angle, by which it differs from the fourth fort.

The tenth fort hath a thick (stalk, which seldom rises more than eight or ten inches high, from which come out a great number of trailing branched stalks which are slender, and grow about a foot in length; these intermix with each other like those of the fourth fort, but they are much (smaller, and do not grow near so long, but have the same appearance, from whence it is called Little Medusa's Head: the ends of these branches are beset with narrow leaves, between which the flowers come out, which are white, and shaped like those of the other species.

The eleventh fort rises with a stalk taller than the tenth, sending out from the top a few tapering stalks, which spread out in every direction; these do not easily, like those of the tenth, but taper, and are garnished at their ends with narrow linear stalks, which drop off. This (on hath not yet been observed here, having been but a (long time in England.

E U P

The twelfth fort hath a (Wt thick stalk, which rises three inches high, so that the branches spread out on the surface of the ground, these seldom grow more than six inches long; and their leaves fall into a ton of protuberance! which are furnished with a few leaves, and very rarely produce flowers in England, but has been long known in the gardens.

The (fourth fort is very like the twelfth, but the (stalks rise more than a foot high, 16 that the branches spread out near the ground, these resemble much the twelfth, but have the same appearance, and are furnished with narrow leaves at their ends, which fall off; the branches are extended in length; this produces a great number of linear white flowers at the end of the branches, which are shaped like those of the other species, and are distinguished by round smooth capsules with three cells, including one or two room till feeds which ripen in the autumn.

These forts have been by most of the modern botanists ranged under the title (if Etmortm, and have been distinguished from the twelfth, more from the linear stalk and appearance of the plant, than from any real difference in their characters, as hath been observed; but the number of species of the twelfth, which Spurge was very desirous to many, is not less than a hundred. Iterate the Euphorbia num that genus, to lessen the number of species.

The twelfth fort is preserved in many curious gardens, more for the oddness of their structure, than any real beauty; but being so extremely different in their form, from almost any plants of European origin, many curious persons have been induced to preserve the several forts in their gardens.

They are all of them full of a milky acid juice, which flows out on their being wounded in any part; this juice will blisters the flesh, if it happen to lie upon any tender part for a short time, and till burn linen. The juice of the aqua iorris, which is prepared from the roots of the twelfth fort, is very caustic; and for the cure of the same, it frequently occasions a swelling of the part to the joint, and sometimes will destroy the whole plant, if those injured branches are not cut off in time; but that whenever the branches appear to have been injured, the twelfth fort they are cut from the plants, the less danger there will be of their suffering from the humors of the twelfth fort between the joints, for the same reason.

Most of these plants were first brought to Europe by the Dutch, who have been very desirous to introduce great numbers of plants from India, and also from the Cape of Good Hope: from the latter there hath been a very great variety of curious plants of late years brought to Europe, many of which produce very elegant flowers.

The twelfth fort is the most common of the conservatory in the winter and spring seasons. These have been brought over in feeds, but the different kinds of Euphorbia came over most of them in pits or cuttings; for the twelfth fort may be transported to any distance, if either of them are put up in boxes, with any luteous package, to prevent the being bruised, or their spines from wounding each other, and kept from moisture and decay; with this care they will be kept six months out of the ground, and if carefully planted will take root, and thrive as well as if they had been newly taken from the old plants, or out of the ground but a short time; which is a much more expedient method of obtaining plants than from feeds, when they can be procured.

The greater part of these succulent plants grow naturally upon barren rocky places, nor in (open fields) (oils, where few other plants will thrive; they therefore mould never be planted in rich or fertile earth, nor be exposed to receive much wet, which would caule them to rot. The best mixture of earth and rubbish is about a fourth part of ferrous rubbish, a fourth part of sea-sand, and half of fresh earth from a common; these should be

EUP

<*ell together, and frequently turned over before it is used, that the parts may be incorporated, and the compost sweetened by being exposed to the air. If this mixture is prepared a year before it is wanted, it will be the better, that it may have the benefit of the winter's frost and the summer's heat to mellow it; and the oftener it is turned over, and the smaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for use.

These sorts are easily propagated by cuttings, which should be taken from the old plants in June; these must be cut at a joint, otherwise they will rot. When these cuttings are taken off, the milky juice of the old plants will flow out in plenty; therefore there should be some dry earth or sand applied upon the wounded part, which will harden and stop the sap; and the wounded part of the cuttings should also be rubbed in sand, or dry earth, for the same purpose; then the cuttings should be laid in a dry part of the stove, for ten days or a fortnight; and some of those whose branches are large and very succulent, may lie three weeks or more before they are planted, that their wounds may be healed and hardened, otherwise they will rot. When the cuttings are planted, they should be each put into a small halfpenny pot, laying stones or rubbish in the bottom, and filling the pots with the mixture before directed; then plunge the pots into a moderate hot-bed, and if the weather is very hot, the glasses of the hot-bed should be shaded in the middle of the day, and the cuttings should be gently watered once or twice a week, according as the earth may dry: in about six weeks or two months the cuttings will have put out roots, so if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day, otherwise it will be better to remove them into the stove, where they may be hardened before the winter; for if they are too much drawn in summer, they are very apt to decay in winter, unless they are very carefully managed. During the summer season, these plants should be gently watered two or three times a week, according

to the season. ~~They should be watered in the winter, but in winter they must not be watered oftener than once a week, and it should be given more sparingly at that season,~~ especially if the stove is not warm: the first sort will require more warmth in the winter than any of the other, as also less water at that season. This, if well managed, will grow seven or eight feet high; but the plants must constantly remain in the stove, giving them a large share of air in warm weather, and in winter the stove should be kept in a temperate degree of warmth.

The sixth sort is at present the most rare in England: the plants of this sort, which have been procured from Holland, have been most of them destroyed by placing them in stoves, where, by the heat, they have in one day turned black, and rotted immediately after. This sort will thrive well if placed in a dry airy glass-case with Ficoides, and other succulent plants in the winter, where they may have free air in mild weather, and be protected from frost; in summer the plants of this sort may be exposed in the open air, in a warm situation, but should be screened from much wet: with this treatment, the plants will thrive much better than when they are more tenderly nursed.

The seventh, eighth, tenth, eleventh, twelfth, and thirteenth sorts, are also pretty hardy, (o will live in a good glass-case in winter without fire, provided the frost is kept entirely out, and in summer they may be placed abroad in a warm situation: as these are very succulent plants, they should not have too much wet; therefore, if the summer should prove very moist, it will be very proper to place these plants under some shelter, where they may enjoy the free air, and be screened from the rain, otherwise by receiving too much wet in summer they will rot in winter. The seventh sort will require to be supported, otherwise the weight of the branches will draw them upon the pots; and, by training of the stems up to stakes,

EUP

they will grow four or five feet high, and a great number of side branches will be produced; these being very succulent and heavy, are very apt to draw down the stem if it hath not support.

The following sorts have been by all the writers on botany, placed under the title of Tithymalus; but the fourteenth and fifteenth sorts should, according to their own distinction, have been placed in the genus of Euphorbium, because they are as destitute of leaves as most of the species which they have there placed.

The fourteenth sort rises with a taper succulent stalk to the height of eighteen or twenty feet, sending out many branches of the same form, which subdivide into many smaller; these are jointed but at a great distance: they are smooth, and of a deep green colour, having a few small leaves at their extremities, which soon fall off. As the plants grow older, their stalks become stronger and less succulent, especially toward the bottom, where they turn to a brown colour, and become a little woody. The branches grow diffused and intermix with each other, so form a sort of bush toward the top, but this doth not produce flowers here.

The fifteenth sort sends out a great number of slender taper stalks of a dark green colour, which are smooth, and twist about each other, or any neighbouring support, whereby they will rise to the height of ten or twelve feet, putting out smaller branches upward, which also twine and intermix with the other stalks; they are naked, having no leaves, nor do the plants flower in England. These grow in India.

The sixteenth sort sends out many taper succulent stalks from the root, which rise about four feet high; they are slender and weak, so require support to prevent their falling to the ground; these have a light green bark, and their lower parts are naked, but their upper parts are garnished with oblong leaves, which are smooth, entire, and placed alternate on every side the stalks: the flowers are produced in small clusters at the end of the branches, they are of a yellowish green colour, and are sometimes succeeded by smooth round fruit, but the seeds rarely ripen in England. This sort grows naturally on the African shore in the Mediterranean.

The seventeenth sort grows naturally in some of the islands of the West-Indies, and also upon the continent there. I received specimens of this sort from the island of Tobago, and also from Carthage, where the plants were growing in plenty; the Dutch gardens were furnished with it from Curacao, where it also grows naturally. This hath an upright stalk, which rises to the height of six or seven feet, covered with a light brown bark, and divides upward into many branches; these are garnished with roundish leaves, which are indented at their ends, and have foot-stalks: they are smooth and of a beautiful green, but fall away in winter, so that in the spring they are almost naked; the flowers come out from the end of the branches, they are yellow and small, soon falling away without having any fruit succeed them here.

These sorts are propagated by cuttings, in the same manner as the Euphorbiums, and the plants must be treated in the same way, as hath been directed for them.

The fourteenth, fifteenth, and seventeenth sorts, are tender, so require a stove; these must have the same treatment as the tender kinds of Euphorbiums, but the sixteenth sort will live in a common green-house in winter, and may be exposed abroad in the summer. The eighteenth sort stands in the list of medicinal plants, but is rarely used in England at present; this is a biennial plant, which germinates after the seeds are ripe. It grows naturally in Italy and the south of France, and where it is allowed to scatter its seeds in a garden, becomes a weed here. This rises with an upright succulent stalk from three to four feet high, garnished with oblong smooth leaves which are placed opposite, and fit close to the stalks; the upper part of the stalk divides by pairs into smaller forked

branches, and from the fork between these divisions come out the umbels of flowers, each fork having one *, that which is situated in the first division being the largest, and those in the upper the smallest; The flowers are of a greenish yellow colour; they appear in June and July, and the fruit follows soon after, which is divided into three lobes, and has three cells, each containing one roundish seed, which is call out at a distance by the elasticity of the pods. This* fort will propagate itself fast enough when it is once introduced into gardens, so requires no care but to keep it clean from weeds.

The nineteenth fort grows naturally in the south of France, in Spain, and Italy. This sends out many trailing branches from the root, which grow about a foot long, lying upon the ground, which are closely garnished with thick succulent leaves; these are flat, short, and pointed; they spread open on every side the branches, and are placed alternate, fitting close to the (stalks: the flowers are produced in large umbels at the end of the branches; the involucre of the principal umbel is composed of several oval-pointed leaves, but those of the small umbels have only two heart-shaped concave leaves, whose borders are rough, the flowers are yellow, and are succeeded by three seeds, inclosed in a roundish capsule with three cells. This plant will continue two or three years upon a dry warm soil, and will ripen seeds annually; which, if permitted to scatter, the plants will come up, and require no other care but to keep them clean from weeds.

The twentieth fort grows naturally in Crete, and in several islands of the Archipelago *, this rises with an upright branching stem to the height of four feet; the leaves of this are oblong and pointed, and are placed alternate on the branches; the flowers come out in umbels from the fork between the branches; they are small and yellow, and are rarely succeeded by seeds in England. It is easily propagated by cuttings during any of the summer months, and requires a little protection from the frost in winter.

The twenty-first fort grows naturally in the woods in many parts of England; it rises with a shrubby stalk three feet high *, the flowers are produced in umbels fitting close to the (stalks, so form a long spike *, the empalements are of a greenish yellow, and the petals black, so they make an odd appearance. It flowers in May, and the seeds ripen in July. If the seeds of this are sown under trees in the autumn, the plants will rise the following spring, and require no culture.

The twenty-second fort stands in the list of medicinal plants by the title of Efula major, but at present is seldom used: this grows naturally in France and Germany upon marshy places, where it rises three or four feet high. It hath a perennial root, by which it may be propagated better than by seeds, which seldom grow, unless they are sown soon after they are ripe.

The twenty-third fort was discovered in the Levant, by Dr. Tournefort, who sent the seeds to the royal garden at Paris -, this hath a perennial root, from which arise many succulent (stalks three feet high, covered with a purple bark, and garnished with oblong smooth leaves, shaped like those of Willow, of a dark green colour. The upper part of the (stalks divide, and in the fork is situated an umbel of flowers of a greenish yellow colour, which are succeeded by round capsules with three cells, each containing a single seed. It flowers in June, and the seeds are ripe in August; this may be propagated by parting the roots, or by sowing the seeds in autumn. The plant is hardy, so will endure the greatest cold of this country, if it is planted in a dry soil.

The twenty-fourth fort grows naturally in Sicily, and on the borders of the Mediterranean Sea; this rises with several shrubby (stalks to the height of five or six feet, having a red bark, and are garnished with oblong, smooth, blunt leaves, which are placed alternate. The flowers grow in small umbels from the

division of their branches; they are yellow, and are succeeded by roundish capsules, which are rough; having three cells like the other species. This is easily propagated by cuttings during any of the summer months, and requires protection from the frost in winter.

The twenty-fifth fort grows naturally in Ireland, from whence the roots have been brought to England; this hath thick fibrous roots, which send up several single unbranched (stalks about a foot high, garnished with oblong leaves, placed alternate on every side. The flowers are produced in small umbels at the top of the (stalks; they are yellow, and are succeeded by rough warty capsules with three cells; it flowers in June, and the seeds ripen in August. This" may be propagated by the roots, which should be planted in a (shady situation and a moist soil*.

This plant was almost the only physic used by the native inhabitants of Ireland formerly; but since the use of mercury has been known to them, the other has been generally neglected.

The twenty-sixth fort grows naturally in the Levant; this hath a knobbed Pear-shaped root, from which arise two or three (stalks about a foot and a half high, garnished with oblong leaves, which are hairy, placed alternate on every side the stalk. The flowers are produced in small umbels from the divisions of the stalk; they are small, of a greenish yellow colour, and are seldom succeeded by seeds here; it may be propagated by offsets, sent out from the main root; these may be taken off in autumn, and planted in a (shady situation, where they will thrive better than in the full sun.

The twenty-seventh fort grows naturally at Aleppo, and in other parts of the Levant *, this hath a perennial creeping root, by which it multiplies very fast where it is once established. The (stalks of this rise a foot and a half high -, the lower leaves are narrow, (stiff, and brittle; but those on the upper part of the stalk are (shaped like the narrow-leaved Myrtle. The flowers are produced in large umbels from the divisions of the stalk; they are yellow, and appear in June, but are rarely succeeded by seeds in this country. The roots of this (should be confined in pots; for when they are planted in the full ground, they creep about to a great distance.

The twenty-eighth fort grows naturally in many parts of the Levant, and also in Spain and Portugal. The seeds of this were brought me from Scanderon, by the late Mr. Robert Millar, who found the plants growing plentifully there; and he assured me, that he saw the inhabitants wounding of these plants, and collecting their milky juice, which they mixed up with the Scammony to send abroad.

The seeds of this plant were sent me from Portugal, by Robert More, Esq; who found the plants growing there naturally, but this plant had been many years before an inhabitant in the English gardens; this rises with a purple (shrubby stalk near three feet high, which is garnished with narrow, spear-shaped, hairy leaves, set closely on the stalk alternately on every side *, the upper part of the stalk is terminated by umbels of flowers, which form a sort of spike. The greater umbels are multifid, but the small ones are bifid. The involucres of the flowers are yellow, and the petals of the flowers black; these appear in May, and are succeeded by seeds which ripen in July: the young plants which have been lately raised from seeds, are generally very fruitful, but the old ones, and those raised by cuttings are barren -, this may be propagated by seeds, or from cuttings, and will live abroad if planted in a dry rubbishy soil and a warm situation, otherwise they are frequently killed by severe frost.

The twenty-ninth fort grows naturally in the south of France, in Spain, and Italy; this is a biennial plant, from whose root arise two or three stalks, which grow two or three feet high, garnished with spear-shaped leaves, which are entire. The umbels of flowers arise from the division of the branches -, the involucres are

pots and placed under a frame in the winter, and the following spring shaken out of the pots, and planted in a warm border, they will come early to flower, and thereby ripe seeds may be more certainly obtained.

The other two sorts may be treated in the same way; for as these seldom flower the first year from seeds, the plants should be either kept in pots, and sheltered under a frame in winter, or placed in a warm border, where they may be sheltered with mats, or some other covering, to preserve them from the frost; and the following summer the second sort will flower and produce ripe seeds, but the third has not perfected any seeds as yet in England.

FAGOPYRUM. See HELIXINE.

FAGUS. Tourn. Inft. R. H. 584. tab. 351. Lin. Gen. Plant. 951. [so called from π^αγ^{ος}, Gr. because supposed to be the food of the first race of mankind.] The Beech-tree; in French, *Hêtre*.

The CHARACTERS are,

It hath male and female flowers on the same tree; the male flowers are collected into globular beads, these have no petals, but have several stamens included in an envelopment of one leaf, which are terminated by oblong stamens. The female flowers have a one-leaved envelope cut into four parts, but have no petals, the germen is fixed to the envelope, supporting three styles, crowned by reflexed stigmas. The germen afterward becomes a roundish capsule, armed with soft spines, opening in three cells, each containing a triangular nut.

This genus of plants is ranged in the eighth section of Linnaeus's twenty-first class, which includes those plants that have male and female flowers on the same plant, and the male flowers have many stamens. To this genus he has joined the Chestnut; but as the male flowers of the Chestnut are collected in long catkins, and those of the Beech are globular, and the fruit of the latter being triangular, there is sufficient reason for keeping them separate.

We know but one SPECIES of this genus, viz.

FAGUS" (*Sylvatica*) foliis ovatis obsoletis ferratis. Hort. Cliff. 447. Fagus. Dod. Pempt. 832. *The Beech-tree; with oval-shaped leaves.*

There are some planters, who suppose there are two distinct species of this tree, one they call the Mountain Beech, which they say is a whiter wood than the other, which they distinguish by the title of Wild Beech; but it is certain, that this difference in the colour of the wood arises from the difference of the soils in which they grew, for I have not seen any specific difference in the trees. There have been seeds of a Beech-tree brought from North-America, by the title of Broad-leaved Beech, but the plants which were raised from them proved to be the common sort; so that we know of no other variety, excepting those with striped leaves, which is accidental, and when the trees are in vigour, the leaves become plain again.

This tree is propagated by sowing the mast, the season for which is any time from October to February, only observing to secure the seeds from vermin when early sown, which, if carefully done, the sooner they are sown the better, after they are full ripe: a small spot of ground will be sufficient for raising a great number of these trees from seed, but you must be very careful to keep them clear from weeds, and if the plants come up very thick, you should not fail to draw out the strongest of them the autumn following, that those left may have room to grow, so that if you husband a seed-bed carefully, it will afford a three years draught of young plants, which should be planted in a nursery; and, if designed for timber trees, at three feet distance row from row, and eighteen inches asunder in the rows.

But if they are designed for hedges (to which the tree is very well adapted) the distance need not be so great; two feet row from row, and one foot in the rows will be sufficient. In this nursery they may remain two or three years, observing to clear them from

weeds, as also to dig up the ground between the rows, at least once a year, that their tender roots may the better extend themselves each way: but be careful not to cut or bruise their roots, which is injurious to all young trees, and never dig the ground in summer, when the earth is hot and dry; which, by letting in the rays of the sun to the roots, is often the destruction of young trees.

This tree will grow to a considerable stature, though the soil be stony and barren, as also upon the declivities of hills, and chalky mountains, where they will resist the winds better than most other trees, but then the nurseries for the young plants ought to be upon the same soil; for if they are raised in good soil and a warm exposure, and afterwards transplanted into a bleak barren situation, they seldom thrive, which holds true in most other trees; therefore I would advise the nursery to be made upon the same soil where the plantation is intended, but of this I shall say more under the article of NURSERY.

The tree is very proper to form large hedges to surround plantations, or large wilderness quarters; and may be kept in a regular figure, if sheared twice a year, especially if they shoot strong; in which case, if they are neglected but a season or two, it will be difficult to reduce them again. The shade of this tree is very injurious to most sorts of plants which grow near it, but is generally believed to be very salubrious to human bodies.

The timber is of great use to turners for making trenchers, dishes, trays, buckets; and likewise to the joiner for stools, bedsteads, coffins, &c. The mast is very good to fat swine and deer; it also affords a sweet oil, and the nuts have in scarce times supported some families with bread.

This tree delights in a chalky or stony ground, where it generally grows very fast; and the bark of the trees in such land is clear and smooth; and although the timber is not so valuable as that of many other trees, yet as it will thrive on such soils and in such situations where few better trees will scarce grow, the planting of them should be encouraged; especially as the trees afford an agreeable shade, and the leaves make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees: therefore in parks, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it.

The two sorts with variegated leaves may be propagated by budding or grafting them upon the common Beech, observing not to plant them in a good earth; which will cause the buds or cyons to shoot vigorously, whereby the leaves will become plain, which often happens to most variegated plants.

FARINA FEGUNDANS is the impregnating meal or dust on the apices or summits of flowers, which, being conveyed into the uterus or vulva of female plants, fecundates the rudiments of the seeds in the ovary, which otherwise would decay and come to nothing. See GENERATION OF PLANTS.

FATHERFEW, or FEATHERFEW. See MATRICARIA.

FENCES. In hotter climates than England, where they have not occasion for walls to ripen their fruit, their gardens lie open, where they can have water fence and prospect, or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing to the sight than a dead wall: but in colder countries, and in England, we are obliged to have walls to shelter and ripen our fruit, although they take away much from the pleasant prospect of the garden.

Since therefore we are under a necessity to have walls to secure our gardens from the injury of winds, as well as for the convenience of partitions or inclosures, and also to ripen our fruit, brick walls are accounted the warmest and best for this purpose: and the walls being built panel-ways, with pillars at equal distances, will save a great deal of charge, in that

the walls may be built thinner, than if they were built plain without these pannels, for then it would be necessary to build them thicker every where: and besides, these theft pannels make the walls look the more formidable.

Stone walls are by some preferred to those of brick especially those of square hewn stones; but where they are used for fruit, they fluek! be faced with brick. Those of rubble made of rough stones, though they are very dry and warm, yet, by reason of their uneven surfaces, are inconvenient to nail up trees on, except where or timber be laid in them here and there for to fallen on trellis to them.

But in large gardens it is better to have the plot open to the pleasure-garden, which is limited by a fence with 3 feet, that from the garden the view of the country may be viewed, but this is the desire of the nation of the place; for if the prospect from the garden is not good, it had better be shut out from the light by a wall, or any other fence, than to be open. As also, where it is a populous town,

and the adjoining grounds are open to the inhabitants, if the garden is open, there will be no walking there in good weather, without being exposed to the view of all the town, which is very disagreeable.

Where these fences are made round a garden which is situated in a park, they are extremely proper; because hereby the prospect of the park will be obtained in the garden, which renders these gardens much more agreeable than those which are common.

In the making of these fences there have been many inventions; but, upon the whole, I have not met any which are in all respects preferable to those which have an upright wall next the garden; which wall should be four feet high, so as to be above the reach of boys; and from the foot of this wall, the ground on the outside should rise with a gradual easy slope to the distance of eighteen or twenty feet; and where it can be allowed, if it slopes much farther, it will be easier and less perceptible as a ditch to the eye, when viewed at a distance. But if the ground is naturally wet, it is as not to admit of a deep fosse, then, in order to make a fence against cattle, if the wall be four feet high, and flight posts of three feet and a half high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it, therefore it will be a fence (fence against them; and if these are painted of a dark lead colour, they will not be discerned at a distance; and at the same time the chain will secure persons walking in the garden from tumbling over: and if another chain is carried through the posts at one foot from the ground, it will more effectually prevent cattle from creeping under.

In such places where there are no good prospects to be obtained from a garden, it is common to make the inclosure of park-paling; which, if well performed, will last many years, and has a much better appearance than a wall: and this paling may be hid from the light within, by plantation of Inrabs and Evergreens; or there may be a quick hedge planted within the pale, which may be trained up, so as to be an excellent fence by the time the pales begin to decay. There are some persons who make these fences round their gardens to keep out cattle, &c. which, when well made, will answer the purpose of a fence, but this being very expensive in the making, and not of very long duration, has occasioned their not being commonly in use.

As to fences round parks, they are generally of paling; which, if well made of winter-fallen Oak, will last many years; but a principal thing to be observed in making these pales, is not to make them too heavy; for when they are so, their own weight will cause them to decay; therefore the pale should be cleft thin, and the rails should be cut triangular, so as to prevent the wet lodging upon them, and the posts should be good, and not placed too far asunder, burning that part of them as good into the ground, if these things are observed,

one of these pales will last upward of forty years very well. The manner of making these fences is, to have every line nine or ten inches above the intermediate one; so that the fence may be six feet and a half high, which is enough for a low deer; but where there are red Jills, the fence should be one foot higher, otherwise they will leap over.

Some incline to park with brick walls; and in countries where stone is cheap, the walls are built with this material; but others will have them of stone.

A kitchen-garden, if rightly contrived, will contain walling enough to afford a plentiful supply of such fruits as require the assistance of a wall for any family; and this garden being situated on one side, and quartered by the height of the ivy; may be surrounded with walls, which will shut out the garden from the light of the sun in the winter season; and being low up, the fruit will be much better preserved than it can be in the public garden; and the occasion of a (a number of) willing is often the occasion that many valuable trees are frequently to be seen in large gardens, where there is no due care observed in their management.

And besides, the borders of pleasure-gardens are generally narrow for the roots of fruit-trees, as well as the view in its proper place, therefore it is in vain to plant them there.

The height of garden-walls should be from ten to twelve feet, which is a moderate proportion; and if the soil be good, it may in time be well with hearing wood in every part, especially those plants planted with Pears, notwithstanding the branches be trained horizontally to the bottom of the wall.

I would recommend the White Thorn, the Holly, the Black Thorn and Crab, for outward fences to a good ground, but I do not approve of their intermixing them.

The White Thorn is the best quick to plant, and it is the most common, and may be clipped so as to render it the closest and hardest fence of any other tree, and being very durable, it is preferred to all others for outward fences, or for the division of fields, where they are exposed to cattle, &c.

The Black Thorn and Crab are very good fences, and are to be valued at the White Thorn; but the kernels of Apples or Crabs be taken, it is better to low the fumace with them, and they will come up the sooner, i. e. the first year, if (own in the autumn) after the frost is ripe.

If Crab-trees be planted while young, in the same manner as quick, they make excellent hedges; and will form forts of Plumbs, I need not say as have thorns.

The Black Thorn is not accounted so good for fences as the White Thorn, because it is apt to run more into the ground, and is not certain as to the growing, especially if the plants are not set very young; but then on the other hand, the bushes are by much the better, and are well known to the White Thorn, or any other, for dead hedges, or to fill a gap; nor are they so apt to be cut off, etc. as the others are. The richer the mould is, the better they will prosper, but yet they will grow on thin soil of soil that the White Thorn does.

The Molly will make an excellent fence, and is preferable to all the rest, but is a slow grower; but when once it does grow, it makes amends by its height, length, and thickness.

It is raised by young seedling plants of berries, as the White Thorn, and the bushes will last as long in the ground before they come up, as the Molly. It delights most in Urong grounds, but will grow upon the drift gravel, amongst trees and houses.

The berries should be all the second spring before they come up, therefore they should be prepared before they are sown (see the article Agricul.) It will be better to sow them in the place where you design they

they should grow, but they should be well weeded both before they come up and afterwards. French Furz will also do well upon dry sandy banks, where few other plants will grow; but they must be kept very clean at the bottom, and cut thin, and never suffered to grow too high: nor should they be cut in dry weather, or late in autumn, nor early in the spring; the doing either of which is subject to make it die in patches, which is irrecoverable; not will it ever break out again from old wood, if cut down in, after it has been suffered long to grow out. Fences may likewise be made of Elder: if the foil be any thing good, you may put sticks of Elder, or truncheons ten or twelve feet long, fopeways in your banks, so as to make a chequer-work, and they will make a fence for a garden the quickest of any thing, and be a good shelter. But these fences are improper for a fine garden, because they shoot very irregular, and are ungovernable; as likewise the roots of these trees spread very far, and draw away all the heart of the ground, so as to starve whatever plants grow near them: and add to this the scattering of the berries, which will fill the ground near them with young plants; which, if not timely weeded out, will get the better of whatever grows near them, therefore this sort of fence is seldom planted, where a hedge of White Thorn can be had.

Elder planted on a bank, the side of which is washed with a river or stream, will make an extraordinary fence, and will preserve the bank from being undermined by the water, because it is continually sending suckers from the roots and lower branches, which is of great advantage where the stream washes away the bank. For middle fences in a garden, the Yew is the most tonfick, governable, and durable plant.

For surrounding wilderness quarters, Elm, Lime, Hornbeam and Beech, are very proper,

FENNEL. See FOENICULUM.

FENNEL-FLOWER. SCCNIOELLA.

FERRUM EQUINUM. See HIPPOCRIPIS.

FERULA. Lin. Gen. Plant. 305. Tourn. Inf. R. H. 321. tab. 170. [takes its name of Ferendo, Lat. because the stalks of this plant are made use of in supporting the branches of trees; or of Feriendo, because in old time sticks were made of them, with which school-masters used to correct their scholars.] Fennel Giant, in French, *Ferule*.

The CHARACTERS are,

// bath an umbellated flower \ the principal umbel is globular, and is composed of several called rays, of the same form; the involucre is composed of several narrow leaves which fall off \ the principal umbel is uniform. The flowers have five oblong erect petals which are equal, and five filaments of the same length* terminated by single summits \ under the flower is situated a turbinated germ, supporting two reflexed styles, crowned by obtuse stigmas. the germ after ward becomes an elliptical, compressed, plain fruit* dividing in two parts, each having a large elliptical plain seed* marked with three lines on each side*

This genus of plants is ranged in the second section of Linnaeus's fifth class, intitled Pentandria Digynia, which contains those plants whose flowers have five stamens and two styles.

The SPECIES are,

- * FERULA (*Communis*) foliis linearibus longissimis simplicibus. Hort. Cliff. 95. *Ferula with the smaller leaves, very narrow, long* and single.* *Ferula major, seu femina Plinii.* M. Umb. *PUnfs Female Fennel Giant.*
- * FERULA (*Galbanifera*) foliis multipartitis, laciniis linearibus planis. Hort. Cliff. 95. *Ferula whose smaller leaves are divided into many narrow parts which are plain.* *Ferula galbanifera.* Lob. Obs. *Galbanum-bearing Fennel Giant.*

3- FERULA (*Tingitana*) foliis laciniatis, laciniis tridentatis inaequalibus. Hort. Cliff. 95. *Ferula whose smaller leaves are cut, and segments ending in three unequal parts.* *Ferula Tingitana** folio latissimo lucido.

Edin. *Broad-leaved shining Fennel Giant from Tangier.*

4. FERULA (*Ferulago*) foliis pinnatifidis, pinnis linearibus planis trifidis. Hort. Cliff. 95. *Ferula with wing-pointed leaves, whose pinnae are narrow, plain, and trifid.* *Ferula latiore folio.* Mor. Hist. 3. p. 309. *Fennel Giant with a broader leaf.*

5. FERULA (*Orientalis*) foliorum pinnis basi nudis, foliolis fetaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves naked at the base, and the smaller leaves bristly.* *Ferula Orientalis, Cachyros folio & facie.* Tourn. Cor. 22. *Eastern Fennel Giant with the leaf and appearance of Cachyros.*

6. FERULA (*Meoides*) foliorum pinnis utrinque basi acutis, foliolis fetaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves pointed at their base on every side.* *Laierpitium Orientate mei folio, flore luteo.* Tourn. Cor. 23. *Eastern Laferwort with a Spiguel leaf and yellow flower.*

7. FERULA (*Nodiflora*) foliolis appendiculatis, umbellae subsessilibus. Lin. Sp. Plant. 247. *Ferula with appendages to the smaller leaves, and umbels fitting close to the stalks.* *Libanotis ferulae folio & femine.* C. B. P. 158. *Libanotis with a Fennel Giant leaf and seed.*

8. FERULA (*Glauca*) foliis supradecompositis, foliolis lanceolato-linearibus planis. Hort. Cliff. 95. *Fennel Giant with linear, spear-shaped, decomposed leaves** *Ferula folio glauco, femine lato oblongo.* J. B. 3. p. 45.

The first of these plants is pretty common in the English gardens; this, if planted in a good soil, will grow to a great height, and divide into many branches: the lower leaves of this sort spread more than two feet every way, and branch but into many divisions, which are again subdivided into many smaller, garnished with very long, narrow, small leaves that are fine, they are of a lucid green, and spread near the ground. From the center of the plant comes out the flower-stalk, which, when the plants are strong, will be near as large as a common broomstick, and will rise ten or twelve feet high, having many joints* if the stalks are cut, there issues from the joints* a foetid yellowish liquor, which will concrete on the surface of the wound. The stalks are terminated by large umbels of yellow flowers, which come out the latter end of June, or in the beginning of July; these are succeeded by oval compressed seeds, which have three lines running longitudinally on each side. These ripen in September, and the stalks decay soon after. When the stalks are dry, they are full of a light dry pith, which will soon take fire.

Mr. Ray says, that the people of Sicily use the pith of this plant for tinder to light their fires. And if this was practiced by the ancients, we may easily guess why the poets feigned, that Prometheus stole fire from heaven, and carried it to the earth in a hollow

Fertile.

The leaves of these plants decay soon after the seeds are formed, so that before they are ripe, there are seldom any leaves remaining, and the stalks afterward dry and become very tough; so it is not unlikely these may have been used for correction in the schools, as they are very light, and cannot do much injury. The roots of this sort will continue several years, especially on a dry soil, and will annually produce flowers and seeds.

The second sort doth not grow quite so large as the first; but the stalks of this will rise seven or eight feet high: the lower leaves are large, and greatly divided; the smaller leaves are flat, and not so long as those of the former, and are of a lucid green colour; the upper flowers are smaller, and the seeds are less. This flower and ripens its seeds about the same time as the former sort.

The third sort hath large spreading leaves near the top which are divided and subdivided into many small parts; the small leaves of this are much broader than those of the other sorts, and these are divided at the end into three unequal segments; the leaves are of a very lucid green. The stalks are strong, and rise to the height of eight or ten feet, and are terminated by large umbels of yellow flowers, which are

These plants glow naturally at the Cape of Good
 Hiiip-, die roo) of the frii fort were lenr me by
 I Jr. Joh iiiti-r, of Z irk zee, who received them from
 the Cope. The root of this is flapsd like that of
 the Bizamine Cornfhg; it has a bright brown fkin
 or cover •, on the upper fide is a hollow like a navel,
 from whence the ilcjuer-lalt. IR&S. The {talk fifes
 a root and a half high, and it alxiut tin- lie of
 a man's middle finger, gttmtflicd with liaves tin • hole
 length; tliclc arc licci-ihayrtt, (-nibracini; the ftalks
 with their bile. Thvirpper • art of the ftalk divides
 into 1 wo or itire branches, v titch ate gsj flicd
 with the lin:<-il;il" d kawes, but they are finaltr ^
 each ut the branches are terminated by- a brae Jfi-
 rh:t or (heath of tlic fame • low with the leaves,
 but this afterward withers and decays i dide (heathi
 arc double, and fptii at tht top, wlvre the flower
 peeps out its petals; thefe fix pct^U art three alter-
 nately target than die otlu-r, ami are ainouSy fringed
 on their bonieni they are of a pale grcmfh colour
 on their outfidc, but of a ti.ney purple within, and
 are of a lhnrt dbnuon ; in the centre of il:c flower
 is Gtumd the ilylf, having 1w three flans in (ixed
 on the fide, and is terminated by twin itirinas ; the
 germ en is fituaid unde! the Sower, which after-
 ward become* u oblong fmooth capite with tiirec
 eclh, filled with ruundilh (beds.

The fecond! fort is rare in England ; this differ . from
 the former in having fmallerVoots, and longer fwood-
 (liapcl) leaves, which have deeper veins ; the ftalk
 allb docs nut divide fo mucli, and tlic flower arc
 lmalicr, and Ms fiinged on their borden.

They aie: both progagated by tiffets lent out from
 tlic rooa, ir; the fmmt way as du; Ixia, and friduld
 be cultivated in the fame manner as is din:fttd for
 tlmcl and the Africin Gladiolus, btin^ 100 tender
 to luive in the open air in England, nor do ti,ey fuc-
 ceed well in a green-K... therefore the belt me-
 thod U, to make 1 buidrr tour (<t widr. 'i-ihcr in
 the firmt of the peei-ihouft 'Jl^ B>va, covering it
 with • proper frame and gaffirs, ib that die plants
 may enjoy die free air in mild weather, but by pro-
 tected from froft. In Inch a frame, moft of the Afri-
 can bulbous and ruberous rooted plants may be
 brought to great perfe: hon.

There a a great (ir:ulariry in the root of ti- firt
 fpecies, which is in i: vegetating only evry other
 year, and ihe intrme! the year it remains at reft.

were few who troubled... dicnifelvc!
the culture of it.
But four years past I had a large collection of these
trees sent me from Venice, by my botanical friend
the Chei alier Radegh, which I planted and pre-
ferred to taste of their fruits, several of which proved
cxcelk-nti tStfe I have pri
ferred and propagated,
and thtjlc 1
these fruit were inferior have been ne-
glected. And as the variety of them u very j...
lo I Elnll here mention oni... ir:m as are t
the bell wyrdi tul... placing... licm iti the
order of their rip... i(i)g.

1. The brown or Chefnut coloured Ilchia Fig. This
is th« lar... fruit of any I have >t ken. it 1
short,
globular, with a pretty lJ> 1 eye, pushed in tear th-
toot-ft a lk, of 3 brown or Chetnnt colour on ••
outside, am! purple within; the grains ate large, and th<
pulp sweet and lig: : Eavouredj th
lost berry often
bun- open when it
tpeta. it ripitiis the latter end
of July, ur tht beginning of Auguft; .I hare ha
this fruii riprtt well on Ibdards, l: a warm soil. If
this lost i... againtt hut wall... two plentiful
crops of fruit may be annually rip • ncd.

.. The black (icitoa Fig. Thi% Is alongfrus'. which
fwctls pretty large at the mp what it tsol... but
the lower part is very (ender tow'rd the itii
the fkinkofa Jark purple colour, alnioftbhck, and hath
ipurplefariniovct 11 like ttail on... one Plum* ; the
iniidv is of a bright red, and the flesh is very hia
Savoured. Itripou l arly in Auguft.

3. Tire linal! wriite early Fig. This hatii 1
roundish
fruit a lk tie flat toil at the crown, with 1 l'try
short
fixM-talk ; tht (kin, when fully ri:
is of a pale yel-
lowish,
lowthf -white cuLur-, thir fkiti is [hin, ihein/ide
and tht (Vlh Iwtit, but fiot liigli-Jlavoured. This
ripens in Auguft.

4. The large while Genoa Fig. This is a large gl-
bular
fruit, a little lengthened toward ilie (blk; t
(kin is thin, fit a yeliowUh colour when fully rip-
and red within-" i h b is a gtxxl fruit, but the l'recs
are not yuod beart-n.

5. The blick Ifchin Fig. Tha is a short fruit, of
a middling liar, a little ll-ituil ai the crown ; l'
thin
it ilmofl black when ripe, and the inGdc iaofade
red; l he flJb is very ht^ri fivouand, and the trees
[luxiitce a ^aod crop of fruii, bur the birds arc ^eat
ourers of diem if they are hot preceded i'ron
thenv This ripen> ii' Augoft.

6. Tht Malta tig. This h a fnial brown fruit,
much toinprllu'il at the top, and gready pint!
toward the foot-ttalk s the ikin is of a pal-
brown col-
our, as is also the inside; the Belfi is very lwee, and
well flavoun • If this •!! is permitted to hang up on
the in... till the !* is (hrivelled, it becomes j !
sweetmeit.

7. The Murry, or brown Naples Fig. This U 1
pretty large globular
fruit, of a light brown colour
on the outside, with finit faint marks »i' t din
white, ill' inside is rwwly °f the fume colour; th
grains are pretty large, and the flesh is well flavoured.
It ripens... lactr end of A;.

S. The fr«n 1 this Fig. This is an
iblong fruii
almolt glabular at the crown, tli kin is t->, of
green colour, but wht
is a fully ripe, it is flamed
through by the pulp... 1 u brownifn cult; the hntdc i
purplt
and will stain linen, or paper... firipV
high l' avoured, especially in warm seasons.
toward the l... of Auguft.

The Madonia Fig, commonly cilled her* the
irunfricll; • or Hanover Fig, is a long, pyriform fruit
of a large size; the skin is brown; the flesh is of a
lighter brown colour, coarse, and hath little fl-
avour.
This ripens rhe ci... of Auguft and the beginning of
September;

September-, the leaves of this fort are tnilchmorcdi-
victed than of moft other.

10. The common blue, or purple Fig is fo well
known, as to need no ddfcription.

11. The long brown Naples Fig. The leaves of
this tree are deeply divididL The fruit is long, some-
what comprtled at the crown. The foor-llalks arc
pretty long ; the (kin is of a dark brown when fully
ripe, the **Hem** inclining ro red ; the grains are large,
and [lit fieth veil flavoured. It ripens in September,
iz. The yellow Ifchia Fig. This is a large fmir,
of a pyramidal form ; the (kin is yellow when ripe,
and the tkh is puqilc and well flavoured, but die
trees do not produce much fruit here; they grow
very luxuriant in branches, the leaves are very large,
and not much divided. This ripens in September.

13. The (mall Brown Ifchia Fig. This is a fmall
pyramidal fruit with a very fbot foot-llalk i the (kin
is of a light brown, the fich indining io purple, of
3 very high flavour ; it ripens late in September -, die
leaves of this tree arc Ids divided than any of the
other forts. This is not a gtxxl bearer.

14. The Gentile Fig. This is 2 middle fized globu-
lar fruit; the fkin, when ripe, ii yellow; the flefh
alfo inclines to the lame colour; the grains arc large,
and the tlich is well flavoured, but it ripens very late,
and the trees are bad bearers, fo that it is not propa-
gated much in England.

There arc feveral other fora which have been lately
introduced from Italy, but all thofe which I have yet
tafted, are inferior to thofe above-mentioned; form:
of them rarely ripen their fruit, and others art very ill
bearers, **not** worth propagating, therefore I have
omitted the mentioning of them here; for as thole
which are enumerated, continue in fuceffion during
the feafon for dicfe fruits, and being preferable to the
other, few perfbns will tare to fill their gardens with
a greater variety of thefe trees than arc of real ufe,
efpecially 35 they require good wails, and a very large
(hare of room.

The firft, fecond, third, ninth, and tenth forts will
ripen their fruits on ftsndards, where they are in a
warm fituation ; but the others require the affiftance
of wails expofed to good afpefts, othcrwife their fruit
will not ripen in **England**.

Fig-trees generally thrive in allfoils, and in every
fituation ; but they produce a greater quantity of fruit
upon a ftrong loamy fult, than on dry ground, for if
the feafbn proves dry in May and June, thofe trees
which **grtw upon very** warm dry ground, are very fub-
jeft to call **their fruit** ; therefore, whenever this hap-
pens, fuch trees fhould tw well watered and mulched,
which will prevent thefruit from dropping offi and the
fruit upon thefe trees are better flavoured, than any of
ihofe » hich grow upon cold moift land. I have al-
ways obferved thofe Fig-trees tobcar the grateft quan-
tity of well-flavoured fruit, which were growing upon
chalky land, where there has been a foot or more of
a gentle loamy foil on the top. They ilfb love :i **free**
Open air ; for although they will (hoot and thrive very
lvill in clofe places, yet they feldom produce any
fruit in fuch rtuationi; and all dioie which are planted
in fmall gardens in London, will be well furnifhed
with leaves, but I have never fetn any fruit upon
them which hive grown to maturity.

Thefe trees **arc** always planted as ftandards in all
warm countries, but in England they are generally
planted ayainit wails, there wine bvit few ftandard
Fig-trees it prefcem in the F.ngliOi **gardens**; however,
fince Ionic or the forts are found to ripen their fruit
well upon **the (tawdirds**, and the crop of Figs is often
greater upon them, than upon thofe trees againft wails,
it h worthy of our care, **to plane** them either in ftan-
dards or cfpidiers; the latter, I think, will fucceed bell
in England, if I he y were managed as in G enn in y, ivl ic re

litter, which prevents their fhoots being injured by
the froft ; and this covering is taken away gradually
in the fpring, and nut wholly removed **until** all the

danger of froft is OVCT, by whiili management they
generally have a very great crop of Figs I whei
England, **where the** trees grow againft warm wails, in
the fpring proves warm, the young Figs are pufhe
out early, and rhe cold, which frequently return* i
April and May, caul« the grateft part at tilt fruit to
drop off; fo that our crop of Figs is generally more
uncertain than mod other forts of fruit; audit in-
quandy happens, that trees which arc planted againft
north and eail-alpeited wails, produce a greater
quantity of fruit in England, than thole **which** ate
planted againit fouth and faurji-c>ft afpeeli ; which
n-ift happen from die latter putting out their **fruit fo**
much earlier inthe fpring than the former; and if there
happen cold trolly nights after die Figs are come osit
(which ii frequently the cafe in this country) the fir-
wardelt of the Figs are generally fo injured as to drop
olf from die trees Toon after. In Italy, and the other
warm countries, diisfirt crop of Figs is little regarded,
being few in number ; for it is die fecond crop of
Figs which are produced from the (boots of the fame
year, which k their principal crop, but theic rarrly
ripen in England ; nor arc there above [hrec or four
(**aro whichever ripen** their fecund crop, lei the fummer
prove ever to good, therefore it is the firft crop which
we muil attend to in England; (b that when **thefe** trees
are growing againft the belt aiptcted wails, it will be
a gxxd method to loofen them from the wall in au-
tumn •, and **after** having diverted the branches of **all**
the latter fruit, to by die branches down from the
wall, (aliening them together in fmill **bundles**, So that
they may be tied to rtakes, to keep them from lying
upon the ground i the damp whereof, when covered
in fruity weather, might CHft them to grow mouldy,
and hereby [fity will be fecurd from being broken by
the wind. When they arc thus managed in autumn,
if the winter fhould prove very levcre, die branches
may be eafily covered witi Pcas-haulm, ftraw, or any
other light covering, which will guard the tender fruit-
bearing branches from the injury of froft; and when
the weather is mild, die covering mult be removed,
otherwife the Figs will come out too early; for the
intention of this management is, to keep them as back-
ward as poffible : then in the fpring, when the Figi
are beginning to pufh out, the trees may be fattened
up co the wall again. By this management I have
fetn very great crops ol Figs produced!!] two or three
places.

I have alfo fcen great crops of Figs in fome particu-
lar gardens, after very [harp winters, when they havr,
in general, failed in other places, by covering up
the trees with Heeds made into pannds, and fixed up
againft the wails.

In the pruning of Fig-trees, the branches mult never
be fhortened, becaule the fruic arc all produced at
the upper part of the (hoots of the former ycr; if
dicfe arc cue off, there can be no fruit expected, betide
the branches arc very apt to die after **the Knife**; fu that
whet the branches are **too** dole together, tin-heft way
is to cut out all the **naked** branches ejuit to the bot-
tom, leaving thofe whichare bell fuinifhed with lateral
branches at » proper diltance from each other, **which**
fliuukl not be nearer dian a foot; and when they **are**
well furnifhed with lateral branches, if they are laid
four or five inches farther aiunder, it will be better.

The belt lealon for pruning of Fig-trees is in autumn,
[ircailit: at that time the branches are not ly full
of Jap, and will not bleed fo much, as when they
are fprung in the fpring -, ant) at this lea ion, the
br.indies (hould be diverted of all the autumnal Figs,
and the fooner diis is done, when the leaves begin to
i'A off, the better will the young fhoots refill the cold
of the winter. There are lbme fcaloni fo cold and
iiHjilt, that the youag (hoots of the Fig-trees will nut
harden, but arc (oft, arJ full of juice; when this hap-
pen-, there is little hope of a crop of Fias the lucced-
ingyear, for the firft froft in autumn will kill the upper
part of thefe [hoots, for a confiderable length down-
ward j whicnever diii happen..., it is the bed way to
cut off all the decayed part 0!! the fhoots, which **will**

prevent

...the lower part
 nitr brandies; and, byth. method. Mmve ften a
 put ovit from Ac lower part of
 the lioiiv •, where, ii ihc llooces had not been ii
 theti • could be •: been no fruit produced, becaufe it
 in chittiy from the four or fire uppicimoltjoiik of the
 (hocN that the fruit com'ts <ut, and r is in this
 rait. I hit as • any of the lliorf lareral b.:
 ihould be preferved as poffible, thole bring the
 productive of fruit; thr where the
 •ur l-iAcoci up, there will be no fruit, but at their ex-
 tremities, fa chut ail thil' lower part of the trcM will
 be naked, if there is not a particular regard had to
 Luppy young ljitwts in cvci-y part of the trees.
 Tinjic trees vvhich are laid down fi on the epalier,
 fhould not be fattened up again til the end of March,
 for rlie rcafoiie before given, and thofc agsuntt walls
 nay cenwin force time longeri and when the lurge
 (hoots of t tefer art nailed u i •: i • «nchci
 arc thruft behind thcle, i» kc
 ii w i II feeu re the young Fig* i rom I i by tl ic
 morning frofts-, and when thi
 r, they
 m ay be trough t forward to th •: tgain:
 during the funimer feafon tin
 other pruninc, but to ilop the (hoots in the Ipring,
 where utr.il branchB are naming-, andas thebranches
 are often blown down by wind, therefore, whenever
 thb hapiwts they iVinuld be imtticidinyfatr;;
 again, otherwiiu they will be in thngcr of breaking ;
 for the leaves of thec trues being very large ai •
 the wind has great power on them •. Ib thnt where
 the branches are not well fccurt'd, they are frequently
 >rnw.

Those trees which art planted againft epaliew may
 heprottae'd from the injury of froft in ihefps: by
 plating Rev!?' on each fide the efpalier, whidi may \K
 taken down every day, and put up again at night but
 this need not be Prattifed in warm weather. In only
 at fuch times as there ore cold mods ind
 morningi •, and although there ii feme traubtc and
 expence ftanding this management, yet the plentiful
 crop of ligit vruch may this way be obtuined, will
 fufnci^ntly rcompc-nfe for both: the belt way of
 making this covering is, to laflen the Reeds with
 ropf yarn in fudi a manner as that it may be
 rolled up like a mat, that the white may with
 great facility:— is_ m -ralten down i anil if thec
 Reeds are carefully rolled up, after the feafon for using
 them is over, and put up in a dry thcd, they will laft
 feveral years.

There are feveral perfons who of late have planted
 Fig-trees in fland JS which h, observing f
 this practice was revived, observing f
 ftandard Fig-trees in fome garbns, which had been
 growing many years, and generally produced a much
 greater plenty of fruit: iluTi any of thole tree^
 were growing againft warm walls; indeed, thec ftand-
 ard Fig-trees are in much greater danger of having
 their branches killed by fevere ftqft, but in
 ters they generally do better than thofe againft walls,
 fo that where thofe trees can be covered in very hard
 winters, there will always be plenty
 thefc may be covered by fattening as
 the branches together as can be convenient lybrougl
 a bundle, and winding fome Hay-bands, Straw, Pea-
 hauler, or any fuch light covering as can be readily
 rd, which in the fpring may be g
 as not to expofe the fhoots all
 is, and if there is fome fuch light covering laid
 round the ftems, and upon the furface of the ground
 about their roots, it will more effectually fecure them
 from the danger of froft; but when this is carried,
 great care fhould be taken that no mix. ^P «. h,r-
 bou, :: the covering, .-II h . a • I have often
 from their fhoots, and have
 obferved thofe trees which were againft walls, have
 fuffered gre«ly! by thofe vermins, by having many
 of their ligit branches difburked near the ground,
 which has abfolutely killed the trees. It is in
 the winter the

Or"ittirf
 • thrlc vrri l l milCniel

them, therefore they (hould be carefully watched
 at hai ffafon.
 The common blue and white Figs, which are the
 forts which have been the moft generally cultivated in
 England, jvr not ib proper I o plant for ftandards, as
 fome other forts which have been lately introduced;
 forihy ^rt mudi tenderer, and art often killed almoft
 to the r'ut, when Ibirc • the other forts, which have
 twer, growing in the fame iituation, have received very
 bttle injury from the fruit i ind> • the white fore i
 generally a great bearer, and the I out is very fweet;
 but to thofe ptkqeiwhj h are accuftomed to Figs, that
 liirt it not much in eftcm, from its want of favour:
 thofe which have fucceeded belt with me, ire I
 and third forts. The fir brandies are rarely I
 froft: w Mer, and their fruit will : \\
 form favourable k::ttns, m?.nyntf
 were growing againft walls, have ripened the fecond
 crop of fruit tolerably well. I have alfo planted many
 of thofe forts of Fig-trees againft north-eaft and
 north-weft atpefls, ftme of I
 planted, have produced a good quantity of well ta(k
 fruit, but were ripe much iwer, which has tl
 me to plant many more of thofe trees in the fame al-
 pefti and all ufo inc. reafciuy number of ilandard trees.
 I am aware, that what I have here advanced, inttla
 tion to the •.iiiiig »:d drefTi
 of Fig-trees, will be
 condemned by great numbers • of people, who will not
 give if' mtefces time to coniiicicrandi
 kJW upon which I have founded thi3pmfti
 make one (ngle experiment to try the truth of it,
 being vafly di Re rent from the general
 gardener, i, who always imagine, that tig-tttet flou
 never have much pruning-, or, it Scalt, that Elmvilioi
 fltways be luffered to grow very rude from the wal
 to fume tl i": ince. That by ihts management i liave <
 am fe n grtat quantities of fruit I cannot deny, b
 rlim tins has been only after mild ts
 ruin, that in tiurp froffa rew of it.
 ihoots cfc.ije being gre;i:
 injured where they are not
 covered; wh
 which are cli-
 down and covered, fuffer the •• damage and tl;
 fruits are always produtcl a fotnighi loimer up
 theft brtnche
 than they are upon thofe which grow
 from the wall: but although :
 h »re lu
 feed 10 grow rude from the walti may produce a got
 quantity of fruit for a year or two, yet affci
 trees will only befir at the ends of trie ft:
 ••
 ll it; nor can the ••
 be reduced again
 to any crop. LirUy, without cutting away the grea
 their branches, b] which a year or two
 will be 1A before they will Lome to licar again.
 The frafan alfo for pruning, which I have laid down,
 brim- vafly diffe rent from the common practice and
 opinion of moft gardeners, will alib bt objecl'd aHaint-

lumn fliall be found to (lop its bleeding in one day's time, or less ; whereas that cut in the spring will often flow a week or more, and the wound will be proportionably longer before it heals.

Of late years there has been some of these trees planted against fire-walls, which have succeeded very well where they have been properly managed; but where they have been kept too close, and drawn by glasses, they have not produced much fruit; therefore whenever this is practised, the heat should not be too great, nor the glasses, or other covering, kept too close, but at all times, when the weather is favourable, a good (hare of free air (ould be admitted ; and if the trees are young, that their roots are not extended beyond the reach of the covering, they must be frequently watered when they begin to shew fruit, otherwise it will drop off; but old trees, whose roots are extended to a great distance, will only require to have their branches now and then sprinkled over with water. If these trees are properly managed, the first crop of fruit will be greater than upon those which are exposed to the open air, and will ripen six weeks or two months earlier, and a plentiful second crop may also be obtained, which will ripen early in September, and sometimes in August, which is about the season of their ripening in the warmer parts of Europe; but the fires should not be used to these trees till the beginning of February -, because when they are forced too early, the weather is frequently too cold to admit a sufficient quantity of fresh air to set the fruit; but the covers should be put over the trees a month before, to prevent the shoots from being injured by the frost.

It may not be improper in this place to mention the great pains which the inhabitants of the Levant are at in the culture of their Figs ; and without which (it is generally said by all the travellers who have written on this subject, as also by Pliny, and other old naturalists) their fruit will fall off, and be good for nothing. I shall here set it down, as I find it in the travels of Monf. Tournefort, chief botanist to the late king of France.

" Pliny, says he, observed, That in Zia they used to dress the Fig-trees with much care *, they still continue to do so. To understand aright this husbandry of Figs (called in Latin, Caprificatio) we are to observe, that in most of the islands of the Archipelago, they have two sorts of Fig-trees to manage; the first is called Ornos, from the old Greek, Erinos, a wild Fig-tree; or Caprificus, in Latin; the second is the domestic, or garden Fig-tree -, the wild sort bears three kinds of fruit, Fornites, Cratitires, and Orni, of absolute necessity towards ripening those of the garden Fig.

The Fornites appear in August, and continue to November, without ripening *, in these breed small worms, which turn to a sort of gnats, no where to be seen but about these trees. In October and November these gnats of themselves make a puncture into the second fruit, which is called Cratitires, and do not shew themselves till towards the end of September; and the Fornites gradually fall away after the gnats are gone; the Cratitires, on the contrary, remain on the tree till May, and inclose the eggs, deposited by the Fornites, when they pricked them. In May the third sort of fruit begins to put forth from the same wild Fig-trees which produced the other two; this is much bigger, and is called Orni; when it grows to a certain size, and its bud begins to open, it is pricked in that part by the gnats of the Cratitires, which are strong enough to go from one fruit to the other, to discharge their eggs.

It sometimes happens, that the gnats of the Cratitires are (low to come forth in certain parts, while the Orni in those very parts are disposed to receive them; in which case the husbandman is obliged to look for the Cratitires in another part, and fix them at the end of the branches of those Fig-trees, whose Orni are in fit disposition to be pricked by the gnats

" if they miss the opportunity the Orni fall, and the gnats of the Cratitires fly away. None but those that are well acquainted with this sort of culture know the critical minutes of doing this; and in order to it, their eye is perpetually fixed on the bud of the Fig ; for that part not only indicates the time that the prickers are to issue forth, but also when the Fig is to be successfully pricked ; if the bud be too hard, and too compact, the gnat cannot lay its eggs, and the Fig drops when this bud is too open.

These three sorts of fruit are not good to eat; their office is to help to ripen the fruit of the garden Fig-trees, in manner following: during the months of June and July, the peasants take the Orni at a time that their gnats are ready to break out, and carry them to the garden Fig-trees; if they do not nick the moment, the Orni fall, and the fruit of the domestic or garden Fig-tree not ripening, will, in a very little time, fall in like manner. The peasants are so well acquainted with these precious moments, that every morning, in making their inspection, they only transfer to their garden Fig-trees such Orni as are well conditioned, otherwise they lose their crop. It is true, they have one remedy, though an indifferent one, which is, to sweep over the garden Fig-trees the Acolimbros, a very common plant there, and in whose fruit there is a sort of gnats proper for pricking; perhaps they are the gnats of the Orni, which are used to hover about and plunder the flowers of this plant.

To sum up all in one word, The peasants so well order the Orni, that their gnats cause the fruit of the garden Fig-tree to ripen in the compass of forty days. These Figs are very good green *, when they would dry them, they lay them in the sun for some time, then put them in an oven to keep them the rest of the year. Barley bread and dried figs are the principal subsistence of the boors and monks of the Archipelago; but these Figs are very far from being so good as those dried in Provence, Italy, and Spain ; the heat of the oven destroys all their delicacy and good taste, but then, on the other hand, this heat kills the eggs which the prickers of the Orni discharged therein, which eggs would infallibly produce small worms that would prejudice these fruits.

What an expence of time and pains is here for a Fig, and that but an indifferent one at last! I could not sufficiently admire the patience of the Greeks, buffed above two months in carrying these prickers from one tree to another. I was told the reason, one of their Fig-trees usually produces between two and three hundred pounds of Figs, and ours in Provence seldom above twenty-five/ The prickers contribute, perhaps, to the maturity of the fruit of the garden Fig-tree, by causing them to extravasate the nutritious juice, whose vessels they tear asunder in depositing their eggs *, perhaps too, besides their eggs, they leave behind them some sort of liquor proper to ferment gently with the milk of the Fig, and to make their flesh tender. Our Figs in Provence*, and even at Paris, ripen much sooner for having their buds pricked with a Straw dipped in olive oil. Plumbs and Pears, pricked by some insects likewise ripen much the faster for it; and the flesh round such puncture is better tasted than the rest. It is not to be disputed but that considerable change happens to the texture of fruits so pricked, just the same as to parts of animals pierced with any sharp instrument.

It is scarce possible well to understand the ancient authors who have treated of caprification (or husbanding and dressing the wild Fig-tree) if one is not well apprised of the circumstances, the particulars whereof were confirmed to us not only at Zia, Tinos, Mycone, and Scio, but in most of the other islands.^M

F I C

Fig-trees are propagated in England, either by the flickers, which are sent out from their roots, and by layers made, by laying down of their branches, which in one year will put out roots sufficient to be removed, or by planting of cuttings, which, if properly managed, will take root* the first of these is a bad method, because all those trees which are raised from suckers, are very subject to send out great quantities of suckers again from their roots; and the branches of the suckers are not so compact, as those of the layers, but are fuller of sap, so in greater danger of being injured by the frost, those plants which are propagated by layers, are the best, provided the layers are made from the branches of fruitful trees; for those which are made from the suckers, or shoots, produced from old stools, are very soft, and full of sap, so are in danger of suffering by the frost, and these will shoot greatly into wood, but will not be very fruitful; for, when trees * have acquired a vicious habit while young, it is seldom they are ever brought to be fruitful afterward, therefore the shoots which are laid down, should be such as are woody, compact, and well ripened, not young shoots, full of sap, whose veins are large and open. The best time for laying down of the branches is in autumn; and if the winter should prove very severe, if they are covered with some old tan, or any other mulch, to keep the frost from penetrating the ground, it will be of great service to them; by the autumn following, these will be sufficiently rooted for removing, when they should be cut off from the old plants, because at that season the branches are not so full of sap as in the spring, so will not bleed so much as when cut off in the spring. If the place is ready to receive them, the layers should be transplanted in autumn, where they are to remain, but if it is not, then the layers may remain till the spring, provided they are separated from the old plants in autumn. As these plants do not bear transplanting well when they are large, it is the better way to plant them at first in places where they are to remain* and after they are planted, the surface of the ground about their roots should be covered with mulch to keep out the frost; and if the winter should prove very severe, it will be proper to cover the branches with Reeds, Sea-haulm, Straw, or some other light covering, which will prevent their tender ends being killed by the frost, which frequently happens where this care is wanting.

The other method of propagating these trees, is by cuttings, which should be taken from the trees in autumn, for the reason before given: these must be chosen from such branches as are compact, whose joints are near each other; and they should have a part of the former year's wood at their bottom, and the top of each should be left entire, not shortened as is usually practised with other cuttings; then they should be planted eight or nine inches deep, in a bed of loamy earth, in a warm situation, covering the surface of the ground, three or four inches thick, with old tanner's bark, to keep out the frost; and in severe frost their tops should be covered with Straw, Peas-haulm, Fern, or other light covering, to protect them from frost, which should be removed in the spring; but the tan may remain, for that will prevent the drying winds of the spring, and the sun in summer, from penetrating the ground, and will be of great use to secure the cuttings from injury; these cuttings will be rooted sufficiently by the following autumn, when they should be transplanted, and treated in the same manner as the layers.

If fruitful branches of these trees are cut off, and planted in pots, or tubs, filled with good earth, and these are plunged into a good hot-bed of tanners bark in the stove, they will put out fruit early in the spring, which will ripen in the middle of May.

We shall now return to the other sorts of Figs, which grow naturally in warm countries, but are preserved in the gardens of those who are curious in collecting rare exotic plants, for these do not bear eatable fruit in their native soil, but their leaves being large and

F I C

beautiful, the plants make a pleasing Variety in the stove.

The second sort grows naturally in the Levant, where it becomes a large tree, dividing into many branches, which are garnished with leaves (shaped like those of the Mulberry, and affords a friendly shade in those hot countries. The fruit is produced from the trunk and larger branches of the tree, and not on the smaller (shoots, as in most other trees; the shape is like the common Fig, but is little esteemed. This is called the Sycamore, or Pharaoh's Fig-tree.

The third sort grows naturally in India, where it is sacred, so that none dare destroy them; it is called by some the Indian God-tree, this rises with a woody stem to a great height, sending out many tender branches, which are furnished with smooth heart-shaped leaves, ending in a long tail, or point; they are entire, smooth, and of a light green, having pretty long foot-stalks; they are between six and seven inches long, and three inches and a half broad toward their base, diminishing gradually to the top, where they run out in a narrow point, an inch and a half long. The fruit comes out on the branches, which are small, round, and of no value.

The fourth sort rises with many stalks, which grow to the height of thirty or forty feet, dividing into a great number of branches, which send out roots from their under branches, many of which reach to the ground; so that in such places where the trees grow naturally, their roots and branches are so interwoven with each other, as to render the places impassable. In India, the Banyans trail the branches of these trees into regular archades, and set up their pagods under them, these being the places of their devotion. In America, where these trees are equally plenty, they form such thickets, as neither man nor beast can pass through. The leaves of this sort are of a thick substance, smooth, and oval; they are six inches long, and four inches broad, with obtuse ends. The fruit is the size of a marble, and round, but of no use.

The fifth sort grows naturally in both Indies; this rises with a woody stem to the height of thirty feet, sending out many branches, which are garnished with oblong leaves hanging upon pretty long foot-stalks; they are about six or eight inches long, and two inches and a half broad, ending in an obtuse point, of a dark green, and smooth on their upper side, but of a light green, and veined on their under side. The fruit is small, and of no value. The branches of these trees send out roots from their lower side, which sometimes reach the ground.

The sixth sort grows naturally in the West-Indies, where it rises to the height of thirty or forty feet, sending out many tender branches, which put out roots in the same manner as the former. The leaves of this are eight or nine inches long, and two inches broad, ending in points. The fruit is small, round, and of a blood colour when ripe, but is not eatable.

The seventh sort grows naturally in India, where it rises to the height of twenty-five feet, and divides into many branches, which are garnished with oval-pointed leaves, which are smooth, and of a lucid green. The fruit is small, and grows in clusters from the side of the branches, these are not eatable.

The eighth sort grows naturally in India; this is a low trailing shrub, whose stems put out roots at their joints, which strike into the ground, so is propagated plentifully where it naturally grows. The leaves are two inches and a half long, and near two inches broad, ending in points; they are of a lucid green, and are placed without order on the branches; the fruit is small, and not eatable.

The ninth sort rises with a strong, upright, woody stem twenty feet high, sending out several side branches, which are furnished with large, oval, stiff leaves, about fourteen inches long, and near a foot broad, and are rounded at the ends; they have several transverse veins, which run from the midrib to the sides. The foot-stalks are long, and frequently turned next to the branches; the upper side of the leaves

F I L

kaves are of a lucid green,¹ and the under fide is of a gray, or sea-green colour, they are of a thick substance, and very smooth; this grows naturally in India, from whence it was brought to the gardens in Holland.

The tenth fort grows naturally in the West-Indies, where it rises twenty feet high, lending out many fide branches, which are covered with a white bark, and garnished with oblong heart-shaped leaves, ending in acute points, they are about three inches long, and one inch and a half broad, near the base of a lucid green on their upper fide, but of a pale green on their under, standing upon very long foot-stalks. The fruit comes out from the fide of the branches, toward their ends; they are about the size of large gray Peas, and of a deep purple colour, fitting close to the branches; these are not eatable.

The eleventh fort grows naturally at La Vera Cruz, from whence it was sent me by the late Dr. Houftoun; this rises with many shrubby stalks to the height of twelve or fourteen feet, and divides into many smaller branches, which are garnished with oval stiff leaves, which are obtuse; they are four inches long, and three broad, of a light green, and stand upon very short foot-stalks, which are joined to a cup, in which the fruit sits, this is globular, and the size of a middling nutmeg, of a deep yellow, when ripe, but is not eatable.

The second fort, I believe, is not in England at present, I raised two or three of these plants from seeds in the year 1736, which were destroyed by the severe frost in 1740, since which time I have not been able to procure any of the seeds. The other forts are preserved in several curious gardens; they are easily propagated by cuttings during the summer season. When the cuttings are taken from the plants, they should be laid in a dry shady place for two or three days, that the wounds may be healed over, otherwise they are apt to rot; for all these plants abound with a milky juice, which flows out whenever they are wounded; for which reason, the cuttings should have their wounded part healed over and hardened before they are planted, after which they should be planted in pots filled with sandy light earth, and plunged into a moderate hot-bed, where they should be shaded from the sun, and two or three times a week gently refreshed with water, if the season is warm; but they must not have too much moisture, for that will infallibly destroy them. When the cuttings have taken root sufficient to transplant, they should be each planted into a separate small pot filled with light undunged earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root; then they should have a large share of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them strength before the cold comes on. In autumn the pots should be removed into the stove, and plunged into the tan-bed, where they should constantly remain, and must be treated in the same manner as other tender plants from the same countries; for although two or three of the forts may be treated in a harder manner, yet they will not make much progress.

FICUSINDICA. See *Oiwria*.

FILAGO. There are several species of this genus, some of which grow naturally upon barren land in most parts of England. They are called by some Cottonweed, by others Cudweed, their leaves being white, and, when broken, have cottony threads. These have been ranged under the genus of Gnaphalium by most botanists, and one of the species which is used in medicine, stands in the list of simples by that appellation. As these plants are not cultivated in gardens, I shall not trouble the reader with a farther account of them.

FILBERT. See *CoRYLUS*.

FILIPENDULA. See *SPIR^A*.

FILIUS ANTEPATREM [i. e. the son before the father] an expression which botanists apply to plants, whose flower comes out before their leaves;

F I R

or those plants which fend forth fide brandies of flowers, which advance above the middle.

FILIX, Fern. There are great varieties of this plant in the different parts of the world, but particularly in America, as may be seen in the Natural History of Jamaica, published by Sir Hans Sloane, Bart, and in Plumier's American Ferns; but as they are plants which are seldom propagated in gardens, I shall pass them over in this place. *

FILM, that woody skin which separates the seeds in the pods of plants.

FIMBRATED [of *Fimbria*, *lat.* a fringe] a term relating to the leaves of plants when they are jagged on the edges, having, as it were, a fringe about them, these are often called furbelowed leaves.

FIRE. However foreign, at the first view, this article may seem to our present purpose, yet I am of opinion, that a tolerable acquaintance with its nature, as *fyp* as it can be attained, and its effects, will contribute no small assistance in forwarding the work of vegetation. And though the theory of fire is indeed philosophical, yet the consideration of its effects, and how it operates on vegetables, will be of no small use in the culture of them.

That which best defines and distinguishes fire from every thing else, is its heating; and so it may be defined, Whatsoever warms or heats bodies.

Heat is something, the presence of which is best perceived by the dilatation of the air or spirit in the thermometer. So then, fire is a body, and a body in motion too. The motion of it is proved by its expanding the air, and that it is a body by experiment. Pure mercury, being inclosed in a phial with a long neck, and kept in a gentle heat for the space of a year, will be reduced into a solid, and the weight also will be increased considerably; which increase cannot proceed from any thing else but the accession of fire.

The nature of fire is so obscure and wonderful, that it was held by many of the ancients as a deity, and several authors of prime note have taken great pains to discover the mystery of it, without having been able to explain many of the principal effects thereof. The learned Herman Boerhaave has used no less industry in making a new set of experiments, in order to come to a clearer knowledge of them, and having laid down a new doctrine of fire, in a course of public lectures, I shall briefly take notice of such of them as I apprehend may be of use.

" Fire (says he) in effect, appears to be the general instrument of all the motion in the universe. The constant tenor of a great number of experiments leaves no room to doubt, but that, if there were no fire, all things would instantly become fixed and immoveable. Of this there are instances every winter; for while frost prevails, the water, which before was fluid, by a mere privation of heat, becomes solid, i. e. hardens into ice, and so remains till dissolved again by fire. Thus, were a man entirely destitute of heat, he would immediately freeze into a statue; and thus the air itself, which is found in continual motion, being always either expanding or condensing, would, upon the absence of fire, contradict itself, and cohere into a firm rigid mass; for also animals and vegetables, all oils, salts, &c. would, upon the like occasion, immediately congeal."

Although this doctrine of fire, here laid down by Boerhaave, seems new and extraordinary, at least to those who have been used to consider fire in the light that it has been set in by the Lord Bacon, Mr. Boyle, and Sir Isaac Newton, and though we ought to pay great veneration to those illustrious authors, yet, in the judgment of themselves, we should be inexcusable, if we should absolutely acquiesce in what they have done, and shut the door against farther and better information.

It may reasonably be supposed, that Dr. Boerhaave has had an opportunity of going beyond them, in that, besides all the experiments and observations that they

have

haveJwd to buiU upon, he ha* bad the advantage of a new jet, which they ...re unacq'uincil with.

" be fpt-ni in making 3 va-ji ...al, vehement, and to ** telrFic commotion oi rje

" whereas the motion of juft comitit."

" This fire is the real caufe . f all the changes in nature, will appear from the following confideration.

All bodies are either folid or fluid; the folid of themfelves are either commonly fuppos'd to be inactive or immovable; the fluid both move and are moved.

And all fluids are found to be fo much the more firm and contracted, as they have the lefs fire in them.

This is evident in iron, which, when heated, expands itfelf into a much greater fpace than when it was cold; fo that any folid and hard body, by being freed from all fire, would fink into a much lefs bulk, and its parts would cohere more nearly, and with greater force than before.

As no fluids, they all harden, fo as to be vifible to the eye upon the abfence of fire; as water, by the cold of a fevere winter, will form itfelf into a folid glob¹, and yet even then contains a great deal of fire,

as appears evidently upon applying a thermometer to it, which is capable of falling twenty divifions lower before it arrive at the point of the moft intense cold; and hence it is, that the fpirit of wine is kept from freezing in the thermometer, which would undergo the common fate of other things, were there not abundantly more fire in it.

" be as much expanded by a greater quantity of fire, and ...erified by a lefs; but it ftill contains a large quantity of fire, where it is mod of all . contracted; this is evident from the ftriking of a flint againft a steel, which is followed by fprk; t-i fire

" ikewil if this fire could be taken from the air, it would b'co! . folid and perfectly atrel, and, by confequenc¹, incapable of change.

" fays Dr. Grazeiande, in Element. Phyf. naturally unites itfelf with bodies, and hence it is, that a body brought near to the fire grows hot,

" in each case it alfo expands or fwells; which expansion is not only obferved in very folid bodies, but in thofe whole parts do not cohere; in which case they likewife acquire a great degree of cold-

" nity, as is obferved in air and vapours."

Fire being thus acknowledged the instrumental caufe of all motion, it remains that itfelf be moved, nay, to move, muft be roorc natural and immediate to fire, than to any other body; and hence force have ventured to make motion efferential to fire; but as this is incon-

" fiftent with the notion of matter, which is defined to be inert and paffive, and as fire is capable of being proved material, we ought rather to agree, that the motion of fire itfelf is derived from fome high¹ inJ metaphyfical caufe. A property of perpetual mobility may indeed be fuperadded to the other properties of fire, but it has no natural neceffary connection with them; nor can it be maintained with them otherwife than by fime extrinfic efficacy of a fuperior caufe.-

Howen r, 1 hat it is by motion that fire produces its effects, is evident; and hence the action of fire cannot make any alteration in the elementary fubftance of bodies; for it is neceffary, that what acts upon an object, be without that object, i. e. the fire muft not penetrate the elementary parts, but only enter the pores and interfaces of bodies; fo that it does not form capable of making thofe tranfmiffions, which Sir Ifaac Newton writes to it.

in effect, as to all our purpofes, it may perhaps be faid, that fire is always in motion. KM tnfunc,

take fix feveral forts of thermometers, and two ve-icb cii water with fal arms . . . rived therrn, and apply the thermometer to it, and the confequence will be, that the air being condensed in them, the 1 pint will drcend in . . . of them; renove the veffel of water, and the air growing warmer, and rarefying, the fpirit will afcend again; fo that the active force in air, which produces fo many effects, does really all arife from the fire contained in it.

F I R

Again: As all bodies placed in a very solid air, do, by degrees, grow cold, motionless, rigid, &c. i. e. though there be still some remains of fire, and in proportion as that is diminished, the effect is accelerated; it follows, that cold, a less degree of heat, is the effect of a lesser action of fire: and all action rises apparently from the same source.

Then, as fire can render the most solid bodies, as stone, metals, &c. (as appears very evident in large burning-glasses, in which gold itself immediately calcines, and emits fumes, i. e. becomes fluid) for the want of fire would convert the most fluid bodies, as spirits of wine, &c. into solids.

Fire is distinguished into two kinds, called elementary or pure fire, which is such as exists in itself, and alone is properly called fire ϕ , or common or culinary fire, which is raised and kindled from the former, and is that which agitates and affects ignited, combustible, and moveable bodies, the particles of which, joining with those of the pure fire, constitute pure flame.

This latter is improperly called fire, in that not only a small part of it is real or pure fire; and in ignited bodies, that which flames, smokes, &c. is not simply fire; whereas pure fire, such as is collected in a burning-glass, yields no flame, smoke, ashes, or the like.

Fire may be present in the greatest abundance, yet without any heat: this is evident in the tops of the highest mountains, illuminated by the sun, where the cold is always extremely pinching, and this even under the equator, there being mountains there which are perpetually covered with snow, though there can be no want of fire.

So a large burning-glass has no effect: the smallest warmth cannot be felt in its focus in a place where the sun does not shine, or when the sun is covered with a cloud, but a piece of metal may be seen to melt the very moment the sun emerges.

Fire may be in exceeding small quantity, and yet burn with great violence: thus spirit of wine when set on fire, does not burn the hands; and though poured on a piece of red-hot iron, does not take fire; so that the fire that is in, should not appear very great: yet if it meet with some harder body while it is burning, the particles of which body it is capable to agitate by the attrition of its own, it will yield a fierce flame, capable of burning a harder body than the hand.

From this it appears, that the relation of heterogeneous particles, agitated by the fire, has more effect in respect to heat than the action of the fire itself: nor need we be far to seek for the mechanical reason of this, for the particles of fire, being all equal and spherical, mud of themselves be harmless; but if they carry certain spicula, or any other bodies along with them, then they become capable of doing much harm.

Hence, though the flame of a piece of wood may give a sense of heat, and burn such things as are applied to it, it does not therefore necessarily follow, that there is any pure fire in it, so that the distinction of pure and common fire is absolutely necessary: though this distinction has been overlooked by most or all the authors before Dr. Boerhaave, who have written on fire ϕ , which has led them into egregious mistakes, inasmuch that most of them have held, that the flame of a piece of wood is all fire, which appears to be false from what has been already said, and also what follows.

Elementary or pure fire is of itself imperceptible, and only discovers itself by certain effects that it produces in bodies, and these effects are only to be learnt by the changes which arise in bodies. These effects are three-, first, heat; 2dly, dilatation in all solid bodies, and rarefaction in all fluids; 3dly, motion.

The first effect of elementary fire on bodies is heat: heat arises wholly from fire, and in such a manner, that the measure of heat is always the measure of fire ϕ , and that of fire, of heat ϕ , for the heat is inseparable from the fire.

F I R

The second effect of elementary fire is dilatation, in all solid bodies, and rarefaction in all fluids.

Numerous experiments make it evident, that both these are inseparable from heat. If you heat an iron rod, it will increase in all its dimensions; and the more it is heated, the farther it will be increased; and being again exposed to the cold, it will contract, and successively return through all degrees of its dilatation, till it arrive at its first bulk, being never two minutes successively of the same magnitude.

The like may be observed in gold, the heaviest of all bodies, which takes up more space when it is fused than it did before; nay, even mercury, the heaviest of all fluids, has been known to ascend above thirty times its height, being placed over the fire in a tube.

The laws of this expansion are; 1st, That the same degree of fire rarefies fluids sooner, and in a greater degree than it does solids. Without this* the thermometer would be of no use; since, if it were otherwise, the cavity of the tube would be dilated in the same proportion as the fluid is rarefied.

2dly, By how much the liquor is lighter, by so much the more it is dilated by fire: thus air, which is the lightest of all fluids, expands the most, and spirit of wine the next after air.

The third effect of fire on bodies is motion ϕ , for fire, in warming and dilating bodies, must necessarily move their parts. And in effect, all the motion of nature arises from fire alone; and if this were taken away, all things would become immovable. All oils, fats, waters, wines, ales, spirits of wine, vegetables, animals, &c. become hard, rigid, and inert, upon the absence of only a certain degree of fire; and this induration will be both the sooner, and the more violent, the less the degree of fire is.

Hence, if the fire was absolutely taken away, and there were the greatest degree of cold, all nature would grow into one concrete body, solid as gold, and hard as a diamond; but, upon the application of fire, it would recover its former mobility.

And, of consequence, every diminution of fire is attended with a proportionable diminution of motion. Pure fire is found in two different manners; either as it exists everywhere, and is diffused equally in all places; or as it exists in certain bodies, in which it makes no great alteration.

That fire should exist in the same quantity in all places, will seem a strange paradox ϕ , and yet that it does so, is demonstrable from innumerable experiments.

This elementary fire is present every where, in all bodies, all space, and at all times, and that in equal quantities ϕ , for let a person go where he will, to the top of the highest mountains, or descend into the lowest cavern, whether the sun shine or not; either in the most scorching summer, or the sharpest winter; fire may be collected by several methods, as attrition or otherwise. In a word, there is no physical point assignable without fire, no place in nature where the attrition of two flicks will not render it sensible.

The Cartesians, as Marriotte, Perrault, &c. hold, that there is a large flock of fire in a perfect vacuum, i. e. a space out of which all the air has been exhausted, as supposing an absolute vacuum impossible: now, the most perfect vacuum that we can arrive at, is that of Mr. Huygens's contrivance, which is as follows: heat a quantity of the purest mercury to the heat of boiling water; and pour it into a hot tube of about forty inches long ϕ , and when the tube is filled, apply a finger upon the orifice of it, and thus invert it into a basin full of mercury: the mercury will now be suspended in the tube to the whole height; but then, if you give it but a little shake, it will sink down to the height of about twenty-nine inches, and thus leave a vacancy of eleven inches.

Yet here the philosophers above-mentioned deny there is any vacuum, and urge, that now so much the more fire is entered into the space as there was of other

matter;

F I R

matter; but this is contrary to experience \ at least, the fire contained there is no hotter than the mercury itself for if a drop or two of water be in a frothy season sprinkled both upon the upper part of the tube, lapped to be full of fire, and on the lower that is full of mercury, they will in each place freeze alike; so that there is no more pure fire in a perfect vacuum, than in any other place.

But whereas it has been said, that fire is found in all bodies, to prove this, set gold against the vacuum before-mentioned, and this gold, though the most ponderous of all bodies, will not contain more fire than Huygens's vacuum, as appears from the thermometer.

But the fire in gold, when ready to fuse, is pure fire for a mass of this being once heated red hot, will retain this fire perfectly for three days; nay, the prince of Mirandola and others, have kept gold ignited for two months, without any diminution of weight.

Mr. Gravesande, Phys. Element, says, That bodies of any kind, being violently moved against one another, will grow hot by such friction, and this to a considerable degree, which shews that all bodies have fire in them for fire may be put in motion, and separated from a body by such rubbing, but can never be generated that way.

Mr. Boyle, Mech. Prod, of Heat, says, That although quicksilver is allowed to be the coldest of all fluids, inasmuch that many deny, that it will produce any heat by its immediate action on any other body, and particularly on gold; yet several trials have assured him, that a particular mercury may by preparation be enabled suddenly to insinuate itself into the body of gold, whether calcined or crude, and become manifestly hot with it in less than two or three minutes.

Mr. Gravesande says, That quicksilver contains fire, is evident hence, that if you make it about in an exhausted glass, it will appear all, luminous.

Elemental fire of itself always lies concealed; nay, it may be perfectly undiscoverable, where it is in the greatest quantity; as is evident in the torrid zone, where the snow never melts, notwithstanding the great abundance of fire.

This fire, in itself thus perfectly latent, may cover itself to be present by five effects, first, by rarefying bodies, and particularly air, secondly, by colour; idly by colour, thirdly, by heat, and fourthly, by light.

That there is a good quantity of fire even in the coldest places, and in the coldest bodies, is confirmed by the following experiment: if you take two large iron plates, and when they are brought together in the north pole, which is only twelve degrees short of the north pole, 2 Z most frosty season, and at midnight, they will grow warm, shine, and heat to such a pitch as will melt the snow.

That the spirit in the thermometer, but

it was there before, but nobody will assert it; and accordingly, unless it be furnished with proper fuel, it will soon dissipate again, and of consequence it pre-exists, and it

appears to be true fire by its rarefying the spirit in the thermometer.

From this, and many other experiments, it is evident, that fire is always found in all parts of space, and in all bodies equally spread in the highest mountain, as in the deepest cavern under ground, and in every

fire in proved, it would thence follow, that the same degree thereof every where; which would really be so, were it not that fire happens by one means or other to be more collected in one place than another, but, notwithstanding the equable difference, fire through all the mundane space does not hinder, but that, for four senses, it appears very unequal in different places, and hence we have two vulgarly

F I R

puted sources or funds of fire, viz; in the sun, at the center of the earth.

As for the first, we have the concurrent opinions of the philosophers of all ages, but one excepted, who held the sun to be cold.

As to the second, the central fire, it is manifest that there is an ample proportion of fire under ground; and even, that fire appears much more abundant there than on the surface; so that at least, a subterraneous fire must be granted.

Thus they who dig mines, wells, &c. constantly observe, that while they are but a little below the surface, they find it a little cool; and as they proceed lower, it proves much colder, as being beyond the reach of the sun's heat, inasmuch that water will freeze almost instantaneously, and hence is the use of houses.

But a little lower, about forty or fifty feet deep, it begins to grow warmer, so that no ice can bear it; and then the deeper they go, still the greater heat, till at length it endangers the stoppage of respiration, and puts out their candles. If they venture yet farther with a lighted candle, the place shall be immediately found full of flame, as once happened in the coal-pits in Scotland, where a hardy digger, descending to an unusual depth, with a light in his hand, the fumes, which were there found very copious, caught fire thereby, and burnt the whole mountain down.

Therefore it seems as if nature had lodged another sun in the center of the earth, to contribute on its part to the giving motion to bodies, and for the promoting of generation, nutrition, vegetation, germination, &c. of animals, vegetables, and fossils.

As to the origin of this subterraneous sun, some doubt whether it were formed there in the beginning, like the sun in the firmament, or gradually produced by a secondary collection of vague fire into this place.

What makes in favour of the former opinion, are volcanos or burning mountains, which seem to have existed from the first ages; for the flames of mount Etna are mentioned as of great antiquity, and there are likewise such mountains found in the coldest regions, viz. Nova Zembla and Iceland, as well as the hottest, as Borneo, &c.

It cannot be reasonably pretended, says Mr. Boyle, that the subterraneous heat proceeds from the rays of the sun, since they heat not the earth above six or seven feet deep, even in the southern countries; and if the lower part of the earth were of its own nature cold, and received the heat it affords only from the sun and stars, the deeper men descend therein, the less degree of heat and flames they would meet with.

The sun contributes much in bringing fire to light, by reason of his rapid motion round his axis, whereby the fiery particles, every where diffused, are directed and determined in parallel lines toward certain places where its effects become apparent.

And from thence it is, that the fire is perceived by us when the sun is above, but that when he disappears, his impulse or pressure being then taken away, the fire continues dispersed at large through the ethereal space.

There is not, in effect, less fire in our hemisphere in the night time, than there is in the day time; only it wants the proper determination to cause it to be perceived.

The effects of elemental fire may be increased ways, viz. first, by attrition, or a swift rubbing or agitating one body against another. This is very manifest in solids. The attrition of a flint against a steel produces sparks of fire, and likewise in fluids, the violent agitation of cream, by churning, will produce a sensible warmth, and separate it into butter; and this effect is rendered still more discernible by a thermometer.

And the heat of animal bodies is owing to the agitation and attrition of the parts of these juices against each other, and the fides of the vessels.

The second manner of increasing the effect of elementary fire is, by throwing a quantity of moist or green

green vegetables, cut down while full of sap, into a large heap, and pressing them close down, by which they grow warm, hot, smoke, and break out into flame,

A third way is by mixing certain cold bodies: thus water, and spirit of wine, being first warmed, grow much hotter by being mixed; also oil of cloves, cinnamon, &c. being mixed with spirit of wine, become exceeding hot, and burst forth like volcanos.

The like effects may be had from several hard and dry bodies, as sulphur and steel filings.

To conclude: on fire and the effects thereof, depend all fluidity of humours, juices, &c. all vegetation, putrefaction, fermentation, animal heat, &c.

As all the four elements, water, air, earth, and fire, are very conducive to the work of vegetation, and no one of them more than this of fire; I conclude, that these few hints, which I have collected from the most approved authors, concerning the nature and properties of it, as they may be useful, would not be unacceptable to the ingenious and studious practitioners of horticulture, which induced me to infer them here.

FLOWER: a flower is a natural production which precedes the fruit, which includes the grain or seed. Though a flower is a thing so well known, yet the definition of this part of a plant is as various almost as the authors who define it. *Jungius* defines it to be the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the fruit. Yet this author himself confesses, that this definition is too narrow; for some of those bodies which he allows to be flowers are remote from the fruit.

Mr. Ray says, it coheres, for the most part, with the rudiments of the fruit. Thus the words, for the most part are hardly to be admitted into definitions.

Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the most part adhering to the young fruit, to which it seems to afford the first nourishment, in order to explicate its most tender parts. Which definition is still more deficient than the former, by this uncertain mode of expression.

Pontedera, the professor of botany at Padua, defines it to be a part of a plant unlike the rest in form and nature, if the flower has a tube, if always adheres to the embryo, or is very, near it, for whose use it is subservient; but if it wants a tube, there is no embryo adhering.

This definition is far from being clear, for it is scarce intelligible, and is liable to this objection, that it may include some parts of a plant which no person ever called by that name, for a root, a stalk, or a leaf, are parts of a plant unlike the rest in form and nature, having no tube, and so do not adhere to any embryo, and thus by *Pontedera's* definition are flowers.

Monf. Jussieu, the Paris professor, seems not to have succeeded much better in this affair: he says, That is properly called a flower, which is composed of chives, and a pistillum, and is of use in generation. But this is too defective; for there are many plants in which the pistillum or style is found a considerable distance from the chives* there are many flowers

that have no pistillum, whether that word be taken to signify the embryo of the fruit, or its appendix, and many which have no chives.

But the late *Monfieur Vaillant* seems to be happier, in forming a clearer idea of this part of a plant. We find in the lecture he read in the Royal Garden at Paris, that the flowers, strictly speaking, ought to be reckoned the organs which constitute the different sexes in plants; seeing they are sometimes found without any covering, and that the coats or petals, which immediately encompass them, are designed only to cover and defend them: but (says he) as these coats are the most conspicuous and most beautiful part of the composition, which is called by the name of flower, of whatsoever structure or colour they be; whether they encompass the organs of both sexes together, or contain only one of them, or only some parts depending on one of them, provided always that they be not of the same figure of the leaves of the plant.

But, in my opinion, *Dr. Martyn* has been happier, in his definition of a flower, than all those above-mentioned: he defines a flower to be the organs of generation of both sexes adhering to a common placenta, together with their common coverings; or of either sex separately, with its proper coverings, if it have any.

The parts of a flower are, i. The germen or ovary; which is the rudiment of the fruit, and so is properly the female organ of generation.

2. The style, which is a body accompanying the ovary, either arising from the top of it, or (landing as an axis in the middle, with the embryos of the seeds round it.

3. The stamens, or apices, which are those bodies that contain the prolific powder, analogous to the male sperm in animals; and generally hang upon slender threads, which are called the chives or lamina.

The petals are those tender fine coloured leaves, which are generally the most conspicuous parts of a flower.

The empalement, or calyx, is those tender leaves which cover the other parts of a flower.

Flowers, according to the number of their petals, are called monopetalous, dipetalous, tripetalous, tetrapetalous, &c.

The structure of flowers is indeed very various; but, according to *Dr. Grew*, the generality have these three parts in common, viz. the empalement, the foliation, and the attire.

Mr. Ray reckons, that every perfect flower has the petals, stamens, apices, and style or pistil; and such as want any of these parts, he accounts imperfect flowers.

In most plants there is a perianthum, calyx, or flower-cup; which is of a stronger confidence than the flower itself, and designed to strengthen or preserve it.

Flowers are distinguished into male, female, or hermaphrodite.

The male flowers are those in which are the stamens, but have no germen or style, the same which botanists call staminate flowers & these have no fruit.

The female flowers are such as contain the germen and style, or pistil, which is succeeded with fruit, and are called fruitful, or knitting flowers.

The hermaphrodite flowers are such in which the two sexes are contained, i. e. the male and female parts are found in the same flower, which are the most general kind; such are the Daffodil, Lily, Tulip, Althaea, Geranium, Rosemary, Sage, Thyme.

The structure of parts is much the same in those where the sexes are divided & the difference between them confiding in this, that the stamens and stamens or apices, i. e. the male parts in these are separate from the styles or pistils; being sometimes on the same plants, and sometimes on different ones.

Among the plants which bear both male and female parts, but at a distance from each other are reckoned

the C: umber, Melon, Gouni, Turkey-Wheat, Walnut, Oak, Bewh, &c.

1. U 1 1) | TV. |Huidius, of Rucre, Lat. to flow.] Having UL-cation to mention fluids and fluidity, in speaking of the propencie* of the elemenu air, water, OK) Sst. I thought || [tcctQty, in this place, I give the following account of tui property, which I have extracted trpm ilir uiiiiil approved authors.

A (laid, ur ltuiii lujdy, ii l' l'ome defined to be a body, whole prudes ire but weakly cowje&ed, their mu COa cohefion lwinj?., in 3 great irmiin., prevented from fome exir-nal caufe: in which tenfe, a fluid (lands opjxjffd to a (olid j and is, by the excellent Sir Ifaac Newton, defined to be mewhofp pam wiiuy gWC place, or iiiuue out of the way, on any force in; dled liijon them, ami by thai rm'siIN do fc calily move one over mother. Which definition is muchbratr than that of •• Cartes . That a fluid isa body whole p,im are in continual motion, becaufe it is neither apparent that tin- parts of all fluids are fo, nor that [lie parts of fume •olid b:«Jic5 are not Jo.

Fluidity is the flatc or affection of bodies, which denominates or renders them fluid, and Hands in direct oppofinan to liiiiiil-ft and folidity.

It ii diilinguiffied from liquidity and humidity, in [hat the idea of fluidity h ablbtiie, and the projitny contained within the tiling itfcfj whereas rhutof hunudity is relative, and implies wetting, or adV' rmp, i. e. fuuiching that °ives ui the fentation of w' rmen or tnoJlluic, and would have no exilUncr, butfot our

Thus melted metals, air, actlirr, ard even fmoke, rind ikme itfcfj, arc Huil bodits, and not liquid ones ; the parti of tLL-m being actually dry, and not leaving any lcnfe of noiiuL-

Fluidity leenib to confit in this, that the pans of ojijr body, being fine and fin all, are fo difpofed by motion and figure, as that they can ealily Hide over one another's furlaces all manner of ways. Mr. Uoylc atib obferves, ThM it is requifite they iliould be variouly and feparatdy ^itated to and fro, anil thvit tiicy rtiould touch one another but in fome parts only ot their furfaws. And the fame gentleman fays, in his H'llfory of fluidity, That the conditions requilite to conflwte a fluid body, ore chiefly the three following.

1ft. The lnuuicnft or fmallnck of us parts: thi u we fee the fire, iij dividing m«ak into part5 very line find fmall, will mck them, and nuke them link * , and after the fune manner tlo acid mL'nfruum diffolvi' lliem, fufciid their liijuor, and render them fluid; and that &re turns die hard body of common fait almost i-holly into» liquor by diftjliation: though it is not improbable, but that the lhape am

thele linal parti may condiice inudi towards producing tiis quality of fluidity: for it U found in the dilhllarian of Olive oil (whidi is a fluid made only by pTeflure) that moft of the oil will, by the action W the parts of the fife (if ir he done in a retort) be <wned intoa kind of confident liManec like butter. Likwife mercury, whole parti arc, wid mnch Krolter than thole of oil uvd water, b vet more fluid than either of them.

sdly, It ieems requifitc w fluidity, that there be ftore of vacuities, or vacant fpict-s, intTijxrled betvet-n the corpufcles of thr fluid body; for die there will BOI be room for cadi panicle to continue its motion and agitation on the furfacej of the neighbouring ones. For,

3dy. The chief condition KtHttfil e to confit: ite a fluid body is, that its partides be agitated rarioudy "d apart, either by their own proper motion, or by foniething of fuUbfice, t'hat tumbles them up and down by its portage through them.

That this qualification is chiefly requifitc to fluidity, you may gather from thai common experiment of putting a little dry powder of abbauVr, or plafter of "arii, finely fiftid, in a flat-bull[timed ver] over the fire-, far In a Irak tirnc ir will boil like water, and imitate all the motions of = boiling-liquor; it will

tumble vsrioiijViwrr : a great wave like that, it will bear iUrrina with i ii; it will do when cold, nay, if it be flured throughly on the i ide of the velle, its waves will appear to dash up againll the foil

out, and laid oti. p'aced paper, you will fee nothing but a dry powder. So that it : evident from hence, that there is a real difference ii tween a folid body and a wating body; for nor only thi. boili

inn for air and refire, and even flure itself, are properl, fluid bodies, though not w'at liquors. This ingenious gentleman found alfo, that by blowing the in: l' of H'ofemary into a thin pipe, and then hohlin; the pipe when filled up'right, the furface of the linote would :rommulate alid in a level f'ur-tion -, and • l'uch way f'ave the tube was inclined, the f'urfaces of the liuea would be parallel to the horiron-, and i: on the glafs was much inclined, would run along it like water.

From whence he inier:.. th.it. jn order to tlic r-ndering a budy Quid, it'ur is no need that it ;<»rul would be clofely condensed, . S thole of wa:r art. And Dr l louk, in hi» Micrograph, p. i -• p'effens us with it very pn; • experiment or two, to prove this account of fluidity . wa. That a diih of fand being lit on a drum head, heftily beaten by the flicks, or on i jn- upper ilune of a mill, turning twifly r'Und on the (empty) lower- one, it in 11 r'ep'ofits, emulate i e properties of a fluid body -, far > heavy body wii immediately fink in it to the bottom, and a light one emerge to the top; each grain of land hath a conflant vibrating, dancing motionj and if a hole l'c made in the fide of tl« difh, the fond will l'pin out like water.

The corpufuliir pliiolophy, before it was wond'fully improve! by Sir Ifaac Newton, d: not go io the bottom of this miner; for« giue no account' of the caufe of die dticf condition reijjuulc io contitute a fluid body, vin. ihe vjriuii motions and f'gti tations nf in particle but thi may, in i great mealure, l' account' I for, it it be fiippuLi! to be one of the)rimary towi of nature, That at all particlrs of nianer v' r'ack out 'lother when du:, come within a certain dirtafice, fo likewife they fly away from, and avoid one anoit'hr, at all great r'iftances from one another.

For then, though their common gravity m iy j rep them together in a maff (it may fometimes be) together wjff the preflure of other bodies upon l'ann; yet their continual endeavour to .OLL one > . other iingly, and die adventitiou impulfes of light, hear, or other external Cftuies, may make the panicles of fluids continually move round about one another, and to produce t' fti quality.

It is indeed a difficultly Dot*afij) got over, to account for ihe particles of fluids il ways keeping at fuch a diflance from one ano! er, as not to co:ue witliin the f'phere of one another's attraiaion. The fabrC and con; itution of that liukl body, water, is amazing; thai a lndy ib very rare, and which has a vnt on r' proportion of pores, or uir f'peifml vauity, to fohd matter, l'huuld yrt be p'offibly incompatible by the g'reateft force; and yet this rli; is eafily reducible into that firm, tranfparent, triable body which we call ice, by being only expofed to a certain degree of cold.

One would think, thai though tht pwricle • water canrii pome neai enough to attract each other, yet th intervening frigiditc matter duth, by being f'nfifi ed per-minuta, f'trongly attr lit them, and it ic f'ic likewise f'trongly attracted by them, and wedges or fixes all the maff into a firm Udy i winch !,.... [X]dy lofes its foldirry amioi wlien by heat the • dil-him i' toh- thole of the water, w art" forced to •,t- out f'ix quackilver. 5' ine fum« of leu' a firm liid body, f'ic When d into a fluid, duth r'ox !; »a meral, n by heat rrdU1 = Q :c di-juin ami (c-

parate its constituent particles, which mutual attraction caused to cohere before, and keep them at such a distance from each other, as that they are without the sphere of one another's attraction as long as that violent motion lasts? And do not they, when that is over, and the heat is flown out, come nearer to, attract one another, and coalesce again?

As therefore the cause of cohesion of the parts of solid bodies appears to be their mutual attraction, so the chief cause of fluidity seems to be a contrary motion impressed on the particles of fluids* by which they avoid and fly one another, as soon as they come at, and as long as they keep at, such a distance from each other.

It is observed also in fluids, that the direction of their pressure against the vessels which contain them, is in lines perpendicular to the sides of such vessels*, which property being the necessary result of the particles of any fluid's being spherical, it shews that the parts of all fluids are so, or of a figure nearly approaching thereto.

Dr. Clarke says, That if the parts of a body do not touch each other, or easily slide over one another, and are of such a magnitude as that they may be easily agitated by heat, and the heat be sufficiently great to agitate them; though perhaps it may be less than suffices to prevent water from freezing*, or even though the parts be not actually moved, yet if they be small, smooth, slippery, and of such a figure and magnitude as disposed them to move and give way, that body is fluid.

And yet the particles of such fluid bodies do, in some measure, cohere; as is evident hence, that mercury, when well purged of air, will be sustained in the barometer to the height of sixty or seventy inches; that water will ascend in capillary tubes, even in vacuum and that the drops of liquors in vacuum run into a spherical form, as adhering by some mutual cohesion, like that between polished marble planes.

To this may be added, that these said bodies, if they consist of particles which are easily entangled with each other, as oil-, or if they be capable of being stiffened by cold, and joined by the interposition of certain cunei or wedges, as water, they are easily rendered hard; but if their particles are such as can neither be entangled as air, nor stiffened by cold, as quicksilver, then they never grow hard and fixed.

In short, the Cartesians define a fluid to be a body, the parts of which are in continual incessant motion; and Dr. Hook, Mr. Boyle, and Dr. Boerhaave, though they differ in opinion widely from Cartesianism, subscribe to the definition, and alledge arguments to prove, that the parts of fluids are in continual motion, and even that it is this motion which constitutes fluidity; and the latter of them ascribes this, and all motion, to fire; See FIRE.

Fluids then are either natural, as water and mercury; or animal, as blood, milk, bile, lymph, urine, &c. or fatitious, as wines, spirits, oils* &c.

FOENICULUM. Tourn. Inft. R. H. 311. tab. 164. Anethum. Lin. Gen. Plant. 326. *Fennel* in French, *Fenouil*.

The CHARACTERS are,

// bath an umbellated flower -, the great umbel is composed of many smaller, which have no involucre; the umbel is uniform-, the flowers have five incurved petals, and five stamina, terminated by roundish summits: the germen situated under the flower, supporting two small styles, crowned by roundish stigmas. The germen afterwards turns to an oblong fruit, deeply channelled, dividing into two parts, each containing a single seed, flat on one side but convex and channelled on the other.*

This genus of plants is ranged in the second section of Tournefort's seventh class, which includes the herbs with umbellated flowers disposed circularly, whose empalement turns to two narrow, oblong, thick feeds. Dr. Linneus has joined this genus to Anethum, which is placed in the second section of his fifth class, with those plants whose flowers have five stamina and two styles. But as the feeds of Fennel are oblong,

thick, and channelled, and those of Dill flat and bordered, it is much better to keep them separate, than to join them in the same genus.

The SPECIES are,

1. FOENICULUM (*Fulgare*) foliis decompositis, foliolis brevioribus multifidis, femine brevior. *Fennel with decomposed leaves, whose small leaves are shorter and end in many points, and a shorter feed.* Faeniculum vulgare Germanicum. C. B. P. 147. *Common Fennel.*
2. FOENICULUM (*Duke*) foliis decompositis, foliolis longioribus, femine longiori. *Fennel with decomposed leaves, whose small leaves are very long, and a longer feed.* Feniculum dulce, majore & albo femine. J. B. 3. p. 2,4. *Sweet Fennel having a larger white feed.*

3. FOENICULUM (*Azoricum*) humiliter nuda caulescente carnofo, feminibus recurvis radice annua. *Dwarf Fennel with a fleshy stalk, recurved feeds, and an annual root.* Foeniculum duke Azoricum. Pluk. Aim. *Sweet Azorian Fennel, called Finocchio.*

The first sort is the common Fennel, which is cultivated in the gardens, and has found itself in many places, where it has been introduced in such plenty, as to appear as if it were a native in England*, but it is nowhere found at a great distance from gardens, so has been undoubtedly brought into England. There are two varieties of this, one with light green leaves, and the other with very dark leaves^ but these I believe are only varieties which arise from, the same feeds*, but this is very difficult to ascertain*, for unless the feeds were sown separately in some place where neither of these plants have been growing before, it cannot be done; for the feeds of these plants which have scattered, will remain in the ground some years, and when exposed near the surface will grow; so that the plants become troublesome weeds, wherever their feeds have been scattered*, and they frequently come up where other feeds are sown, and thereby the two sorts may accidentally mix.

The common Fennel is so well known, as to need no description. This hath a strong fleshy root, which penetrates deep into the ground, and will continue several years. It flowers in July, and the feeds ripen in autumn. The best time to sow the feeds, is soon after they are ripe; the plants will come up in the autumn or the following spring, and require no other care but to keep them clean from weeds, and thin the plants where they are too close-, it will grow in any soil or situation. The leaves, feeds, and roots of this, are used in medicine*, the root is one of the five opening roots, and the feed one of the greater carminative feeds. There is a simple water made from the leaves, and a distilled oil from the feed.

The sweet Fennel has been by many supposed only a variety of the common sort, but I have cultivated it in the same ground with that, where it has always retained its differences. The leaves of this are very long and slender, growing more sparingly, and do not end in so many points as those of the common sort; the stalks do not rise so high, and the feeds are longer, narrower, and of a lighter colour. These feeds are generally imported from Germany or Italy, and are by some preferred to those of the common sort for use, being much sweeter.

This may be propagated in the same manner as the former sort, being very hardy, but the roots are not so long duration.

The third sort is supposed to have been originally brought from the Azorian Islands^ it has been long^ cultivated in Italy as a fallad herb, under the title of Finocchio; and there are some few gardens in England, where it is now cultivated, but in small quantities, for there are not many English palates which relish it, nor is it easy to be furnished with good feeds; those which are annually brought from Italy seldom prove good; and it is difficult to have it in England, because the winter frequently kills those plants which are left for feeds^ and when any good plants of the early sowing are left for feeds, they do not ripen, unless the winter proves very favourable.

This fort hath very fhort ftalks, which fwel juft above the furface of the ground, to four or five inches in breadth, and almoft two thick, being fleftiy and tender: this is the part which is eaten when blanched, with oil, vinegar, and pepper, as a cold fallad. When thefe plants are permitted to run for feeds, the ftalks do not rife more than a foot and a half high, having a large fpreading umbel {landing on the top. The feeds of this for^are narrow, crooked, and of a bright yellow colour \ they have a very ftrong fmell like Anifeed, and are very fweet to the taft.

The manner of cultivating this plant is as follows : Your firft care muft be to procure good feeds from fome perfon who has been careful in the choice of the plants, otherwife there will be little hope of having it good -, for the plants will run up to feeds before they fwel to any fize, fo will not be fit for ufe : then make choice of a good fpot of light rich earth, not dry nor very wet, for in either extreme this plant will not thrive. The firft crop may be fown about a fortnight in March, which, if it fucceeds, will be fit for ufe in July ; and by fowing at feveral times, there may be a fupply for the table till the froft puts a ftop to it. After having well dug and levelled the ground fmoother, you muft make a fhallow drill by a line, into which you muft fcatter your feeds pretty thin ; for if your plants are fix inches afunder in the rows, it will be full near enough; but however, you muft exped fome of your feeds to fail, and therefore you fhould fcatter them about two inches diftance; then cover the feeds about half an inch thick with earth, laying it fmoother: thefe drills fhould be made eighteen inches afunder, or more, that there may be room to clean the ground, as alfo to earth up the plants when they are full grown. When the plants come up, which will be in about three weeks or a month after fowing, you muft with a fmall hoe cut up all the weeds between them, and where the plants are too clofe, they fhould be thinned to about three inches diftance; and as they advance, and the weeds fpring again, they fhould, from time to time, be hoed; and at the laft time of thinning them, they fhould be left feven or eight inches afunder at leaft. If your kind be good, the ftems of the plants will increafe to a confiderable bulk juft above the furface of the ground; which part fhould be earthed up in the manner of Celery, to blanch, about a fortnight or three weeks before it is ufed, and this will caufe it to be very tender and

crifp.

Your fecond crop fhould be fown about three weeks after the firft, and fo continue fowing every three weeks or a month till the end of July, after which time it will be too late for the plants to come to any perfe&ion. But you fhould obferve to fow in April, May, and June, on a moifter foil than that which you fowed the firft on ; as alfo what you fow in the latter part of July, fhould be fown on a drier foil, and in a warmer fituation -, becaufe this crop will not be fit for ufe till late in autumn, and therefore will be fubjeft to injuries from too much wet or cold weather, if on a moift foil. But as the ground is often extreme dry in June and July, and the feeds more apt to mifcarry and not come up, you fhould therefore obferve to water and fhade the beds where this feed is fown at that feafon, until the plants come up. And if the feafon fhould prove dry, the plants muft be duly watered, otherwife they will run up to feed before they are of any fize-, therefore there fhould be a channel made where every row of plants grow, to detain the water which is poured on them, to prevent its running off. In the autumn, if there fhould happen fharp frofts, it will be very proper to cover the plants with fome Peas-haulm, or other light covering, to prevent their being pinched; by which method they may be continued for ufe till the middle of winter.

A fmall bed of this plant will be fufficient at each fowing for a middling family -, and for a large family, a bed of about twenty feet long, and four feet broad, will be fu] enough at a time.

FCENUM BURGUNDIACUM. Ste Mi-

DICA SATIVA. . . ;

FGENUM GRJECUM. See TIUGONELLA.

FOOT-STALKS, are thofe fmall ftalks which immediately fuftain the leaves, flowers, or fruit.

FOUNTAINS are, fources or fprings of living water, arifing out of the ground. As to the original of them, fee under the article SPRINGS.

Of artificial fountains there are great variety, the mechanism of which not being to my purpofe, I will not dwell upon it ; though I may affert, that they are not only great ornaments to a fine garden, but alfo of great ufe. But they ought not to be placed too near the houfe by reafon of the vapours that arife from the water, which may be apt to ftrike a damp to the wall, and fpoil the paintings, &c. and the fummer vapours may caufe a malignity in the air, and fo be prejudicial to the health of the family ; and likewife the noife may be incommodious in the night.

Fountains in a garden fhould be fo diftributed, that they may be feen almoft all at one time, and that the water-fpouts may range all in a line one with another, which is the beauty of them ; for this occafions an agreeable confufion to the eye, making them appear to be more in number than they really are. See JET D'EAU, SPRINGS, VAPOURS, WATER, &c.

FRAGARIA. Lin. Gen. Plant. 558. Tourn. Inft. R. H. 295. tab. 152. [is fo called for its fragrant aromatic fcent.] Strawberries ; in French, *Frajflert*,

The CHARACTERS are,

The empalement of the flower is of one leaf, which is cut into ten parts at the top. The flower hath five roundijh petals, which are inferted in the empalement, and fspread open. It hath twenty ftamina, which are inferted in the empalement \ terminated by moon-Jhaped fummits. It hath a great number of germes collected into a beady each having a Jingle Jiyle, inferted in the Jide of the germen, crowned by Jingle ftigmas ; this bead after ward becomes a large, foft, pulpy fruit \ which if left, falls away, leaving many fmall angular feeds in the empalement.*

This genus of plants is ranged in the 'fifth fe&ion of Linnseus's twelfth clafs, which includes thofe plants whofe flowers have at leaft twenty ftamina and many ftyles, which are inferted to the empalement.

The SPECIES are,

1. FRAGARIA (*Vefca*) foliis ovatis ferratis, calycibus brevibus, fructu parvo. *Strawberry with oval fawed leaves, fhort empakments, and a fmall fruit.* Fragaria vulgaris. C. B. P. 226. *The common or Wood Strawberry.*
2. FRAGARIA (*Virginiana*) foliis oblongo-ovatis ferratis, infernè incanis, calycibus longioribus, fructu fubrotundo. *Strawberry with oblong, oval, fawed leaves, hoary on their under Jide* longer empakments, and a roundijh fruit.* Fragaria Virginiana fructu Coccineo. Hift. Ox. 2. 186. *Virginia Strawberry with a fear let fruit, commonly called the Scarlet Strawberry.*
3. FRAGARIA (*Muricata*) foliis ovato-lanceolatis rugofis, fru&u ovato. *Strawberry with oval, fpear-Jhaped, rough leaves, and an oval fruit.* Fragaria fru&u parvi pruni magnitudine. C. B. P. 327. *Strawberry with fruit as large as a fmall Plumb, commonly called Hautboy Strawberry.*
4. FRAGARIA (*Chiloenfts*) foliis ovatis carnofis hirtutis fructu maximo. *Strawberry with oval, Jiefby, hairy leaves, and a large fruit.* Fragaria Chiloenfts, fructu maximo foliis carncfis hirtutis. Hort. Elth. 145. tab. 120. *Strawberry of Chili with a large fruit, and hairy Jiefhy leaves, called Frutilla, in America.*

There are fome other varieties of this fruit, which are now cultivated in England -, but I have not feen any other which can be called a diftinct fpecies, tho' I are here enumerated, and thefe, I think, may be allowed to be fo, for they never aker from one to the other, by any cultivation, though the fruit is frequently improved, fo as to be of a larger fize thereby j therefore thofe who have fuppofed them but one fpecies, have greatly erred in fo doing -, I (hall therefore mention the feveral varieties of Strawberry, which arc;

at

at present to be found in the gardens under the species to which they naturally belong.

The first fort is the common Wood Strawberry, which grows naturally in the woods in many parts of England, and is so well known as to need no description of this there are three varieties, i. The common fort with red fruit. 2. The white Wood Strawberry, which ripens a little later in the season, and is by many persons preferred to it for its quick flavour, but as it seldom produces so large crops of fruit as the red fort, it is not very generally cultivated. 3. The green Strawberry, by some called the Pine Apple Strawberry, from its rich flavour. The fruit of this is greenish when ripe; it is very firm, and hath a very high flavour; this is a late ripe fruit, but unless it is planted in a moist loamy soil, it is a very bad bearer, but in such land where it does succeed, it merits cultivation as much as any of the forts.

The Scarlet Strawberry is the fort which is first ripe, for which reason it merits esteem, had it nothing else to recommend it; but the fruit is so good, as by many persons of good taste to be preferred to most other forts. This was brought from Virginia, where it grows naturally in the woods, and is so different from the Wood Strawberry in leaf, flower, and fruit, that there need be no doubt of their being distinct species.

There is a variety of this which hath been of late years introduced from the northern parts of America, which has the appearance of a distinct species. The leaves of this are rounder, and, not so deeply veined; the crenatures on their edges are broader and more obtuse. The leaves which compose the empalement are much longer, and are hairy, and the fruit is larger but as in other respects it approaches near to the Scarlet Strawberry, I have chosen to join it to that, rather than make a distinct species of it, this I have been informed grows naturally in Louisiana.

There has also been another variety of this (if not a distinct species) lately introduced to our gardens, which is commonly known by the title of Alpine Strawberry, the plants of this greatly resemble those of the Scarlet Strawberry, but the fruit is more pointed, it is a well flavoured fruit, and continues bearing from the common season of Strawberries, until the frost in autumn puts a stop to it, which renders the fort very valuable: I have frequently gathered the fruit in the beginning of November; this has occasioned the Dutch gardeners titling it Everlasting Strawberry.

The Hautboy Strawberry, which the French call Capitons, came originally from America, but it has been long cultivated in the English gardens, and is very different from the other forts in leaf, flower, and fruit, as that no one can doubt of their being different species there is an improvement of this fort, which is commonly called the Globe Hautboy. The fruit of this is larger, and of a globular form, but this difference has certainly arisen from culture; for where these have been neglected a year or two, they have degenerated to the common Hautboy again; where the ground is proper for this plant, and their culture is well managed, the plants will produce great plenty of fruit, which will be large, and well flavoured, and by some persons are preferred to all the other forts.

The Chili Strawberry was brought to Europe by Monsr. Frazier, an engineer, who was sent to America by the late king of France, and was first planted in the Royal Garden at Paris, from whence it was communicated to several curious persons in Holland, and in the year 1727, I brought a parcel of the plants to England, which were communicated to me by Mr. George Clifford, of Amsterdam, who had terge beds of this fort growing in his curious gardens at Hartcamp. The leaves of this fort are hairy, oval, and of a much thicker substance than any fort yet known, and stand upon very strong hairy foot-stalks; the runners from the plants are very large, hairy, and

extend to a great length, putting out plants at several distances. The foot-stalks which sustain the flowers are very strong, the leaves of the empalement are long and hairy. The flowers are large, and are often deformed; and so is the fruit, which is very large, and when cultivated in very strong land, the plants produce plenty of fruit, which is firm, and very well flavoured; but as it is a bad bearer in moist places where it has been cultivated, it has generally been neglected.

The Strawberries in general love a gentle hazely loam, in which they will thrive and bear greater plenty of fruit than in a light rich soil. The ground should also be moist, for if it is very dry, all the watering which is given to the plants in warm dry seasons, will not be sufficient to procure plenty of fruit; nor should the ground be much dunged, for that will cause the plants to run into suckers, and grow luxuriant, and render them less fruitful.

The best time to remove these plants is in October, that they may get new roots before the hard frosts set in, which loosens the ground, so that if the roots of the plants are not pretty well established in the ground, the plants are frequently turned out of the ground by the first thaw, therefore the sooner they are planted when the autumnal rains begin, the better will their roots be established, so there will be less danger of their miscarrying, and sometimes those which are well rooted, will produce a few fruit the first year; there are some who transplant their plants in the spring; but where that is done, they must be duly supplied with water in the dry weather/ otherwise they will not succeed.

The ground in which these are planted should be thoroughly cleaned from the roots of Couch, and all other bad weeds -> for as the Strawberry plants are to remain three years before they are taken up, so if any of the roots of those bad weeds are left in the ground, they will have time to multiply so greatly as to fill the ground, and overbear the Strawberry plants. The ground should also be well trenched and made level; then the usual method is to lay it out into beds of four feet broad, with paths two feet or two feet and a half broad between each of these paths are necessary for the convenience of gathering the fruit, and for weeding and dressing of the beds, and also for watering the plants, after the beds are marked out, there should be four lines drawn in each, at a foot distance, which will leave six inches space on each side, between the outside rows and the paths, then the plants should be planted at about a foot distance from each other in the rows, in a quincunx order, being careful to close the ground to the roots of the plants when they are planted, and if there should not happen rain soon after, the plants should be well watered to settle the earth to their roots.

The distance here mentioned for the plants to be placed must be understood for the Wood Strawberries only, for as the other forts grow much larger, their distances must be proportioned to their several growths; therefore the Scarlets and Hautboys should have but three rows of plants in each bed, which should be at fifteen inches distance, and the plants in the rows should be allowed the same space from each other, and the Chili Strawberry must have but two rows of plants in each bed, which should also be two feet apart in the rows, for as these grow very strong, if they have not room to spread, they will not be very fruitful.

In choosing proper plants of any of the forts, depends the whole success; for if they are promiscuously taken from beds without care, great part of the plants will become barren these are generally called blind, which is when there are plenty of flowers, but no fruit produced; if these flowers are well examined, they will be found to want the female organs of generation, most of them abounding with lamina, but there are few, if any styles, so that it frequently happens among these barren plants, that some of them will have a part of an imperfect fruit formed, which

The teeds flipuld be immediately fown when the fruit is ripe; the bed was to low the feeds in pots, placing

(Kern i ... the fhade.

In the spring of the year 1724, there was scarce any rain from February till about the middle of July, so that most of the Strawberries and Raspberries in the gardens near London, were burnt up, and came to no perfection; but upon plenty of rain falling in July, they recovered and put out plenty of flowers, which were succeeded by fruit, which ripened in September, when the markets of London were supplied with a great plenty of both those fruits at that season of the year.

FRANGULA. Tourn. Inf. R. H. 612. tab. 383. Rhamnus. Lin. Gen. Plant. 235. [is so called of frangendo, breaking, because of the brittleness of its wood.] Berry-bearing Alder,

The CHARACTERS are,

The *makment of the flower is of one leaf cut at the top into five segments, which are ereSt. The flower hath one petal, which is cut into five acute segments; these are placed between the segments of the empalement, into which they are inferted, but are shorter, and stand ereSt. It hath five stamina, which are the length of the petal, terminated by obtuse summits; in the center is situated a globular germen, supporting a slender Jyik crowned by an obtuse stigma. The germen afterward becomes a round berry, inclojing two plain roundish feeds.* This genus of plants is ranged in the second section of Tournefort's twenty-first class, which includes the trees and shrubs with a Rose flower, whose pointal turns to a berry. Dr. Linnaeus has joined this genus with the Palurus, Alaternus, and Ziziphus, to the Rhamnus, making them only species of one genus; but according to his own system, they should be separated to a great distance from Rhamnus, and be placed in his twenty-second class, because it hath male and female flowers on different plants; whereas it is placed in the first section of his fifth class, from the flower having five (lamina and but one style.

The SPECIES are,

1. FRANGULA (*Alnus*) foliis ovato-lanceolatis glabris. *Frangula with oval, spear-shaped smooth leaves.* Frangula, five alnus, nigra baccifera. Park. Theat. Black Berry-bearing Alder.
2. FRANGULA (*Latifolia*) foliis lanceolatis rugosis. *Frangula with rough spear-shaped leaves.* Frangula rugiflore & ampliore folio. Tourn. Berry-bearing Alder with a larger and rougher leaf.
3. FRANGULA (*Rotundifolia*) foliis ovatis nervosis. *Frangula with oval veined leaves.* Frangula montana pumila faxatilis, folio subrotundo. Tourn. Low mountain, rocky, berry-bearing Alder, with a round leaf.
4. FRANGULA (*Americana*) foliis oblongo-ovatis nervosis, glabris. *Frangula with oblong, oval, smooth veined leaves.* Frangula Americana foliis glabris. Dale. *American Berry-bearing Alder with smooth leaves.*

The first fort grows naturally in the woods in many parts of England, so is seldom planted in gardens; this rises with a woody stem to the height of ten or twelve feet, sending out many irregular branches, which are covered with a dark bark, and garnished with oval spear-shaped leaves, about two inches long, and one inch broad, having several transverse veins from the midrib to the sides, and stand upon short stalks. The flowers are produced in clusters at the end of the former year's shoots, and also upon the first and second joints of the same year's shoot, each standing upon a short separate stalk, on every side the branches; these are very small, of an herbaceous colour, and do not expand; they are succeeded by small round berries, which turn first red, but afterward black when ripe. The flowers appear in June, and the berries ripen in September > this stands in the Dispensary as a medicinal plant, but is seldom used.

The second fort hath larger rough leaves than the first. It grows naturally on the Alps and other mountainous parts of Europe, and is preserved in some gardens for the sake of variety.

The third fort is of humble growth, seldom rising above two feet high & this grows on the Pyrenean Mountains/ and is seldom preserved unless in botanic

gardens for variety & it may be increased by laying down the branches, but must have a strong foil.

The fourth fort grows naturally in North America* from whence I received the seeds; this is pretty like the first fort, but the leaves are longer and broader, they are smooth, of a lucid green, and have many veins. The flowers are very like those of the first fort.

These shrubs are easily propagated by seeds, which should be sown as soon as they are ripe, and then the plants will come up the spring following, but if they are kept out of the ground till spring, the plants will not come up till the year after. When the plants come up, they must be kept clean from weeds till autumn, then they may be taken up and planted in a nursery in rows, two feet asunder, and at one foot distance in the rows, in this nursery they may remain two years, and may then be planted where they are to remain; they may also be propagated by layers and cuttings, but the seedling plants are best.

The fruit of the first fort is often brought into the markets of London, and sold for Buckthorn berries; of which cheat, all such as make use of Buckthorn should be particularly careful; they may be easily distinguished by breaking the berries, and observing how many seeds are contained in each, the berries of this tree having but two, and those of Buckthorn generally four seeds in each berry, and the juice of the latter dies paper of a green colour.

FRAXINELLA. See DICTAMNUS.

FRAXINUS. Lin. Gen. Plant. 1026. Tourn. Inf. R. H. 577. tab. 343. The Ash-tree in French, *Frêne*.

The CHARACTERS are,

It hath hermaphrodite and female flowers on the same tree, and sometimes on different trees. The hermaphrodite flowers have no petals, but a small four-pointed empalement, including two erect stamina, which are terminated by oblong summits, having four furrows. In the center is situated an oval compressed germen, supporting a cylindrical style, crowned by a bifid stigma. The germen afterward becomes a compressed bordered fruit, shaped like a bird's tongue, having one cell, inclojing a seed of the same form. The female flowers are the same, but have no stamens.

This genus of plants is ranged in the second section of Linnaeus's twenty-third class, which includes the plants which have flowers of different sexes on the same or different plants, which are fruitful.

The SPECIES are,

1. FRAXINUS (*Excelsior*) foliolis ferratis, floribus apertis. Lin. Sp. Plant. 1057. *AJh-tree whose smaller leaves are ferrated, and flowers having no petals.* Fraxinus excelsior. C. B. P. 416. *The common AJh.*
2. FRAXINUS (*Rotundifolia*) foliolis ovata-lanceolatis ferratis, floribus coloratis. *AJh-tree whose smaller leaves are oval, spear-shaped, and sawed, and the flowers coloured.* Fraxinus rotundiore folio. C. B. P. 416, *AJh-tree with a rounder leaf, commonly called Manna AJh.*
3. FRAXINUS (*Ornus*) foliolis ferratis, floribus coloratis. Lin. Sp. Plant. 1057. *AJh-tree whose smaller leaves are sawed, and flowers having petals.* Fraxinus humilior five altera Theophrasti, minore & tenuiore folio. C. B. P. 416. *Dwarf AJh of Theophrastus with smaller and narrower leaves.*
4. FRAXINUS (*Paniculata*) foliolis lanceolatis glabris, floribus paniculatis terminatricibus. *AJh-tree with smooth spear-shaped leaves, and flowers growing in panicles at the ends of the branches.* Fraxinus florifera botryoides. Mor. Pral. 265. *The flowering AJh.*
5. FRAXINUS (*Nova Anglia*) foliolis integerrimis, petiolis teretibus. Flor. Virg. 122. *AJh-tree with the small leaves entire, and taper foot-stalks.* Fraxinus ex Nova Anglia, pinnis foliorum in mucronem productioribus. Rand. Cat. Hort. Chelf. *New England AJh with long acute points to the wings of the leaves.*
6. FRAXINUS (*Caroliniana*) integerrimis petiolis teretibus frudu latiore. Prod. Leyd. 533. *AJh-tree with entire leaves and taper foot-stalks.* Fraxinus Caroliniana, latiore fructu. Rand. Cat. H. Chelf. *Carolina AJh with a broad f.*

The first fort is the common Ash-tree, which grows naturally in most parts of England, and is so well known as to need no description. The leaves of this sort have generally five pair of lobes, and are terminated by an odd one, they are of a very dark green, and their edges are slightly sawed. The flowers are produced in loose spikes from the side of the branches, which are succeeded by flat seeds, which ripen in autumn; there is a variety of this with variegated leaves, which is preferred in some gardens.

The second fort grows naturally in Calabria, and is generally supposed to be the tree from whence the manna is collected, which is an exudation from the leaves of the tree. The shoots of this tree are much shorter, and the joints closer together than those of the first fort; the small leaves are shorter, and deeper sawed on their edges, and are of a lighter green. The flowers come out from the side of the branches, which are of a purple colour, and appear in the spring before the leaves come out. This tree is of humble growth, seldom rising more than fifteen or sixteen feet high in England.

The third fort is a low tree, which rises about the same height as the second; the leaves of this fort are much smaller and narrower than those of the first, but are sawed on their edges, and are of the same dark colour. The flowers of this fort have petals, which are wanting in the common Ash.

The fourth fort was raised by the late Dr. Uvedale at Enfield, from seeds which were brought from Italy by Dr. William Sherard, where the trees grow naturally; but it was supposed to be a different fort from that mentioned by Dr. Morrifon, in his *Præsentia Botanica*, but by comparing them together they appear to be the same.

The leaves of this fort have but three or four pair of lobes (or small leaves) which are short, broad, and smooth, of a lucid green, and irregularly sawed on the edges; the midrib of the great leaf is jointed, and swelling where the leaves come out. The flowers grow in loose panicles at the end of the branches; these are most of them male, having two stamens in each, but no germen or style; they are of a white herbaceous colour, and appear in May. As this fort very rarely produces seeds in England, it is propagated by grafting or budding it upon the common Ash.

The fifth fort was raised from seeds, which were sent from New England in the year 1724, by Mr. Moore. The leaves of this tree have but three, or at most but four pair of lobes (or small leaves) which are placed far distant from each other, and are terminated by an odd lobe, which runs out into a very long point; they are of a light green and entire, having no serratures on their edges: this tree shoots into strong irregular branches, but doth not grow to a large size in the trunk. It is propagated by grafting it upon the common Ash.

The sixth fort was raised from seeds which were sent from Carolina in the year 1724, by Mr. Cateby. The leaves of this fort have but three or four pair of lobes, the lower being the least, and the upper the largest; these are about five inches long and two broad, of a light green colour, and (slightly sawed on their edges; the foot-stalk, or rather the midrib, of the leaves is taper, and has short downy hairs; the seeds are broader than those of the common Ash, and are of a very light colour. As this fort hath not yet produced seeds in England, it is propagated by grafting it upon the common Ash.

These trees are now propagated in plenty in the nurseries for sale, as there has been of late years a great demand for all the hardy sorts of trees and shrubs, which will live in the open air; but all those trees which are grafted upon the common Ash, are not so valuable as those which are raised from seeds, because the stock grows much fatter than the grafts; so that the lower part of the trunk, so far as the stock rises, will often be twice the size of the upper; and if the trees stand much exposed to the wind, the grafts are frequently broken off to the stock, after they are

grown to a large size, which is a great disappointment to a person after having waited several years, to see their trees suddenly destroyed. Besides, if the wood of either of the sorts is valuable, it can be of little use when the trees are so raised.

The fourth fort is generally planted for ornament, the flowers making a fine appearance when they are in beauty, for almost every branch is terminated by a large loose panicle; so that when the trees are large, and covered with flowers, they are distinguished at a great distance.

All the other sorts serve to make a variety in plantations, but have little beauty to recommend them; and as their wood seems to be greatly inferior to that of the common Ash, so there should be few of these planted, because they will only fill up the space where better trees might grow.

The common Ash propagates itself in plenty by the seeds which scatter in the autumn, so that where the seeds happen to fall in places where cattle do not come, there will be plenty of the plants come up in the spring; but where any person is desirous to raise a quantity of the trees, the seeds should be sown as soon as they are ripe, and then the plants will come up the following spring; but if the seeds are kept out of the ground till the spring, the plants will not come up till the year after, which is the same with all the sorts of Ash; that when any of their seeds are brought from abroad, as they seldom arrive here before the spring, the plants must not be expected to appear till the next year; therefore the ground should be kept clean all the summer where they are sown, and not disturbed, lest the seeds should be turned out of the ground, or buried too deep to grow; for many persons are too impatient to wait a year for the growth of seeds, so that if they do not come up the first year, they dig up the ground, and thereby destroy the seeds.

When the plants come up, they must be kept clean from weeds during the summer; and if they make good progress in the seed-bed, they will be fit to transplant by the autumn; therefore there should be some ground prepared to receive them, and as soon as their leaves begin to fall, they may be transplanted. In taking them up, there should be care taken not to break or tear off their roots; to prevent which, they should be taken up with a spade, and not drawn tip, as is frequently practiced; for as many of the plants which rise from seeds will outstrip the others in their growth, so it is frequently practiced, to draw up the largest plants, and leave the smaller to grow a year longer before they are transplanted; and to avoid hurting those which are left, the others are drawn out by hand, and thereby many of their roots are torn off or broken; therefore it is much the better way to take all up, little or big together, and transplant them out, placing the larger ones together in rows, and the smaller by themselves. The rows should be three feet asunder, and the plants a foot and a half distance in the rows; in this nursery they may remain two years, by which time they will be strong enough to plant where they are to remain; for the younger they are planted out, the larger they will grow; so that where they are designed to grow large, they should be planted very young; and the ground where the plants are raised, should not be better than that where they are designed to grow; for when the plants are raised in good land, and afterward transplanted into worse, they very rarely thrive; so that it is much the best method to make the nursery upon a part of the same land, where the trees are designed to be planted, and then a sufficient number of trees may be left standing upon the ground, and these will outstrip those which are removed, and will grow to a larger size.

Where people live in the neighbourhood of Ash-trees, they may supply themselves with plenty of self-sown plants, provided cattle are not suffered to graze on the land, for they will eat off the young plants, and not suffer them to grow; but where the seeds fall in hedges, or where they are protected by bushes, the

plant* will come up and thrive, and in the hedge

particles that it are the chief caulcof freezinp are finlinc, mase: in a doc proportion, congelation bearing a near relation ; • i ryflattiaftwn.

This lilli is liij'pofrd 10 be of the nitrous kind, and to be funilicid by the air, which is generally found to abound in nitre.

It is indeed no diijicult matter, to account fur the particles of nitre preventing the fluidity of water. Theft panicle arc luppold to be fo many rigid pointed fpiculn, which arc cafily impelled or driven into the fiamina or globules of water; which, by this means, becoming varioufy mingled and entangled wiih it, do, by degrees, weaken and deftroj the motion of it.

The Fedbfl that this effect arifh only in l'evere winter weather, is, that it is then only that the retracing action oi' the nitrous rpicula is more than equal to the power or principle by which the fluid is otherwile kept in motion, or dilpold for motion.

Several experiments of artificial freezing fupport tiii* opinion.

For if you mix a quantity of common faltpetre with f'now, or ice pulverized, and difflve the mixture in the fire, and then immergc a tube full of water in tin-fetation; the water, that part of it next the mixture, will freeze pfcntly, even in a warm air.

Whence they argue, that die l'picuh of the fait are driven through the pores of tlieglafs, and mixed with the •rater, by the gravity of the mixture, and of the inLiinbent air; for fhac it is evident, that the fait has this effect, in at much as it is certainly known, that the particles of water cannot find their way through xhe pores of the glafs.

In ihclb artificial freezings, in whatever part the mixture is applied, there is pfcntly a (Un or lamina of ice produced, whether at the top, bottom, or fides, by rrafon that there is always a Rock of lalinc corpufcles, fufficient to overpower the particles of fire; but natural congelations are confined to the top of the water, where the lair, moft abounds.

But this fyltem is oppofcd by the author of the Nouvelle Conjecture pour expliquer la Nature de la Glace, who objects, that it docs not appear, that the nitre m enters the compofition of ice -, but if it did, it would tjll flort of accounting for fome of the principal effects -, as,

1 In*- fhmiJ tie particles of nitre, by entering the pores of the water, and fixing t!- parts, caufe the water • ro dilate, and render it fprurioilly fighter? They flouid naturally augment its wcis

This and fome other difficulties, (heir the a occafity of a new theory ; and therefore the ingenious author advances this which follows, which jhttnomena in a manner that ismoreciiy and fimple, as not depending ujjon the aJ million <>y t\ u lion of any heterogeneous matter.

lhi- water freezes in the winger only, becaufr its parts, then being more dolL-y jomed tothmer, mutually embarrais one another, and that tlic air, or rather an alteration in the fpring and force of the air, h the caufe of this clufer union of water.

It is evident from experiment, that there arc an infinite number of particJcs of giols air inteif-jrkd araoi! the gales of water; and it is allowed, that each particle of air has the virtue of a font.

licnce this author argues, that the fmall fprngs of grofs air, mixed witi water, have more force in cold winter weather, and do then unbend themselves more, than at other times. Hence thofe i'prir unbending thcinklves on or.efidr, and thcexti continuing

Surface of the water on the other, the particles of tlie water, being ill con-ftrnged and lod kod up together, mull KHC their motion ind (uiddy, ami form a hard, confident body, till a relaxation (the fpring of the air, from an increafs of heat, reduce the pai ticles to their old ctimenlioni, ir.d leave room for the gale to flow again;

But this fyltem leems to be built upon a fulc prin-

ciple, for the tying or tlafticity of the air is ; crtaicd by cold, but dimini(hi:di ur ctwuient cold, and exjtands ltfelf by hrat; and it ii di ftrable in pneumatics, tliu the elailk forte oi i , ptnoed air is to that of LIC finne air condenfed, ri the bulk when rarefied is to its bulk when oodei Indeed, fome authors, in order to account . increafcof the bulk and dimenfton of the l'pciiSc gravity of frozen water, have advanced as follows, ris. That the aqueous particles, in their natural itaw, were nearly cubes, and fo filled their fpace without i, terpofition of many pores ; but that they are c! from cubes to l'phtres, by congelation, from v it will necclUtrily follow, that there mult be a gtrjt deai of empty fpace between them.

But, in oppoliuon to this hypothees, the nattirt: of fluidiry and Bratnefi cally fuggcltt, thit fpherical partieei are much pnpvrcr to conftitute a fluid than cubical ones, and lets dilpold to form a iiaal than cubic one.

But after .til, in order to come to a confident theory of freezing, we mufl either have recourfe to the fr-"oric mawer of the Corjmfcularians, confidered uider tlic new light and advantages of the Newtonian philofbphy, Or to the ethereal matter of the CaneA-ans, under the improvtments of Monf! Gsuteron.

The true caul"; of treeeing, or the congelation I water into ice, lay the former, fecms plainly to be the introduction oi the frigorific particles into the pores or interfaces between the particles of rhe water, and by that means getting fo near them, u to be juft within the ipheres of one anotlier's at! rifting force, and then they mult cohere into one folid or firm body •, but heat afterwards fpirating tlien, and putting them into various motions, breaks this union, and feparaKi the i particles & . far from one another,

that they get out of the diftance ofthe attracting force, and into the verge of the rcjjielling force, and wen the water re-affliimes its fluid form.

Now, that cold and freezing proceed from fbmc fub-lbncc of a filinc nature floating in the air, feems probable from hence:

That nil fait?, and more eminently fame particular ones, do prodgtiouly increale the force and eff< of cold, when mixed with (how or ice, it is ailb evident, that all fjline bodiet | produce a fl llhcsand r: gidity in the paru of tin. • bodies into which they enue.

It appears, by nikrofcopical ubfervations upon falo, dial the figure of foim licks, before they be K in, o niaffeE,arc thin, duubl< • wenged, like parliUrs which have abundance a furface, in tclpeli to their lolidity ; and is the reafun why tlity fwim in water, when once r.iifed in it, thotij • fpeculically heavier.

Their fmall i points, gen tug inco lie porei of tlie water, whereby they an able, in fome meafure, fuf-pended in the winter time, when tJ heat of • be fun as no: (jr'i:mrly ftrroc • wough to diOWve ihr fairs into a fluid, to break tlic points, and to keep them in perpetual motion, being Ic6 diturbed, arc at more Liberty to approach one inDtber i and, by ihooring into crydais of the form aboi/t-mentioned, d •, by both their extremities, infinuai themselves into the purw of die water, and by tliat means freeze it into % folid form. And it ii apprcnt, that the dim en (ion* of WIKT are increaicd by freezing, the partitles of it being kept at lbme diAance from one another, by the intervention of the frigorik matter.

But belicta this, tie« *fe many little volumes, or finall particles of air, included at leveral difta b;ith in the pore* of the wait ry panicles, and

ces foniH-d by their fpl. Now, Tj the infinuation of the cryftan. the vulmci of air an: driven otit of the watery pfniclet, and many of them uniting, form tar er volumes, ••• h thereby b a greater force tq]fipand thcmlelvw than when they arc difperiedi a ra both enlarge the dinicnfotis, and il'en the fjieicfic gravity of watef thus congealed into ice.

And h • (fays Dr. C. r-ynr, from whom AM lafl account is taken) we may guef at J)K rranner boa wa-

ter, impregnated wiili fats, fulphurs, or earths, which are 100l wfiu diffiilvabl, may form itfelf into mixals, minerals, gums, and other (bflik; the parts of thef mixture* becoming a cement 10 the pa of water, or getting into their pores, diangc them inio tliije dffiereni lubllances.

tor ihe- fecund- as an ethereal matter or medium is generally allowed to be the caule of die motion of fluids, and as the air itfelf fiat all its morion fwn thi- fame principle, it follows, thur: all linkla nuill reni.iin in a fiate of refc or fixity, when that maner lo ici necefiiry fonct. And co nfcqciucly, the a< ; lefs vanned in the "inter tune, by real'on of the ob- liquity of the fin rays, is more denfc and fixed in winter than any tidier fealou of the year.

But farther: I is evident, from divers experiments, that the air doc-, contain a fait which u fuppoted to be of the nature «i" nitre. If this be grameii, and the denfity of the air allowwi, it will follow, tint the pinkies L' this nitre mull likewik; I brought nearer together, and illitkened by the condert- tion of the air; as on the contrary, a ratrficcion o' the air, and an augmentation of its fluidity, moil divide and (e- pame them.

And if the ferae happens to all liquors that liaw im- bided or illululvci any the li- quid keep the fill <w< and if the cool- nefs of a cellar, or of ice, auk die particles of the diflblvd ffl to approach, tun into taih other, and fnuot into • which is al- lowed to tic a luid, L« onm : gtiwral law cffitfr.

It is true, that the nitre of the air, being gn cold weather than in hot, muil have a left velocity, but dill the product at' i« augmented rmb into the velocity that remains, will give it a greater momen- tum-, ur quantity of tnot ion. Nor is here any thing farther required to mate this hit art with greater force againil the parts of fluids, and this may proba- bly bo die caule of the great cvajKiracfoii in Imly tpeather.

TiLs aercal nitre inuft ivceflarily promote tilt con- cretion of Equidsi for it is not the ait, nor yet the nitre that it contain OH to Htiids^

The first fort grows naturally in Italy, and other warm parts of Europe; and from the seeds of this there have been great varieties raised in the gardens of the florists, which differ in the size and colour of their flowers; and as there are frequently new varieties produced, so it would be to little purpose to enumerate those which are at present in the English and Dutch gardens, which amount to a great number in the catalogues of the Dutch florists, who are very fond of any little distinction, either in the colour or shape, to enlarge their lists.

The forts which are here enumerated, I think may be allowed as distinct species, notwithstanding Dr. Linnaeus has reduced them to five; for I have raised many of all the forts from seed, which have constantly produced the same as the seeds were taken from, and have only differed in the colour or size of the flowers; for the fort with broad leaves produced the same fort again, and the umbellated and spiked forts produced the same, though there are several varieties in the colours of their flowers.

The first hath a round compressed root, in shape like that of Cornflag, but is of a yellowish white colour; the stalk rises about fifteen inches high, having three or four narrow long leaves placed alternately, and the top is divided into two slender foot-stalks which turn downward, each sustaining one bell-shaped inverted flower, composed of six petals, which are chequered with purple and white like a chess-board; and in the center is situated a germin supporting one style, crowned by a trifid stigma, the six stamens stand about the style, but are shorter. At the bottom of each petal there is a cavity, in which is situated a hedtarium, filled with a sweet liquor; after the flower is fallen, the germin swells to a pretty large three-cornered blunt capsule, and then the foot-stalk is turned and stands erect; when the seeds are ripe, the capsule opens in three parts and lets out the flat seeds, which were ranged in a double order. The flowers of this appear the latter end of March or beginning of April, and the seeds are ripe in July. There is a variety of this with a double flower.

The second fort grows naturally in France, the leaves of this are broader, and of a deeper green than the former; the lower leaves are placed opposite, but those above are alternate, the stalk rises a foot and a half high, and is terminated by two flowers of an obscure yellow colour, which spread more at the brim than those of the first fort, but are turned downward in the same manner. This flowers three weeks after the first. There is a variety of this with greenish flowers, which grows naturally in some parts of England.

The third fort seldom rises more than a foot high, the leaves are narrow like those of the first fort, but are shorter, each stalk is terminated by three or four flowers, which arise above each other; they are of a very dark purple, chequered with yellowish spots. This flowers in April, about the same time with the second.

The fourth fort rises about a foot high, the stalk is garnished with spear-shaped leaves four inches long and one broad, of a grass-green colour; these are sometimes placed opposite, but are generally alternate the stalk is terminated by one large bell-shaped flower of a yellowish colour, chequered with light

purple. This fort flowers about the same time as the first. There are two or three varieties of this, which differ in the size and colour of their flowers and the breadth of their leaves, but retain their specific difference, so as to be easily distinguished from the other forts.

The fifth fort rises a foot and a half high; the stalk is garnished with shorter and broader leaves than the first fort, which are of a grayish colour; the flowers are produced round the stalks like those of the Crown Imperial; they are of a dark purple colour, chequered with a yellowish green. This flowers about the same time with the second fort.

The sixth fort is commonly called the Persian Lily, and is supposed to grow naturally in Persia, but has been long cultivated in the English gardens, the root of this fort is round and large, the stalk rises three feet high, the lower part of it is closely garnished with leaves which are three inches long, and half an inch broad, of a gray colour, standing on every side of the stalks, but are twisted obliquely; the flowers grow in a loose spike at the top of the stalk, forming a pyramid, they are shaped like those of the other species, but are much shorter, and spread wider at their brims, and are not bent downward like those. They are of a dark purple colour, and appear in May, but are seldom succeeded by seeds in England, so are only propagated by offsets.

The seventh fort hath a much shorter stalk than the last, but is garnished with leaves like those, only they are smaller, the stalks branch out at the top into several small foot-stalks, each sustaining one dark coloured flower. This is commonly called the small Persian Lily, from its resemblance to the former fort. These plants are propagated either by seeds, or offsets from the old roots; by the first of which methods new varieties will be obtained, as also a larger flock of roots in three years, than can be obtained in twenty or thirty years in the latter method; I shall therefore first treat of their propagation by seeds.

Having provided yourself with some good seeds, saved from the fairest flowers, you must procure some shallow pans or boxes, which must have some holes in their bottoms to let out the moisture; these you should fill with light fresh earth, laying a few pot-sheards over the holes, to prevent the earth from flopping them; then, having laid the earth very level in the boxes, &c. you must sow the seeds thereon pretty thick, covering it with fine sifted earth a quarter of an inch thick. The time for sowing the seed is about the beginning of August, for if it be kept much longer out of the ground it will not grow; then place the boxes or pans where they may have the morning sun until eleven o'clock, observing, if the season proves dry, to water them gently, as also to pull up all weeds as soon as they appear; for if they are suffered to remain until they have taken deep root into the earth, they would draw the seeds out of the ground whenever they are pulled up. Toward the latter end of September you should remove the boxes, &c. into a warmer situation, placing them close to a hedge or wall exposed to the south, if they are sown in pots, these should be plunged into the ground, but they are best in tubs, these should be covered in severe frost. In this situation they may remain until the middle of March, by which time the plants will be come up an inch high; you must therefore remove the boxes, as the weather increases hot, into a more shady situation; for while the plants are young, they are liable to suffer by being too much exposed to the sun: and in this shady situation they may remain during the heat of the summer, observing to keep them clear from weeds, and to refresh them now and then with a little moisture; but be careful not to give them much water after their leaves are decayed, which would rot their roots. About the beginning of August, if the roots are very thick in the boxes, you should prepare a bed of good light fresh earth, which must be levelled very even, upon which you should spread the earth in the boxes in

which

F R I

Which the small roots are contained, equally covering it about one fourth of an inch thick with the same freit earth: this bed should be situated in a warm position, but not too close to hedges, walls, or pales, which would cause their leaves to be long and slender, and make the roots weaker than if placed in a more open exposure.

In this bed they may remain until they flower, which is generally the third year from sowing; at which time you should put down a mark to the roots of all such as produce fair flowers, that at the time of taking them out of the ground (which ought to be done after their green leaves are decayed) they may be selected into a bed amongst your old roots of this flower, which, for their beauty, are preserved in the best gardens; but the other less valuable flowers may be planted in the borders of the parterre-garden for their variety, where, being intermixed with other flowers of different seasons, they will make a good appearance,

The fine sorts of this flower should remain undisturbed three years, by which time they will have produced many offsets; and should be taken up when their leaves are decayed, and planted into a fresh bed, taking such of their offsets as are large enough to produce flowers to plant in the flower-garden; but the smaller roots may be planted into a nursery-bed, until they have obtained strength enough to flower, but you must never suffer these roots to lie out of the ground when you remove them, but plant them again immediately, otherwise they will perish.

During these three years which I have advised the roots to remain in the beds, the surface of the earth should be stirred every autumn with a trowel, observing not to go so deep as to bruise the root, and at the same time lay a thin cover of very rotten dung or tanners bark upon the surface of the beds, which, being washed into the ground, will cause the flowers to be larger, as also the roots to make a greater increase: you must also observe to keep them constantly clear from weeds, and those roots which you would preserve with care, should not be suffered to feed.

When a stock of good flowers are obtained, they may be preserved and increased in the same manner as other bulbous rooted flowers, which is by offsets sent out from their roots, which should be taken off every other year from the finest sorts; but the ordinary flowers may remain three years undisturbed, in which time they will have multiplied so much, as that each root will have formed a cluster; so that if they are left longer together, the roots will be small, and the flowers very weak, therefore, if these are taken up every other year, the roots will be the stronger. These roots may be treated in the same manner as Tulips, and other bulbous rooted flowers, with this difference only, that the roots will not bear to be kept out of the ground so long; therefore, if there should be a necessity for keeping them out of the ground any time, it will be best to put the roots into sand to prevent their shrinking.

As these flowers come out early in the spring, they make a pretty appearance in the borders of the pleasure-garden, where they are planted in small clumps; for when they stand single in the borders, they make but a poor figure.

The eighth sort is the Crown Imperial, which is now very common in the English gardens. This grows naturally in Persia, from whence it was first brought to Constantinople, and about the year 1570, was introduced to these parts of Europe, of this flower there are a great variety now preserved in the gardens of florists, but as they have been produced accidentally from seeds, they are but one species; however, for the satisfaction of the curious, I shall here mention all the varieties which have come to my knowledge.

1. The common Crown Imperial; this is of a dirty red colour.
2. The yellow Crown Imperial; this is of a bright yellow.
3. The bright red Crown Imperial, called Fufai.

4. The pale yellow Crown Imperial.
5. The yellow striped Crown Imperial.
6. The large flowering Crown Imperial.
7. The broad leaved late red Crown Imperial.
8. The double and triple crowned Imperial Crown.
9. The double red Crown Imperial.
10. The double yellow Crown Imperial.
11. The silver striped leaved Crown Imperial.
12. The yellow striped leaved Crown Imperial.

There are some few other varieties which are mentioned in the catalogues of the Dutch florists, but their dimensions are so minute, that they are not distinguishable, so I shall pass them by, as those here inserted are all that I have seen growing either in England or Holland, which deserved any distinction.

The Crown Imperial hath a large round scaly root of a yellow colour, and a strong odour of a fox; the stalk rises to the height of four feet or upward; it is strong, succulent, and garnished two-thirds of the length on every side, with long narrow leaves ending in points, which are smooth and entire; the upper part of the stalk is naked, a foot in length, then the flowers come out all round the stalk upon short footstalks, which turn downward, each supporting one large, spreading, bell-shaped flower, composed of six spear-shaped petals; at the base of each petal is a pretty large cavity, in which is situated a large white nectarium, filled with a mellous liquor. In the center of the flower is fixed a three-cornered oblong germen, upon which sits the single style, which is the length of the petals, and is crowned by a spreading obtuse stigma; round the style there are six awl-shaped stamina which are shorter than the style, and are terminated by oblong four-cornered summits. These flowers hang downward, and above them rises a spreading tuft of green leaves, which are erect, and from between these come out the footstalks of the flowers: when the flowers decay, the germen swells to a large hexagonal capsule, shaped like a water-mill, having six cells, which are filled with flat seeds. This plant flowers the beginning of April, and the seeds are ripe in July.

The sort with yellow flowers, that with large flowers, and those with double flowers, are the most valuable; but that which hath two or three whorls of flowers above each other, makes the finest appearance; though this seldom produces its flowers after this manner the first year after removing, but the second and third year after planting, the stalks will be taller, and frequently have three tier of flowers, one above another, which is called the Triple Crown. The stalks of this sort frequently run flat and broad, when they produce a greater number of flowers than usual, but this is only a luxuriance of nature, not constant, though many of the writers have mentioned it as a particular Variety;

As this is one of the earliest tall flowers of the spring, it makes a fine appearance in the middle of large borders, at a season when such flowers are much wanted to decorate the pleasure-arden: but the rank fox-like odour which they emit, is too strong for most people, so hath rendered the flowers less valuable than they would have been if there is something very pleasing in the sight of them at a distance, so that were it not for the offensive smell of the leaves and flowers, it would be more frequently seen in all gardens for pleasure.

This may be propagated by seeds, or offsets from the root; the first is too tedious for most of the English florists, because the plants so raised, are six or seven years before they flower, but the Dutch and Flemish gardeners, who have more patience, frequently raise them from seeds, so get some new varieties, which rewards their labour. The method of propagating these flowers from seeds, being nearly the same as for the Tulip, the reader is desired to turn to that article, where there are full directions for performing it.

The common method of propagating them here, is by offsets sent out from the old roots, which will

flower from the second year after they are taken from the roots, but in order to have plenty of these, the roots should not be transplanted oftener than every third year, by which time each root will have put but several offsets, some of which will be large enough to flower the following year, so may be planted in the borders of the flower-garden, where they are to remain; and the smaller roots may be planted in a nursery-bed, to grow a year or two according to their size, therefore they should be fortified and the smallest roots planted in a bed together, which should remain there two years, and the larger by themselves to stand one year, by which time they will have acquired strength enough to flower, so may then be removed into the pleasure-garden.

The time for taking up these roots is in the beginning of July, when their stalks will be decayed; and they may be kept out of the ground two months, but they should be laid single in a dry shady room, but not in heaps, or in a moist place, which will cause them to grow mouldy and rot. The offsets should be first planted, for as these are small, they will be apt to shrink if they are kept long out of the ground.

As the roots are large, they must not be planted too near other flowers; and when they are planted in beds by themselves, they should not be nearer than a foot and a half in the rows, and two feet row from row; they should be planted six inches deep at lead, especially the strong roots: they delight in a light soil, not too wet, nor very full of dung, therefore, if any dung is laid upon the borders where they are planted, it should be buried pretty deep, so as to be two or three inches below the roots.

The ninth and tenth sorts grow naturally at the Cape of Good Hope, from whence they were brought into the European gardens. The ninth has been many years an inhabitant, where it has been usually titled *Corona Regalis*. This has a tuberose root, from which arise in the autumn six or eight obtuse leaves, near five inches long and two broad toward the top, growing narrower at their base, and are crested on their borders, lying flat on the ground; these continue all the winter: in the spring arises the flower-stalk in the center of the leaves, about six inches high, naked at the bottom; but the upper part is surrounded by bell-shaped flowers, composed of six greenish petals, with an oval germin situated at the bottom, surrounded by six stamina, supporting a triangular style, crowned by a trifid stigma; the germin afterwards becomes a roundish capsule, but rarely perfects seeds in England. This flowers in April, and the leaves decay in June.

The second sort I raised from seeds, which were sent me from the Cape of Good Hope: the root of this is like that of the ninth sort, but the leaves are more than a foot long, broad at their base, but are narrowed to the top, where they end in acute points; the flower-stalk rises rather higher than that of the ninth, but the flowers are of the same shape and colour: this seldom flowers till August. The roots of this sort were stolen out of the Chelsea garden the following spring after it had flowered, and were sold to some persons whose love for rare plants exceeded their honesty.

FRITILLARIA CRASSA. See ASCLEPIAS.

FRONDOSA [frondosus, *Lat.*] full of leaves, or shoots.

FROST may be defined to be an excessive cold state of the weather, whereby the motion and fluidity of the liquors are suspended, or, it is that state of the air, &c. whereby fluids are converted into ice.

By frost metals contract, or are shortened. Monf. Auzout found in an experiment, that an iron tube twelve feet long, upon being exposed to the air in a frosty night, lost two lines of its length; but this may be supposed to be wholly the effect of cold.

On the contrary, frost does not contract fluids, but, on the other hand, swells or dilates them near one tenth of their bulk.

Mr. Boyle gives us several experiments of vessels made of metals exceeding thick and strong, which being

filled with water, close flopped, and exposed to the cold, the water, being expanded by freezing, and not finding either room or vent, burst the vessels.

A strong barrel of a gun, with water in it, being flopped close, and frozen, was rent the whole length and a small brass vessel, five inches deep, and two in diameter, filled with water, &c. and frozen, lifted up its lid, which was pressed with a weight of fifty-six pounds.

There are also related many remarkable effects of frost on vegetables. Morery, Hist. de France, says. That trees are frequently scorched and burnt up with frost, as with the most excessive heat, and that even in so warm a climate as Provence;

Mr. Bobart relates, That in the great frost anno 1683, Oaks, Alhes, Walnut-trees, &c. were miserably split and cleft, so as they might be (ten through, and this too with terrible noises like the explosion of fire arms; that the cliffs were not only in the bodies, but continued to the larger boughs, roots, &c. Philof. Tranfact. N^o 105.

Dr. Derham says, That the frost in 1708, was remarkable through the greatest part of Europe; and the greatest in degree, if not the most universal, in the memory of man, that it extended throughout England, France, Germany, Denmark, Italy, &c. but was scarce felt in Scotland and Ireland. All the Orange-trees and Olives in Italy, Provence, &c. and all the Walnut-trees throughout France, with an infinity of other trees, perished by the frost.

Monf. Goueron says, They had a gangrene on them, which he takes to be the effect of a corrosive fait, which corrupted and destroyed their texture. He adds, That there is so much resemblance between the gangrene befalling plants through frost, and that which the parts of animals are liable to, that they must have some analogous cause. Corrosive humours burn the parts of animals, and the aerial nitre, condensed, has the same effects on the parts of plants. Memoires de P Academie Royale de Sciences, an. 1709.

Dr. Derham says, That the greatest sufferers in the animal kingdom were birds and insects, but vegetables were much the greatest sufferers, that few of the tender sorts of vegetables escaped the severity of the frost, Bays, Laurels, Rosemary, Cyprif, Alaternufes, Phillyreas, Arbutufes, Laurustinufes, and even Furz, with most sort of the frutescent herbs, as Lavenders, Abrotanums, Rue, Thyme, &c. were generally destroyed. He adds, that the sap of the finer wall-fruit was so congealed and destroyed, that it stagnated in the limbs and branches, and produced disorders like to chilblains in human bodies, which would turn to mortifications in many parts of the trees; that the very buds of the finer trees, both in the leaf, buds, and blossom buds, were quite killed, and dried into a farinacious matter.

Dr. Derham relates it as a common observation, That vegetables suffered more from the sun than from the frost, in that the sun-shine, melting the snow, and opening the ground, left it more exposed to the rigour of the ensuing night. It was likewise observed, at a meeting of the Royal Society, That the calamities which befall trees, arose not purely from their being frozen, but principally from the winds shaking and rocking them when they are frozen, which rent and parted their fibres. Philof. Tranfact. N^o 324.

Hoar frost, or white frost, is the dew frozen, or congealed early in cold mornings, chiefly in autumn. This (as Mr. Regis observes) is an assembly of little parcels of ice or crystals, which are of various figures, according to the disposition of the vapours which meet and are condensed by cold.

Dew is, to all appearance, the matter of hoar frost, though many of the Cartesians suppose it to be formed of a cloud, and either congealed in the cloud, and so let fall, or ready to be congealed as soon as it arrives at the earth.

In the year 1728-9, there was a remarkable frost, which continued for some months, and destroyed a great number of trees and plants in several parts of Europe,

a' brief account of which may not be improper to Be h're inferted.

The autumn began with cold north and east winds; and early in November the nights were generally frofty, though the froft did not enter the ground deeper than the fun thawed the following day; but toward the end of November the winds blew extremely cold from the north, which was fucceeded by a great fnow, which fell in fuch quantities in one night, as to break off large arms* is alfo the tops of many Evergreen-trees, on which it lodged. After the fnow had fallen, it began to freeze again, the wind continuing to blow from the north -, the days were dark and cloudy for some time, but afterwards it cleared up, and the fun appeared almoft every day, which melted the fnow where expofed to it, whereby the froft penetrated deeper into the ground. It was obfervable, that, during thefe clear days, a great mift or vapour, appeared in the evenings, floating near the furface of the ground until the cold of the night came on, when it was fuddenly condenfed, and difappeared. About the 8 th of December, the nights were extremely cold; the fpirits in the thermomoter fell 18 degrees below the freezing point, and on the 10th of the fame month the froft was as fevere as had been known in the memory of man 5 the fpirits of the thermomoter fell to 20 degrees below the freezing point. At this time vaft numbers of Lauruftinufcs, Phillyreas, Alaternufcs, Rofemary, Arbutus, and other Evergreen-trees and drubs began to fuffer; epecially fuch as had been trimmed up to heads with naked ftems, or had been clipped late in autumn. At this time alfo there were great numbers of large deciduous trees di(barked by the froft, as Pear-trees, Plane-trees, Walnut-trees, with many other forts, and it was chiefly on the weft and fouth-weft fide of the trees, that the bark came off.

About the middle of December the froft abated of its intenfenefs, and feemed to be at a ftand till the 23d of the fame month, when the wind blew extremely fharp and cold from the east, and the froft increafed again, continuing very fharp till the 28th day, when it began to abate again, and feemed to be going off, the wind changing to the fouth; but it did not continue long in this point, before it changed to the east again, and the froft returned, though it was not fo violent as before.

"Thus the weather continued for the moft part frofty, till the middle of March, with a few intervals of mild weather, which brought forward fome of the early flowers; but the cold returning, foon deftroyed them : fo that thofe plants which dually flower in January and February, did not this year appear till March, and before they were fully blown, were cut off by the froft, of this number were all the Spring Crocufes, Hepaticas, Perflan Irifes, Black Hellebores, Meze-reons, with fome others.

The Cauliflower plants, which were planted out of the beds in the open ground, during the intervals between the froft, were moft of them, deftroyed, or fo much cut, that they loft moft of their leaves; the early Beans and Peas were moft of them killed, and many fruit and foreft trees, which had been lately removed, were quite deftroyed. The lofs was very great to fome curious perfons, who had been many years endeavouring to naturalize great numbers of exotic trees and fhubs, abundance of which were either totally killed, or deftroyed to the furface of the ground; amongft this number there were many forts deftroyed, which had endured the open air many years, without receiving the leaft injury from the cold, fuch as Paffion Flowers; Cork-trees, Ciftufes, Rofemary, Stoechas, Sage, Maftich, and fome others. In fome places the young Afh and Walnut-trees were killed; but when the froft went off, there appeared to have been much more damage done in the gardens, than there really was, which occafioned many people to dig up and deftroy large quantities of trees and fhubs, which they fuppofed were killed; whereas thofe who had more patience, and fuffered them to remain, fared better;

for great numbers of them (hot out again, fome firft their ftems and branches, and others from their roots; the following fumrher.

Nor was the froft more fevere in England, than in other parts of Europe, but, on the contrary, in comparifon, favourable; for in the fouthern parts of France, the Olives, Myrtles, Ciftufes, Alaternufes; and feveral other trees and fhubs, which grow there almoft fpontaneoufly, were either deftroyed, or at leaft were killed to their roots; and about Paris, and the northern parts of France, the buds of their fruit-trees were deftroyed, although they remained clofed, fo that there were very few bloffoms which opened that fpring. The Fig-trees were in feveral parts of France quite killed, and in England their tender branches were deftroyed, fo that there was very little fruit on thofe trees the following fumrher, except where they were protefted from the froft.

In Holland the Pines and Firs; With feveral other trees, which are natives of cold countries, were greatly injured by the cold; and moft of the trees and fhubs, which were brought from Italy, Spain, or the fouth parts of France, which had been planted in the full ground, in that country, were entirely killed, though many other forts, which had been brought from Virginia and Carolina, efaped very well in the fame gardens; but the perfon who fuffered moft in that country, was the learned Dr. Boerhaave, who had been feveral years endeavouring to naturalize as many exotic trees and fhubs as he could poffibly obtain from the feveral parts of the world, great numbers of which were entirely deftroyed by the froft this winter.

In fome parts of Scotland they not only loft many of their curious flowers, plants, and trees, but great numbers of fheep, and other cattle, were buried under the fnow, where they perifhed; and many poor people, who went to look after their cattle, were equal fullerers with them, being buried in the fnow, which in fome places fell eight or nine feet deep in one night.

It has been obferved by thermometers* when that kind of hovering lambent fog arifes (either mornings or evenings) which frequently betokens fair weather* that the air, which in the preceding day was much warmer, has, upon the abience of the fun become many degrees cooler than the furface of the earth, which being near 1500 times denfer than the air, cannot be fo foon affected with the alteration of heat and cold; whence it is probable, that thofe vapours which are raifed by the warmth of the earth, are by the cooler air foon condenfed into a vifible form. The fame difference has been obferved between the coolnefs of the air, and the warmth of water in a pond, by putting a thermometer, which hung all night in the open air in fummer time, into the water, juft before the rifing of the fun, when the like reek* or fog, was rifing on the furface of the water.

In the year 1739-40 we had another fevere winter, which did great mifchief to the gardens, fields, and woods, the effects of which are yet, and will be many years, felt in Europe. Some particulars of thefe depredations, may not, perhaps, be unacceptable to the reader, if they are here mentioned.

The wind fet in blowing from the north and north-east, about the autumnal equinox, and continued to blow from the fame quarter, with little variation, upward of fix months. Early in November, there was a continued fharp froft for nine days, in which time the ice upon large ponds, and other ftanding waters, was frozen fo hard as to bear perfons who fskated thereon; but toward the end of November the froft abated, and there was little more than flight morning frofts until Chriftmas day, when it froze pretty hard that morning, and continued every morning fo to do; but on the 28th day of December, the wind blew with great ftrength from the north-east, and brought on fevere cold; that night the froft penetrated very deep into the ground, and the next day, viz. the 29th, the wind changed to the fouthward of the east, and blew with great fury; the thermometer fell this day to

Twenty-five degrees below frost; in the morning (some) the violence of the wind carrier) it off; but cold dill in creating, the waters were all frozen over, and that day it was so intense, as to freeze the water of the river, which melted by the force of the wind into ice, before it fell down again. The wind continued to blow with the same force, and from the same quarter, all the following day, the cold increasing, so that at this time the frost penetrated into the heart of the green-houses in England, but especially into all those whose fronts had the least inclination to the east; the furrows of them is fronted the fourth-week escaped belt, where the back walls were of a sufficient thickness to keep out the frost, the spirits in the thermometer fell in the night of the 30th day 10 thirty-two degrees below the freezing point, which was lower than it had been known in England before; the violence of the wind made it very troublesome for persons of the most robust constitutions to be abroad, and this also caused the frost to penetrate through chick walls, and in the space of two days, the Evergreen-tree* and firrubs appeared as if they had been scorched by fire, so that they seemed to have no life; the only trees of all the sorts of Evergreens which retained their verdure at this time, were the Portugal Laurel, Savin, and the tubby Hurtwood which in the midst of this severe frost remained unhurt, when all the others were as brown as if they had been dead a year; and it was very late in the spring, before any of them returned their usual verdure: during these severe days there laid but little snow fallen, so that the frost penetrated deep in the ground, and decayed the roots of great part of the Vegetables, where they were not well secured, the Artichoke roots were most of them killed in all the kitchen-gardens, some few only escaped, these were such as were not intended to be preserved. A single row of licit roots, which were growing in a place where a great quantity of dung had been wheeled over them, whereby the ground was rendered as hard as that of a common foot-way, though there was no covering upon these roots, yet they survived the frost and did well; another parcel which were growing near a tan-yard, where, by accident, some tan had been thrown, were preserved, so that from some of the Town accidents we were so lucky as to retrieve the good kind of Artichoke, which the English gardens were so famous for being stocked with.

By the sharp piercing winds the Grapes were almost totally burned up, so that there was not the least verdure to be seen in the fields, and in many places the sweetest and best kinds of the herbage were entirely killed, so that there remained only the strong rough kinds of grass, whereby the pastures were in general much damaged; but on the next day in the evening, the wind being much abated, the severity of the frost was not so great, and there seemed an appearance of 3 thaw on the first and second of January, but on the third in the evening the frost let in again with great violence; and on the fourth of January in the morning, the thermometer was fallen one degree lower than it had been before. The same morning there was the greatest hoary frost which had been seen, the woods, trees, and hedge*, appeared as if they had been covered with snow, and although there was no wind stirring, yet the air was so sharp and penetrating, as to render it difficult to endure the cold even without exercise.

All timber-trees suffered grievously that morning, especially the Oak*, which were split with great violence, and the noise in the woods that morning, resembled that of great branches breaking down in every part of the woods, and when heard at a distance, like the firing of guns. This was likewise attended to at the time, but the timber which was once fallen, sufficiently proved the great violence which the woods then sustained; nor was it here the vicinity (lopped, for the Oaks in general had received so much injury from the frost, as 10 occasions the weakness and distemper among them, that all

following (bring they were infilled with ice) to fulfil a degree, as that their ledges were entirely destroyed by their ice, so that at Midluramer the trees were as naked as if it had been the beginning of April; the frost continued for two years after, almost as bad as at first, and has increased by degrees, so the tree* has recovered their strength and where the trees were old and weak, they have not yet gotten the better of this distemper.

The herbage was all so much weakened by the severity of the frost, as not to be able to refill the tracks made upon it by insects, but that innumerable quantities of them were discovered in various parts of Europe, beginning first in the northern countries, and afterward spreading to the south; and the insects in many places were so numerous, as to destroy the fruit of the Grape, and it is to be observed the distemper which (so long raged among the cattle) have been owing to this cause; for wherever the distemper spread, it has been observed, that numbers of these insects have harboured about the ribs of the Grapes: and as a farther proof of this, it has constantly been remarked, that when the grub has changed into a sort of beetle, and take their flight (which is commonly about the beginning of May, the distemper ceases to annoy; the beetles have deposited their eggs in autumn, the distemper has raged again. Another remark has been made, that these beetles always cluie to deposit their eggs at a great distance from rivers, and large pieces of water, and in such places the cattle have been most attacked. There might be many more circumstances mentioned in favour of this opinion.

Several experiments which have been made by the members of the Academy of Science* at Paris, which are sufficient to prove, that the distemper is not infectious, nor can be communicated by the cattle, notwithstanding it has been treated as such in many countries, where has been an immense loss to the public of such numbers of cattle and their hides; but this may require a particular treatise, therefore I shall not enlarge farther on this head at present.

The frost still continued very hard till toward the end of January, but not so violent as at the beginning; for had the wind continued to blow with the same force as it had done the three first days of the frost, for any considerable time longer, there would have been few vegetables able to have survived the cold, nor would the animal kingdom have been so much better; for the cold was so intense during the few days, as to kill several of the weaker sort of cattle, where they were much exposed to the wind.

The Walnut-trees, Ash, and several other trees, most of their roots of the former were destroyed, which caused them to be very late before they produced their new shoots the following spring, and their shoots were produced from the two and three year branches. The Fig-trees in many places were killed almost to the ground, especially those which were growing again in the open field, for the old standard Fig-trees were better, but all their roots and barks of the trees, which were growing in the nursery-gardens, were so much injured by the frost, as not to be recovered under three years, during which time there were scarce any of these plants to be sold. The trees of the Vine, as also of the Oriental Plane-tree, in the nurseries, were likewise killed to the ground, and the old fruit was so much injured, that they had better have been dug up and thrown away, than to have continued them, for their shoots in the summer, that their wood had not time to harden, and the first frost in autumn frequently killed them half to the ground.

Many other deciduous trees were equal successively by this severe frost, and the Evergreens were more generally injured, and abundance of them killed. The Pine and Fir were so much hurt, as to lose all their verdure, and in the young plants of the

the former fort were entirely killed. The Rosemary, Lavender, Stoechas, Sage, and many other aromatic plants, were in many places quite destroyed, so that it was two or three years before the markets could be supplied with these; and in general the esculent plants in the kitchen-gardens were killed, so that for some months the markets were not supplied with any quantity of garden stuff. The flower-gardens also were great sufferers by this winter for as the seasons for some years before had been very temperate, few persons had made any provision for a hard winter; and the cold setting in so very intense at the beginning, the mischief was done before people could be provided with covering.

The Wheat in many parts of England, but especially in the open common fields, was very much hurt, particularly on the top of the ridges, where, in several places there were broad naked spaces on the middle of the ridges, which in the spring appeared like so many foot-paths. And as the spring following was very dry, and the wind continuing to blow from the north and east; these piercing winds entered the ground, which had been loosened by the frost, and dried up the tender roots of the Corn, to the great prejudice of it; but some of the more expert farmers, who rolled their Wheat after the frost was over, were well repaid by the great crops which their land produced them.

Were I to enter into all the particulars of the damages sustained by this severe frost in the gardens and fields, it would swell this work beyond the limits intended, so I hope, on the other hand, I shall not be condemned for having inserted thus much, since, by the mention of these things, persons may be instructed how to save many of their valuable plants in future winters, as also what sorts are more liable to danger from frosts than others.

FRUCTIFEROUS [*frudifcr, Lat.*] fruit-bearing, fruitful.

FRUCTUS. See **FRUIT.**

FRUIT is the production of a tree or plant, for the propagation or multiplication of its kind; in which sense fruit includes all kinds of seeds, with their furniture, &c. botanists use it to signify properly, that part of a plant wherein the seed is contained, which the Latins call *Fru&us*, and the Greeks *Kap-or*.

The fruit of some plants are produced singly, as are their flowers, and sometimes they are produced in clusters, as in most fruit-trees, which are also fleshy, but in many plants they are dry.

The word fruit is also used to signify an assemblage of seeds in a plant; as in a Pea, Bean, Ranunculus, &c. and in its general signification, for all kinds of grain, whether naked, or inclosed in cover, capsule, or pod, whether bony, fleshy, skinny, membranous, or the like.

Fruit is the product or result of the flower, or that for whose production, nutrition, &c. the flower is intended.

The truest and parts of different fruits are different in some things, but in all the species the essential parts of the fruit appear to be only continuations or expansions of those which are seen in the other parts of the tree.

Dr. Beale suggests some very good reasons for a direct communication between the remotest parts of the tree and the fruit; so that the lame fibres which constitute the root, trunk, and boughs, are extended into the very fruit.

Thus, if you cut open an Apple transversely, you will find it to consist chiefly of four parts, viz. first, a skin, or cortex, which is only a production of the skin or outer bark of the tree, and, secondly, a parenchyma or pulp, which is an expansion and intumescence of the inner bark of the tree. The fibres, or ramifications of the woody part of the tree, which is the produce of the pith, or medulla of the plant, indurated or enlarged by rings of the wood and fibres inoculated therewith. These fibres to furnish a cell, or lodge, for the kernels, filtrates

the juice of the parenchyma, and conveys it thus prepared to the kernel.

Of the fibres, authors generally reckon fifteen branches, of which ten penetrate the parenchyma, and incline to the basis of the flower, the other five ascend more particularly from the pedicle or stalk, and meet with the former at the base of the flower, to which branches the capsule, or coats of the kernels are fattened.

These branches being first extended through the parenchyma to the flower, furnish the necessary matter for the vegetation of it; but as the fruit increases, it intercepts the aliment, and thus the flower is starved, and falls off.

In a Pear there are five parts to be distinguished, viz. the skin, parenchyma, ramification, kernel, and acetarium.

The three first parts are common to the Apple. The kernel, observed chiefly in Choke Pears, or Breaking Pears, is a congeries of strong corpuscles, that are dispersed throughout the whole parenchyma, but in the greatest plenty, and clost together about the center, or acetarium; it is formed of the stony or calculeous part of the nutritious juice.

The acetarium is a substance of a tart acid taste, of a globular figure, inclosed in an assemblage of several of the stony parts before-mentioned.

In a Plumb, Cherry, &c. there are four parts, viz. a coat, parenchyma, ramification, and nucleus, or stone. The stone consists of two very different parts; the external or harder part, called the stone, or (hell, is a concretion of the stony, or calculeous parts of the nutritious juice, like the kernel in Pears, within it. The inner, called the kernel, is soft, tender, and light, being derived from the pith, or medulla of the tree by feminal branches, which penetrate the base of the kernel.

The nut, or acorn, consists of a (hell, cortex, and medulla. The shell consists of a coat and parenchyma, derived from the bark and wood of a tree.

The cortex consists of an inner and outer part, the first is a duplicature of the inner tunic of the shell; the second is a mossy substance, derived from the same source as the parenchyma of the shell. But authors are not agreed, whether the medulla, or pulp of the kernel does arise from the pith of the tree, or the cortical part thereof.

Berries, as the Grape, &c. contain (besides three general parts, viz. coat, parenchyma, and ramification) grains of a stony nature, to do the offices of feeds. Fruits in general are serviceable in guarding, preserving, and feeding the inclosed seed, in filtrating the coarser more earthy, and strong parts of the nutritious juice of the plant, and retaining it to themselves, Vending none but the most pure, elaborated, and spirituous parts to the seed, for the support and growth of the tender delicate embryo or plantule, which is therein contained.

FRUMENTACEOUS [*Frumentaceous, Lat.*] a term applied by botanists to all such plants as have a conformity with Wheat (called in Latin *Frumentum*.) in respect either of their fruits, leaves, ears, or the like.

FRUMENTUM INDICUM. See **ZEA.**

FRUTEX, a shrub; a vegetable of a genus between a tree and an herb, but of a woody substance. It is pretty difficult to determine wherein most of the writers on gardening and agriculture have made the distinction between trees and shrubs, or where to fix the difference or boundary, between the trees and shrubs, to say where one ends, and the other begins, for that cannot be determined by their growth; therefore the best definition which can be made of a shrub, to distinguish it from a tree, is its sending forth many stems from the roots, whereas the trees have a single trunk or body.

FRUTEX PAVONIUS. See **POINCIANA.**

FRUTICOSE [*Fruticofus, Lat.* shrubby,] are those plants which are of a hard woody substance, and do not rise to the height of trees.

>) HtSI A. Plum. Nov. Gen. (4. Lin. Gen. Plant. 1097. This plant was fo named by Father Plumier, who difcovered it in America, in honour of the memory of Leonard Fuchfius, 3 learned botanift.

The CHARACTERS are,
The ftwiar bash «o anpalemcnl -, ft bath one petal, with a efefed tube, wbkb is flightly cut into eight parts ; t the brim-, aiding in arute points; it bath four flamina the length of the tube, which are terminated by obtufe fummit's. The oval gertnen isfitusttd under tbt flower, fupprtlng a fmgle flyle, crowned by an obtufe fligma. The germen afterward becomes a fucadftit berry with four furrows, having four cells, containing feveral final! oval fieds.

This genus of plants is ranged in the firft fection of Linmus's fourth dais, intified Tetrandria Monogynil, the flower having four ftamina and one ftylr.

We know but one SPECIES of this genus at precent, viz.

FUCHSIA [Triphylla.] Lin. Sp. Plant. 1191. Three-leaved Fuchfitti. Fuchfia triphylla, flore coccineo. Plum. Nov. Gen. Tbtret-ltoved Fuchfia with a fcarlct fewer.

This plant is a native in the warmed parts of America; it was difcovered by Father Plumier, in fome of the French Iflands in America, and was fince found by the late Dr. William Houltoun, at Carthagtna in New Spain, from whence he fent the feeds into England.

This is propagate, by fords, which muft be lbwn in pots filled with rich 11 "lit earth, and plunged into a hot-bed of tanners bark, and treated in the fame way as other feeds from warm countries. In about a month or fix weeks alter the feeds are fawn, the planes will begin to appear, when (tin-) fhould be carefully cleared from weeds, and frequently refreihed with water to jromore their growth; and n'hen they arc about two inches high, they (hould be lbakenout of the pot, and feparaid carefully; then plant each into a (mall pot filled with light rich earth, and plunge them again into a hot-bed of tanners bark, being careful to Screen them from the fun until they have taken new root; after which time they muft have frth air admitted to them every day in proportion to the warmth of the feifon, and mould be frequently watered. As the fea- (m advances and becomes warm, the glides of the hot-bed fhould be raifed higher, to admit a greater (hare of air to the plants, ro prevent their drawing up weak; and when the plants arc grown fo tall as to reach the glaffes, they mould be removed intothe bark-ftove, and plunged into the tan-bed. In winter thefe plants requite to be kept very warm, and at that feafon they muft not have much water, but in lummer it muft be often repeated.

Thefe plants arc too tender to thrive in the open air in this country, even in the hottelt part of the year; therefore they fhould constantly remain in the Sove, obferving to lft in a large fhare of frelh air in fumnw, but in winter they muft lie kept warm l with this management the plants will product- their flowers, and make a beautiful appearance in the ftavCj amongft other tender exotic plants,

The firft fort is the common Fumatory which is ufcd in medicine. This grows naturally on arable llnul in mod parts of Engiand \ it is a low annul phut, and flowers in April, May, and June-, and very often from plants which rife late in the fummer, there will be a fecond crop in autumn. The juice of riii* plant b greatly commended for bilious eitejk*. h is never cultivated In gardens.

The fecond fort grows naturally in the foiiih Of France, Spain, and Portugal, but is preferred in botanic fi article ibr the fake of variety. U is an annual plant.

plant, which rises from the scattered feeds better than when it is sown with care; the stalks of this grow more erect, the leaves are very finely divided, and the flowers grow in a clove spike; they are of a deep red colour, and flower about the same time as the common fort.

The third fort grows naturally on the borders of the Mediterranean Sea; it was first brought to England from Tangier. This is a perennial plant, which sends out from the root many branching stalks, which rise about six or eight inches high, growing in tufts or bunches; the leaves are very much divided, the stalks are angular, and the flowers grow in loose panicles upon naked foot-stalks, which come out from the divisions of the branches; they are of a whitish yellow colour, and there is a succession of them most part of the year.

The fourth fort hath an appearance very like the third, and by some it is supposed to be only a variety of that, but is undoubtedly a distinct species; for I have cultivated both more than forty years, and never yet found either of them to vary. The stalks of this fort have blunt angles, whereas those of the third are acute; they are of a purplish colour, and the flowers grow in looser panicles, each having a longer foot-stalk than those of the other -, they are of a bright yellow colour, and there is a succession of them great part of the year.

These two forts continue green all the year, and except in very severe frosts, are always in flower, which make a pretty appearance; they grow best on walls or rocks, and are very proper for the joints of grottos, or any rock-work; where, if a few plants are planted, or the feeds scattered, they will multiply fast enough from their scattering feeds, which are cast out of the pods by the elastic spring of the valves when ripe, to a considerable distance; and as the plants will require no care to cultivate them, they should not be wanting in gardens.

The fifth fort grows in stony and sandy places in some parts of England; it is an annual plant with trailing stalks, sending out clasps from the leaves, which fatten to any of the neighbouring plants. It flowers in May and June, but is never cultivated in gardens.

The sixth fort is an annual plant with many trailing stalks, which grow about a foot long, sending out a few short tendrils, whereby they fatten to any neighbouring support; the flowers come out from the side of the stalks in loose bunches; they are of a whitish herbaceous colour, with a purple spot on the upper lip. This flowers in May and June. It grows in France and Italy, on stony places in the shade.

The seventh fort grows naturally in the south of France and Italy, and was some years past preserved in the English gardens by way of ornament, but is now rarely to be found here; it was titled *Radix cava*, or hollow root, from its having a pretty large tuberosus root hollowed in the middle. The stalk of this fort rises about six inches high, and does not divide, but is garnished toward the bottom with one ramous leaf, somewhat like the common Fumatory, but the lobes are broader; the flowers grow in a spike at the top of the stalk; they are of a pale herbaceous colour and appear in April. This plant delights in the shade, and is multiplied by offsets, for it rarely ripens feeds in England.

The eighth fort is pretty common in many of the old gardens in England; it grows naturally in the south of France, in Germany and Italy. This hath a pretty large round solid root of a yellowish colour, from which come out branching leaves like those of the last fort, but the lobes are longer; the flowers grow in spikes on the top of the stalks; they are of a purple colour, and come out early in April. The stalks of this fort are lingle, and rise about four or five inches high.

There is a variety of this with green flowers, which is mentioned in most of the books; but all the plants of this fort which I have yet seen, are only abortive,

having no real flower, only a green bractea, which has been generally taken for the flowers: there is also mentioned a larger fort; but if there is one which is really different from the common fort, I have not seen it in the English gardens, nor the yellow and white flowering forts, which are also mentioned in many of the books.

The ninth fort grows naturally in North America; this hath a fealy root about the size of a large Hazel Nut, from which come out three or four leaves upon slender foot-stalks; these are divided into three parts, each of these parts is composed of many smaller divisions, which have narrow lobes, divided into three parts almost to the bottom; the flower-stalk is naked, and eight or nine inches long; this is terminated by four or five flowers, growing in a loose spike; these have two petals, which are reflexed backward, and form a sort of fork toward the foot-stalk, and at their base are two horned anthers, which stand horizontal. The flowers are of a dirty white colour and appear in May, but rarely produce feeds here.

This is propagated by offsets from the root; it loves a shady situation and a light soil; the best time to transplant the roots is in autumn, when the leaves are decayed, for it shoots pretty early in the spring, therefore it would not be safe to remove them at that season.

The tenth fort grows naturally at the Cape of Good Hope; this is an annual plant, with trailing stalks which are two or three feet long, dividing into many smaller, which are garnished with small branching leaves shaped like those of the common Fumatory, but end with tendrils, which clasp to any neighbouring plants, and thereby the stalks are supported -, the flowers are produced in loose panicles, which proceed from the side of the stalks; they are of a whitish yellow colour, and are succeeded by globular swollen pods, in which are contained a row of small shining feeds.

This is propagated by feeds, which should be sown upon a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a small pot filled with light earth, and plunged again into the hot-bed, where they must be shaded from the sun till they have taken new root; after which they should have a large share of air admitted to them at all times in mild weather, to prevent their drawing up weak; and as soon as the season is favourable, they should be inured to bear the open air, to which they may be removed the beginning of June, when they may be shaken out of the pots, preferring all the earth to their roots, and planted in a warm border, where their stalks should be supported with flicks to prevent their trailing on the ground; and in July the plants will flower, and continue a succession of flowers till the frost destroys the plants; the feeds ripen in autumn.

The eleventh fort grows naturally upon old walls or rocks in Spain and Italy; this hath weak trailing stalks which are much divided, and are garnished with small leaves divided into three parts, each of which hath three heart-shaped lobes. The flowers are produced in small loose panicles from the side of the stalks, they are of a greenish white, and appear most of the summer months. It is an abiding plant, which propagates itself by the feeds that scatter, and thrives best in a shady situation, and on old walls or buildings.

The twelfth fort is an annual plant with an upright stalk, which grows a foot and a half high, round and very smooth, sending out several branches upward; these are garnished with smooth branching leaves of a pale colour, which are divided like the common fort, but the small leaves are larger and more obtuse; the flowers are produced in loose panicles from the sides of the stalks, and at the extremity of the branches; they are of a pale purple colour, with yellow chaos (or lips); these are succeeded by taper narrow pods an inch and a half long which contain many small shining black feeds. This flowers during most of the summer months, and the feeds ripen in July, Au-

F U M

guft, and September. If the feeds of this plant are permitted to fcatter, the plants will come up without any trouble, and require no other care but to thin them where they are too clofe, and keep them clean from weeds.

Thefe plants may be fuffered to grow on walls, and in fome abjeft part of the garden *, for if they are admitted into the borders of the pleafure-garden, they will fcatter their feeds, and become troublefome weeds j but they are very proper plants to grow on ruins, or on the fides of grottos or rock-work, where, by their long continuance in flower, they will have a good effect.

The fifth, fixth, feventh, and eighth forts are propa-

F U R

gated by offsets, as other bulbous-rooted flowers * thefe produce their flowers in the beginning of April, and are very pretty ornaments to borders in a fmall flower-garden. They are extreme hardy, but do not increafe very fall, feldom producing feeds with us; and their bulbs do not multiply very much, efpecially if they are often tranfplanted. They love a light fandy foil, and fhould be fuffered to remain three years undifturbed, in which time they will produce feveral offsets. The beft feafn for tranfplanting them is from May to Auguft, when the leaves begin to die off; for if they are taken up when their leaves are freffi, it will greatly weaken their roots.

G A L

GALANTHUS. Lin. Gen. Plant. 362. Narcifflb-leucoium. Tourn. Inft. R. H. 387. tab. 208. The Snow-drop 5 in French, *Perce-neige*.

The CHARACTERS are, *the fpatha or Jheath of the flower is oblong, blunt, and compreffed. Tins opens fideways, and becomes a drykin; the flower bos three oblong concave petals, which Jpread open, and are equal \ in the bottom is ftuated the three-leaved neffarium, which is cylindrical, obtufe, and indented at the top -, under the flower is ftuated the oval germen, fupporting a flender fyle, which is longer than the ftamina, crowned by fingle ftigma; this is attended by fixjhort hairy ftamina, terminated by oblong pointed fummits, which are gathered together. The germen afterward becomes an oval capfule which is obtufe and three-cornered, opening in three cells, which are filled with roundijh feeds.*

This genus of plants is ranged in the firft fettion of Linnaeus's fixth clafs, intitlei Hexandria Monogynia, which includes the plants whofe flowers have fix ftamina and one fyle.

This plant, as alfo the great Snow-drop, was by Dr. Tournefort ranged together under the title of Narcifflb-leucoium; which being a compound name, Dr. Linnaeus has altered it to this of Galanthus *, and has feparated the great Snow-drop from this, and given the fimple name of Leucoium to that genus.

We know but one SPECIES of this genus, viz.

GALANTHUS (*Nivalis*.) Lin. Hort. Cliff. 134- The common Snow-drop. *Leucoium bulbofum trifolium minus*. C. B. P. The lead bulbous Snow-drop with three leaves.

There is a variety of this with double flowers.

Thefe flowers are valued for their early appearance in the fpring, for they ufually flower in February when the ground is often covered with fnow. The fingle fort comes out the firft, and though the flowers are but fmall, yet when they are in bunches, they make a very pretty appearance; therefore thefe roots fhould not be planted fingle, as is fometimes pra&ified by way of edging to borders; for when they are fo difpofed, they make very little appearance. But when there are twenty or more roots growing in a clofe bunch, the flowers have a very good effect; and as thefe flowers thrive well under trees or hedges, they are very proper to plant on the fides of the wood-walks, and in widernefs-quarters \ where, if they are

G A L

fuffered to remain undifturbed, the roots will multiply exceedingly. The roots may be taken up the latter end of June, when their leaves decay, and may be kept out of the ground till the end of Auguft, but they muft not be removed oftener than every third year.

GALE. See MYRICA.

GALEGA. Lin. Gen. Plant. 770. Tourn. Inft. R. H. 308. tab. 222. Goat's-rue.

The CHARACTERS are,

The empalement of the flower is Jhort, tubulous, and of one leaf, indented in five parts. The flower is of the butterfly kind; the ftandard is oval, large, andreflexed-, the wings are near the length of the ftandard \ the heel is erect, oblong, and compreffed; the under fide toward the point is rounded, but the upper is acute; there are ten ftamina, which join above their middle, and are terminated by fmall fummits. In the center is ftuated a narrow, cylindrical, oblong germen, fupporting a flender flyk, crowned by aftigma terminated by a punOure. The germen afterward becomes a long pointed pod, incloftng feveral oblong kidney-ftaped feeds.

This genus of plants is ranged in the third fe&ion of Linnaeus's feventeenth clafs, intitlei Diadelphia Decandria, which includes thofe plants whofe flowers have ten ftamina joined in two bodies.

The SPECIES are,

1. GALEGA (*Officinalis*) leguminibus ftriftis eredtis, foliis lanceolatis ftriftis nudis. Lin. Sp. Plant. 1062. *Goafs-rue with ereil clofe pods, and fpear-ftaped naked leaves.* Galega vulgaris, floribus caeruleis. C. B. P. 352. *Common Goats-rue with blue flowers.*
2. GALEGA (*Africana*) foliis lanceolatis obtufis, floribus fpicatis longioribus, filiquis craffioribus. *Goafs-rue with obtufe fpear-ftaped leaves, flowers growing in longer fpiques, and thicker pods.* Galega Africana, floribus majoribus filiquis craffioribus. Zeyl. 77.

The first sort grows naturally in Italy and Spain, but is propagated in the English gardens for medicinal use. This hath a perennial root, composed of many strong fibres, which are frequently jointed, from which arise many channelled hollow stalks, from two to three feet high, which are garnished with winged leaves, composed of six or seven pair of narrow spear-shaped lobes, terminated by an odd one, which are smooth and entire; the flowers terminate the stalks growing in spikes, they are of the Pea-blossom shape, **ami 01** a pale blue i . . . and are disposed in loose spikes. They appear in June, and are succeeded by racemes about one inch and a half in length, having one row of kidney-shaped seeds, which ripen towards the end of A i . . .

There is a variety of this > iti white Rowers, and anoilii with variegated flowers, . . . which have accidentally hem; . . . arc ngrconflam, therefore are only mentioned here.

¹igh *lle* ports of the flcin, and i. . . kinds of fevers. Mr. Boyle, in his treatise of the Wholness and Unwholness of the Air, be- fides three or four pages, in celebrating the virtues of Goat-sue in pestilential and malignant distempers, from his own observation and experience.

The third sort was discovered by the late curious botanist Dr. William Hanfman, at Coneyhead, from whence he sent the seeds into Europe. This, pUntis propagated by seeds, which must be sown in a bed early in the spring; and when the plants come up, and are fit to transplant, they must be transplanted each into a separate small pot, and plunged into a hot bed of tanner bark, shading them from the sun till they have taken new roots; then they must be treated as hath been directed for other

sooty plants, which are kept in the hot-bed. With this management they will flower in July, and in September they will perfect their seeds, but the plants may be preserved through the winter in the hot-bed.

The fourth sort grows naturally in Virginia and Carolina; this hath a perennial root, and an aerial stalk which rises three feet high; the lobes of the leaves are oblong and oval, generally seven or nine to each leaf; the whole plant is covered with a silvery down. The flowers are of a red colour, and are produced in spikes at the end of the branches; these are succeeded by kidney-shaped compressed pods of a fleshy colour, containing one row of kidney-shaped seeds.

This plant, although it is tolerably hardy, yet it is with difficulty preserved in England; for the seeds rarely ripen in England, and the plants are often destroyed by frost in winter. The only method in which I have been able to keep the plant, has been by getting them, and placing them in a common frame in winter, where they enjoyed the free air in mild weather, but were protected from frost; in this way I have kept the plant three years, but it has not ripen- i fecci here.

The fifth sort grows naturally in Ceylon, and in many parts of India, from whence I have received (i the seeds. This sort was annual here, and decay; J bl- fore the seeds were ripe. It hath an herbaceous stalk, which rises two feet high, pinn- . . . with winged leaves, which are either of eight or nine pair of oval lobes, terminated by an odd one; the first stalks of the flowers come out opposite to the leaves; these contain a long loose spike or stipe of small purple flowers, which are succeeded by slender erect pods.

This may be cultivated in the same way as the third sort; and if the plants are brought forward early in the spring, if the summer proves warm, the feeds mi-^r ripen.

GALLENIA. Lin. Gen. Plant. 422. Siccandia. Pomet. Epil. 14.

The title of this genus was given to it by Dr. Linnaeus, from the famous physician Galien.

The CHARACTER is, *The flower hath a small upright expansion of one leaf; it hath no petals, but four right very firmish the length of the expansion, terminated by double points. In the centre is situated a roundish cavity, possessing two vertical styles, crowned by large flowers. The expansion afterwards becomes a straight capule with two ribs, containing two oblong angular seeds.*

This genus of plants is ranged in the second section of Linnaeus's eighth class, marked Octandria Digyna; which includes those plants whose flowers have eight stamens and two styles.

We know but one Species of this genus, viz.

GALLENIA (Siccandia) Hort. Cliff. 120. Siccandia Galien. Siccandia. Pomet. Epil. 14. and Dr. Anderson. African. Ignis fraxinea, vulvarum talis. Hort. Pl. 20. Straly. Africae rursu straly, and Remyoy *leuca*.

This ftirub p grows naturally at the Cape of Good Hope, and in other parts of Africa; it rises with a slender stalk about four or five feet high, sending out many weak branches, garnished with very narrow leaves, which are placed irregularly on every side the branches; they are of a light green, with a furrow running lengthwise through the middle; the flowers are produced in loose panicles from the side and at the end of the branches; they are very small and have no petals, in make little appearance. The flowers come out in July and August, but are not succeeded by seeds in England.

This plant will not live through the winter in the open air in England, it must be placed in the greenhouse, or under a glass, with other hardy exotic plants, where it may have a large flow of air in mild weather, but is only exposed to be protected from frost. In the summer it may be exposed in the open air, with other plants of the same country, and in dry weather it must be frequently watered. This may be propagated

propagated by cutting; wliidi, if [>Um] during iny of the llimmer montls, ami watered frequently, will tike root in about five or li weeks, and n:af then be treated !. is directed for tlicold ph

The first of these plants (which is the last commonly used in medicine) is very common in moist meadows, and in pasture grounds, in several parts of England. The other varieties are preserved in curious botanic gardens, but as they are plants of very little beauty, and are not so common, they are seldom cultivated in other gardens. These facts may any of them be propagated by parting their roots, which spread and increase very fast, either

G A R

in the tiring or autumn, and will grow almost in any foil or situation, especially the firil ibrt -, the other foro require a drier foil, but will all grow in any It-taiaion.

GALLERIES, VC ornaments made with trees of various kinds, which are very common in all the gardens, but are seldom introduced into the English gardens, especially since the taste for clipper trees is now so much altered, that as there may be some who j fancy these obsolete ornaments, I liuti ult on the way of constructing them.

In order to make a gallery in a garden with porticoes and arches, a line must first be drawn of the length and breadth of the gallery; to be done, it is to be measured with a line, and the ground under the article HORNUEAMI should then be cleared, and it is to be the foil: of the gallery.

The management or tlim isnoi very difficult; they require only to be digged about, and fitted when there is occasion.

The chief curiosity required is in the uttering the fort-part of it; for gaiety, and in for the article.

Kashmiri of the fruit is; south of the; to 1 feet diameter of the fruit; other; dir galh-g) I for two or three pcfbts to vn]

When the height of the pillars well regulated, and the ground-work of the gallery finished, the next thing to be done is to form the porticoes.

W jitr ifrui whkii you must stop the [ornbeaai between two pillars; it is the bright, md run np a trellk made for ih>t pafafe, which forms the roof.

Ai itgrwi up you must w; your floor: even those boughs that outlitto; in the other: B time, W will grow strong, and may be kept in Form by the shears.

Portico galUericamay be covered with vine-trees.

GARCINIA (M. 5 Hort. Cliff. 154. The Mas- g /, cr Mt>- Arbor pcrgrina aurantia il-

Mi the Otatgt.

This tree grows naturally in the Molacca Islands, and also in the inland parts of New Spain, from whence I received perfect specimens, which were sent: roe by Mr. Robert Miller, who gathered them near Lima, but did not know the tree. It rises with an upright stem n *r twentj feet high, sending out many branches on every side, which are placed opposite, and stand oblique to each other, and not at right angles; the back of the branches is smooth, or a grey colour, but on the tender parts it is green, and that of the trunk is of a darker colour and full of cracks: the leaves are of the heart-shape, and entire, they are seven or eight inches long, and about half so much in breadth in the middle, gradually diminishing to the ends, of a lead green on their upper side, and of an Olive colour on their under, having a prominent midrib through the middle, with several small veins running from that to both sides of the leaf. The flowers are like that of a single Rose, composed of four roseate petals, which are thick at their base, but are thinner toward their ends; they are of a dark

G A R

red colour. The fruit which succeeds the flower is round, the size of a middling Orange; the top is covered by a cap, which was the stigma on the top of the style, and remains in the top of the fruit, and is indented in rays to the number of six or seven, which are obtuse. The flesh of the fruit is like that of the Pomegranate, but softer, thicker, and fuller of juice; it is green at first, but changes to a dark brown with some yellowish spots; the inside of the fruit is of a Rose colour, and divided into several parts by thin partitions, as in Oranges, in which the seeds are lodged, surrounded by a soft juicy pulp of a delicious flavour, resembling of the Strawberry and the Grape, and is esteemed one of the richest fruits in the world; the trees naturally growing in the form of Pyramids, whose branches are well garnished with large shining green leaves; they have an elegant appearance, and afford a kindly shade in hot countries, therefore are worthy of cultivation, in all those countries where there is warmth enough to ripen the fruit. As there are but few of the kinds in these fruit which come to perfection (for the greatest part of them are abortive) so most of those which have been brought to Europe have failed; therefore the surest way to obtain the plants, is to sow their seeds in tubs of earth in the country, and when the plants have obtained strength, they may be brought to Europe; but there should be great care taken in their passage, to keep them from air water and the heat of the sun, as this not to give them much water, especially when they are in a cool or temperate climate, so that plants are very impatient of wet. When the plants arrive in Europe, they should be carefully inspected, each into a separate pot, filled with light kitchen-garden earth, and plunged into the tub, observing to shade them from the sun till they have taken new root; then they must be treated in the same manner as other tender plants from hot countries.

GARDENS are distinguished into flower-gardens, fruit-gardens, and kitchen-gardens: the first, being designed for pleasure and amusement, are to be placed in the most conspicuous parts, i. e. near to, or just against the back front of the house; the two latter being principally intended for use and service, are placed less in sight.

Though the fruit and kitchen-gardens are here mentioned as two distinct gardens, and have by the French gardeners, as also by some of our own countrymen been considered as such, yet they are now usually in one; and with good reason, since they both require a good soil and exposure, and will equally require to be placed out of the view of the house. And as it will be proper to inclose the kitchen-garden with walls, and to secure the gates, that no persons may have access to it, who have no business in it, for the sake of preserving the produce, so these walls will answer the purposes of both. Moreover, in the disposition of the kitchen-garden, when it is properly divided into quarters, the planting of espaliers of fruit-trees round each of the quarters, will be of use in screening from the view the kitchen-herbs growing in the quarters; and, by that means, give an elegance to both parts, and save besides a great expense. The only objection which has been made to this of any consequence is, that the gardeners are too apt to crowd the borders near the walls with kitchen-herbs, whereby the trees are deprived of their nourishment; but this is in every gentleman's power to remedy, by not suffering the borders to be thus crowded. But I shall treat more fully of this under the article of Kitchen-Gardens.

In the choice of a place to plant a garden in, the situation and exposure of the ground are the most essential points to be regarded; hence, if a valley be made in that point, all the care and expense will in a manner be lost.

In a garden for pleasure, the principal things to be considered, are, first, the situation; secondly, the soil, aspect, or exposure; thirdly, water; fourthly, prospect.

ift, Siwaticy>: tins ought to be fuch an one an is
wishome, in a plain: that is no: high nor
too low; tor if a garden be ruo bigli, ii will be ex-
posed to the winds, whic art very [opposid to
trees, if it be too law, the dampness of the ground,
•ermin, and venomous creati
• ponds and morphy pkc«, add much Co th
• ritf.

A fitiuori on a rifin^ "rmtntl, Or on the fide of a
• hill is molt hn: • especially if the Bund &e not
too steep; if the slope be easy, and in I manner im-
perceptible, if a good deal of level ma be had near
the house; and if it abound i, with fprings of water,
• for, being sheltered from the fury or the winds, and
the violent heat of the sun, a temper lie air will be
there enjoyed; and the water that defends from the
i of the hills, either t from fpringior rain, will not
only lupply fountains, canals, and cascades, for orna-
ment, but when it has perfrmed ii office, will
wjcti the adjacent valleys ami render them fertile
ami whiuliume, if it be not fuferred to itagme in
tbero.

• if the declivity of the hill be too steep, and
if tin water be abundant, a gar
ay often fuller, by having the trees turn up hv
the torrents and floods i and ilic earth above tumbling
the walls may be demolished, a]

it cannot however be denied, that the frustion on a
plain is not; Hoods and rains make no
• is a continued profpeft of diamj
covered with buildings or woods; and the level lur-
face is less exposed to the winds, and let rfiar]
• fiat on the fide of a hill: thic terricc>w.
steps an; not neclary; bgt the greatfl dilidvantage
of flat ground; ff is the want of an exteii:
• riling grounds afford.

It is scarce possible to make a line garden in a bad
foil, there are indeed ways 10 mclionte ground, but
they are very expenfive, and frn times, when the
• ce ha. tjeen befowed of laying gn
fast deep over the whole furfaec, which for a large
garden is in expence too great for most perlbna-, and
after this a wate garden has been run
ing thc expo lure has been fouterlj and health-
ful, when the roots of the treci have come i i
the natural boitom.

To make a quilitj- of ihe foil, obftTve wheljier
there be Heath, Thistles, or LICE like weeds,
mowing fjontancouly in it, for they are crum n iigns
Out the ground is poor. Ljkewif if there be large
moss growing thereabouts, obietve whether they grow
coolled, ill shaped, of a fKjed green, and full of
• viti vermin-, or is to
be neglected; but on the contrary, if it be covered
with good Grass fit for pasture, then you may betn-
• ilur depth, of the ftril.

To know the depth of the soil, dig a trench
and four feet deep, if you find three iict of good
earth it will do well, but icJs than two will be
• ient.

The tU*ity of good ground is neither to I, stony,
nor too hard to work, neither too dry, Jiortuomoit i
nor too sandy and light, nor too frong and e
• rdens.

• dly. The third requisite is water. The want of Jsk
is one of the greatest inconveniencies that can befall
a garden, Mil • ill bring a certain mortality upon
whatever is planted in it, especially in the greater
• droughs that often happen in a hot and dry situation
in summer, besides the usefulness of it in fine gar-
• for making jets d'eau, canals, cascades, &c. which
are the greatest ornaments of a garden.

• ible. The fourth thing required in a good situation
is, the view and prospect of a fine country, and
though this is not so absolutely necessary as water, yet

it ia orcr of the tnoft agreeable bcatties of a fir-
den: beides, if a garden be planted in a place
that is buried, a I may say, and has no kind of pro-
spect, it will be not on! disagreeable but unselctive,
by ban; t much shaded and obscured; as that most
will rather retain insalubrious damps, than i come
care the rrfrelhv air, than ts fa punt; to a wog-
cable nature.

In fiioit, a garden necessarily require s [besides the
care of the gardener] the fun, tt good ibil, a ! all, or
at least an open profpeft, and » air, the i i i
all; and it would be egregious folly K> j' !. and a garden
where any of these are wanting.

Of the Deligning or Manner of Laying out a Plea-
sure Garden,

The area of a lundfome garden nwy tike up thirty
or forty acrei, a more.
And as for the disposition and distribution at thia
gardon, the foUowing distributions may be observed.

1st, There ought always to be a delicti fr i a the
house to the garden not less than titim thRr steps, but if
there are six or seven it will be better. This elevation
of the building will make it more dry and wholsome,
also from the head of these steps there will be a fir-
tjer profpeft or view of the garden.

In a jitte garden, the first thing that should present
itself to the sight, should be an open lawn of Grass,
which, in size, should be proportionable to the grs-
den; in a large garden it should not be less than six
or eight acres; but in middling or small gardens, the
width of it should be considerably more than the
front of the house; and if the depth be one half
more than the width, it will have a better effect. The
figure of this lawn need not be regular, and if in die
sides there are trees planted irregularly, by way of
open grove, fonic of which may be planted forward
upon the hiwn than the others, whereby the regularity
of die lawn will be lessened, it will render it more
like nature, th< tenatives of which should always be
studied. In the laying out and planting of gardens;
for the most part, these gardens approach to nature, the
longer they niU plejlc; tar I hat is a garden, bui a
natural spot of ground: dredicd and properly orna-
ment'd; there are those who have erred in coming
of what they call nature, as much as those who have
drawn a whole garden into straight lines, grave alleys,
fairs, &c. by bringing the most artificial and most
fi.rtof niirure into the composition of gardens; &
for inflance, where the gixiund has been naturally
level, they have at great expence, made hollows and
raised mole-hills; so that the turf has been rti:
not only more unpleasant to walk upon, but much
work to keep; and after all the pains that have been
taken to ape nature, the whole is as easily discovered
to be the work of art, as the finest flo; es MKI the
most finished pictures.

The best art in laying out of gardens, is to adapt
the artificial parts to the natural position of the ground,
so as to have as little earth to remove as possible; for
this is often one of the greatest expences in making
of gardens; and it may with truth be affirmed, that
whenever this has been practis'd, one time in ten
it has proved for the worse; so that if instead of lev-
elling hills to form large terraces, Cliff slopes, and
even pastures, as have been too often practis'd, or
the sinking of hollows, and raising of hills, as hath
by others been done; if the nature of the ground
had only been smoothed and well cur'd, it would
have had a much better effect, and been more ge-
OCTAL: approved than the present number of these
gartl; , which have been made with an infinite ex-
pence both of time and money.

Thic ncit thitf to be i- served is, to omrive a drf
walk, which should lead quite round the whole gar-
den-, for gardens are delign'd to promote the ex-
ercise of walking, the greater the extent of this dry
walk, the better it will defend the person from
b*d weilh. or in dewy marshes and evening

when the fields are unpleasur'd or unfa'r to walk over these dry walks in gardens become usef'ul and pk-aftn'r; and fucl' walks, it laid either with gravel or fend, may lead through the different plantations, gently winding about in an easy natural way, which will be more agreeable than those long thrait walks, which are too frequently us'd in gardens.

But as the ta'ct of designing gardens has of late altered from the former method, there are many persons; who have gone into the opposite extreme; and in the forming of what they term serpentine walks, have twist'd them about in so many illort turns, as to render it very disagreeable to walk on them; and in the same time they strike the fight with as much difficulty and appearance of art, as any of the methods formerly practis'd. In short, the fewer turns there are in these walks, and the more they are conceal'd, the better they will appear; and yet the turns being easy, and at great distances, will take off all the appearance of contrivance. And here let me observe, that there can be no better, or more easy or natural method of laying out these walks, than by tracing the easy runs made on a road, where if bend'd by the track of the coach wheels.

These walks should lie so contriv'd, as to lead into shade as soon as possible; as also into the recesses of shrubs, where they may be pleas'd to walk in private, and to be shelter'd from the wind; for no garden can be pleas'd where there is want of shade and flicker. Another thing absolutely necessary is, where the boundaries of the garden are fenced with walk or rail, they should be hid by plantings of flowering shrubs, intermix'd with Laurels, and some other Evergreen; which will have a good effect, and at the same time conceal the tenets, which are disagreeable, when left naked and expos'd to the sight.

In situation where there is a good supply of water, the designer has room for adding one or two great beauties to the garden, especially if it will admit of a constant stream; for in such places, if the water is properly conducted through the garden, it will afford infinite pleasure; for although these streams may not be so frequent, yet if they supply a large surface, yet if they narrow rivulets are judiciously led about the garden, they will have a better effect than numerous of the large stagnating ponds or canals, so frequently made in large gardens; for where these pieces of water are large, if all the boundaries can be seen from every point of view, they cannot be pleas'd by judgment; and frequently the landing waters are brought so near the house, as to render the air damp and unhealthy; and many times they are so situated, as to occasion this inconvenience, and at the same time are not seen to any advantage from the house.

Where wildernesses are intended, these should not be cut into straits, and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design is not proper, but the walks should be noble, and lined by tall trees, and the spaces of the quarr' plantings with flowering shrubs and Evergreens, whereby they will be rendered pleasant at all seasons; and the year will be rendered pleasant by flow'rs which will and X there are hardy sorts of flow'rs (which will thrive with little care) scattered about near the sides of the walks, they will be a great ornament, making a variety of natural beauties almost through the year.

The situation of these wildernesses should not be too near the house, lest they should occasion dampness; therefore it is much better to contrive some open groves, through which there may be a communication under shade from the house to these wildernesses; which are much the best when they are planted at the finest part of the garden, provided they do not obstruct the view of fine objects.

But things which are also very proper ornaments in a garden, if they are well design'd and properly placed, but the modern taste of crowding the garden with these buildings, I perswade myself to think is a very bad way, with regard to the propriety of the expense. Situations and places are all very beautiful objects, but

the fountain by no means be placed too near the house; other; for when several of them appear at once, they fill and confound the eye, and in the beautiful effect which they would have, if now and then one properly engag'd the eye.

What an expense might be spared, and applied to nobler purposes, if nature only were to be untuned, if simplicity were studied in this design'd art, rather than ostentation! for any thing may be said to be more of nature, than what we misse the grandeur.

Fountains are also very ornamental to a garden, if they are magnificently built, and where a constant supply of water can be obtained; but if they are meanly erected, they have not water to keep them constantly running, they should be introduced into gardens, for nothing can be more ridiculous than to see a dry fountain, which, perhaps, at a great expense, may have been raised up, to supply it for an hour or two, and no more; and that perhaps not in dry seasons, when there is a scarcity of water. The lame may be observ'd of cascades, and other falls of water, which ought never to be contriv'd in gardens, where there cannot be a constant run of water; but where the situation of a garden is so happy, as to be naturally supplied with water, these falls and jets of water, may be rendered very great beauties, especially if they are well design'd, and not made in the low mean taste, in which so many of them! now in being appear, and where the water is made to foil over a parcel of regular trees; of Hone; but they should be in one sheet from top to bottom, when they should be placed in large rough stones to break and dilate the water, and to increase the noise of the fall.

Where the ground is naturally uneven, and but a few trees and falls, these may be admirably humoured in the laying out of the ground, as can be rendered very great beauties; but the inequalities of the ground must by no means be cut into regular straight lines, or amplified, as has been too much the practice; but if the knolls are properly planted with groups of trees or shrubs, and the lying sides finish'd and left in their natural situation, they will have a much better effect, than can be given them by all the regular logics, lines, and other illogicals, which have been till of late, introduced by the delvers of gardens.

The taste in laying out of gardens has greatly altered, and is now generally introduc'd in England, in the company of a few years; for, with the revolution, the Dutch taste of laying out of gardens was introduc'd, which consist'd of a wide inure than flower-border laid out in several rows of Box-work, clipped ivy greens, and such low exjunctive things; as also the walling round, and dividing the several parts of gardens by croft walk; in that garden consist'd of eight or ten acres, was generally divid'd by brick walk, into three or four separate gardens, and these were reduced to a small level, having many grass walks and the borders on each side crowded with clipped trees and Evergreen hedges, dividing these small inclosures again; so that the little making and planting of these small gardens was attended with a great expense, as was the keeping of them afterward. Dim gardens of six times the extent, when design'd after nature.

Whether this taste universally prevail'd in England, I near cannot determine; but late Mr. J. Kiiip William, or wisomman to the low grovelling taste of those persons, who had the designing of most of the English gardens, is difficult to determine; but it is very certain, that the gentlemen, at that time, were serv'd little the less, to the dissipation of their gardens, but were contented to leave the whole direction of them to persons of the meanest sort; that tried the art, to the utmost in the year, when another taste prevail'd, the quarters were almost entirely demolish'd, and it would have been a good deal better, if a natural wild hint succeed'd to the other, but this was not the case; for though a more open and extensive way of laying out gardens was introduc'd, yet the same lies

tie more than copying after the French, whose taste was in making long avenues, straight walks, stiff regular dopes, cabinets, fret-work tall hedges cut into various shapes, jets d'eau, fountains, &c. so that there was little of nature studied; but, on the contrary, all the geometrical figures introduced in wicker-work, as also in the parterres, and other compartments of the garden: nor is it so much to be wondered at, that this taste prevailed in France, when the designs of all the principal gardens were there formed by architects, who were as studious to have the symmetry of the opposite, or corresponding part of the garden, as exact as the apartments of a habitation, nor has length of time, nor the improvements already made in other countries, amended their taste, or convinced them of its absurdity.

As the gardens of Versailles, Marli, and others, were extolled for their magnificence, so the plans of them were almost universally copied; the designers, or imitators rather, only varying the parts according to the situation or figure of the ground, and this was practiced for several years, at a time, when great sums of money were expended in gardens, which might have rendered this country the most beautiful of any in Europe, had a natural taste then prevailed in the designing of gardens; which is the more to be lamented, as the plantations then made, have been many of them rooted out, to make way for the alterations and improvements which have been since introduced. Many persons, I am sensible, will have it, that, in the designs of gardens, the taste should alter from time to time, as much as the fashion of apparel, but these cannot be persons of judgment, for wherever there are natural beauties in a country, they will always please persons of real knowledge, and frequently it is observed, that persons of but little skill in the art of gardening, are struck with these beauties without knowing the cause; therefore where the beautiful parts of nature are justly imitated in gardens, they will always be approved by judicious persons, let the taste of gardening alter as it will.

When trees have been long growing in a garden, nothing can be more disagreeable than to have them destroyed, to alter the garden according to the fashion of the time, because it requires much time to bring up trees to such a height as to afford shade and shelter; and, as time is precious, so, where the disposition of the garden is altered, there should be great attention given to the preservation of all the good trees, wherever they can be either useful or ornamental.

There is another essential part of gardening, which cannot be too much considered by persons who design gardens, which is that of adapting the several sorts of trees and shrubs, to the situation and soil of the garden, as also to allow the trees a proper share of room; but, however necessary this will appear, yet very few persons have made this their study, inasmuch that when one views many modern gardens, and sees the great number of trees and shrubs, which are crowded into them, one would be induced to believe, that private interest has had a greater influence than any other motive, with the designers. Indeed this fault may often be ascribed to the master, who, perhaps, is too much in haste for shade and shelter, so will have three or four times the number of trees and shrubs planted as should have been, or that can remain long without injury, where the plantations succeed, and to this over-haste are owing the miserable plantations of large trees, so often seen in gardens and parks, where trees of all sorts, and of any age are taken out of woods, hedge-rows, &c. and removed at a great expence to stand and decay annually, till they become so many dead sticks, than which nothing can be a more disagreeable sight to the owner; who, after an expectation for several years, attended with an expence of watering, digging, and cleaning, finds himself under a necessity either of replanting, or giving up the thoughts of having any. Numbers of persons have indeed amused themselves with the hopes of success, by seeing these

new planted trees put out branches for a year or two, which they generally do; but in three or four years after, instead of making a progress, they begin to decay at the top, and continue to do so gradually, until they quite perish, which, perhaps, may not happen in eight or ten years, especially if no severe winter, or very dry summer, intervenes, either of which generally proves fatal to these plantations, so that persons may be led on with hopes, for so many years, in the best part of their lives, when there is a certainty of their failing, or at least of their never increasing in size; but of this I shall treat more fully in the article of PLANTING, and shall proceed.

In the business of designs, a mean and pitiful manner should be studiously avoided, and the aim should be always at that which is noble and great, not to bring too many little things into a garden, nor to make small pieces of water, narrow walks, &c. especially in large gardens; for it is much better to have a few great things, than four times the number of small ones, which are trifling. In small gardens there is more excuse for this, nor indeed would it be right, to have either large lawns, broad walks, or large pieces of water in such; but yet even in these there ought to be a medium, and persons should never attempt to crowd too many things in these, whereby the whole will appear only as a mean and trifling model of a large garden. Before the design of a garden is entered upon, it ought to be considered, what it will be in twenty or thirty years time, when the trees and shrubs are grown up, and spread; for it often happens, that a design, which looks handsome when it is first planted, and in good proportion, in process of time becomes so small and ridiculous, that there is a necessity either of altering or totally destroying it.

The general distribution of a garden, and of its parts, ought to be accommodated to the different situations of the ground, for a design may be very proper for a garden on a perfect level, which will by no means do for one where there are great inequalities in the ground; so that, as I have before intimated, the great art of designing is, in properly adapting the design to the situation, and contriving to save the expence of removing earth, to humour the inequalities of the ground, to proportion the number and sorts of trees and shrubs to each part of the garden, and to shut out, from the view of the garden, no objects that may become ornamental.

There are, besides these, many other rules relating to the proportions, conformity, and disposition, of the different parts and ornaments of gardens, of which more may be seen under their several articles.

GARDENIA. See JASMINUM.

GARIDELLA. Tourn. Inf. R. H. 655. tab. 430. Lin. Gen. Plant. 507. [This plant was so named by Dr. Tournefort, in honour of Dr. Garidel, who was professor of physics at Aix, in Provence.]

The CHARACTERS are,

"The flower bath a finally oblong serene empalement of five leaves, // bath no petals* but five oblong equal nestariums occupy their place & these are bilabiate. The outer part of the under lip is bifid and plain & the interior part of the upper lip is short and Jingle. "The flower bath eight or ten awl-shaped stamina, which are shorter than the empalement and are terminated by obtuse erect funtits. In the center is situated a bree germina, which are oblong & rompreffed and sharp-potted having no styles, but crowned by simple stigmas; these Tiecome three oblong compressed capules with two valves inching several small feeds.

This genus of plants is ranged in the third section of Linnseus's tenth class, which includes those plants whose flowers have ten stamina and three germen.

We know but one SPECIES of this genus, viz..

GARIDELLA (*Nigellastrum*.) Hort. Cliff. 170. Garidella foliis tenuissime divisis. Tourn. *Garidél!* with very narrow divided leaves, and the *Nigella Cretica* fejo Foeniculi. C. B. P. 146. *Fennel flower of Crete with a Fennel leaf*

This plant is very near akin to the *Nigella*, or *Fennel-flower*, to which genus it was placed by the writers on botany before Dr. Tournefort, and was by him

GAU

him separated from it, as differing in the form of the flower.

It grows wild in Candb, and on mount Baldu., Italy, as also in Provence, where it was discovered by Dr. Garidel, who sent the seeds to Dr. Tournelbrr, for the Royal Garden H Pel is.

This is an annual plant, which rises with an upright stalk a foot high, dividing into several slender branches, garnished at their joints with very slender

leaves like those of Fenm-i. The flowers are ternate of one final flower, of a pale herbaceous colour.

Each is succeeded by three capsules, each containing two or three linear seeds. It flowers in June and July, and ripens in September. It is propagated by seeds, which should be sown in autumn, on a bed or bonier of light friable earth, where the plants

when they first appear should be thinned (for they will not thrive if sown too thickly) when the plants are come up, they must be carefully cleared from weeds, and when they are too tall, they must be thinned, leaving them about four or five inches apart; in autumn it is recommended to lean the plants, and if the seeds are sown in a lean soil, the plants will come up without any farther care.

Ti.jj is a perennial plant, which grows naturally in Virginia and Pennsylvania: it is a very high, spreading, herbaceous plant, which is covered with oblong leaves, which are very pretty dofe.

The anther is produced in clusters at the end of the stem: the flowers are of a white colour, and are very fragrant.

The flowers appear in September, and when the autumn grows favourable, the seeds will ripen towards the end of October.

If it is sown in a garden, it will grow very well, and is very useful for the purpose of medicine.

It is a very useful plant, and is very common in the mountains of the Andes.

Wher ever there is a new arrangement, or composition of the elements, there is, in reality, a new generation, and thus generation is reduced to motion. Generation is more immediately understood of animal and vegetable bodies from seed, or the coition of others of different sexes, but of the same genus or kind.

Monf. Perrault, and some of the modern naturalists after him, maintained, That there is not properly any new generation, that God created all things at first, and that what is by us called generation, is no more than an augmentation and expansion of the minute parts of the body of the seed, so that the whole species, which are afterwards produced, were, in reality, all formed at the first, and inclosed therein, to be brought forth and exposed to view in time, and according to a certain order and oeconomy.

And accordingly Dr. Garden says, It is most probable, that the stamina of all the plants and animals that have been formed, ab origine mundi, by the Almighty Creator, within the first of each respective kind; and he who considers the nature of vision, that it does not give us the true magnitude, but only the proportion of things; and that which seems to our naked eye but a point, may truly be made up by as many parts as seem to be in the whole universe, will not think this an absurd or impossible thing.

Dr. Blair, treating of the generation of plants, says, That when Almighty God created the world, he so ordered and disposed of the materies mundi, that every thing produced, from it should continue so long as the world should stand. Not that the same individual species should always remain; for they were, in process of time, to perish, decay, and return to the earth, from whence they came; but that every like should produce its like, every species should produce its own kind, to prevent a final destruction of the species, or the necessity of a new creation, in order to continue the same species upon earth, or in the world.

For which end he laid down certain regulations, by which each species was to be propagated, preserved, and supported, till, in order, or course of time, they were to be removed hence; for, without that, those very beings, which were created at first, must have continued till the final dissolution of all things, which Almighty God of his infinite wisdom did not think fit.

But, that he might still the more manifest his omnipotence, he set all the engines of his providence to work, by which one effect was to produce another by the means of certain laws, or rules laid down for the propagation, maintenance, and support of all created beings; this his divine providence is called nature, and these regulations are called the laws, or rules of nature, by which it ever operates in its ordinary course, and whatever exceeds from that is said to be preternatural, miraculous, or monstrous.

Moses, in his account of the creation, tells us, that plants have their seeds in themselves, in these words: And God said, Let the earth bring forth grass, the herb yielding seed, and the fruit-tree yielding fruit, after his kind, whose seed is in itself upon the earth. The ancients, indeed, distinguished the generation of animals into two kinds, i. e. into regular, called univocal*, and anomalous, called also equivocal, or ipontaneous.

The first was effected by parent animals of the same kind, as that of men, birds, beasts, &c. The second they supposed to be effected by corruption, the sun, &c. as that of insects, frogs, &c. but this latter is now generally exploded.

Many, indeed, have essayed to treat of the generation of animals, but few have been able to give that satisfactory account of it that were to be wished for, and far fewer yet have been able to treat of the generation of plants as it ought to be; for that which still kept them in the dark, was,

First, That though there were two different sexes in animals, by whose mutual assistance the species was

propagated, yet there was no such thing then known in plants.

Secondly, That though it can now be made appear, that every animal is produced by univocal generation, i. e. from an egg, and not by corruption, &c. as most of the ancients imagined the insects were; yet there are still those who maintain, that those which they call imperfect plants, are the product of a certain rottenness in the earth.

The generation of plants bears a close analogy to that of some animals, especially such as want local motion, as muscles, and other immoveable shell-fish, which are hermaphrodite, and contain both the male and female organs of generation.

The Power of a plant is found to be the pudendum, or principal organ of generation; but the use of so much mechanism, and so many parts, has been but little known till of late years.

The flower of a Lily consists of six petals, or flower-leaves, from the bottom of which, in the middle, arises a kind of tube, called by Tournefort, the pistillum, and by Dr. Linnaeus the style; this rests upon the germen, which is the female organ of generation; round this are placed pretty fine threads, called the stamina, or filaments; these stamina arise likewise from the bottom of the flower, and terminate at the top in little summits, called by some apices, which are replete with a fine dust, called farina; these are the male organs of plants.

This is the general structure of the flowers of plants, although they are infinite ways diversified, and to such a degree, that some have no sensible pistil, and others want the stamina; others again have the stamina, but want the apices, and some plants exceed all others in this, that they have no visible flowers; but if it be allowed, that this before-mentioned is the most common structure of flowers, it will follow, that these parts that seem wanting are usually only less apparent, or are situated in different plants, or in different parts of the same plant.

The fruit is usually at the base of the pistillum, so that when the pistillum falls with the rest of the flower, the fruit appears in the stead of it; but oftentimes the pistillum is the fruit itself, but still they have both the same situation in the center of the flower, and the petals, or flower-leaves, which are disposed around the little embryo, seem to be designed only to prepare a fine juice in the little vessels, for the support of it during the little time that they last, and it requires; but some suppose the chief use of them to be to defend the pistillum, &c.

The apices of the stamina are small capsules, or bags, full of a farina, or dust, which falls out when the capsule grows ripe, and bursts.

Monf. Tournefort supposed this dust to be only an excrement of the food of the fruit, and the stamina to be nothing but excretory ducts, which filtrated this useless matter, and thus discharged the embryo; but Mr. Morland, Mr. Geoffroy, and others, find nobler uses for this dust; on their principle the stamina, with the apices and farina, make the male part of the plant, and the pistil, the female.

Mr. Morland says, It hath been long ago observed, that there is in every particular feed a femal plant conveniently lodged between the two lobes, which constitute the bulk of the seed, and are designed for the first nourishment of the tender plant.

But the admirable Dr. Grew to whose generous industry, and happy sagacity, we are indebted for the best improvements of this part of knowledge, is the only author I can find, who hath observed that the farina, or fine powder, which is, in its proper season, shed out of those thecae, or apices' Ceminiformes [i. e. seed-forming cases] which grow at the top of the stamina, doth some way perform the office of male sperm. But herein, I think, he falls (hot; in that he supposes them only to drop upon the outside the uterus, or vasculum feminale, and to impregnate the included seed by some spirituous emanations, or energetic impres.

That which is now subject . . . to the disquisition ant

Jkwers I have mentiuneil, their true anil real a
L'r nothing CM bem . . .
natural than to conclude,
that where a fine powder is curiously prepared, care-
fully reposed, and then abroad at a peculiar feafon,
where there is a tube fo placed as to be fit to receive

[r,a::: . . . each cafe as difpofes this tube, where it doth
not lie directly under the cafs that shed the powder,
it hath a particular apparatus at the end, to insure its
tnna . . .

Not . . . ing can be nioro^ . . . deduced from any
premises, than it may from this, that this powder,
or fome of it, was designed to enter this tube. If thefe
Bamina had been fo by extemporary chance, as has been
thems supposed, and enter the greater parts, and leave
the juft diameter for the accommodation of the seed
itself, what need was there to have thicker
Ciments in fuch various repositories? They would
have been discovered any where, rather than where
there was fo much danger of their dropping into the
feed-veffels, as there is here.

Again: the tube, out of the mouth of which they are
shed, and into which they enter, leads always directly
into the feed-veffels.

To which we muft add, that the tubes always hegets
to the when thefe chaces are emptied of their contents,
if they last any longer, it is only while the globules,
which enter at these orifices, may be fuppofed to have
finished their passage. Now, can we well expect a more
conceding proof of their intention, designed to con-
vey their globules, than that they wither when there
are not more globules to convey.

If I could now fhew, that the ova, or unimpregna-
ted seeds, are ever to be observed without this terminal
plant, the proof would arife as a demonstration; but
having not been fo happy as to observe this, I fhall
not be obliged at present with fuppofing, that hence

Concent
unc wou
rather designed to fever fuperfluous juices from what
was left to stored in the Bamina, than the ftamina to
perform this office, either for them, or the unimpreg-
nated femina, and observe the analogie between ani-
mal and vegetable generation, as far as was necessary
there fhould be an agreement between them: I fhall
recommencd the enquiry to thofe gentlemen who are
matters: >r rhe hi
microscopes, and address in ufing
them; though, in the mean time, I have made fome
fteps to
root of this fort, and have mixt with
Ibine m
I hint, as make me out details of being able,
in about time, to give the world even this fatisfaction.

Fur, . . . to build upon this, that the feminal plant
always lies in that part of the feed which is always
nearest to the inferior of this ftyle, or fome propaga-
tion of it into the feed-veffels, I have difcovered in
Beans, Peas, and Kidney-beans, juft under one end of
that we call the eye, a manifold perforation, (incomparable
by 1
greater fort of magnifying glaffes) which leads
directly to the feminal plant, and at which I fuppofe
the femi J pbnt did . . . enter, and I am apt to think,
the Beans . . . or feis tha: via no: thrive well, r . . .
may be
found definite of it.

But I muft now proceed to describe fome other
plants, whereby it will appear, that there is a parti-
cular care always exercifed to convey this powder, fo
often mentioned, into a tube, which may convey it
to the ova.
Now, in Leguminous plants, if we carefully take off
the petals of the flower, we fhall difcover the pod, or
filiqua, clofely covered with an involucring membrane,
which, about the top, feparates from upon ftamina,
each charged with its quantity of farina; and thefe
ftamina clofely adhere to the ftyle, which is confide-
rable at the end of that tube, which were alfo lead di-
rectly to the pod; it ftands not upright, loofely, but
fo bem . . . as to make out a right angle with it.
In Roies there ftands a chamber, confiding of many
tubes clofely close together, though eafily feparable,
each leading to their partner cell, the Bamina is a
great number placed all round about.

In Tit] . . . , there rife a tubulous
veffel, that, while it is fmall, is not eafily difcernible,
lies ai
the incum nil it is increafed, but af-
terwards grows up, and ftands upright upon a tall
pedicle of an oval, as would tempt one to think, that
there was to be no communication betwixt this and
the apice.
In the Strawberries and Raspberries, the hairs which
grow upon the eye (root) which, I fuppofe, may be
forfeiting to fuch, as fo many tubes leading each to
their particular feed; and therefore we may observe,
that in the leaf opening of the flower there ftands a
ring of ftamina, within the pedicel, and the whole in-
ward part appears like a little wood of three hairs or
poles, which, when they have matured and conveyed
their globules, do break forth, and rife as a carnosus
milk. Thus for Mr. Mufland.

We may observe a veffel at the bottom of the pillil
of the Lady, which veffel we may call the uterus, or
womb, in which are many ovaries filled with
little
eggs, or rudiments of feed found in the ovaria,
which ftays decay, and come to nothing, unless im-
pregnated with the farina of the fern plant, or fome
other of the fame kind; the ftamina alfo ferve for the
conveyance of the male feed of the plant to be
per-
ffittd

fitted in the apices, which, when ripe, burfl forth in little particles liko dull; fomc of them fall into the orifice of the piftil, and arc either conveyed thence into the utriclc, to fecundify the female ova, or lodged in the pillH, where, by their magnetic virtue, they draw the nourifhmelit from the other parts of the plant into the nnLuryos of die fruit, making then: fwell, grow, &c.

tn Doivers that turn down, as the Cvdamen, and the Imperial Crown, the piftil is muclt longer than the ...;:ri, dial tlicir duft may fal! from their apices in fulchicnt quantities on the piltU, fur the buUnclit of impregnation.

Mr. Geoffrey aflures us, That in all the obfervations he had made, the cutting off the piftil before it could be impregnated by the farina, actu^:y rrrdrnd the plant barren for the feafbn, and the fruit abortivi.

In many kinds of plants, as the Oak, Pine, Willow, &c. the flowers, Mr. Gcoffroy obferves, have their (lamina and apices, whofe farina may cafily impregnate the rudiments of the fruit, which arc not far off!

Indeed there is fome difficulty in reconcile this frilem widi a certain fpties of plants, which bear flowers -without fruit ; and another IpecieS of the fame kind and denomination, which bear fruit without flowers; fudi arc the Palm, Hemp, Hop, Poplar, &c. which are hence diftkguifhed into male and female •, for how fhould die farina of the rmk here, come to impregnate the ova of the female ?

This difficulty Mr. Gtoffroy fal ITS, by fuppofins the wind to be the vehicle thiat'convcys the mole dull to the female uterus, which it confirmed by winftance of Jovianus Potanus, of a [ingle female Paltn-trec

Cwng in a forcft, which never boic fhiii, till, ing rifen above the other trees of the forftl, and being then in a condition to receive the farina of the male by the wind, it began to bear fruit in abundance.

As to the manner wherein the farina fecundities, Mr. Gcoffroy advances two opinions ;

I'irit, That the farina being always found of a fulphureous compofition, and full oi libed an i penetrating pccca (as appears from its (prightly odourj vvhich fill ling on the pillils of die flowers, th are mliives, and the fubtllell parts of it, penetrating the Jubltance of the piftil, excite a fermentation, which putting the latent juictrj of the young; iruit : in motion, occafions the parts to unfold the young plant that Uinclofed in the embryo of the feet

En this hypothefis, the plant in miniature is fuppofed to bt contained in the f<d, mt (to -want only a proper juice to unfold its parts, and 10 make them

ffrow.

The fecond opinion ii, That the firina of the male jiljrit ii thie firft germ or femcn of the new plant, ajid iians in need of nothing to enable it w grow or unfold, but a fuitable nidui with the juice i: fin pared in the cmbri i :l or ovary.

h may be obferved, that thiefe two theories of vegetable generation bear a ttrir of animal generation, viz. either that the young animal is in the icir.cn maltulinum, anil in need of the juice of the matrix to dirrifh and bring it forth; or that the female ovum conuim the animal, and requires only the male feed to ew lermenutation.

Mr. Gcuffroy rfther makes the proper feed to be in the Lrina, inafmuch as th. fcopea Oo noc

I When they are examined, their duft, which betwixt ed with the manufop, ack late, are to become grains, or fill the

luce,
 Experiment 1. Mr. Geoffroy having cut off all the
 flammcoat rufis of male flowers from the • top of the
 ftalk, in the Maiz or Turkey-wheat, as foon as the T ap-
 peared, and before the fpikc loaded with the um-
 brvcs of the fcemc had put forth from the ala: of the
 leave'. Several of thefe embryos, in a mi Bid ilncj
 up aii' they were pretty big; but fome grain upon
 tlicir: follicles all along the ftalk fwellcd confiderably,
 and itemed DO be full of the bud, and were confe-
 quently fertile, while all the others mit; rrricd, and
 there was not one fpikc where the whole : i-Js did not
 npei! m'Ac lull.

This experiment is a fufficient p'roof of the ufc of
 the male flowers of this plant: for whatsoever that is
 which flows from the raceme of thefe flowers, it feems
 it muft be eflential not only for the impregnation of
 the feed; but alfo for the growth and im'pregdⁿation of
 tiit fruit.

As to (lent we lhall lien-, tin: what nourifhment it
 ufoally furnifhed by the pedicle 10 the embrj'o*, do a
 not appear to be capable to dilate or expand itfelf, or
 contribute to the continual fupply of nutrition: par-
 li tries, unles the tmb'roj were animated or enlivened
 by the fpirit which flows th' ha'c fluwtd from the male
 flow:-y to that they were iti debilitated, v i weak-
 ned, in ncfcnding from the body of the plain 6Jwards
 the emliryos, before tipy could arrive at them, that
 they -inch other-. The might hew frived for the aug-
 mentation and increafe of all! the embryos upon the
 fpikc, cook not now de any thing more than i con-
 tribute to the r'p'ring of a few. And though Mr.
 G'uffroy might have imagined, that thefe few feeds
 which came to perfection • were fertile alfo, becaufe
 they were full of g'rrmn, yet it could not be fure of
 that, fince he had fown the fame feeds next feafon,
 and they did not chit or put

I'd whether chey We
 Gardn'ws wlio !• • • • • ili-lifd brought
 ifrom * rath'rb' commonly try the following experi-
 rinifiii: they pile a few of tl feeds into a pot of wa-
 ter mixed with earth, • • • • • all if they find they begin to
 fpring, oi- lend forth the liminal leai th fibre of the
 ruat, af:cr a few days, they plunge it into the pot of wa-
 it; and nui< • • • • • fupporting all the feeds with n this
 trial m • • • • • to be productive, being equally liTh,
 hiird, and foft, perhaps not more than one (in) of
 ihem will prove fertile.

And this barrenicU may proatd, either I- • • • • • they
 lut m • • • • • been impregnated by the male parts of the
 flowc; or that they I • • • • • been too -dich expo-
 to the air; being fome rime or other too much tn
 d'encd, and not afterwards been carefully d'ri- il, or h've
 been kept thv Inng, by which negli • • • • • they foie their
 fplrit or life.

Now, • • • • • the fubtil, folidity and firmnefs of a feed is
 not i Sure Sign • • • • • Its fertility, then Mr. Cltdifroy
 luve been mifliten in his o' • • • • • mion of the ferti-
 lity • • • • • the plant, fince he did not make
 • • • • • by committing it to the ground.

WjifM
 In like r02f • • • • • fofecidit, where he raised • • • • • : the
 Mwctrafte C • • • • • lbme plants
 which produced fruit, and others which produced no fruit - (la-
 mifious flowers, and removed the barrennefs p- (la-
 before the flowers were blown, every one of the feeds
 upon the fructiferous plant, except five or fix, and
 carried; which feeds were to fall, that he was per-
 fuded they were capable of producing new plants,
 and the like was found by Caeftarius in the Chanada.
 Yet inasmuch as feveral of them tried the experi-
 ment, by fowing the fame feed the fecond year, they
 could not be fure but that they might have e tailed in
 their c'p'eciation.

Mr. B'art, overfeer of the phyfic-garden at Oxford,
 many years fince, which was before the doctrine of
 the eflentialnefs of plants was well under flood, being
 herbacizing, found a plant of the L'china fyftem

implex, no apices i and taking nniice that this w,w not only in one, but in ill the flowers upon [lie fiunc plant, he imagined it might be a new fpedes -, and therefore marked" the piant, and took care to have it pn lerved till the feeds were ripe; and then, tlicy bcifc full, harJ, Mid Icm, and " i outward appearance . full of germ, hi: (owed tlunt in a p: • per place in the garden the next Itaion, but not a plant fprun]* up from them. Tlicfc and oilier iniliitices, fet the opinion of tlic Jit-fenmt Jews of planrs m»n another tooling than has been receiv'ed by 11 Kill oi'our modern authors j for it imports, it it is not the nouribment of the groft UBljtutt of the Iced iilclf which U hereby meant, nor the increafe of ihc feed-veffel, which is thereby de-lignd; for (as is already obkrved) a lien enn by an <gp, without having before hul congrct with a cock; and ihis, when newly bill, (hall be of the fan: big-nCi, colour, tafte, and imell, with anotbn which has been cocked las ihcy wd it \) i <•, which lias been fecundated by the nialculinc. feminal materiel: but the difference will appear, when both are put under tlic hen, in ortcr to be Hitched •, tor the one Ou pul-lulate or cliit, and tlic Other (kill become 111 and tot.

The cafe ii juft the fame with the feed of a plant, it may be augmented and increafed in its bulk; it may become firm, hard, and lolid, and have ail the tokens cfaperffitt ripen: ; the feed-veff: may be enlarged, aril cbc pulp of parenchyma of the trait may be aur-gment; d i and yet ilic particles of tlic Ice J may remain crude, iruligrlicd, and incapable to be cpticaird and dilated, or let in a (Suitable motion, whereby to pro-tude the fibrilla of the root at one end, and tilt fit-mma i leaves ac the c:; •, except fore be re-ceived foniexir: reous matter, or fome active •nicies from the male parts of the flower, or from the male Ib-ver id'eIE

In order to confirm the neceffiry of cwo fates of planes, as • il as in animals, this fmiiJiar confitiation may be added: that the fertility or barrennefs. < if .my trie, in the more or lels fruiful feafons - may be known to ignorant or left control perjbna, by the ijuantity of the Howen wltidi appear in the fpring tittu- . ••••• that rot only in uws alone, where die Aqvtr -nd fruit art upon one and the e foot fivB but alio in fuel trees, where the Etemen are upon diftinf trees, or fe-parate- places upon the fame tree; for ir is only to determine by the catkins or iuli tijion the V. ••••• Filis'i, or Hasle-trees, whether (iidi or fiieh trees ••••• be fertile or birren for die enliing Icafon, before any of the embryos begin to break, be j: ••••• forth, or spew,

Havin 5 already treated of the mile and fanile parts of Howen, wt lhal) next confide* thdr ufe.

Flowers, in this refpefi, may apdy be divided into that of mile flowers, which (as has been, before ah-ferved; were formerly refuted barren) anil the plants which produce them were alfo called firmak ; plants, becaafc chofe perfws not liaviug any nutium I: dif-ferent leaze in plants, I iry wetc a diled female, upon account of their weaknefs, or if they had any thought of ••••• xea in them, it was only illulive.

The ancients were iKnarant (f chofe which are BBW-n-diys tilled hermapliroditr flowers; as J they, not having a true notion of feces of plants, could not ima-pine that the parts of both leaze fhould be in otie flower, upon one ••••• ad the tame fooi-ftalk.

Anil although hermaplirodite artitals bear the leaf proporibn in tlic animal kingdom, yet henr ••••• idices havt the gr ••••• tress than to the vegetable. iough ilTy arc no; &> nvimcTous as they have been liiyipoicd to be I fur upon a ilnci exar; ••••• it will be found, that a great man) more plants have diftinc ••••• a n d femal ••••• wers, than n is formerly believed.

The neceffity of diircti ••••• leaze in plants having been demonftraied, tod that the lemale feed, tho' though it fhould ripen to the full, ex ••••• Ot he fcniii ••••• except it be impregnated by what it receives from the male parts of flowers, we fhall not ••••• cx)bin tut organs of generation ii, both sexes,

In the animai ceconomy, there are, bsftdi> thofe vt-flels t'lat arc dvHinatJ for nutrition, and die lccv*-i ion of the fe veral juices in tin; bod\, ••••• did ••••• s, which tunftif of prxpjiramr.' ••••• determinat, and cun-ncotin femcn. i ••••• nan in :n, ••••• are the blood-vcITUj and die I ••••• the air convey; i the biuod, and the other fepanuts the femcu from blowl, and elaborates it.

So liki ••••• in plants there are veflels that receive the nutritious particles from i'bc ••••• and convey ic to the extremity of the plant j fonur of which tend di-rectly to th ••••• and exerts to the flowers.

Thole which go r ••••• the foot-ftalk of the flawa; rmy nut improperly be called fpenna' ••••• veflels. ••••• r ii from them that tin; Jenimal] pstrudei in naok, fejtofc, and heomipl ••••• flowers ••••• IL- feparated; therefore the foot-ftalks of the herniapiirodin: fiowtxa lire pro-portionuobly larger than thole either of the mat ••••• or fe-male; they have a double ••••• oice, aod coDtribut ••••• fac-cessivly to I •••••

In thofe where the caiyx becomes the fruit, the greateft ••••• fupply i'; ••••• to it fied, and diftribut ••••• in its coru ••••• parts, as it vifible in the Rose, in which the (boi ftalk a (b far ciiarged at lirlt, as to L. of an equal bignr& with the bud.

After the calyx is thus formed, the next dift ••••• UEion is to tlic inner or centriul p.ict of the flower, ••••• likii Dr. Grew calls acicitt, and where the pitillum becomes the tri lit; the pitillum and ityluj arc furmtd al the fame I ••••• with the flamina and apices.

The ftylus ••••• the very ••••• firilraiv; in its dur-; ••••• nffiii and ••••• i'nefs; for tlic til ••••• tributes particles according to the centre nevt. Hop till the ••••• is ftretched out to its full length; and in fuch ••••• as are furnished with a peculiar apex, that is formed by the neck oi the ftylus, oi iluit ••••• art new to ••••• thenti ••••• is gradually decoreat in its growth, till it comw w dr^ pitillum. Thi is callly perceived by thole who will take the pain; to 'open the ••••• α" a Lily, Tulip, &c. ••••• before they are half bl ••••• own.

The ••••• when is furnished neat with an extraordinary fupply of cbc nutritious particles before tlwflowwu blown; ihcfr, whctlicr fewer or more, aft ••••• lift brought to their propaniooal Itrgeoea, bridg round and j ••••• acy.

The ••••• ix is the th ••••• which receives this ••••• extra-ordinary fupply of the nouriliii ••••• ont, for after that the ftylus is formed, that it may lean to it after the ••••• of the flamina and flumina are extended to their full length, anil (o formed, that they can convey fuch a quantity of ••••• Jiiimry quantij t particles as may fill up the capacity of the apex; it is then more enlarged than ever afterj for if the fii ••••• of a Lily be opened before it be blown, the HJ ••••• will be found to be as long as the flamina; but as the ope half of the apex covers the Jhuncn, fixed to il ••••• center, in the other half <J. it is fo far exceeded above tlic flamina, as the llamen rriainrJ uncovered below it, tow Ith the pe-dick or foot-ftaik.

The fourti part of a (lower is ch ••••• petals, which re-ceive this cictraordinary fupply of ••••• nourishment be-fore tlic biuv. ••••• ing; thefe upon the petiole, are firft en-larged towards the pedick, and aft afterwards, cal-ended wsd firclied fui ••••• in proportion to the en-tringement of the acric ••••• at firft they are all equal, ar.tl mod- focculi ••••• it grows to the origin, and gradually bceonu' iiiiinL-tr and broaJi' ••••• The flamina of mono-petalous flowers do, for th ••••• part, arifc partly from the [jclalo; ••••• itself, and partly from the calyx; eljjecitly it" the i ••••• flamina corre- ••••• to number to the psula, as in the ••••• of Polyperale; of Tournefort ••••• here every 11 flamina arifc oppofite to the middle of the j ••••• ctalon.

This (bfm'riort how and when ••••• the flowe than or-dinary fupply of nourishment is carry'd to the flowers) callly demonftrates wherein the main ••••• of the organs of generation in plants and animals confifts.

In animals, the feminal matter is received by the ••••• veflels from the fame blood from whence the other ••••• parts ••••• animal organ

nomy proceed-, fe that the l'-x>d in anunals being the Sime with the 6p in pl.-mts, and be g conveyed after the same Banner dLrouyhout die : bodies, it neccflarily tut laws, thm • the one as well as (he other, mult have proper veffels far fecit:!

than ihac of being the means of fcuxidadang the female feed in piano, as thc Other is of die fen

oval in animals. If any one Hull take a flower Full blown, and pull one eff the Itemina from the pedicle, Ec will , and a rough vifcid liquor, liliu to the fperma, which remains iwre till it; molt fubtle parts have ascended the flamen, or p<

remained there, after i!lc molt fubi before the Rower was blown •. itis Is ns jluin i. monfrable is tan be in the Lilies, particular!) i Omnge Lily, md mult of the Maroigon Lilies, there is a nrvivorce more obvious.

Thi» vifcid liquor nfcending by pai to the apex, there this lubule matter 13 retained till it h farther elaborated by the evaporations of the IIUTC humid and aqueous particles, by the heat of t.' and then it becomes a molt fubak, Enc, impalpable duft, which is iten fnd to be ripe, and is en!; farina.

Dr. Blair, afur having given the femimeats of feven dificent authors own tl« fubjeft, preceeds to his own, without fubfcrljing IQ the fendmnt (if either the one or ibe odw t and enueJavours by a frifrl t-x- uninationoaf the : . . . rfulves, to find out which of ihcfe two opinions, fo diametrically mipotite to cadi other, are molt agreeable to fact.

But before he begin*, ht: lays down this general maxim, which he takes for panted, dun lumtn: is uniform in all her operations, and never recedes from thofe rules laid d. . . . iwn by the wife Dipoler of all things at the creation, by performing the fame thing after two different and contrary methods; and thence con-

t, SU if the ftmna be a congeries of lemal phinti in one fpecies, it mult be fo m all. If there be an open . . . / direct piflagc, ur though It be not fo direct, yet it, by which i(can bctfcomfnttfe that one fingle e^in - farina can enter every individual feed in one . . . vants . . . mult be (b . . . in all . . . but if neither of thefe . . . 110, ^ Bpo&t and if it «•• be pceded by o . . . cubr infpction, without 1 he affifbnee of a micmcape, in chofe verj exemplified by/Mr. Morland, Mr. . . . id Mr. Bradley, that *e farini in lubiarK . . . of the fen- . . . or it it do, . . . direct r it ha; iititujsi dwn he hopes,

fa!! ample given Ai for the Corona Imperwlii, the firft «a

by Mr. Morland, the fowers of which hang down- ward, though he does not deny but as Hylas may be hollow all the way, and that it may be open at the extremity, yet by its ftructure, and several other circumftances, it does not feem to him to favour this opinion.

For ill, as there is a continual conflict of particles through the fan in animal bodies, it is allo to be irregular; this appears by the immediate fading of Itwrcs, or after it has been ; which proceeds from the transpa- rion ai the particles in the ; le tube;, without anjr more fucceeding in their place.

He if' . . . it is reasonable to fuppofe, that thofe par- tides How . . . by the hollow Hylas, as by any other part, and alfo more freely there than elsewhere, be- cauli-1f their being concentrated within fuch narrow hauuids; and thi- if thofe particles defcend by the Hylas lunginc; downwards, tti: particles, or rather grainioF thi farina, can never afcend the fame way.

idly, That if it I! could be granted, that thofe grains did afcend by the Hylas, doty got into the lemin;ii 1 cife!, that being clofely fhut up, as will ap- pear to any one who fhall obferve it.

3.dly, Whertij Mr. Morland fuppofes, that the rain either down the tube, till it 1 reaches the feminal vefel; Dr. Blair obferves, that the extremity which is the upper part of the Hylas in all i flower, mult be the lower in a dependent one i that if either the rain or wind have access to it, it mull li- either wash or drive it away from the leu.inal vefel, which is no- die Ityim.

B'jt hi . . . the Ductus takes notice of atwtiier cantri- vance, for afcending that purpofe, i. e. a . . . of a pelvis or rilern, called by Linnæus uterulus, fi- tutedattli. tofeach | Iwitli

a vifcid liquor which contains . . . there, and never ex- ceeds its bounds fo long as the petal . . . in health:

for fince the apices are not fo aftually fixed, that they turn eifry wfy with the le.ill wind, as Mr. M' ftand

exactly obferves, when they burst, and the farina is Jnven to and rrcs though i; 1 cannot fo eafily raze the tube, yet ii

may conveniently be blown up towards the orifice of the petala furrounding the Hylas, where it is opped or llad b; this vifcosity, till it has per- formed . . . i iu office.

To con jinn this, he infantcet Mr. Fairchild, who, he fays, being perfuaded that this vifcid liquor did fome way or oihcrcontnt ure towards the fructifying of this plant, but not understanding how it did fo, he tried the experiment, by wiping this liquor off as foon as it was depofited in the pelvis, and the flower which helbfa did not bear any fruit.

And ll. . . way the doctoe accounts for this is, that the humkiii. being retained, the farina is no longer blown upwards, than it immediately falls down, without producing an; and that which he takes to be a confirmation of this is, that both Tulipa and Psi- Ollariaa have 1 in the pelvis or bafe, yet it is for the molt part dry and empty; becaufe the flowers of the former bou they have no fuch need of this liquor

to rctir; the duft, for that the rain, having immediate access to them, may wash the duft towards the origin of the petala, where it can remain till it has performed its office: whereas the rain having no access to the inner face of the flower of the Corona Imperialis, it is (ia- tually radiated with this humidity, deposited

there bj li in order to render it Btfor notice 0' this fungus; y in flower, though he at- tribes no ufe to it. The 1' example propofed by Mr. Morland, is the l'ellow

Lily, which, according to his fpecie, is repre- fented as having the apices equally high with the top of the Hylas, and the petal, over-topping each other; whereas he fays, that by the narrowft infpection he ever could make, the top of the apices (they being thro; particularly fixated) reaches no higher than the neck of the bottom upon the top of the Hylas, and [ha! thi is before the apices begin to burst and

mod the duft i but as soon as the flower begins to open, they depart from the stylus, and force the petals outwards, by a certain elasticity, and expand themselves; this being done, they immediately change their posture from a perpendicular to an oblique or horizontal one; nor do they ever pour out their duft or farina, till they can conveniently drop it upon the bottom of the flower, and towards the root of the pistillini.

But taking it for granted that it was so, [the style of the stylus (which the Doctor calls the button, in opposition to the apices of the stamens); in (the style) is locomotive, and of so firm a substance, that it is next to impossible, that the farina in substance, or in integral parts, could pass through it.

• If the integral part, the complete grain, or minute globuli, in which the whole lemma is contained, cannot then enter, the whole compound must be diffused, and the minute seminal particles to this small grain of duft must be diffused; and if so, how shall these again come to cement, so as to make up one continued body? or how (shall this little body, so united, penetrate a second time the partition-wall betwixt the stylus and pistillum? and again, how shall it find one its way to its nest, in the proper embryo of the seed?

The Doctor takes notice of the White Lily, the Orange Lily, the M. magnum Lily, &c. as objections to the opinions of Mr. Morland, Bradley, &c. and also mentions the Iris, as a moll pregnant instance, that the farina cannot so much as come at the pistillum; for having six petals, the three stamina with apices lie mid between the three petals which hang downwards, and three large expansions of the bristly stylus, and the upper part of the down-hanging petal: the farina can never reach the center of the stylus, though it were hollow, which it is not, but must defend along its outside, to the top and outside of the rudiment of the fruit, there to emit its effluvia. These and other instances he concludes, are sufficient proof, that the farina cannot enter the stylus, pin into the pistillum, or inner part of the h-minimum, nor have the leaf access to the embryo of the seed.

As to the objection, that there is not passage sufficient to admit the male seed into the uterus, or even into the ovaries, it is thus answered:

If it be considered how every flower, when it is prepared for the act of receiving the male seed, is so much under the influence of the sun, that the petals open at its approach, and shut up again at its departure, it very well explains how the pistillum, or fertilizers of generation, are relaxed at one time more than another, i. e. that the female parts are more relaxed at the opening of the flower, than when the flower is fruit up for the flower leaves adhering to the bottom of the pistillum, must consequently, when they bend back, put every part of the pistillum into a different posture to that in which it was when the petals were thus.

And it is certain, that it is the presence of the sun that ripens the male duft in the apices, and opens the little odes in which it is contained, giving them a springiness that flings forth that duft as soon as it is ripe, so as to scatter it to a considerable distance. The female parts are at this time dilated by the opening of the flower-leaves, and the apices and chives, concurring at the same time in flinging forth their male duft, answer the same end in the generation of plants, that the act of copulation does among animals.

Having thus given (even) reasons and arguments tiled by various authors, who have made it their duty to investigate the mode of generation of vegetables, whether the impregnation of them proceeds from the farina focundans, or male duft, entering the uterus of pi Lima in ubi Unccs, or by effluvia, I shall not take upon me to determine the dispute, especially (incc Mr. Boyle has proved, that all effluvia are subtle particles of matter; so that it matters not how (in minute) the particles are, incc a body is its firmness; may be so minute as to be scarcely perceptible.

I shall therefore conclude with mentioning a few ex-

periments of my craft, which I communicated to Dr. Patrick Blair, which he improved; and a proof of his opinion of effluvia; and Mr. Bradley's, as a proof of the farina entering the uterus in libitudo, and leave the curious enquirer to determine on era of the question, to which reason and experiment shall influence him.

I castrated the male plants of i bed of S. each from the female; and die con-; Juice was, mat fac Ituil did swell to the usual bigness, but when sown it did not grow after.

and having g into the Thai, I found it wanted the punctum vitæ, or what Geofroy calls thegermen.

I set twelve Tulips by themselves, about six or seven yards from any other, and as soon as they blew, I took out the stamina with their stamens, ia very carefully, that [scattered none of the male duft] and about two days afterwards I few bees working on a bed of Tulips, where I did not take out the stamina; and when they came out, they were loaded with the farina or male d... on their bodies and legs, and I saw them fly into the Tulips, where I had taken out the stamina, and when they came out, I found they had left behind them sufficient to impregnate: little flowers, for they bore good ripe seeds which afterward grew.

In a parcel of Savoys, which were planted for seed near white and red Cabbages, when blown, produced half red, and some white Cabbages, and some Savoys with red ribs, and some neither on the one nor the other, but a mixture of all sorts Loggia in one plant, which I suppose might happen by the effluvia of the different sorts impregnating the uterus of each other.

In the letter communicated by Paul Dudley, Esq; to the Royal Society, written from New England, he mentions the interchanging of the colour of the Indian Wheat, in the various colours at planted in rows near each other, but if they are separately, they constantly keep to their own colour; and the interchanging of colours has been observed, when the difference between the rows of Cam has been several yards, though he says, if there happens to be a high board fence between the different coloured Corns, the alteration of colours is entirely prevented.

It is from this circumstance of impregnating each other, that the several varieties have been produced; and this gives new light to the fact, that raifin a much greater variety of flowers, for by planting; the different coloured flowers near each other, so that the flowers when fully blown may be intermixed, their Burin will impregnate each other, so that the seed will produce variegated flowers partaking of both colours. But it must be observed, that flowers of different genera will not impregnate each other, therefore the plants must be of the same genus which are placed together.

Cucumbers and Melons always produce male and female flowers upon different parts of the same plant; the male flower (which appears upon a slender stalk, and has a pistillum in the middle, covered with an Orange-coloured farina) is by the gardeners commonly called false flowers, and some (by a malicious and unkindful persons) pulled off soon after they appear, supposing that they weaken the plant, if they remain, which is a mistake; for, in order to try this:

I set many Cucumbers in a place pretty far distant from any other; and when the flowers began to appear, I instantly pulled off all the male flowers from time to time before they opened; the conference was, that at all the young fruit dropt off soon after they appeared, and no one young Cucumber remained to grow. I set some Cucumbers in another place, where I cut off all the male flowers to remain upon them, from which I had a great quantity of fruit. But this doctrine is now so well established among the gardeners, being confirmed by experience,

that Cucumbers now carry the male flowers of the Cucumbers and Melons to the female, it is true; and

fituated very near them, and gently ftrike the farina o the male, into the bofom of the female flowers, and thereby fet the young fruit, which would otherwife drop off.

There are feme perfons, who fill obje6t to this theory of the generation of plants, from having obferved fome plants, which were termed female, growing fingly, and at a very great diftance from any male plants of the fame kind, which had for fome years produced feeds which were perfected, and grew when ibwn; and indeed I was myfelf a little ftaggered in my opinion, op having obferved a female plant of the white Briony, which grew fingly in a garden, where there were no other plants of the fame kind; which for feveral years produced berries, which grew and flourifhed perfectly well. This put me upon examining the plant more carefully than I had before done, when I found there were great numbers of male flowers intermixed with the female, on the fame plant; and fince then I have frequently found the fame in many other plants, which are fometimes male and female in different plants, yet have fometimes both fexes on the fame plant; fo that the objections which have been made to this dodtrine, may not have proper evidence for their fupport.

It is certain, that the female plants may produce fruit, without the impregnation of the male -, but it is not certain, that this fruit or feed will, if fown, produce another plant. What has been fo often related by travellers and hiftorians, of the neceffity of the male Palm-tree being near the female, in order to render it fruitful, hath been fully confirmed by Father Labat, in his account of Africa, where he has treated of the feveral forts of Palms: he fays, that he obferved in Martinico a large Palm-tree, which grew by the fide of a convent, which produced plenty of fruit, though there was no other Palm-tree growing within two leagues of this; but he alfo obferved, that none of thefe fruit would grow, though they had made many trials of them; fo that they were obliged to procure fome frfuit from Barbary, in order to propagate thefe trees. He likewife adds, that the fruit which grew on this female tree, never ripened fo perfectly, nor was fo well tafted, as thofe which came from trees which had ftood near fome of the male: therefore we may conclude, that the fruit or feed may be produced by the female plants of moll kinds, without the affiftance of the male fperm, which may appear to fight perfected, and fit to produce others; but if we examine the feeds, we (hall find that mod of them have not the germ or little plant inclofed, nor will grow if they are fown.

From thefe and many other experiments, it is very plain, that there is a neceffity that the embryo of the female flower (hould be impregnated by the farina or male duft, in order to render the fruit perfect; but how, or in what manner it is performed, is what we can only guefs at, fince in the generation of animals, our greateft naturalifts differ very much in their opinion?; nor can any of them afcertain any particular method how it is performed. I fhall therefore conclude with quoting the words of the Rev. Dr. Hales, which are a moft ingenious fummary of the whole dodtrine of the generation of plants.

< If I (fays he) may be allowed to indulge conjecture u in a cafe in which^m moft diligent enquirers are, w as yet, after a\ thejr laudable reſearches, advanced b but little farther, j man ipere conjecture, I would p propofe it to &c; c; confideration, whether from the m manifelt proof, f have, that fulphur ftrongly a tradts air, a h<t may not be taken, to confider c whether this may not be the primary ufe of the f- rina fcecutis, to atradt or unite with elastic^ or other reſaaja active particles. That this farina a abounds ffr i fulphur, and that a very refined fort, u is projofc from the fubtile oil which chymifts ob- j p i i & n the chives of Saffron; and if this be the u ue of it, was it poffible that it could be more aptly u placed for the purpofe on very moveable apices

" fixed on the (lender points of the ftamina, whereby
" it might eafily, with the leaf breath of wind, \\
" difperfed in the air, thereby furrounding the plant,
" as it were, with an atmofphere of fublimed fulphii-
" reous pounce? for many trees and plants abound
" with it, which uniting with the air particles, may,
" perhaps, be infpired at feveral parts of the plant,^
" and efpecially at the piftillum, and be thence con-
" veyed to the capfula feminalis, efpecially towards
" evening, and in the night, when the beautiful pe-
" tala of the flowers are clofed up, and they; with all
" the other parts of the vegetable, are it a ftrongly
" imbibing itate. And if to thefe united, fulphureous
" and areal particles, we fuppofe fome particles of
" light to be joined (for Sir Ilaac Newton has found,
" that fulphur attracts light ftrongly;) then the re-
" fult of thefe three by far the moft adtive principles
" in nature, will be a pundtum falienſ to invigorate
" the feminal plant; and thus we are at laft con-
" ductedj by the regular analyfis of vegetable nature,
" to the firft enlivening principle of their minuteft
" origin."

GENISTA . Lin. Gen. Plant. 766. Tourn. Inft. R. H. 643. tab. 412. Broom; in French, *Genit*.

The CHARACTERS are,

The empalement of the flower is of one leaf tubuhus and divided into two lips; the upper lip is deeply cut into two* and the under into three equal parts. The flower is of the butterfly kind, the ftandard is oval* acute* and remote from the keel, being wholly reflexed* the wings are a little ſhorter than theftandard, and are loofe: the keel is ereft, and longer than theftandard* and is indented at the top. It bath ten ftamina joined in two bodies* which areftuated in the keel, terminated by Jingle fummifs. In the center is an oblong germen* fupporting an afcending ftyk* crowned by an acute twiftedftigma. *the germen afterward becomes a roundjib turgid pod with one cell, opening with two valves, inclojing kidney-ftaficid feeds.*

This genus of plants is ranged in the third fedtion of Linnaeus's feventeenths clafs, which includes the plants with flowers having ten ftamina, joined in two bodies; and to this he adds fome of Tournefort's fpecies of Spartium, and the Geniftella of Tournefort.

The SPECIES are,

1. GENISTA (*Sagittalis*) ramis ancipitibus artictilatis, foliis ovato-lanceolatis. Hort. Cliff. 355. *Jointed Broom, with two-edged branches* and jointed, oval, fpear-jhaped leaves.* Chamse Genifta fa^li*. C. B. P. 395. *Dwarf errow-ftaped Broom.*
2. GENISTA (*Florida*) foliis lanceolatis, ramis ftriatis teretibus racemis fecundis. Hort. Cliff. 2 55* *Brcomwith fpear-jhaped leaves, and ereft taper branches abounding with flowers.* Genifta tindtoria Hifpanica. C. B. P. 395. *Spanijh Dyers Broom.*
3. GENISTA (*Tinfforia*) foliis lanceolatis glabris ramis ftriatis teretibus ereftis. Hort. Cliff. 355. *Broom with fpear-fbaped leaves which are acute, and taper channelled branches proceeding from the fide of theftalk.* Genifta tindtoria Germanica. C. B. P. 395. *Common Dyers Broom* or Wood-waxen.*
4. GENISTA (*Purgans*) fpinis terminalibus, ramis teretibus ftriatis, foliis lanceolatis fimplicibus pubefcentibus. Lin. Sp. 999. *Broom with taper-ftreaked branches terminated by faines, and fimple ^fpear^Jbaped hairy leaves.* Genifta five fpartium purgans. J. B. 1. p. 404;
5. GENISTA (*Candicans*) 1 foliis ternatis fubtus villofis, pedunculii lateralibus fubquinquefloris foliatis, leguminibus hirtutis. Amcen. Acad. 4. P. 28 4- *Trifoliate Broom with hairy leaves* foot-ftalks from the fide of the branches having five flowers* and hairy pods.* Cytiius Monfpelfulanus, medicse folio, filiquis denſe congettis & villoſis. Tourn Inft. 648.
6. GENISTA (*Tridentata*) ramis triquetris fubarticulatis, foliis tricufpidatis. Lin. Sp. Plant. 710. *Broom with three-cornered jointed branches* and leaves ending in three points.* Geniftella fruticofa Lufitanica. Tourn. Inft. 646. *Shrubby Portugal Dyers Broom.*
7. GENISTA (*Pilofa*) foliis lanceolatis obtufis, caule tuberculato dQumbente. Hort. Cliff. 355. *Broom with*

poiftmooa umbdliftroos roots, but on comp' with ibme dried I lenbane. I found they wen; the fame. V have -wife jm ^ 0 ^ ^ of

Surpmm Mibe-rmeanim, which nucomi; in the author by IV. rhomai Molyneujt, phyfieUn to the ite, it wis as followi:

Th* Dran of Clo ,aking fome alterarion, m Lil, garden, and, looking over his workmen, L ob- fayed them to dig up m-ny roots, which he too, for bkirrets, anl therefore ordemi fame of them to be earned in and dreffid for dinner, wlieli wa^ accord- ingly dune s but all tholr «ho eat of them were in a ftiore tiin Itict-d wkii dier.incs in their :

fticli at the itomach, atn-nd-ti with an unual heat and dnnds in thir throats, and two, who JwJ eatn a larger ihare than rht- ref, UAi the uferfftheir rra- fon, ndbecame ddiriom, which condnued ftirfome days -, and as it appeared evident the I dieridiers were occafioned by the roots, the Dean caufed (brae of them to be planted, that he might be ruTured wht the Ulant via wholi; roots i. ad the bid (jtiality^ and In the fpring, when they pni out thir leaves, Vvy proved to be die Hcnbant-, which has been noticed by old writers to be poffeffed of thefe qn.ilitic; And as [he diforders which were occaConed by dwfc fupposed Gentian rooti, were nea by the fame , as, j, s ^ ^ , ,

lated, I diought it mi^lit be of nle to inferc ii here, to caution others agairifl eating of roots which they are unacquainted with.

This pfcnt delights in a light loamy foil and a A dly Cnumn, where it will thrive much better dian in a light try foil, or in an open atpofbi . It is pja- gated jly feeds, wl, ch thould be frown i. poo),,,,,, alter it is ripe, for if it is kept til! [lie fpring, it will not filtered ; theft [Kit? ftould be placed in a Qiidy fituauon, and kept clean from weeds. In the Iprini; the plant! will appear, when they mud be duty

ii dry weather, and kejn clean from «tti is till the following itomn; then they Ihoild be care- fully ftiackn out of the pots, in (is not to break or injure their roots j and a fhuk Uirdcr of loainy cant) ftitnuld be w ll dug and prepared to re; ;ve rlicin, into which dieplann flmuid be planted at about fix inch:5 dittance each way, obferving to let ,[.u top of die routs be a little below the (urfacc of the

ground,

ground, then prefs the earthdole to **the root** i af-
itr [his they »ill r-quirc no farther care, but to keep
them confanily clean from weeds; and if the fol-
lowing fpring fhould prove dry, they fhould be
il:ite waicred, which will greatly forward their
growth. In this border the plants mjiy Hand two
yeas, by which time they will be fit to rranfplant
where they arc dcligned to remain i therefore in au-
tumn, fo loon as their leaves decay, they may be re-
moved i but as the roots of theft plants run deep into
the ground, like Carrots, there muft be great care
taken in digging item up, not to cut or break their
roots, for thai* will greoajr weaken, if it docs not kill
ihcm. After the planes are well fixed in their places,
they require no other culture, but to dig the ground
about them early in the fpring before they begin to
fhooi, And in the fummr to keep them clean from
weeds. The roots of thefe plants will continue
many years, but the flkfc decay every autumn; the
fame roots do nut nWcr two years together, nor fel-
dom cfienec thin every third year^lm when they
flower frong, they make a fine appearance j and as
thelc delight in Qwly moift ground, where but few
ornamental plants will thrive, fo they fhould *tax.* be
wanting in good gardeu.

The itcond fort grows naturally in moift pafures in
many parti of England, but particularly in the north;
this rites with on upright italk about a foot high,
garaiihed with 1 mouth leaves an inch and a half
king, and lefs than a quirt.r of an inch broad; ihcy
arc placed oppofue, and *have* no foot-ftalks. The
flowers ire produced on the top of the ftalk, three or
low in number, Handing upon foot-IUlks alternately
above each (ithcr; they arc large, txll-lhaped, and
divided into five points « their brim, and arc of a
deep blue colour, fu make a fine appearance ; thefc
came out the latter end of July in the warm parti
of England, but in the no.th they arc full a month
later.

It may IK propagated by feeds in the feme manner as
(he firft fort, and (he plants may be treated in the
lame way ; but as this fort does nut (hoot its roots
(Jeep into the ground, it may be tnwfgUnttd with left
hazard -, however, if thefc arc removed with a ball of
earth to their roots, they wili not feel their removal
fo much as when the earth is all tiken from them.
This fort fhould be planted in a iirong, moilr, loamy
foil, in which the plants will thrive and flower annu-
ally, but in a warm dry foil they will not thrive or
flower.

The thin! fort grows naturally upon the Helvetian
mountains; tba nib with an upright ftalk near a
foot high, garnifhed with ftnooih leaves about two
inches long, *tod* ibr-e quarters of an inch broad at
their bale, where they embrace the !Vilk, but they end
in acute points; they arc placed oppofitf, and arc of
a fine green, and diminun in their fize as they arc
nearer the topi they have five longitudinal veins,
which join at both end*, but diverge from each other
in the middle. The flowers come out by pairs op-
pofite, rrom the bottoms of the leaves, Handing on
fljort foot-ftalks (they art pretty targe, bell-lhaped,
and of* fine blue colour, fo make a fine appearance
when they arc open. This fort flowers in June and
July.

It may be propagated by feeds in the fame manner
as the firft Jon, and the plants may be [reared in die
lame way, bur thej muft have a moift loamy foil,
otherwife they wit^{nol} thrive. Ir. tmy alfo be propa-
gated b> *affets*, whi-U may be-divided from the
roots •, thde fhould b; taken off in autumn, which
is the bed fcafon for removing aJ thefc *font* of
plants; but thefc fhould not be removed, or parted
offene than every third year, where they *are expofed*
to produce irrm^ flowers.

The fourth fort grows naturally on the Alp* and
l-iclvMan mountains, but has been long culo
in molt of the curious pirdens in Europe; this k com
only known by the title of Gentabella. It is a low
plant, the tUlki Idilom growing more than three or

four inches high j they arc garnifhed ft; smooth
leaves pliced Ojipolice, whit It arc v«o (ndic^, lunc,
aiid hid'an inch broad, fitting-dole to tin *talk*. The
ilowers grow creel on the top of the [talk, fo (Und
quite above them ; theft arc often iinglc, but fume-
times, when the plants arc frong, there will *be* four
or five it the end of each ftalk ; they ate lar^c, lxil-
fhapctf, and of a deep azure blue, to is the i in eft of
that colour of any Bower yet known, [t ufuaily
flo-Hers in May, but foiatimes tht plants B *lower*
again in autumn.

This is commonly propagated by parting of the root*,
in the fume manner as *h* before directed for the third
fort, but thefe muft not be offer. [ranfplanted, or
parted, if they arc wanted to i:^^: r lirrong-, this fort
fhould have 'a loft loamy foil and a fluidv ikua-
tion, where the plants will thrive and Uower well
eveiy year.

It may alfo be propagated by feeds, which, in a
good loil, the plants will jri *plantys* trefc
JhtHilci be fown in aununn, in the faint manner a? is
before tincted for rhe firftloif, and i: *the plants*
•re planted in i good *tb'd*, tin: will be frong enough
to flower the fecond ye after they come \ and
thele feeding plants will flow *friget* than
thole which arc propagated by prui'».

The fifth and eighth ibrts art low annul planu,
•which grow natimlly upon the Alps and other moun-
tainous places inEunrpc, and arc very rarely cultivated
in gardens. The firft leldom rirnnioreihatitwoinchet
hinh, branching out from the root into fevcfal (ender
luik; , garnifhed with very fmall i *by*
pairs, and each fUlks is termnatcd byonulniallerblue
flower (landing erect. The i *grows* ibouc
four inches high, with a Gngl- *talk* of i pur-
ple colour. The leaves at tl *are oval*, but
thofe upon the ftalk ire narcw, und Hand oppoGte.
i hi; ftalk a tenninawd by o *blue flowers*, wjth i
large bellied empalsmcnt, which is *plated*, and the
petal of the flower tifes but a Little *above the caly-*
merit, *io* docs not make much ap>efranc.\ After the
top flower decays, there arc frequently two 1 mailer
flowers which come out from the fide of rite itdk. at
the mo upper joints ; thefr flower akcr each other,
the upper one coming Grit, fo that there in lueccffion
ot flowera till autumn.

As ihell- plants ufually grow upon nio;lt fpongy
ground, it is ver difficult to cultivjtc ihem in gar-
dens ; tor unitrs they hive a foil approaching near to
thst in which they nairally grow, they will not
thrive; the only method to obtain them is, ci:her to
fow their feeds inpo«*,orupoi* a moift boggy ground
in autumn, but it muft be in the llwdej and when
the plants come tip, they may be thinned, and the
furi'ace of the ground about them covered with
mol's, which mould be conllanriy kept moift; with
this management I have l'ten the planes thrive and
flower very well.

The fixth fort is a perennial plant, which grows na-
turally upon the Appeninei and the Helvetian i *in-*
tains i tins rife with an upright (talk about ffr in
high, garnifhed with fsmooth Ipear-thaped lea'
about two imhet long, and one broad in the middt,
fitting clofe to the llalk i they arc parcil oppofite,
and each pair of leave; cruh one another, from whence
it ii called Croflu-oriGiT' *flowers* are pro-
duced in whorls round the lijlks vit th^ upperjoitts,
fitting very dole to the ftalk and at the top there
is a large dutier growing IntJie *tin*v form; thefc
arc of a light blue colour, and i>psar in May. TiiU
may be propagated by feeds, or >fkts, in the fame
manner as thf thir.l and *fourth* foie, and i the plants
mult be treated in the fame way, •.

The feventh ibrt grows naturally upijn the Alps, and
other mountainous pans of liurope; f, is is a H *low* pe-
rennial plant, whose talks are *very ftead*, and rarely
[& more thin three or ; *the talks* are garnifhed
with fmall, narrow, acute-pointed leaves, placed in
pairs*, each !>ilk is ;, *mutated* by one large blue
dower, which in hiiry on the infute *us*. the brim. The
flowers

GER

flowers in July and August; and may be ...
ajid treated in the fame, m-uineras the third and fourth
fora.

The ninth fort is the Letter Centaury of the (hop?)
this grows naturally upon dry paitures in moll part
of England, where it rites in height projjortiotisble ti
the good ne Is of the foil; for land it is fre
fjuently a foot high, but in poor foil) nut more tSin
three or four inches. It is at annual plane, with upright
branching (talks, garnified with Jmall Lives placed
by pairs. The flowers grow in form of an umbel at
the top, and ire of a bright: purple colour; they
come out in July, ami the feeds ripen in drame.
Tills plant cannot be cultivated in the gardens.

The tenth fort grows naturally op on diskly grounds
in many parts or England. It is an annuat pkmt, rnfing
with an upright ftalk *foot high, garnimed with ovaf
pointed leaves, whofc bafc lurroui. i they
grow by pairs, ant! arc of o gray colour-, the ftiiiks
and leaves are very smooth. The flowers grow
in form of an umbel on the top of the [talk ,
they are of a bright yellow colour, and are en; into eight
parts at the top. Thefe appear in July, and the feeds
ripen in autumn.

The eleventh fyct is an annual plant, which grows
naturally in the ibuth of France and in Italy s itmrfirs
with an upright ftalk about a foot hij'h, lending out
fevefal branches toward the top, which arc ga! nified
by fmill leaves placet! oppoiite. The flowers are
produced from the fide and at the lop of rji(
m formofjoofc irregular umbels-, diey arc white,
and about the fac of thole of the common Ceniaury.

The twelfth fort grows naturally in the Wei!>Indies,
where it was dftovcred by father Plmnicr, and the
Ince Dr. Houftoun found it growing in pltnry at La
Vera Cruz, in low moilt places where the water Stag-
nates, but at a remoter diftants from ttic tea. The
feeds uf this plane !w fent to England, which (be-
ceeded in tile Cltclfca garden , this rifes with an up-
right branding fULK near two feet Jijj>h, garnifhet
with oblong, Imooth, acute-pointed leaves, pbced
oppofite i the upper part of the flalk divide) into le-
veml forks, between which are la or feven long na-
ked foot-ftalks, each iurtaining one large blue flower,
divided imo five fegmrms at the brim. The flowers
arefucceded by oblong capfules with one cell, filled
with Im all feeds.

This is propagated by feeds, which muft be fown
on a hut-bed loon aft« they arc ripe, and the plants
afterward treated in the lime routiner as other tender
annual plants from warm countries, being too tender
to thrive in the open air in England. If the feeds of
thij plant are (own in autumn, in pots placed in the
tan-bed of the ftove, they will Juccced better than
when they arc fown in the fpring, and the plants will
flower early, fo good feeds may be obtained.

G E R

from which trifoliate (several branching stalks, which grow about one foot high, garnish the stem with leaves at each joint, which are divided into five lobes; and are directed at the top into many (about) ferments, which are seen on their edges; they are of a light green, and smooth. The flowers are produced at the end of the branches, many growing together in a bunch, but each stalk bears two flowers. The flowers have fourteen empalements, resembling inflated bladder-stalks. The joints are pretty large, equal, and of a fine bright purple colour, and the stem is much longer than the petals in the whole plant, when rubbed, emits an agreeable odour. This flower is propagated and treated in the same manner, the plant being equally hardy.

The third fort grows naturally in many parts of England, but is often admitted into garden; this hath a very thick, fleshy, fibrous roots, which grow to a large head, from which arise many stalks, garnished with leaves, divided into five lobes, which are finely divided almost to the midrib. The flowers stand upon long hairy foot-stalks, which come out from the side of the stem (talk, each sustaining one flower, composed of five broad regular petals, which are of a deep purple colour. This flower is in June and July there are two varieties mentioned of this fort as distinct species, one whose stalks grow more erect, and the other hath leaves more deeply divided, but the plants which I have raised from seeds of these do not come up the same as the parent plants, for they are only femal varieties.

This hath a perennial root, which may be parted in summer, and thereby propagated; or it may be propagated by seeds, and the plants treated in the same manner as the lily.

The fourth fort hath been supposed by some to be only a variety of the third, but it is undoubtedly a distinct species for I have frequently raised the plants from seeds, which have always proved to be the same. The stalks of this plant are shorter than those of the third, and the leaves are much less, and not so deeply divided, and the flowers much smaller and of a pale colour, marked with purple; it grows naturally in Lincolnshire and Westmoreland, where I saw it in plenty. This may be propagated and treated in the same manner as the others.

The fifth fort is a perennial plant, of smaller growth than either of the former. It rises with branching stalks about six inches high, garnished with leaves, having three pretty broad lobes, which are undivided, and continue on their edges; and on the lower part of the stem (talks are placed opposite, upon pretty long foot-stalks, but the upper leaves fit close to the stalks and are single. The flowers are produced at the end of the stem (talks, [standing together upon two short foot-stalks. They are of a dirty purple colour, and appear in June. It grows naturally in France. This may be propagated and treated in the same manner as the first.

The sixth fort grows naturally on the Alps and Helvetic mountains, and is found in low places in the North of England: it hath a perennial root, from which arise several stalks near a foot high, with leaves which are divided into five or six lobes, which are continued on their edges; those which grow near the root have long foot-stalks, but those on the upper part of the stem (talks fit close to the stem (talks branches out at the top into three or four divisions, each bearing a flower, of a dark purple colour, with erect petals. This flower is in June, and may be propagated by seeds or by parting of the root, in the same manner as the first.

The seventh fort is very like the sixth, but the leaves are broader, the lobes shorter, broader, and not so much cut; they are striped with black (the stalks rise higher, the flowers are larger, and the petals are reddish. These differences are prominent, but are

G E R

sufficient to constitute a specific difference between them. It is propagated and treated in the same manner as the first fort. It grows naturally on the Alps.

The eighth fort hath a perennial root, which sends up many branching stalks a foot and a half high, garnished with light green leaves; the lower part of the stem (talk hath five lobes, and (standing upon long foot-stalks) jointed above [at the upper part] but three lobes, lit close to the stem, and arc (hardly indented) on the edges; [the flowers [stand upon long slender foot-stalks, each sustaining two flowers, composed of five obtuse petals, which are deeply indented at the top; they are of a dull white, with many purple stripes running longitudinally through them. These appear in June, and in cool seasons there will be a succession of flowers a great part of July. This fort is very hardy, for it may be propagated by dividing of the root, or from seeds, in the same manner as the first fort.

The ninth fort grows plentifully in the meadows in Lower Hampshire and Wiltshire; it hath a perennial root, which sends out three or four upright stalks about nine inches high, garnished with leaves, having five lobes, which are fringed on their edges; they are placed opposite on the stalks; those on the lower part have pretty long foot-stalks, but those on the upper part lit close. The flowers are situated on the top of the stalks, (standing upon short foot-stalks, each sustaining two pretty large blue flowers, with entire petals. This flower is in May and June, and may be propagated and treated in the same way as the first fort.

The tenth fort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the Royal Garden at Paris; this hath a perennial root, from which arise a few weak stalks about a foot high, garnished with leaves which are round, and divided into five lobes, which are indented at the top, and placed opposite on the stalks. The flowers stand upon pretty long foot-stalks, which come from the joints of the stem (talks, each sustaining two petals, which are entire petals, having very few empalements. It is in June, and may be propagated either from seeds, or by parting of the roots in the same manner as the first fort, but these plants require a drier soil and a warmer situation for although common winters it will live in the open air, yet several of these plants are sometimes killed, especially when they are planted in moist cold land.

The eleventh fort grows naturally on the Pyrenean mountains; this hath a perennial root, from which arise many branching stalks a foot and a half high, garnished with round leaves, divided into many obtuse segments at the top, placed opposite. The flowers are produced upon short foot-stalks, which cuttle out at the divisions of the stem (talks, and at the top of the stem (talks they are of a dark purple colour, and in others white. The petals or the stamens are broad, like those of the common Crane's-bill, to which the whole plant bears some resemblance; the stem is erect, the leaves and flowers much larger, and the root is perennial; this will propagate itself well enough by the root, where it has once got possession, and will thrive in any soil or situation.

The twelfth fort grows naturally upon the Alps. The seeds of this were lent me by Sig. Valerius, of Trente, this hath a perennial root, which runs very deep into the ground. The lower leaves are of a light green, and have very long foot-stalks; they are doubly winged and smooth. The upper leaves are of a dark purple colour, which are garnished with leaves of the stem (talks, which are smaller, and (standing upon very long foot-stalks, they are of a purple colour. This flower is in June, but has never ripened in England. The plant is hardy, and lives in the open air, but as the root puts out no offsets, nor periodically sends up new ones, we have not been able to propagate it.

The thirteenth fort grows naturally on the Alps; this liath a very thick perennial root, from which come out roundfil leaves, divided into many parts, Handing upon pretty long foot-ftalks; they are very filvery, and (hininglike filk. The flower-ftalks rife about four or five inches high, garnifhed with one or two fmall leaves like thofe below, which fit clofe to the ftalk. The ftalks are terminated by two pretty large pale flowers, whofe petals are entire, and ipread open flat. It flowers in June, but rarely ripens feeds here; it may be propagated by parting of the roots in the lame manner as the firft, and mull have a fhady fituation.

The fourteenth fort grows naturally in North America, from whence the feeds were fent to England •, this hath a perennial root, from which arife feveral ftalks about one foot high, which divide by pairs, and from the middle of the divifions come out the foot-ftalks of the flowers, which are pretty long and naked, each fufftaining two pale purple flowers with entire petals. The leaves are divided into five parts, which are cut on their edges, and are placed oppofite, the lower having pretty long foot-ftalks, but the upper fit clofe to the ftalks. It flowers in June, and frequently ripens feeds, from which the plant may be propagated; it thrives very well in the open air, and requires no other culture but to keep it clean from weeds.

The fifteenth fort grows naturally in Bohemia; this is an annual plant, which fends out many ftalks, dividing into feveral fmaller, which are garnifhed with leaves divided into five lobes, crenated on their edges; they ftand upon long foot-ftalks, and are for the moil part oppofite. The flowers ftand by pairs upon pretty long flender foot-ftalks, which come out from the fide of the ftalk; they are of a fine blue colour, and are fucceeded by feeds, whofe capfules and beaks are black. It flowers mod part of fummer, and the feeds ripen foon after, which, if permitted to fcatter, there will b? a fupply of plants, which want no other care but to keep them clean from weeds.

The fixteenth fort grows naturally in Siberia. The feeds of this plant were fent me by Sir Charles Linnaeus, profeffor of botany at Upfal; this fort hath a perennial root. The leaves are divided into five ac Jte lobes, which are cut into many Iharp wing-like fegments on their edges; they are placed oppofite, and have long flender foot-ftalks. The foot-ftalks of the flower come out from the wings of the ftalk; they are pretty long, flender, and each fufftain one pale purplilh flower. This fort flowers in June, and perfe&s its feeds very well, fo may be eafily propagated; it will grow on any foil, or in any fituation.

The feventeenth fort is an annual plant, which is fometimes found growing naturally in England, but is frequently preferved in gardens for the mufky odour of the leaves, which in dry weather is very ftrong. The leaves of this are irregularly winged, the lobes grow alternate, and are cut into many obtufe fegments on their edges. The ftalks branch into many dm-ions, and frequently decline to the ground. The dowers are produced in umbels upon lone foot-ftalks, which arife from the wings of the ftalks; they are fmall, blue, and have but five ftamina in each, their empalements are compo&d of five leaves. It flowers in May, June, and July, and the feeds ripen foon after; which, if permitted to fcatter, there will be a fupply of plants without care, which will require no other culture but to keep them clean from weeds, and thin them whe'e they are too clofe; it will thrive on any foil, or in/ny fituation.

The eighteenth,ortgrows naturally in Crete; this is an annual plan^with very broad leaves, which are cut on their ficte* regularly, in form of winged leaves, and are crenated^on their borders. The flowers are produced^ftferetty long foot-ftalks, which come out FHWWHC wings of the ftalk; they have five-leaved empalements, and are compofed of five entire blue petals; thefe are fucceeded by the largeft and longeft beaks of any fpecies of this genus yet knpwn. It

flowers in June and July; this ripens feeds very well, and if they are permitted to fcatter, the plants will come up without care; or they may be fown in the fpring where they are defigned to remain, and will require no other culture but to thin them where they are too clofe, and keep them clean from weeds.

The nineteenth fort grows naturally in Germany and Italy; this is an annual plant, which hath feveral proltrate ftalks near a foot long, garnifhed with winged leaves, cut into feveral acute parts, placed oppofite. The flowers come out from the wings of the ftalk, upon foot-ftalks about three inches long; fome of thefe fufftain many flowers, but others have no more than two; they are of a pale blue colour, and are fucceeded by very long beaks, but not fo long or large as thofe of the former fort; but the feeds of this are frequently ufed for hygrometers, to fhew the moifture of the air: if the feeds of this are permitted to fcatter, the plants will come up and thrive without any other care than to keep them clean from weeds, and the plants which come up in autumn will flower early in May, but thofe which are fown in the fpring feldom flower till July. Dr. Linnaeus fuppofes this and the former fort to be the fame, but whoever has feen the two plants, cannot doubt of their being diftinf fpecies.

The feeds of the twentieth fort were fent to the Chelsea garden by Dr. Juffieu, profeffor of botany at Paris; this is an annual plant, which hath upright ftalks near two feet high, which are garnifhed with double winged leaves, ending in many points; thefe are very vifcous, and ftand oppofite. The flowers are produced on long naked foot-ftalks, Handing many together* upon each; they are of a pale blue colour, and have but five ftamina; their empalements are compofed of five leaves, which end with awns. It flowers in May, June, and July, according to the times when the feeds are fown, and the feeds ripen a month after; this requires no other culture than the two former forts.

There are feveral other forts of annual Geraniums, fome of which grow naturally in England, and are troublefome weeds in a garden, others grow naturally in France, Spain, Italy, and Germany, and are preferved in botanic gardens for the fake of variety; but as they are plants of little beauty, they are rarely admitted into other gardens, therefore I (hall not trouble the reader with an enumeration of the fpecies, which would fwell this article too much; fo I {hall next treat of the African Crane's-bills, which are preferved in moft of the curious gardens, where there is conveniency to fcreen them from the froft in winter.

The twenty-firft fort grows naturally near the Cape of Good Hope; this rifes with a fhubby ftalk eight or ten feet high, fending out feveral irregular branches, garnifhed with roundilh leaves, whofe fides are ereft, fo form a fort of hood by the hollow cavity made in the leaf. The bafe of the leaves are cut in form of a heart-fhaped leaf, and from the foot-ftalk run many nerves arifing from a point, but diverge toward the fides; the borders of the leaves are Iharply indented, thofe on the lower part of the branches have long foot-ftalks, and are placed without order on every fide, but thofe on the upper part have fhorter foot-ftalks, and ftand oppofite. The flowers are produced in large panicles on the top of the branches; their empalements are of one leaf, deeply cut into five fegments, and clofely covered with foft hairs. The petals are large, entire, and of a purple blue colour. It flowers in June, July, Auguft, and September, and the flowers are*fucceeded by feeds, having ftfort hairy beaks.

The twenty-fecond fort has fome appearance of the twenty-firft, but the leaves are of a thicker fubftance, divided into many acute angles, having purple edges, which are acutely indented. The ftalks and leaves are very hairy. The branches are not fo irregular as thofe of the former, nor are the bunches of flowers near fo large; thefe differences are permanent in the plants which are raied from feeds, fo it is undoubtedly a diftina

a distinct species, though Dr. Linnæus supposes them to be the same.

The twenty-third fort comes from the Cape of Good Hope, but is one of the oldest, and the most common in the English gardens; this rises with a single stem to the height of four or five feet high, and divides into a great number of smaller branches, so as to form a large head, which will reach eight or ten feet high. The branches are furnished with roundish heart-shaped leaves, which are cut into three cilyvs in several oblique segments, which are cut into three or four sharp points, these have a pithy circle, a mark, like ahuife-Duic, through the middle, going from the upper side of the leaf; their leaves when they are fully tubed, have a faint blue tincture. The flowers are produced in small clusters about the end of the branches, and are of a pale blue colour, and are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort. The leaves are larger, and are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort.

The twenty-fourth fort grows naturally at the Cape of Good Hope; this rises to the height of six or ten feet, folding out several branches, which are generally erect, and are furnished with roundish kidney-shaped leaves, which are of a hick substance, and of a lucid green. Hanging on pretty long foot-stalks; they are covered with (bit hairs on their under side, and are placed without any order. The flowers grow in small clusters upon long foot-stalks, which come out from the wings of the fort; they are of a tirigir tartaric colour, to make a fine appearance, and there is a variety of these flowers during the summer months.

The twenty-fifth fort grows naturally at the Cape of Good Hope, but has been many years an inhabitant of the English gardens: this rises with a single stem to the height of four or five feet high, dividing into several weak irregular branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

The twenty-sixth fort is a native of the Cape of Good Hope; it rises to the height of five or eight feet, sending out many pretty (long branches, garnished with leaves (shaped like those of the Vine; those on the lower part of the stem upon long foot-stalks, but the upper have short ones, when the leaves (if this are rubbed, they have a scent of Balsam. The flowers grow in compact clusters on the top of the stem, which come out from the wings of the fort, but rise much higher than the branches, they are small, and of a pale blue colour, but make a great beauty, but there is a succession of them most part of the year.

The twenty-seventh fort rises to the height of five or six feet, with an upright shrubby stalk seven or eight feet high, sending out several branches, garnished with large, angular, rough leaves, hanging upon long foot-stalks. The flowers are produced in small clusters about the end of the branches, these are shaped somewhat like a butterfly, with two upper petals, which are pretty large, and stand upward like a standard in the leguminous flowers, these are finely variegated, but the three under petals are so small, as not to appear at a small distance, they are reflected downward, so are screened from light, unless the flowers are viewed near. This fort flowers in May, at which time the plants make a line of appearance, but they are not succeeded by any

man afterwards, as most of the other sorts are; this grows naturally at the Cape of Good Hope. The twenty-eighth fort is from the same country; this rises with a shrubby stalk six or seven feet high, sending out several branches, garnished with oblong, oval, lellily, smooth, of a gray colour, which are twisted on their edges, and have an acid taste like Sorrel. The flowers stand upon pretty long foot-stalks, which arise from the wings of the stalks, each stalk bearing three or four Boverj, which are narrow and unequal in size; these are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort. The leaves are larger, and are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort.

a distinct species, though Dr. Linnæus supposes them to be the same.

The twenty-ninth fort hath a thick, fleshy, knotted stalk, which rises to the height of two feet high, sending out a few slender lellily branches, garnished with double-winged leaves, which, on the lower part are of the (talk, (and upon foot-stalks, but the upper are of a different nature. The flowers are produced in small clusters at the end of the branches, and are of a pale blue colour, and are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort. The leaves are larger, and are of a pale bluish colour, with fine stripes of a light red, these are common in the summer; there is a variety of this with larger flowers, which is said to have been raised from the seed of this fort.

The thirtieth fort hath a round fleshy stalk with swelling knobby joints, which rise to the height of three feet high, and send out several irregular branches, which are finotid, they are thickly garnished with smooth, Eclhy, winged leaves, ending in obtuse points; they are of a gray colour, and (land upon (short foot-stalks. The flowers are four or five in each foot-stalk, which arise from the wings of the stalk, and are of a dark purple colour. The petals are broader than those of the former fort, and are of a very agreeable scent in the evening, after the sun is down, they are of a long time; these are the former sort, supposed to be one species by Or. Linnæus, but they are very different in particulars, which are permanent in the plants, and are of a very different nature.

The thirty-first fort hath a fleshy stalk, which rises to the height of two or three feet, and sends out several branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

The thirty-second fort hath a fleshy stalk, which rises to the height of two or three feet, and sends out several branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

The thirty-third fort hath a fleshy stalk, which rises to the height of two or three feet, and sends out several branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

The thirty-fourth fort hath a fleshy stalk, which rises to the height of two or three feet, and sends out several branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

The thirty-fifth fort hath a fleshy stalk, which rises to the height of two or three feet, and sends out several branches, which are hairy and wavyed on their edges, they are placed alternate on the branches, and are hairy upon their upper side. The flowers grow in dome-shaped heads on the top of the foot-stalks, forming a sort of corymbos; they are of a pitiful blue colour, and continue in succession great part of the year. The leaves of this fort, when rubbed, give an odour like dried roses, from whence many have given it the name of Rose Geranium.

together upon very long foot-stalks there is a junction of chafe during all the summer months, and the flowers ripen arc singly about a month after the flowers are fallen: there is a variety of this sort which has a dark circle in the middle of the leaves, which is as a distinct species, but I find it is apt to vary in ram feeds.

The thirty-fourth sort for: hadi a very fort fc* stalk, which divides near the ground into several small, each having in any leaves, which arilr on separate foot-stalks from the heads, these are heart-shaped, soft, and very succulent like Anilised, and are very fine.

ri>tn in autumn. This is the fort which has been long cultivated in the gardens, and is known by the title of Geranium noctu olens, or Night-footed Geranium.

The thirty-sixth fort hath a knobbed tuberous root like the lill, from which come out several pretty long leaves, composed of many lobes, its along the ribs in the form of a winged leaf, these are narrow at their base, and are rounded at their ends, which are rounded, and cut all along their side and top into many acute points, the stalks which sustain the flowers arise immediately from the root, and sometimes have one or two small leaves inward

die Li of cn divi. foot, stalks, each being terminated by J btinai rf pal* reddish flowers, which smell sweet and agreeable.

The thirty-seventh fort hath oblong tuberous roots, from which come out several decomposed winged leaves, ending in many acute points, the segments of these leaves are broader than those of the thirty-fifth fort, and the leaves are very hairy. The stalks rise a foot and a half high, which are garnished with a

Hn'l-, »v'a lower ml the fegmennaw jii" the kwtr leaves s it the mo low-r knots or •

Wife two long nal nattedbyabunchcfyellowwilh, he

has left thera. This grow - naturally at the Cape of Good Hope.

The thirty-eighth fort hath a tuberous root like the former, from which spring out many hairy leaves, which are finely divided like those of the Palladia, which are hairy appearance, and rise immediately from the root, spreading on every side near the ground.

Thr ! of stalk of the flower is naked, and rises from the root; this grows about nine inches high, and is terminated by a single bunch of flowers, which are of a very red; purple colour, and last long in the evening.

The thirty-ninth fort hath fleshy tuberous roots like those of the former sorts, from which come out three or four broad leaves, divided into their borders into many lobes, in form of a Vine leaf, their spread flat on the ground; they are hairy, and terminate on their edges, standing upon short foot-stalks. The foot-stalks of the flowers arise immediately from the root,

and grow about a foot high, they are naked, and are terminated by a bunch of dark purple flowers, with long tubes, lining close to the foot-stalks, which have a very agreeable odour in the evening.

The four first sorts of tuberous-rooted Geraniums are by Linnæus supposed to be but one species, but I have propagated them from seeds several times, and have never found either of them vary from their parent plants, so I make no doubt of their being distinct species, for their difference of leaves is as great as in any of the other species.

The fortieth sort is an annual plant, which grows naturally at the Cape of Good Hope; this rises with herbaceous branching stalks near a foot high, which are garnished with doubly-winged leaves at each joint; the lower leaves stand upon long foot-stalks, but those on the upper part sit close to the stalks. The flowers stand upon short foot-stalks, which proceed from the side of the stalks, on the opposite side to the leaves; they grow three or four together upon short separate foot-stalks; these are shaped somewhat like a pophyonaceous flower; the two upper petals, which are large, form a kind of standard, the other three petals are narrow, and reflexed downward; they are of a pale flesh colour, appearing in July, and the seeds ripen in September, soon after which the plants decay.

The forty-first sort hath a prickly thick tuberous root, from which is sent out several irregular stalks, which divide into branches, and grow diffusely; their lower joints, and are somewhat ligamentous; they are garnished with one double winged leaf at each of the joints, and the leaves come out the first-stalks of the flowers; these which are situated on the lower part of the stalks, are very long and naked, but those which terminate the branches are shorter, and have one or two small leaves fix at their base; thick foot-stalks are terminated by a small bunch of flowers, shaped like those of the former sort, but larger, and of a paler colour; these continue in blossom until the part of the summer; this and the former sort are supposed to be one species, but the former is an annual plant, and the latter is a perennial.

ro br, rheflint¹ by Dr. I onnirr jiinual pL, in every country, perishing soon after the leaves are perished, and I die latt-i is an abridg plain with liguir • in stalks.

The forty-second sort is a biennial plant, which naturally at the Cape of Good Hope; this sends out a grm nutntier a I very slender trailing stalks, which are prostraw on the ground, and extend a foot and a half in length, garnished with small, roundish, heart-shaped leaves, which are creased on their edges.

The flowers sit upon short slender foot-stalks, which come out at every joint from the side of the stalks; they are very small, and of a reddish colour; sometimes they are single, and at other times there are two or three flowers upon a foot-stalk. They continue in succession all the summer, in J the feeds i upon in about five weeks after the flowers decay.

The forty-third fort hath a double stalk, which rises to the height of four or five feet, sending out several branches, which are garnished with oblong leaves, indented, and unequally lacerated on their edges; the flowers stand upon long foot-stalks, which come out from the side of their branches; these are large, of a red colour, and the two upper petals are larger than the others; this sort flowers in June and July.

The forty-fourth sort grows naturally in the Isle of Cio in the Levant. This is an annual plant, which sends out several branches a foot long; the lower leaves are almost heart-shaped, but those on the branches are hearted in the shape of an ancient lyre. These are placed alternate on the branches; the first-stalks of flowers are produced on the side of the branches; these are six inches long, sustaining many bright purple flowers at the top, which are succeeded each by five seeds, having long slender beaks; these ripen in five or six weeks after the flowers fall away, and if they are permitted to scatter, the young plants will come up in the autumn; and if the winter is favourable, they will live in the open air, so will flower early the following

following spring; but if these should be killed in the Winter, some seeds should be sown in the spring, on a Si border of light ground, and when the plants come up they should be thinned, and kept clear from weeds; these will flower in July, and their seeds will ripen in August.

The forty-fifth fort grows naturally in Portugal and Spain; this is an annual plant, whose lower leaves are heart-shaped, and divided into three lobes; the footstalks of the flowers are placed on the side of the branches, which extend a foot and a half each way; these incline to the ground. The footstalks sustain many bright red flowers, which are succeeded each by five seeds, having pretty long beaks. This flowers and seeds about the same time as the former fort, and requires the same culture.

The forty-sixth fort grows naturally in Egypt. This is an annual plant, having oval fawed leaves of a gray colour; the branches extend a foot in length, adorned with small leaves placed alternate, and toward the end have three or four footstalks produced from their sides, sustaining several pale blue flowers, which are each succeeded by five seeds, having long feathery beaks.

This fort is much tenderer than the two former, therefore if the seeds are sown on a moderate hot-bed in the spring, and when the weather becomes warm, the plants are carefully transplanted on a sheltered border, there will be greater certainty of their perfecting seeds.

The forty-seventh fort grows naturally in Carolina, and is an annual plant, greatly resembling our common Dove's-foot Crane's-bill, but is smaller, and the branches are shorter, the flowers are very small, of a pale blue colour, these are succeeded by five seeds, having short tredd beaks, which are black. If the seeds of this fort are permitted to scatter, the plants will arise without farther care, and if thinned and kept clear from weeds, will produce flowers and seeds.

The forty-eighth fort has some resemblance of the forty-fifth, but the leaves are more of an oval heart-shape; the flowers are also of a bright red colour, this grows naturally at the Cape of Good Hope; the plant is tender, therefore will require the same treatment as the forty-seventh fort, with which they will produce flowers and seeds, after which the plants decay.

All the forts of African Crane's-bill may be propagated by seeds; these may be sown upon a bed of light earth toward the end of March, where the plants will appear in a month or five weeks after, and by the beginning of June the plants will be fit to remove; when they should be carefully taken up, and each planted into a separate pot, filled with light kitchen-garden earth, and placed in a shady situation till the plants have taken new root; then they may be removed into a sheltered situation, and placed among other of the hardier green-house plants, where they may remain till autumn, when they must be removed into the green-house, and treated in the same manner as other hardy kinds of green-house plants.

But those who are desirous to have their plants large, and flower soon, sow the seeds upon a moderate hot-bed in the spring, on which the plants will come up much sooner, and will be fit to remove long before those which are sown in the open air; but when these plants come up, there must be great care taken not to draw them up weak; and when these are transplanted, the pots should be plunged into another moderate hot-bed, observing to shade them from the sun till they have taken new root; then they must be gradually inured to bear the open air, into which they should be removed the beginning of June, and placed in a sheltered situation with other exotic plants. If these plants are brought forward in the spring, most of the forts will flower the same summer, and the plants will be very strong before the winter, so will make a better appearance in the green-house.

The shrubby African Geraniums, from the twenty-first to the thirty-second inclusive, and also the for-

ty-first and forty-third forts, are commonly propagated by cuttings, which, if planted in a shady border in June or July, will take good root in five or six weeks, and may then be taken up and planted into separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated in the same manner as the seedling plants. The twenty-ninth, thirtieth, thirty-first, and thirty-second forts, have more succulent stalks than either of the other, so the cuttings of these forts should be planted into pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun in the heat of the day, and should have but little water; for these are very apt to rot with much moisture, so they must only be gently refreshed now and then with water. When these are well rooted, they may be separated and planted in pots filled with the same sort of earth, and placed in the shade till they have taken new root, then they may be removed into a sheltered situation, where they may remain till autumn. These four forts should be sparingly watered at all times, but especially in the winter, for they are apt to take a mouldiness with moisture, or in a damp air: they will thrive much better in an airy glass-case than in a green-house, because in the former they will have more sun and air than in the latter, so will not be so liable to have a mouldiness or rot. But all the other shrubby forts are proper furniture for the green-house, where they will only require protection from frost, but should have a large share of free air when the weather is mild; they will require water every week, in mild weather once or twice, but it should not be given them in too great plenty, especially in frosty weather. These plants should be hardened in the spring gradually, and toward the middle or latter end of May, they may be taken out of the green-house, and at first placed under the shelter of trees, where they may remain a fortnight or three weeks to harden; then should be removed into a situation where they may be defended from strong winds, and enjoy the morning sun till eleven o'clock, where they will thrive better than in a warmer situation.

As these shrubby forts grow pretty fast, so they soon fill the pots with their roots; and if they stand long unremoved in summer, they frequently put out their roots through the holes at the bottom of the pots into the ground, and then the plants will grow vigorously but when they are suffered to grow long in this manner, it will be difficult to remove them, for if their roots are torn off, all the younger branches will decay, and many times the plants are killed. Therefore the pots should be moved once in a fortnight or three weeks, in the summer months, and the roots which may be then pushing through the holes in the pots cut off, to prevent their linking into the ground. These plants will also require to be new potted at least twice in the summer; the first time should be after they have been three weeks or a month out of the green-house; the second should be towards the end of August, or the beginning of September, that the plants may have time to establish their new roots before they are removed into the green-house.

When these are new potted, all the roots on the outside of the balls of earth should be carefully pared off, and as much of the old earth drawn away from the roots, as can be done with safety to the plants. Then if they require it, they should be put into pots a size larger than those out of which they were taken, putting a quantity of fresh earth into the bottom of the pot; then place the plants upon that, being careful the ball about the roots of the plant is not so high as the rim of the pot, that some room may be left to contain the water which may be given to the plants. Then the cavity all round the ball should be filled up with fresh earth, which should be gently pressed down, and the bottom of the pot beaten upon the ground, to settle down the earth; then the plant should be well watered, and the stem fastened to a rail, to prevent the

the wind from displacing of the root before they are fixed in the new earth.

The compost in which I have always found these plants thrive best (where there has not been a convenience of getting some good kitchen-garden earth) was fresh hazel loam from a pasture, mixed with a fourth or fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is preferable to dung; but if it is light and warm, then a mixture of neat dung is best: this compost should be mixed three or four months before it is used, and should be turned over three or four times, that the parts may be well mixed and incorporated; but where a quantity of good kitchen-garden earth can be had, which has been well worked, and is clean from the roots of bad weeds, there will need no composition, for in that they will thrive full as well as in any mixture which can be made for them, especially if the earth has lain in a heap for some time, and has been two or three times turned over to break the clods, and make it fine: these plants should not be planted in very rich earth, for that will cause them to grow very luxuriant, but they will not flower so well as in a poorer soil.

The thirty-third sort hath herbaceous stalks, so is best propagated by feeds, which the plants produce in great plenty; but the cuttings of this will take root as freely as either of the other, but the seedling plants are preferable to those propagated by cuttings, and where the feeds of this and many other of the African sorts are permitted to scatter, there will be a supply of young plants come up the spring following, provided the feeds are not buried too deep in the ground. The thirty-fourth sort may be propagated by feeds, or from heads flipped off from the short fleshy stalk; these heads should have their lower leaves stripped off, that the stalk which is to be planted may be clear of leaves; then they may be planted single into a small pot, or if the heads are small, there may be two or three put into one small pot; then they may be plunged into a very moderate hot-bed, which will forward their putting out roots, and if they are shaded from the sun and gently refreshed with water, they will take root in a month or five weeks, when they must be hardened gradually, and removed into the open air, where they may remain till autumn, when they must be removed into shelter for the winter season.

The thirty-fifth, thirty-sixth, thirty-seventh, thirty-eighth and thirty-ninth sorts are generally propagated by parting of their roots; the best time for doing this is in August, that the young roots may be established before the cold comes on. Every tuber of these roots will grow, provided they have a bud or eye to them; they may be planted in the same sort of earth as was before directed, and if the pots are plunged into an old tan-bed, under a good frame in winter, the plants will thrive better than in a green-house; the glasses of the frame may be drawn off every day in mild weather, whereby the plants will enjoy the free air; and if in hard frost the glasses are well covered to prevent the cold penetrating to the plants, it is all the shelter they will require; but in this situation they should have but little wet in winter, therefore the glasses should be kept over them in heavy rains to keep them dry; but in mild weather the glasses may be raised on the upper side to admit the fresh air to the plants, which will give them greater scope to carry off the wet. With this management the roots will thrive and flower very strong every year. * These sorts may also be propagated by

feeds.

The fortieth sort is an annual plant, and is only propagated by feeds, which should be sown upon a gentle hot-bed in the spring, to bring the plants forward; otherwise if the season should not prove very warm, the plants will not perfect their feeds in this situation. When the plants are come up, and grown strong enough to remove, they should be each planted into a separate small pot, and plunged into a moderate hot-bed again, observing to shade them till they have

taken new root; then they must be gradually hardened to bear the open air, into which they should be removed in June; and when the plants have filled the small pots with their roots, they should be shaken out, and the ball of earth preserved to their roots, and put into pots a size larger, in which they will flower and ripen feeds, and soon after the plants will decay.

The forty-second sort is also propagated by feeds, which may be either sown upon a moderate hot-bed in the spring, or upon a bed of light earth in the open air, where the plants will come up very well, though they will not be so forward as those on the hot-bed. Those which are sown in the open air will require no other care but to keep them clean from weeds, and thin the plants where they are too close. These plants will flower in July and August, and if the autumn proves favourable, the feeds will ripen in September; but if these should fail, those which were raised on the hot-bed will come earlier to flower, so there will be no danger of their perfecting feeds, and these plants, if they are in pots, may be preserved through the winter, if they are plunged into an old tan-bed under a frame, and treated in the same manner as the tuberous-rooted sorts before mentioned.

The shrubby sorts must be looked over frequently during the winter, while they are in the green-house, to pick off all decayed leaves from them, which, if left on, will not only render the plants unflourishing, but by their falling off, they will occasion litter among the other plants; and if they are suffered to rot in the house, they will occasion a foul, nasty, damp air, which will be very prejudicial to all the plants; therefore to avoid this, they should be constantly picked off every week; and during the summer season, they will require to be picked every fortnight or three weeks to keep them clean from dead leaves, for as the branches advance, and new leaves are produced on their top, the under ones are constantly decayed; and if left on till they drop off, will render the plants very unflourishing.

GERMANDER. See TEUCRIUM,

GEROPOGON Goat's-beard.

The CHARACTERS are,

The empalement is single composed of notched keel-shaped leaves which are longer than the corolla; the flower is composed of several hermaphrodite florets, which are imbricated and shorter than the empalement, and are of one petal, divided into five segments at the top. They have each five short stamens, terminated by cylindrical summits, and an oblong germen with a slender style, supporting two thread-like stigmas which are recurved; the feeds are included in the empalement, and are crowned by five bearded spreading rays.

This genus of plants is ranged in the first edition of Linnaeus's nineteenth class, entitled Syngenesia Polygamia Inequalis, the florets having five connected stamens, and are fruitful.

The SPECIES are,

1. GEROPOGON (*Glabrum*) foliis glabris. Lin. Sp. 1109. Goat's-beard with smooth leaves. *Tragopogon gramineo folio glabrum, flore dilute incarnato.* Kaim Sup. 149.

2. GEROPOGON (*Hirsutum*) foliis pilosis. Lin. Sp. 1109. Goat's-beard with hairy leaves. *Tragopogon gramineo folio, fuaue rubente flore.* Col. Euphr. 1. p. 233.

The first sort grows naturally in Italy; this hath an erect stalk more than a foot high, garnished with smooth, grass-like, long leaves; the stalk branches upward into two or three divisions, each being terminated by one flesh-coloured flower, composed of several florets.

The second sort grows naturally in Italy and Sicily. This rises with an erect stalk a foot high, garnished with hairy narrow leaves, and seldom divides into branches, but is terminated by one flower composed of four or five hermaphrodite florets, which are succeeded by so many bearded feeds.

These plants require the same treatment as the TRAGOPOGON, to which article the reader is directed to turn for their culture.

3ESNER. Flumier Nov. Gen. 27. tab. 9. Lili. Son. Plant. 167. The pls< v. is JO named by 1 flumi-er, who discovered it in America, in honour of Conrad Gesner, :: very learned boianift, and natural tulturian.

The CHARACTERS are, Tbt i. palement of the flower is of one leaf, and into five SUU.; petals at the top, and is permanent, in which is fl- luattii the venes of the flower both are petal which is to be seen, and soft hair inward, and afterward are equal like a high-bird, the stem is divided into five equal joints which are equal; it hath four flowers which are flower than the petal, terminated by single stamens; the venes which fill under the petal supports a single crooked style, crowned by a beaded stigma. The germen afterward becomes a roundish capsule with five cells, filled with small seeds, which are found on each side the partition.

This genus of plants is ranged in the second section of Li: naxos's nineteenth class, entitled Didynama Angioiperma, which includes those plants whose flowers havt- <• long and two shorter stamens, and • lie fre^li are in< loaded in a capsule.

The SPECIES are,

1. GRASSIA (Yucca) folis tereto-lan- colius ciana- tis hirsuta, pedunculo lateralibus longioribus curvato- bite; Hort. Cliff. 318. Gesner with small hairy, (taw: h havi, and long fan-like spreading from the side of the stalk, supporting flowers in a corymbus. Gesner's ample distans folio truncato. Plum. Gen. 27.

2. GESNERIA (Hemelia) folis laccolatis serratis scilicet- bus ! educeulis nervosis multilobis. Lin. Sp. Plant. 612. Gesneria with four-flor'd lateral leaves having teeth to the stalk, and branching fan-like having many flowers. Gesneria humilis flore hirsutis. Plum. Nov. Gen. 27. Low Gesneria with a yellowish flower.

The first sort grows naturally in We(t-Intl: the seeds of this were sent me from Jamaica, which succeeded in the Chelsea garden; this is rifo wi rli aflimuby ro the height of fm or seven feet, which (£ into two or three irregular branches, covered with a lulii't wool, and garnished with hairy leaves which are from six eight inches long, and two and a half >ii) in the middle • iiviing a ruti- r woolly mulch, and [In edges are crowded, these are placed on every side the branches without order, and have their foot- stalks ; towards the end of the branches come out the foot-stalks of the flowers at every joint, arising from the wings of the stalk. they are fiakt, and nine inches in length, branching at the top into many I. smaller foot-IWks, <ch fuftjiniig a single fiowtr, ii^ving a ihort crooked tubt', intleniw! at the top in five .-bit-id' j.ij. im, and of an chiulete purple colour. These are cutwcd by raii: into clove in the empale in ent, tic divisions of which arise above the fBpfl: which Dr. Linnæus, from Plüster's figure, has taken for the empalement lying upon the capsule, whereas the capsule is distinct from the empalement u>d is indofet Ly it. The capiuu is divided into two cells which are fillet) with small seeds. It Bowers hrte in : ay and A Jijust, but hath not ripened [

The frond fur i^ a pl=lit of humbler gK*wtl; this feldo:: ties more than three Ged high •, die leaves are much fmalli , are from, oil their ei ges, and fit clear tu tic flak . the flowers stand upon branching foot- each fullaming many yellowish flowers, which mr deeper out at their brims than those of the first fort. This was found growing naturally by the late Ilr. H. Hudson at Carthagena in New Spain.

There is a third species of this genus mentioned by Flumier, which grows to be a tree, and hath spiced and fringed flowers; but that I have not seen in any of the Rio della gardens. These plants are propagated by seeds, which must be procured from the countries where they grow naturally; these should be brought over in their capsules, which is the best way to preserve the seeds good; for as they are very small and light, so when they are separated from the partition to which they adhere, they lose all their vegetative quality; for I have received the seeds fr-

vraI tinwi from America, which were rskep - os of 11 ic vtfTeSj, but not ont (it th-m grcv i- ul f- p- ti:red ibrc to be font in their vefiek, wlicli focc eded very well.

The ietds flwukl be fown in pots filled with light earth, and • plunged into a hot-bed) of tannen birk. as soon as • lit-y arrive, for they fometimj lie long in the ground; those which I have fown in autumn, ihc follomng fpring-, therefore when chev- happen • • rive here at thai season, the pots in which the seeds are llijvn (hould be plunged into the lan-berd in the flow-, and during the w-mtr the earth shoud be now a/d then gently watered to present its drying two much, but it niuft not be too muill. In the fpring the pors shoud be removed out of the Itove, and plunged • If a frofb hot-bed, wMch will bring up tic movr, they should be • h planted into a feparate pot, tnd ptm^ed into a good hw-bed of tan, obll-rvinj DO shade them till they have taken new root, then they • inR be treated in the same way as 1-her tender • jljnis from the :ame countries.

In autumn they must be plunged into the tan-bed in the flow-, where, during the winter, they should have but little watof given to them; tor if they receive much wet, it will deftroy them. In thii stage the plants must constantly remain, for they will not thrive if they are kept out of the tan. In the summer, they should have free ilir admitted to tfrim ar all times when the weatier is warm ; and they must be frequently re/fridied with waier during : ; it seasons, but it must not be given to (hem in tou > vi plenty. As the plants advance in growth they will require Larger pan, but [here mult be care taken not to tiver : for tley will not thrive in lar • jx>:s. With thii managedirnt tht plants will flower the freoid uar, antiiriii be continued three or four years, but they are not of long duration it their tu- fire country.

GEUM. LID. Gen. Plane 501. Caryophyllafa. Tourn. Inf. R. H. ;ri^ jib. 151. Avcns, or Herb Bennet-, in French, her:ete.

The firft fort grows naturally in arable land ui mott of the warm countries in Europe, ami wat fonnrcly cultivated in the Englifh Kartknj, where the root have multiplied fo greatly as to become a molt troublefome weed, jmd are very difficult to eradicate; ihis bath a round, compressed of a yelltwil'i cwouT, covered with a brow; • furrowed (tin, like thole of the large >clow vernal cus ; fru>> the root arife two flat (word- lthiprd ! hawks, which embrace each other a: their bife, and bi tiefc anfc . . . flawet-ll-^1 which . . . near the feet I.,p], liliving 01 v: ui two narrow leaves CO . . . leading it like a (heath i the Halts arc terminated by five or fx purple flowers, Hanging above cith other at lonie 'lilbnce, and ranged on one fide- ui the IUII; . . . each of tiefc has a fpatha [or (heath) which . . . GAVES the flower-bud before it expands, but fpto upen length- wiys when the flower blow, and llinvel up w a dry (kin, remaining about the feed- vdTel til the leads are ripfc The flower lwh one petal, which . . . in cut nlmolt: to the bottotn in fix parts, fa ns to aj>P, . . . like * flower of fix pelals, the thir' • UPP< Kgnwna Hand near tosetiirr, and rife like a bhattd flower; the under ont turns <low>ward, and the two lide legmcots form die ch<w of the Bower, and fprea . . . open at ch; top, b E but

but are curved downward at the bottom. They are ranged along one side of the stalk, and like of a purple red colour. This Bowers the latter end of May, and in June, and the feeds ripen the beginning of August > it requires no cart, for when it is once planted in a garden, it will multiply too fast, so as to become 3 trouble dome weed.

There is a variety of this with white flowers, and another with fleck-coloured flowers, which have accidentally risen from feeds, so we not different species.

The second fort differs from the first, in having the flowers ranged on both sides the stalk, but in other respects it is very like to that; and of this there is a variety with white (Was. but the; are not so common in the English garden: as the former.

The third fort hath longer roots than either of the former, but arc of the same form; the leaves are also much broader and longer, the veins or channels of the leaves are deeper, the Bower-fallu rii. light; the flowers are much larger, and of a deeper red colour than those of the former fort*, and the (heaths are longer. This plant makes a fine appearance in flower, so is worthy of a place in every garden; and the rather, because the roots do not increase so fast as to become troublesome. This is propagated by offsets, which are lent off from the roots in the same manner as Tulips. The roots may be taken out of the ground at the end of July, when they begin to decay, and may be kept out of the ground till the latter end of September, or the beginning of October; at which time they should be planted in the borders of the (lower-garden, where they will thrive in any situation, and being intermixed with other flowers of the same growth, they will add to the variety.

The fourth fort grows naturally at the Cape of Good Hope, from whence I have several times received the seeds. This has been many years cultivated in the English gardens, but very rarely in our gardens; for in near thirty years since I have cultivated this fort, I have never seen it but once in flower, though I have kept it in all situations, and planted it in various soils. The roots increase very fast, but will not live in the open air through the winter in this Country. The roots of this fort are broader and flatter than those of any of the other forts, and are covered with a netted skin; the leaves come out in the same manner, embracing each other like the former forts; they are longer, smoother, and of a brighter green, than any of the others; they begin to appear in September, and continue growing in five weeks after Christmas; they begin to decay in March, and the latter end of June are quite withered, when the roots may be taken up, and kept out of the ground till August; the time of planting is in January. The flowers of this fort are placed on the stalk, and fit close to it; like the flowers of the flat Barley; the heaths between the roots are not so long as those of the other forts,

and form a kind of fealy covering to them. The flowers are of a pile red colour without, but the three lower segments are yellow within toward their base. The flowers do not all open at the same time, but the lower ones decay before those above; the part of the spike are in beauty; they make a good appearance at a season when all flowers are withered.

This fort propagates by offsets-very fast, therefore should be planted in a warm border of kitchen-garden, and in winter they should be covered with glass or mats to preserve them from frost; for I have preserved those which were planted in pots under a common frame, and some which were planted in the full sun, which were not so well preserved; and I have always found that those plants which were kindly treated, grew much faster than those which were not.

placed in moderate degrees of cold in winter, if they are covered with glass in the winter, if

these roots are planted in the full ground, where they may be protected from die frail, the probability of their flowering, than the method of culture.

The fifth fort grows naturally at the Cape of Good Hope, from whence I received the seeds, which were first introduced in the Chelita garden, where the plants annually produce their beautiful flowers.

It hath a round, bulbous root, which is covered with a thin dark-coloured skin, from which come out in autumn two or three narrow grassy leaves, folded over each other in a fan-like manner; the root above, and rises near two feet high. In the spring of the year arises a single flower

about two feet long, which is a single flower; it is toward the upper part of this come out two or three flowers, ranged on one side of the stem, (landing upright, each having a narrow spatula, or hood, and long slender tubes, which issue upward, and are divided into six parts, which are nearly equal. The Sower is at the beginning of the year, each segment of the root has a rhomboidal mark of a dark red, or purple colour; afterward the tube of the flower opens, and the three divisions of the petals is seen, and the three stamens with their filaments appear, attended by the style with its trilobed stigma, arising from the germin. This plant flowers in May and the beginning of June; as it is a native of a warm country, it requires protection from the frost in winter; therefore should be placed in pots filled with light earth, and placed in the green-house in winter; or, where there is a convenient

place, they may be put under a hothouse, where they will thrive very well.

This is propagated by offsets from the roots, which are frequently perfected in the latter end of August, and placed in a shady frame till the middle of September; then the pots should be removed, and they may have the sun for part of the day, and in October they may be placed in a hot-bed frame, where they may be protected from the frost; but they enjoy the free air in mild weather. In the spring the young plants will appear, when they should be given them sparingly, for too much wet will rot the tender bulbs. In May, when the danger of frost is over, the pots should be removed to the open situation, where they may be watered till noon; and, if the season proves dry, they must be watered with waier. Toward the latter end of June, the leaves of these plants will decay; then the roots should be taken up, and kept in a dry room till the end of August, when they should be planted again; and is this time should be planted in each half-penny pot, filled with light earth.

placed where they may have only the sun till the middle of September, when they should have a warmer situation; and in October they may be placed under a hot-bed frame as before, and a hot-bed in the same way during the winter; and in the spring they may be placed in the open air till their young plants appear, when they may be taken out at the ground, and treated as before; but the roots will have grown to a larger size, so when they are taken up again, they should each have a separate half-penny pot, because when they will be large enough to flower, they should be treated as before.

The fifth fort is native of the Cape of Good Hope, from whence I have several times received the seeds of this fort is oval, not compressed at the ends, and narrow, having two deep furrows running the whole length, the

to have the appearance-of a four-cornered loaf. The leaves are simple, and wrapped dnie about theflow- ilalk at that bate to awnfidctahie length ; ±

 into nurfery-beds, at a fow diltanc- t'ow fhan row,
 and

and

and

and

and

and

and

and fix inches afunder in the rows; but this fhould not be performed till April, after the danger of hard froft is over; for as the plants do not put out their leaves till very late, fo there will be no hazard in removing them any time before May. If the feafon fhould prove dry, they mull be watered; and if the furface of the beds is covered with mofs, or mulch, to prevent the earth from drying, it will be of great fervice to the plants. In thefe beds the plants may remain two years, during which time they muft be confantly kept clean from weeds; and in the winter there fhould be fome rotten tan, or other mulch, fpread over the furface of the ground to keep out the froft. If the plants thrive well, they will be fit to tranfplant to the places where they are to remain after two years growth, for they do not bear removing when large. The beft feafon for tranfplanting of thefe trees, is late in the fpring; they thrive beft in a light deep foil, for in ftrong fhallow ground they become moffy, and never grow large; they fhould alfo have a fheltered fituation, for when they are much expofed to winds, their branches are frequently broken in the fummer feafon, when they are fully clothed with leaves.

GLOBULARIA. Lin. Gen. Plant. 106. Tourn. Inf. R. H. 466. tab. 265. *Blue Daify.*

The CHARACTERS are,

It hath a flower compofed of many floret s, which are included in one common fcaly empalement \ each floret has an empalement of one leaf which is tubulous, and cut into five figments at the top. The florets have one petal, wbofe bafi is tubulous, but the brim is cut into four parts; the upper figment, which is the leaf, is reflexed; they have four ftamina the length of the petal, terminated by diftintt funmits; in the bottom of the tube is fituated an oval germen fupporting a fingle fyle, crowned by an obtufifigma. The germen afterward becomes an oval feed, fitting in the common empalement.

This genus of plants is ranged in the firft fedtion of Linnaeus's fourth clafs, intitled Tetandria Monogynia, which includes thofe plants wjiole flowers have four ftamina and one fyle.

The SPECIES are,

1. **GLOBULARIA** (*Vulgaris*) caule herbaceo, foliis radicalibus tridentatis, caulinis lanceolatis. Flor. Suec. 109. *Globularia* with an herbaceous ftalk, the lower leaves divided into three points, and thofe on the ftalks fpear-fhaped. *Globularia vulgaris.* Tourn. 467. *Common Globularia.*
2. **GLOBULARIA** (*Nudicaulis*) caule nudo, foliis integerrimis lanceolatis, Lin. Sp. Plant. 97. *Globularia* with a naked ftalk, and fpear-fhaped entire leaves. *Globularia Pyrenaica,* folio oblongo, caule nudo. Tourn. 467. *Pyrenean Globularia,* with an oblong leaf and naked ftalk.
3. **GLOBULARIA** (*dlypum*) caule fruticofo, foliis lanceolatis tridentatis integrifque. Prod. Leyd. 190. *Globularia* with ajhrubbyftalk, fpear-fhaped leaves, fome ending in three points, and others are entire. *Globularia fruticofo,* myrti folio tridentato. Tourn. 467. *Shrubby Globularia* with a trifid Myrtle leaf
4. **GLOBULARIA** (*Spinofa*) foliis radicalibus crenato-aculeatis, caulinis integerrimis mucronatis. Lin. Sp. Plant. 96. *Globularia* with lower leaves crenated and prickly, thofe on the ftalks entire, ending in a point. *Globularia fpinofa.* Tourn. 467. *Prickly Globularia.*
5. **GLOBULARIA** (*Cordifolid*) caule fubnudo, folis cuneiformibus tricupfidatis, intermedio minimo. Lin. Sp. Plant. 96. *Globularia* with a naked ftalk, and wedge-fhaped leaves ending in three points, wbofe middle figment is the leaf. *Globularia Alpina minima,* origani folio. Tourn. 467. *Smalleft Alpine Globularia* with a wild Marjoram leaf.
6. **GLOBULARIA** (*Orientalis*) caule fubnudo, capitulis alternis feffilibus, foliis lanceolato-ovatis integris. Lin. Sp. Plant. 97. *Globularia* with a naked ftalk, alternate beads fitting clofi to the ftalks, and oval, fpear-fhaped, entire leaves. *Globularia Orientalis,* floribus per caulem fparfis. Tourn. Cor. 35. *Eaftern Globularia* with flowers flattered along the ftalks.

The firft of thefe plants grows plentifully about Montpellier, as alfo at the foot of the mountains Jura and Saleva, and in many other parts of Italy, and in Germany; this plant hath leaves very like thofe of the Daify, but are thicker and fmoother. The flower-ftalks rife about fix inches high, fupporting a globular head of flowers, compofed of feveral florets, which are included in one common fcaly empalement \ they are of a fine blue colour, and appear in June; thefe are fucceeded by feeds, which fit in the empalement, and ripen in autumn.

The fecond fort grows plentifully in the woods, near the convent of the Carthufians, and on the Pyrenean mountains; this is much larger than the former, and hath a fhubby ftalk a foot and a half high; the foot-ftalk is quite naked. The leaves are narrower, and much longer.

The firft fort may be propagated by parting of the roots after the manner of Daifies. The beft feafon for parting and tranfplanting of the plants is in September, that they may take new root before the frofty weather comes on. They fhould be planted in a fhady fituation, and require a moift loamy foil, in which they will thrive much better than in a light ground and an open fituation; but the plants fhould not be removed oftener than every other year, if they are required to flower ftrong.

The third fort grows about Montpellier in France, and in Valentia, and feveral other parts of Spain. This has a hard woody item, which rifes about two feet high, having many woody branches, befet with leaves like thofe of the Myrtle-tree. On the top of the branches the flowers are produced, which are of a blue colour, and globe-fhaped; this plant may be propagated by cuttings, which fhould be cut off in April, juft before they begin to make new fhoots; the cuttings fhould be planted into pots filled with light frefh earth, and then placed into a very moderate hot-bed, obferving to water and fhade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In fummer thefe plants may be expofed with other hardy exotic plants, and in winter they fhould be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but fhould be freed from hard froft, which will deftroy them, if they are expofed thereto, but in mild winters they will live in the open air. This plant never produces good feeds in this country.

The fourth fort was found in the mountains of Granada, by Dr. Albinus; this plant is of low growth, and may be propagated as the firft -, as may alfo the fifth fort, which is the leaf of all the forts, and the moft hardy -, therefore fhould have a fhady fituation, and a cool moift foil.

The fixth fort was found by Dr. Tournefort in the Levant; this is fomewhat tender, and fhould be fheltered from the froft in winter, under a frame, but in fummer it fhould be expofed with other hardy exotic plants, and will require to be frequently watered in dry weather. This may be propagated by feeds, or by parting of their roots, as was direcded for the firft fort.

GLORIOSA. Lin. Gen. Plant. 374. Methonica. Tourn. Acad. R. Scien. 1706. *The Superb Lily.*

The CHARACTERS are,

The flower hath no empalement; ^t bath fix long fpear-fhaped petals, which are waved, and reflexed to the foot-ftalk. It bath fix ftamina, which fpread open each way and are terminated by pioftrate funmits. In the center is fituated a globular germ & ^fupporting a flender inclining fyle, crowned by an obtufi irijxe jigma. The germen afterward becomes an oval thin capfite having three cellsj filled with globular feeds, difpofid in a double range**

This genus of plants is ranged in the firft fedtion of Linnaeus's fixth clafs, intitled Hexandria Monogynia which includes the plants w/hofe flowers have fix ftamina and one fyle.

1. **GLORIOSA** (*Superba*) foliis longioribus capreolis terminalibus. *Superb Uly* with longer leaves ending vntb clafpers.

The first fort grows naturally in Virginia, this hath roots composed of several knobs, or tubers, which hang to each other by small fixings; from these come out in the spring (tender twining stalks, which rise to the height of eight or ten feet, garnished with winged leaves, composed of three pair of oval spear-tipped lobes, terminated by an odd one. The flowers come out in short spikes from the side of the stalks, they are of a Pea-blossom kind, of a dirty flesh-colour, having little scent. These appear in August, but do not produce seeds in England. The stalks decay in autumn, but the roots continue, this is propagated by parting of the roots, each of the tubers being separated from the principal root, will grow; the best time for this is about the end of March, or the beginning of April, before they put out shoots. The roots should be planted in a warm situation, and in hard frost covered with tan or mulch to protect them, otherwise they will not live abroad in this country: where they have been planted against a fourth wall, they have thriven and flowered extremely well, which they seldom do in any other situation, and those roots which are planted in pots rarely flower, nor do their stalks rise near so high as those which are planted in the full ground, some ignorant persons call this the Twickenham Climber.

The second fort was brought from Carolina, but has been since observed in Virginia, and some other places in North America; this has woody stalks, which twist themselves together, and also twine round any trees that grow near, and will rise to the height of fifteen feet, or more. The leaves are winged, and in shape somewhat like the Ash-tree, but have a greater number of pinnae. The flowers are produced in clusters from the wings of the leaves, which are of a purple colour; these are succeeded by long cylindrical pods, shaped like those of the scarlet Kidney-bean, containing several kidney-shaped seeds, but these are never perfected in England.

This climbing shrub is propagated in several nurseries near London, where it is known by the name of Carolina Kidney-bean-tree. It is increased by laying down the young branches in October, which will be rooted well by that time twelvemonth (especially if they are duly watered in dry weather) and may then be transplanted, either in a nursery for a year to get strength, or to the place where they are to remain for good, which should be in a warm light soil and a sheltered situation, where they will endure the cold of our ordinary winters very well; and if their roots are covered with straw, Fern, Peas-haulm, or any other light covering, there will be no danger of their being destroyed by the frost.

The third fort grows naturally in both Indies, and also in Egypt. This is a perennial plant, with tender twining stalks, which twist about any neighbouring support, and rise to the height of eight or ten feet, garnished with winged leaves, composed of sixteen pair of small, oblong, blunt lobes, set close together; these have the taste of Liquorice, from whence the inhabitants of the West-Indies have given it the name of Wild Liquorice, and use the herb for the same purpose as the Liquorice in Europe. The flowers are produced from the side of the stalks in short spikes or bunches; they are of a pale purple colour, and shaped like those of the Kidney-bean, these are succeeded by short pods, each containing three or four hard round seeds of a scarlet colour, with a black spot or eye on that side which is fattened to the pod. The seeds of this plant are frequently sown, and are worn as ornaments by the natives of those countries, where the plants grow naturally: they are frequently brought to England from the West-Indies, and are wrought into various forms, with shells and other hard seeds.

This plant is propagated by seeds, which must be sown upon a good hot-bed in the spring; but as the seeds are very hard, so unless they are soaked in water twelve or fourteen hours before they are sown, they frequently lie in the ground a whole year before they

vegetate; but when soaked, the plants will appear in a fortnight after the seeds are sown, if they are good, and the bed in a proper temperature of heat. When the plants are two inches high, they should be each transplanted into a separate pot, filled with light earth, and plunged into a hot-bed of tanners bark, where they should be shaded from the sun till they have taken new root, after which they must be treated in the same manner as other tender plants from the same countries, always keeping them in the bark-fove, for they are too tender to thrive in any other situation in England. This fort will flower the second year from seeds, and sometimes ripens seeds here.

There are two other varieties of this plant, one with a white, and the other a yellow seed, but the plants do not differ from the other in leaf or stalk; but as these have not as yet flowered in England, I do not know how their flowers may differ.

The fourth fort hath a perennial root and an annual stalk, which decays in the autumn. This rises from two to three feet high, with tender herbaceous stalks, which are garnished with trifoliate hairy leaves, fitting close to the stalks, the small leaves or lobes, are of the oval spear-shape, ending in acute points. The flowers come out from the side of the stalks, at the foot-stalk of the leaves, the naked part of the foot-stalk is about two inches long, and the spike of flowers is about the same length, and is recurved, the flowers are of a Pea-blossom kind, fitting close together. They are small, and of a fine blue colour, coming out the beginning of June, and are sometimes succeeded by seeds in England, which ripen in August.

This fort grows naturally in North America, and is hardy enough to live in the open air in England. It may be propagated by seeds, or parting of the roots, the former is the best method, where good seeds can be obtained: these may be sown on a bed of light earth in the spring, and if the season should prove dry, they must be frequently refreshed with water, otherwise they will remain a long time in the ground before they vegetate: when the plants come up, they must be kept clean from weeds in the summer, and in the autumn when their stalks are decayed, if some rotten tanners bark is spread over the surface of the ground, it will protect the roots from being injured by the frost. In the spring, the roots should be transplanted to the places where they are desired to remain, which must be in a warm (sheltered situation, but not too much exposed to the sun, and in a light soil, where they will thrive and produce flowers annually. If this is propagated by parting of the roots, it should be done in the spring, before the roots begin to shoot, which is the best season for transplanting the plants: but these roots should not be parted oftener than every third year, for if they are often removed they will not flower so strong.

The fifth fort hath a perennial root and a climbing stalk, which rises near four feet high, garnished with woolly trifoliate leaves: the flowers come out in short bunches from the side of the stalks, they are small, of a yellow colour, and are succeeded by short pods, which contain two roundish seeds in each. This flowers in June, and the seeds ripen in autumn. It grows naturally in America, but is too tender to live in the open air in England. This is propagated in the same manner, and requires the same treatment as the third fort.

GLYCYRRHIZA. Lin. Gen. Plant. 788. Tourn. Inf. R. H. 389. tab; 210. [so called of *γαυκ*, sweet, and *ρίζα*, Gr. a root, q. d. sweet root: the ancients called it Scythiaca, because the Scythians first brought it into use.] Liquorice; in French, *Reglisse*.

The CHARACTERS are,

The flower hath a permanent tubercle empalement of one leaf, divided into two lips; the upper lip is cut into three parts, the middle one being broad and bifid, the under lip is single. The flower hath four petals, is of the butterfly kind, having a long erect standard, with

The firrf'1... with a shrubby stalk, which rises about three feet high, branching out into long slender stalks irregularly, the lower branches are furnished with obtuse leaves, two, three and a half long, and an eighth of an inch broad as the leaf paint, I see these upon the flowers - cr-lhiks an* very narrow, ending in a point; the whole is very woolly; the flowers terminate in a compound eorymbusi their colour is of a filvery colour not white, and very neat, but afterward rum of a yillomili ftlphur colour. If these are gathered in the autumn they are much speeded, the heads will conanui in beauty many years, especially if they are dried in a dry place, and the plants are dried in a dry place.

The plants begin to flower in June, and there is a succession of flowers all the summer, some of which will continue in beauty most part of the winter. This is generally supposed to be the true golden Callifony of the shops, but I have seen a usually substituted for it in England.

It is propagated by slips, which may be taken in June or July, in it be cut in pieces, and covered with glass, and watered with water, observing to refresh them frequently with water, but not to give them large quantities; their cuttings will put out roots in six or eight weeks, then they should be taken up and planted in pots filled with light earth, and placed in a shady fituidon * they have taken root, M, ivien they may be removed to an open situation, and placed among other hardy exotics, till about the middle of the autumn, at which time they should be placed under a common frame, where they may be sheltered from frost, but in mild weather they should be exposed to the open air. When the ratnaacment in winter, die plants will be much more than those which are kept in the greenhouse, where they generally draw to rot; for this sort of plant wants to be freed from hml frost, being so hardy as in the winter to live about the house, where they may be kept with little labour.

The second sort is covered with a white down, and forms a thick bushy under shrub, and rises near three feet high, furnished with very narrow leaves, hoary on their under side, but green on their upper, jilaed without other on every side the stalks; the flowers are produced in a compound corymbus at the end of the branches; their heads are small, and are of a yellow colour when fully blown; they are continued in succession most part of summer. The grass naturally in France and Germany, and is hardy enough to live in the open air or in a garden. It is propagated by slips or cuttings, which may be planted in a shady border during any of the summer months, and in the autumn they may be transplanted into the places where they are designed to remain. This should have a dry moist soil, in which it is rarely injured in the most severe frost.

The third sort is an annual plant, which grows naturally in Italy and Sicily; this has an herbaceous stalk, which rises little more than a foot high, furnished with acute indented leaves, which are hoary on their under side; the flowers stand upon long five-fingered stalks, which rise far above the branches, each containing one small whitish flower. These appear in July, and the seeds ripen in September. It is propagated by seeds, which should be sown in various ways, but at eight or ten, where the plants are designed to remain; and when the plants come up in the spring, they should be thinned when they are two days, and kept clear from weeds, which is all the culture they require.

The fourth sort is an annual plant with woody leaves, which rise with woolly stalks about eight inches high, furnished with oblong leaves which embrace the stalks with their base; the flowers grow in close clusters at the top, and from the side of their stalks, which are included in dry silvery empulments.

There is another species of this with narrower leaves, run quite so woolly; the stalks rise higher, and are more branched; the flowers grow in close bunches on the top of the stalks, and are of a pale yellow colour. Both these sorts will come up sooner than the former, and when they are sown by art, but if the seeds are sown, it must be done when they are ripe, other wife they will not succeed. The plants require no other rare bin CO keep cheih clean from weeds, and thinned when they are two days. They flower in July, and the seeds ripen in autumn.

The fifth sort is an annual plant, which grows naturally in many parts of England, on places which are covered with water in the winter; this is a low branching plant, with silvery leaves and dark heads of flowers, but being of no use is not cultivated in gardens.

The sixth sort is also an annual plant, with narrow leaves, which are hoary on their under side; the stalks grow erect about a foot high, and at every joint it produces a flower spike of white flowers, with dark-coloured empulments. This is found growing naturally in some parts of England, so is not often admitted into gardens. If the seeds of this sort are permitted to mature, the plants will come up in the spring with greater copiousness than if sown, and they will require little culture. Their flowers in July, and the plants decay soon after they have ripened their seeds.

The seventh sort grows naturally in the northern parts of England, upon the tops of hills and mountains, where the flowers which are sent out from every side of the plant put out roots, whereby it is propagated in great plenty; the leaves of this grass close to the ground, they are narrow at their base, but rounded at the end where they are bound; they are near an inch long, and hoary on their under side; the stalks are single, and rise about four inches high, terminated by a single flower which is single. This flowers in May and June.

There are two varieties of this, one with a purple and the other a variegated flower, which have risen accidentally from seeds, but continue their difference in the next generation. They are easily propagated by seeds, which should be sown in the autumn, in a shady situation, where they will require no other care but to keep them clear from weeds. This plant is called Pex Cari, or Catfoot.

The eighth sort grows naturally on the Alps. This is a low plant, with under leaves like the last mentioned; the stalks are single, and rise about six inches high, furnished with very small acute leaves, and terminated by four or five oblong flowers, which in some plants are white, and in others of a purplish colour. They appear about the same time as the former sort, and the plants may be propagated and treated in the same manner.

The ninth sort grows naturally in Spain and Italy. This is a low plant with a lignous stalk, which seldom rises more than six inches high, furnished with very narrow leaves, want on their under side; the flowers are produced from the side of the stalks, each standing upon a separate foot-stalk; their empulments are hoary and long, ending in acute stiff points, and are of a purplish colour. This sort flowers in July, but seldom perfects itself in this country.

G N A

The first fort has been brought first from the beauty of its golden head; of (towers, which, if gathered brurc they are too open, will continue in beauty several years, but that in the winter ft-jfon day omnmn their rurdies with ihtf flowers, and many of them are annually brought to England, and fold for ornaments to the ladies. These plants have o ihon flrubby (talk, fldoro riling more than three or four inches high, pun ing out many heads; the leavei nre narrow and woolly on both sides, and come out with! or lower-ftilks arile from these head*; thr, grow eight or...n inches high, arc jjanifbrt! i II the way with narrow hoary leav - and *-minaic! by a compound corymbis of bright yellow flowtrs with large heads. Theie begin to flower in May, and there : a succession of ...; mejfi part of fummcr. Thb a propagated by flipping off the I seats during any i of the summer months, -nd after (tripping off the lower ienv , they should be planted in a bed of lightcarth, cov rring them with -nd-gln/Tei, which n jft be fhieed even' d jy when the fun is warm; and the rutting"; mu- be supplied with water, which floulii b : often reflatcd, bu; not in too great quantities, when these arc rooted tiev* should b! glinted i; ; etc, nri creaced • the lame banner take hi been divided for the Brll fort. These plants in mild i inners will live abrt'i: in . • very warm bord. with little water, and the trai ller they are treated, ilic greater number of flowers they will produce; for when the are drawn weak in a green-house, they ncvc! flower fo ilrong. The eleventh fort hath very woolly stalks and leaves, which are much longer than those of the tenth. stalks rise a foot high, sending out a few side branches, these are terminated by a comp. •nd coymbis of flowers, whose heads are small, and of a gold colour, changing a little red as they fade. This is propagated iy flips in the lame manner as the last mentioned, but the plants will live in the open air, if they art planted on i a dr hill.

The twelfth fort grow naturally in North America, but : has been Joni in the English gardens. This hath a creeping root, which spreads far in the ground, so as to become a troublesome weed very often. un!ris it is kept whole bound; the stalks of this are woolly, rising a foot and a half high, h, gamiflied with long leaves ending in iicuti: points, which are placed alternate, ami arc woolly on their un' side; the upper part of lite i'alk branches into two or thlireedi. each being terminated by a clofe enymbis of Jwcrs, withprtty large filvery empalements, which, if gathered and properly dried, will retain their beauty several years. This fort will thrive it; airoofl any foil or Gtation, and is easily y... spread by in creeping roots. It flowers in June anil July, and the IULks decay in autumn.

The thirrtinLh JbK grows naturally at >he Gape of Good Hope. This is an annual plant, whid leav out many otion* blunt leav-t near the root; the futlu rifeafooiandaMlfhigft, garnifhed with leaves placed alternate, which ut broati at their bal! where they embrace the A stalks, but end in acute point; B i they arc woolly, and when handled, <mm I vrr)- rink odour; the stalks are terminated by a corymbis of • ivers, in large filvery empalement, which will retain their beauty several years.

The fourteenth fort grows naturally at the Cape of Good Hope, and is an annual plant, very like the former fort, but the leaves are • r a ycUowilh green on their upper side, and woolly • r. their under j the stalks branch, and the heads of flowers are of a bright yellow colour, and these differences are permanent. Both these plants are propagated by feeds, which, if sown in the summer on a warm border, will more certainly succeed, than when they are sown in the spring; or if the feeds are permitted to scatter, the plants will come up without care, and may be transplanted while they are young, to the places where they are designed to inhabit: when the plants have taken root, they will require no other care but to keep them clear from

G N A

weeds. They flower in July, and the feeds ripen j autumn.

The fifteenth fort grows in Africa, and nlfo in Noitli America, from both ihelc countriw I have received the feeds, it a an -iriial pbnc, with oUcng • arcs at the bottom, which arc n little wavwi, MK hi ary on their under Jidc. The stalks life about a foot high, and arc gurnifcd with acun-pointed leaves from their bjfc runs a Ixirdcror wing along tlic (talk ; (he whole plant has a difagrccable odour. The Bowers grow in a mytttbui on the top of the ftafks, they art white, and apfjar in July. The feeds ripm in tlic autumn, which, if penttted to scatter, the plants will •itime up without care, n the two former forts.

The fifteenth fort riles with a Iiin thby stalk : rce oc four feet high, (i-ndin^ out many bi lower part, garnifhet! with narrow fj ear-shaped leaves, which half embrace (ie ihllis wi; their base, thty arc of a dark grirt on their upper lide, but are hoary on thrir under-, the ftulks are terminated by a compound corj mbi)5 of yellow flowers, whose heads are lmall : their cymbe iii fuccctTon great part of llic fummcr, but are rarely lucccddcd by feeds in England. k is esily ; ropag, ed by cuttings in a • of the fittmer months, which may be plaite-! in a shady bonier, and duly watered. Tlwfc will take root in a month or five weeks, and may then be taken up ind : lanted in pots, placing them in a (hady firuarjoo hill they have taken fresh root -, then they may be rrrr need to a (helrered situation, ad placed wtlit other liardy green-houli: plant's till aurium, when they r-: be carried into the grctri-hanfe, where, doling the winter fciibn, tll-y floukl iuve Hi much trei air as [joffible in tniUl weather, • r fi only requirir* prOEccium from froft; as they should be treated in the lame manner as other har.

The leventeenth (on is an annual plant, which gmvrS naturally in France, Italy, and Spain. This hath a woolly herbaceous stalk, which riles six or eight inches high, garnifhed with obtuse, spear-shaped, woolly leaves. The fiowenart- : reduced in short spikes from the fl - • id at the top of the stalks; they are of a filvery colour, and spj ; r in June and July. TUC feeds ripen in autumn, which, if permitted to scatter, the pi will come up without care, and require no other culture, bin to keep them clear from weeds.

The eighteenth fort grows naturally at the Cape of Gucc 'lope; this riles with a slender shrubby stalk, which ien is otic i may lateral branches below, these are garnifhed with very narrow leaves, which are hoary on ihrir under fide. The li. iwers are produced in a cuul I" bus at the end of t he bra n ch<> -, the y art at their first appearance of n pale red colour, but alterma change to a gold • Jour-, thr empalement ot itiss lbrtare linal!, and dry like i i other species of this genus. !his fort is propagar by cutte 55, in the lame manner as the leventeenth, and the plants require hefiuenaB ment.

The nincw th fort grows vs nuun'ly in l'arvpt and fl-lelline. This is a perennial plant, whose under leaves spread near the ground; they are woolly on their under fide; the stalks rise about six inches high; the leaves upon I hese are spear-shaped, ending in acute points; the tail:t and lev are woolly, and the stalk is terminated by a large corymbis of flowers fitting very clof i thett are 1 it' 3 line tot' red colour, so make a pretty appearance in the month of June, when they are in beauty.

This fort is propagated by cuttes in the lame manner M the seventh and eighth forts, but their doth not produce them in plenty, so is very scarce in the English gardens at present: it requires a drier soil than the seventh, and a warmer situation, but not too much r posed to the mid-day sun, it should be planted to a south-east aspect.

The twentieth fort grows naturally at the Cape of Good Hope, but has been long preferred in many curious gardens in Europe; the stalk riles three or four feet high, sending out several long irregular L... which are terminated by a compound corymbis

G O M

LJimrt-u!!! eighth d*6, intitled OaandrwM,,
the I ... having eight flammis and one style k s1

We have but one species of this genus, viz.
1. GOMPHRENA (Purshia) folia lanceolata, lobulata, flo-
ribunda, verticillata, aggregata terminalibus. Lin. Sp.
Plum. 274. Gomphrena with four-angled leaves, and flowers
... which is chiefly in colour resembling the flammis. Kapun-
culus foliis nervosis linearibus, floribus argenteis non
paleatis. Purn. Ann. 117.

This plant grows naturally in Ethiopia. It hath a
low shrubby stalk, which rises three or four feet high,
bearing out a few side branches, garnished with narrow,
oblong, acute-pointed leaves, which are green on their
upper side, but pale on their under, with a strong
longitudinal ... i] nerve, ran

the flowers come out almost in which form between
the leaves on the extremity of the branches, standing
(in Korr foot stalks) they have long slender tubes, and
are divided at the top into four segments which spread
horizontally, having eight very short flammis in the
middle of the tube, and several germs with a slender
style infixed to the side of the flammis; the germ
is upward succeeded by one oval pointed leaf.
There are two varieties of this, one with a white, and
the other hath a blue flower.

This is usually propagated here by cuttings, which if
carefully planted during the summer months, in pou-
ders filled with light earth, plunged into a very moderate
hot-bed, and covering the pots closely with either bull or
straw to exclude the air, being careful to shade
the cuttings daily, the cuttings will put out roots in six
weeks, when they should be gradually exposed to the
open air. In winter the plants should be placed in a
dry airy place, where they may enjoy free air in
mild weather, but protected from frost and damp air.

G O M

leaves, quite under the head of flowers arise from the ends of the branches. The heads are first appearance are globular, but as they increase in size become oval; these are composed of many leaves or petals, placed imbricatum like the llales of fifti-, under each of these is found a tubular flower, which will peep out of the covering, but it is not much enlarged by the neutrality (ji) people, for the Italy impostment which covers them is a beautiful, and these if gathered before they are too much faded, will retain their beauty several years. After the flowers are faded, the genus which is situated in the bottom of each, becomes a large oval seed, intended in a duty covtving, with ripens Lie in autumn, and the plants grow in the following year.

There are two varieties of this plant, one with fine bright purple heads, the other is white or filvery head, and these never alter from each other, so that they are permanent varieties, though in some respects they do not differ; there is also one with mixed colours, but varieties that arise accidentally from the seeds of either of the former, I cannot determine, for the varieties continue from seeds, and the other two I have cultivated more than thirty years, and have never found either of them vary.

There are also two varieties of the white which grow naturally in the West-Indies, one with purple, and the other with white heads, which are much smaller and rounder than the former mentioned. The plants grow much larger, and spread more into branches, and tilt) an later before they flower, so that in cold seasons the seeds rarely ripen in England; these are called *Bambos* by the inhabitants of America, but whether they are specifically different from the former, I cannot certainly determine.

The second sort hath much slender stalks than the first, which grow taller, and are irregular. The leaves are broader, and the flowers are broken, or divided into three or four parts, with a purple colour. The seeds of this were lent me by the late Dr. Hudson from Compochy.

The third sort hath slender upright stalks, which are parallel, with spear-shaped leaves placed opposite; they are heavy, and fit close to the stalks, which also are upright, and terminate in heads of flowers, which are open from each other, so as that the end of the stem appears distant, and are of a pale straw colour, and appear in June. The seeds are not ripen in England, but the plants will live two or three years, if they are preserved in a pot.

The two first sorts will grow heads of flowers which are mentioned, one with purple, and the other which are coloured, are very ornamental plants in gardens, and are now very commonly cultivated in the English garden; in Portugal, and other warm countries, they are cultivated to adorn their churches in the winter; for if these are gathered when they are fully grown, and dried in the shade, they will retain their colour a long time, especially if they are not exposed to the air; these plants are annual, so are only propagated by seeds, which should be sown in the first week of the beginning of March, but if the seeds are not taken out of their chaffy covering, it will be proper to immerse them in water for twelve hours before they are sown, which will greatly facilitate their growing.

When the plants are come up half an inch high, they should be transplanted on a fresh hot-bed, at about four inches distance, observing to shade them till they have taken root; then they should have fresh air admitted to them every day, in proportion to the warmth of the house; they will also require to be frequently refreshed with water. In about a month's time, if the hot-bed is of a proper warmth, the plants will have grown to large, so as to nearly cover, therefore they will require more room, otherwise they will draw up weak; thus a fresh hot-bed should be prepared, into which there should be a sufficient number of three farthing pots plunged, filled with light

G O R

itli eaiti, and when the bed is in a proper temperature of warmth, the plants should be carefully taken up with their roots, and each planted into a separate pot, observing to shade them till they have taken new roots, afterward they may be treated in the same manner as other tender exotic plants. Who the plants have situated the roots, they should be shaken out of the pots, and their roots on (be out of the bottom of the pot) must be carefully pulled off, then they should be put into pots a little larger, and when they have taken new roots, they should be plunged into mother ground, and it will bring the plants early to flower, and cause them to grow much larger than those which are placed abroad. In July the plants should be moved gradually to bear dii; open air, into which they may be removed alxii; the middle of the month, and intermixed with other annual plants to adorn the pleasure garden; but it will be proper to keep a plain or two of each sort in the kitchen for use, because when the autumn grows cold, or wet, these plants will be ruined, and their roots will produce small seeds.

GOOSEBERRY. See GADUSARIA.

GORTERIA.

The CHARACTER: me, *thetmfetc* of the flowers is stiff, simple, entire, and singly *spisec;* (fe/jwr ij i) of the leaves is compound, bipinnate, *mapht* in the form of a fan, and the rays or barbs, the female flowers are funnel-shaped, five pointed, having five short filaments terminated by cylindrical funnels, with a hairy genus supporting a slender style, crowned by a white stigma; the female flowers are funnel-shaped, have five rays or barbs, and are barren.

This genus of plants is ranged in the third section of Linnæus's nineteenth class, initial *Syngenia* Polygonia fruticosa, the flowers being composed of hermaphrodite florets in the disk, which are fruitful, and female florets in the border, having neither style or stigma, to be barren.

The SPECIES are, 1. *GORTERIA (Riviera) Scapis uniflarij, folijs lanceolatis*

pinnatifidis, caule depresso. ANTON. Acad. p. 86. Gorteria with one flower on each leaf-stalk, spear-shaped, long-pointed leaves, and a diverging stalk. ARTZNERI Rami circumscissilis, folijs foveis lanceolatis rigidis lobatis argenteis. Ed. prior.

2. *GORTERIA (Riviera) folijs lanceolatis integris denatis spinosis lobis terminalibus, caule fruticosa. LINN. Sp. i. 284. Gorteria with entire spear-shaped leaves, which terminate in five points, usually on their under side, and a shrubby stalk. CARTHAGENSIS Africainis fruticosa, folijs ilicifolij, flore aureo. WALT. Hort. 13. tab. 7.*

The first sort grows naturally at the Cape of Good Hope; it is a low spreading plant, with lignous stalks six or eight inches long trailing on the ground, having two or three side branches, each terminating in a close head of leaves, which are narrow, green on their upper side, but livid on their under, cut into three or five segments at their ends. The leaf-stalks or the joints arise from the base, and are six inches long, naked, supporting one large orange-coloured flower at the top, composed of several hermaphrodite florets in the disk, which are fruitful, but the female florets on the border are tongue-shaped, spreading open, each having a dark mark toward their base, with a white spot in the middle. The flowers appear in May and June, but are seldom succeeded by seeds in England.

This plant is easily propagated by cuttings planted in a shady border during any of the summer months, and the plants must be alternated treated as is directed for *ARTZNERI*.

The second sort grows naturally at the Cape of Good Hope. This differs with a shrubby slender stalk three feet high, sending out a few weak branches, furnished with oblong leaves fitting close to the branches; they are smooth on their upper side, woody underneath, and indented on their edges, each indented ending with a weak spine. The flowers terminate the stalks, having

'me uie of grafting is to propagate any citriotis forts of fruits, fo as to be certain of the kinds, which cannot be done by any other method ; for as all the good fruits have been accidentally obtained from feeds, io the feeds of thefe, when fown, will many of them degenerate, and produce fuch fruit as are not worth cultivating; but when fhoots are taken from fuch trees as produce good fruit, thefe will never alter from their kind, whatever be the flock, or tree, on which they are grafted \ for though the grafts receive their nourifhment from the flocks, yet their varieties arc never altered by them, but continue to produce the fame kind of fruit as the tree from which they were taken-, the only alteration is, that when the docks on which they are grafted do not grow fo faft, and afford a fufficient fupply of nourifhment to the grafts, they will not make near fo great progrefs as they otherwife would do, nor will the fruit they produce be fo fair, and fometimes not fo well flavoured.

Thefe fhoots are termed cions, or graffs; in the choice of thefe the following direCTIONS fhould be carefully obferved. ift, That they are fhoots of the former year, for when they are older, they never fucceed well. 2dly, Always to take them from healthy fruitful trees, for if the trees are fickly from whence they are taken, the grafts very often partake fo much of the diftemper as rarely to get the better of it, at leaft for fome years; and when they are taken from young luxuriant trees, whofe veffels are generally large, they will continue to produce luxuriant fhoots, and are feldom fo fruitful as thofe which are taken from fruitful trees, whofe fhoots are more eompaft, and the joints clofer together; at leaft it will be a great number of years before the luxuriant grafts begin to produce fruit, if they are managed with the greateft (kill. 3dly, You fhould prefer thofe grafts which are taken from the lateral, or horizontal branches, to thofe from the ftrong perpendicular fhoots, for the reafons before given.

Thefe grafts, or cions, fhould be cut off from the trees before their buds begin to fwel, which is generally three weeks or a month before the feafon for grafting; therefore, when they are cufoff, they fhould be laid in the ground with thcut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a fmall joint of the former year's wood is cut off with the cion, it will preferve it the better, and when they are grafted, this may be cut off-, for at the fame time the cions muft be cut to a proper length before they are inferted in the flocks; but, till then, the fhoots fhould remain their full length, as they were taken from the tree, which will preferve them better from fhinking; if thefe cions are to be carried to a confiderable diftance, it will be proper to put their ends into a lump of clay, and to wrap them up in mofs, which will preferve them frefh for a month, or longer; but thefe fhould be cut off earlier from the trees than thofe which are to be grafted near the place where the trees are growing.

Having given direCTIONS for the cions and graffs, we next come to that of the flock, which is a term applied to the trees intended for grafting; thefe are either fuch old trees as are already growing in the places where they are to remain, whofe fruit is intended to be changed, or young trees, which have been raifed in a nurfery for a fupply to the garden; in the former cafe there is no other choice, but that of the branches, which fhould be fuch as are young, healthy, well fituated, and have a fmooth bark * if thefe trees are growing againft walls, or efpaliers, it will be proper to graft fix, eight, or ten branches, according to the fize of the trees, by which they will be much fooner furnifhed with branches again, than when a lefs number of cions are put in; but in ftandard-trees, four, or at moll fix cions will be fufficient.

In the choice of young flocks for grafting, you fhould always prefer fuch as have been raifed from the

feed, and that have been once or twice tranplanted; Next to thefe, are thoiç flock& which have been raifed from cuttings, or layers, but thofe which are fuckers from the roots of other trees fhould always be re-jedted, for thefe are never fo well rooted as the others, and confantly put out a great number of fuckers from their roots, whereby the borders and walks of the garden will be always peftered with them during the fummer feafon, which is not only unfightly, but they alfo take off part of the nourifhment from the trees.

If thefe flocks have been allowed a proper diftance in the nurfery where they have grown, the wood will be better ripened, and more compadt than thofe which have grown clofe and have been there drawn up to a greater height; the wood of thefe will be foft, and their veffels large, fo that the cions grafted into them will fhoot very ftrong, but they will be lefs difpo'ed to produce fruit than the other *, and when trees acquire an ill habit at firft, it will be very difficult to reclaim them afterward.

Having directed the choice of cions and flocks, we come next to the operation, in order to which you muft be provided with the following tools.

1. A neat fmall hand-faw to cut off the heads of large flocks.
2. A good ftrong knife with a thick back, to make clefts in the flocks.
3. A fharp penknife to Cot the grafts.
4. A grafting chiffel and a fmall mallet.
5. Bafs firings, or woollen yarn, to tie the grafts with, and fuch other inftruments and materials as you fhould find neceffary, according to the manner of grafting you are to perform.
6. A quantity of clay, which fhould be prepared a month before it is ufed, and kept turned and mixed, like mortar every other day, which is to be made after the following manner:

Get a quantity of ftrong fat loam (in proportion to the quantity of trees intended to be grafted, then take fome new ftone-horfe dung, and break it in amongft the loam, and if you cut a little ftrajv, or hay, very fmall, and mix amongft it, the loam will hold together the better; and if there be a quantity of fait added, it will prevent the clay from dividing in dry weather -, thefe muft be well ftirred together, putting water to them after the manner of making mortar; it fhould be hollowed like a difh, and filled with water, and kept fvery other day ftirred; but it ought to be remembered, that it fhould not be expofed to the froft, or drying winds, and the oftener it is ftirred and wrought the better.

Of late years fome perfons have made ufe of another compofition for grafting, which they have found to anfwer the intention of keeping out the air, better than the clay before defcribed. This is compofed of turpentine, bees-wax, and rofin, melted together, which, when of a proper confiftence, may be put on the flock round the graft, in the fame manner as the clay is ufually applied; and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will Harden this, there is no danger of its being hurt by froft, which is very apt to caufe the clay to cleave, and fometimes fall off* and when the heat of fummer comes on, this mixture will melt, and fall off without any trouble. In ufing of this, there fhould be a tin, or copper-pot, with conveniency under it to keep a very gentle fire with fmall-coal, otherwife the cold will foon condense the mixture; but you muft be careful not to apply it too hot, left, you injure the graft. A perfon who is a little accuftomed to this compofition, will apply it very faft, and it is much eafier for him than clay, epecially if the feafon fhould prove cold. There are feveral ways of grafting, the principal of which are four:

1. Grafting in the rind, called alfo fhoulder-grafting, which is only proper for large trees; this is called crown-grafting, becaufe the grafts are fet in form of a circle, or crown, and is generally performed

formal show the Inner end of March, or the beginning of April.

2- Clasp-grafting, which is al(b) called flock, or flit-grafting; this is proper for trv« or flocks of i i7i-, from an inch, to two inches or more diameter; this gijitmir j, to be performed in the months of February and March, and supplies the failure of the first-chorr: way, which is practised in June, July, and August.

3. Wliiii'j'ril'iing, whii is also called tongue-grafting; this is proper for stocks of an inch, half an inch, or Iris, diameters this is the nioft t: way is, and which is most in use.

4- Grafting by approach, or abliibrinn; this js to be performed when the stock y «•• and the tree from which you take your graft, are to meet together, that they may be joined; this is performed in the month of June, July, and August.

to bo perron n«l in the motith <J: >ril, antl h allb calk-, and ischi jr Jafmincs, Oranges, and other tender cjoico trees. We [ome new] a the manner of performing the feveral nm of gr.:

The Hrtt itrttrod, which is termed rind, or ihoulcter-grafting, is itldum prttfitti bu(on large trees, when either the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

ferted into the flit madr • the slope of the stock, and thecion mull be placed on one side of the stock, so as to be the two ends of both cion and stock may be cut Uni, and join together exactly; then there should be a figure of both to insure the cion, Ib ns thar i* may not be easily displaced, onJ afarwaid clay it over, ai in thefirmrr methods,

The fourth fort of i- grafting is termed inch-grafting Iv. approach, orabjsfialion. This is only to be performed when the stock, v. hich are deji« to be grafted, and the tree from which the graft is to be taken, are to be joined together, or may be brought together, as that their branches may be united; this method is practised on tender rjotic plants, and some other forts which do not succeed in any of the oilier mciioodi,

In performing thii operation, a part of the stock, or branch, mull be slit off about two in the: in length, observing dwuva to make a notch in the end of the stock; then a small notch should be made in the end of the branch, and a slit made in the middle of the branch, to receive the slit of the stock, observing to join their ends equally, that they may unite well together; then make a figure of both, so keep them exact; and afterward clay the part of the stock over well, to keep out the air; in this method the cion is not separated from the tree, and it is firmly united with the root.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

When the head, or the large branches, art cut off hoi essentially, and two or three are put in, according to the size of the branch, or the diameter of the tree.

Dunelm-graf, or Corn-graf. Raii fpeciebus vocibus,
fiofe
The first sort of Grab is that which is chiefly to be
used in medicine; the roots of them are chiefly used,
and are accounted aperitive and diuretic, opening ob-
structions of the reins and bladder, promoting urine,
and an; of Itrvier ,uzzant the gravel and stone. The
juice of the leaves and stalks was greatly esteemed by
Dr. Boerhaave, who generally prescribed this small
cure where he i (K>lc! them v
in die 'ble conclud.

This hath a creeping root, which spreads far in the
ground, and is a very troublesome weed in gardens
and waste land; for every small piece of the root
will grow and multiply exceedingly, fo it is very dif-
ficult to extirpate whole it once gets foot hold in
gardens, the common method of destroying it is, to
take out the roots as often as the blades appear above
ground, where this is done or three times carefully
repeated, it may be totally removed, but when the
surface of the ground is very full of the roots of this
Grab, the best way of destroying it is to touch

the ground two fpts and a flivoclling deep, turning all the couch into the bottom, where it will rot, and never fouth up v but this can only be praftified, where there is a fufficient depth of foil; for in (hallow ground the roots cannot be buried fo deep, as to lie below the depth to which they naturally Jhoot.

Where the roots of this Grafs get poffeffion in arable fields, it is very difficult to root out again \$ the ufual method is by laying the land fallow in fummer and frequently harrowing it well over to draw out th roots t where this is carefully praftified, the ground may be fo well cleaned in one fummer, as that the roots cannot much injure the crop which may be town upon it i but fuch land ihould be cropped with Beans, Peas, or fuch things as require the horfe-hoeing culture ; for where the land can be frequently ftirred and harrowed afterward, it will be of great fervice in cleaning it from the roots of this Grafs and other bad weeds. The blade of this Grafs is fo rough, that cattle will not feed upon it.

The fecond fort is frequently cultivated, efpecially introng cold land, upon which this Grafs will fucceed better than any other fpecies, and is an earlier feed in the fpring-, but this is a very coarfe Grafs, and unlefs it is cut very early for hay, it becomes hard and wery in the ftalks, fo that few cattle care to eat it j for this fpecies has but few leaves, running all to italk, fo is ufually called Bents, and in fome counties Bennet -, when this grafs is fed, it wiu be proper to mow off the Bents in the beginning of June, otherwife they will dry upon the ground, and have die appearance of a ftubble field all the latter part of fummer ; fo that it will not only be very diagreeable to the fight, but alfo be troublefome to the cattle that feed on it, by tickling their noftrils *, fo that the want of better pature only, will force them to eat of the young Graft which fprings up between thefe Bents, for thofe they will not touch; therefore thofe who fuppofe that thefe are eaten in fcarcityof feed by the caSe, are greatly miftak*n> for I have many years dofeiy attended to this, and have always found thefe Bents remaining on the ground untouched, till the froft, rain, and winds, deftroy it in winter; and, by permitting thefe to ftand, the after-growth of the S b l r e a d y retarded, and the beautiful verdure t toft for s three or four months * fo that it is good

mulberry to come and take the old made into the hay, cows feed in winter, and will pay the expence of mowing it.

There is not, whi growing hard much fooner, and having nar-ftalks >> B common in moft pature roWer W V S J h comes Jarly to flower, fo the feeds grounds, for ash >> Jarly to flower, fo the feeds

f^fl T J E S t fupplied with plenty of falling feeds the r J ^ f e who are defirous to keep this fort; < I o S e n r this Grafs afpofible, their patures as clear y m

lands as are defigned to be ploughTm few it with years, and the common method is to tow it m

Spring Com; always found, whas there has the Grafs, that any which has been fown in the common way. Grafs has often been fo rare, as to afford a good feed the fame autumn; and the following fpring there has been a ton and a half of hay per acre mowed very early in the feafon, and this has been upon cold foul land; fo that I was convinced of that being the belt feafon for fowing thefe Grafs; though it will be very difficult to perfuade thofe perfons to alter their praftice, who have been long wofided to old cuftoms. The fee, who have been long wofided to old cuftoms. The quantity of feeds which I allow to an acre is about two bufhels, and eight puckets of the common Clover, which, together, will make a good plants upon the

? j K 5 3

@ 3 £

ground as can be defired; but this is not td be praftified upon fuch lands where the beauty of the verdure is principally regarded, therefore is fit for thofe who have only profit in view.

The third and fourth forts are the two bed fpecies of Grafs for patures, fo that if the feeds of thefe were "carefully collected and fown feparately without any other mixture of Grafs-feeds, they would not only afford a greater quantity of feed on the fame fpacc of land, but the Grafs would alfo be better, the hay fwetter, and the verdure mere lafting than of any other forts; but there requires fome attention to the faving of thefe feeds pure without mixture. I have tried to lave the feeds of feveral fpecies of Grafs, feparately, in order to determine their qualities, but have found it very difficult to keep them diftint in gardens where the feeds of other forts of Grafs have been fcattered: the only method in which I could fucceed, was by fowing each fpecies in a diftint pot, and when the plants came up, to weed out all the other kinds of Grafs which came up in the pots; by this means L preferred a great variety of the graffy tribe feveral years, but not having ground enough to propagate the moft ufeful fpecies in any quantity, I was obliged to abandon the purfuit: but I muft recommend this to perfons of leifure and (kill v/ho have a fufficient quantity of land for the purpofe, to carry this projeft into execution, which ijjay be of fingular benefit to the public; for we have an influence of the advantage which the inhabitants of the Netherlands have made, by faving the feeds of the White Clover, or Honeyfuckle Trefoil, which is a plant common to moft of the Englilh patures *, yet few perfons in this country ever gave themfelves the trouble to collect the feeds from the fields for fowing, but have purchafed vast quantities of this feed annually, at a confiderable price from Flanders, where the peafants have been fo induftrious, as to collect the feeds and fow great quantities of land with it, with a view of fale to this country only. This is not an inconfidrable article in hufbandry, but deferves the attention of all thofe, who, by choice or otherwife, are engaged in the bufinefs of agriculture; for one acre of land will produce as much feeds of this fpecies of Trefoil, as will fell for 12l. where it is well planted and faved from the fpring crop *, and if the Grafs-feeds before-mentioned were feparately fown, and carefully weeded from all other fpecies, and permitted to ftand till their feeds were ripe, it might be of equal advantage with the other, especially now, when every gentleman is endeavouring to improve the verdure near their habitations.

The fifth and fixth forts are alfo very good Graffes for patures, and have perennial roots, fo are the next belt forts for fowing to thofe before-mentioned, which, in my opinion, deferve the preference to all the other; but as it will be difficult to fave a fufficient quantity of feeds of thofe alone, to fupply the demand which may be for their feeds j fo thefe two fpecies may be admitted in aid of the other, as they are very leafy kinds of Grafs, and their ftalks do not become ftiff and harfh like many other fpecies, but with proper care may be, made very fine; and, if duly rolled, their roots will mat and form a very dofe fward, therefore thefe fhould be included in the number of fown Graffes.

The feventh fort is mentioned for the fake of variety, and not for ufe j this hath an annual root, which fends up many broad hairy leaves, between which arife (lender ftiff ftalks from a foot to near two feet high, dividing upward into a large loofe panicle, garnifhed with heart-ftaped fmall fpikes, each having about feventeen fmall flofcules or florets; thefe, after the flowers are paff, have a fingle feed fucceeding them; the heads hang by flender long foot-ftalks, which are moved by every wind, fo that they generally appear fhakinf, from whence it had the title of Quaking Grafs.~ There are four fpecies of this Grafs, two of them grow naturally in England; and thefe Graffes coming to head in May, occasioned the following

Engliih proverb, M<\$ temtjb early come for late, wafri she cam pah. The Inrge IOM here mentioned, grows naturally in the fonth of France a rv italy, and is only preserved in fomic Englifli gardens for the £ of variety.

If the fctels of this iVirt are (own in the autiirfin, or permitted ro fesrtter when ri]e plws will come up fronger, and ilower mudi earlier, th when they arc frown in the i rring, fo good feeds may al"*ps be txpvi- id from : am, which can : klijin lie attained iron; the fring; plants in Engle...; and as • wo of thr: mans to this I will be hill enough in o garden for variety, fo thrff l'houed be allowed'w frjrtai • or where they grow at a diiljncce from eai h other, the roots will tend o'-'agreatnutnbTDflalL , which will b- fcortger, and produce much larger (Mnides than thofe which ire too near together.

The Cock.*foot Gnfce, CapanVwil GttJ and Millet Grades are. toocofrc todefrve attei- land, though fonth of their faecies arc very ufrifful in the warm parts of Amvrica, where [here i. .. great fec- city or finer Grj] and fome of thofe are much bet- r-T adapted to thofe: warm country , than any of our European Grats...; for many of them lie fiat on the grouiid, and tmit roots from, theii joints, fo are well prepared for this; their th! are large and juicy, fo will live in heat where tew of th; European Grats can be madi" to thrive.

The land on which Grats-feed is intended to l. form, fhould be well plougtd, and CICLE d from the roots of noxious wecl.i, fuch as Couch-™rafe, Ft m, Ruffes, Hual; Gurfce, froom, Rell-harrow, &c. which if Jcfi in the ground, will foon get the liccter •; the Gr'fs, and <> - run the land. A barrow in fuch places wlcrc eiijhcj • their weeds abound, it will be a good method to plough up the furface in \prlli and let it be fome time to tj ilr.; then harro¹ ihi roots into small heaps, and burn them. The afhes fo produced, when tptcad on thr land, will bcag. Ii manure for it. The method of burning the root? is particularly duced undi'r the artikle LAND, which fee: but wlcrc Couch-grals, Fern, or Refi-harrow i in plenty, which roots run I under ground, the Lndnuill be ploie and two or three times prtll deep in dry weather, and the roots carefully ham

which is the moll: hire n • thod to dclroy them. Winter the land is very low, and of a Riff clayey nature, which holds water in winter, it will be of lingular lcr- vice to make fame undi... and drains to ..any off the wet; which, if it'ained too long on the groun l, wjl render the Gratu lour. The i method of making thofe drains is prdu-ibecel under rhe nrricL-L ash, which fee.

Before iht freil is fown, the furface of the ground I'ould be m'adc li and lin , orhtrwic t'e ii. will be bi ried unequal. When d'le foil is fown, it muft be gently h arrow rd in, and the ground roll Id • with a wooden roller, which will make the furface even, and prevent the iceds being blown in patchei. When the tij.ih. comes up, if there fl uid be an; bare fpois, where the Jcxii hu no; grown, icy may U- fown agnir. and the ground roller. :L[[will tiji the feedi , and the belt kindly thofers will bring up the Grats, and make it very thok.

Where the land is defigned to continue in palture, it fhould be fown with the belt forts of Grats-feed, and when Death Gower, or what is commonly called Hon- ncrtable Grats in many parts of England, but there is a great difficulty of procuring hay-feeds which are good; for in all the good paltures near London, which abound with the belt forts of Grats, the hay is voin- mooly cut before the feeds of the Grats are ripe. fo that thofe feeds which are procured from the ftables where thi hories are fed with the belt fort of hay, are little moi

than chaff, or at belt are only dry; as any of the early kinds of Grats, with a great quantity of Ph- ton and other weeds: which has d'couraged many gentlemen from fowing them, nor had any one at- tempted to fave thofe feeds properly, and as it requires longer rime, and more attention, to ft

Jkd) of the purer fort of Grats than the generality of people ciir; tobi ihaw, fo I would recommend the fetting fume of thofe upland paltures, which are deaneft ftvrr weeds, and have the fceared herbage afide, to Jb: I for feeds; and although by fowing the Lry wlt /v: !• I valuable, yet from the fize of the feeds, it may uufw'r better to the palturer, than to mow it merely for the hay; for any gentleman who has regard to the beauty of his land, and better pve

Λ r;; as the price for fuch feeds, is exactly paid for the ordinary feeds, fince the difadvantage of weds is not to be put in comparifon with the beauty and ad- vantage of having fuch a fure feed; for when the land is brought to a good feard (which may be done in one yi ar, where it is properly prepared and fown with gi>d feidsj it rr.; be kept in good order, and by gotnl ni3nag< mci. improved annually, and thus con- unuc lb, is lon^ as ; wprc cam is taken of it. I know lonii-)ind which was fown in the method here- after Uired' d above forty years ago, which are now as good as uiriS a^ zΛ I have feen, and may be di- ways c: ;iljird lo.

Thefe grounds abounded with many bad weeds, fo they il iwint'lf, and fummer's fallow, in which time they were five times ploughed and fed times harrowed in order to dclroy the weeds, and on the furface of the ground, fince in Auguft they were fown with the belt Grats-feed as could be procured, three bu- chels of this, and nine pounds of the white Dutch Clover-feed were allowed to each acre; arthens happened rains foon after the feeds were fown, fo the Grats took up well; but altho' it were a great number of weeds, which were drawn up and carried off the ground, and in the beginning of October the fields were rolled with a heavy roller, in the fpring the fields were again weeded, and after-ward mowed, and that fummer there was more than two fies of hay per acre mowed off the land; and by conflant weeding twice a year, fceeping it with a heavy harrow, rolling and drifling of the land, the Grats has been vortally improved fince, and is now a good palture as any in England; and I in« I hi e land thofe great quantities of land in the fame manner, and with equal fuccefs; therefore from many years experience can recommend it, as the beft method of having good paltures.

But I know the generality of farmers will object to the belt forts of their crops, and will not be ex- pectic - weeding, rolling, &c. as too great for com- man practice: however, I muft be fatisfied from ex- rjcr!:-r, that whatever will be at the expence, will find it'eir accouj I in it; for the crops of hay will be ut much better, and the after palture alfo, that it will mart than pay the expence, as from many good ac- counts, which ha have been kept of the whole, is fully andly demonstrated, and the vendors of thofe paltures is charifing to all thole who have any talk of annual fecundities.

The proper management of palture land is the leaft underllocii of any part of agriculture; the farmers never luvé attr. led to this, being more inclined to the plough, though tl ; who depending that have not of late year; fawn fo pr: as to encourage them in that par of husbandry; but thofe people never think : laying down land for palture, to continue longer than three years, at the end of which time they plough it up again, to fow it with grain.

There is a fort of limped Grats which is preferred in many gardens for the beauty of its variegated leaves, which conrinu frith the .retteiV] part of the fummer. This fort is eafily propagated by parting the roots, either h fpring or autumn, for every other will ac- creafe to be a large root in six years time. It will grow on any lull or in any fituation, therefore may be planted in any fubject part of the garden, where it will thrive, and afi,jrj m^ nrrteable v; may. This fort is by many peribn^ callil Kibbai Grats, from the fimples of white and green, which run the whole length of the blade, like the ftripes in fome rib- bands.

GRASS, The English Grass is of so good quality for milks & other uses, that if they be kept in good order, they have that equality of beauty that they are famous for in France, and elsewhere. But green walks and green plots are, in this part, not made by sowing the Grass seed, but by cutting turf, and, indeed, the turfs from a fine green, are much preferable to sown Grass. In sowing a fine green plot, it is not to be sown in the bay left without distinction; for that seed is not so good, and making large balks, the lower part will be naked and bare, and although it be mowed ever so often, it will never make handsome Grass; but, on the contrary, will come to nothing but a little of the common kind.

It walks or plots be made by sowing, the best way is to procure the seed from those parts where the Grass is naturally fine and clear, or else to keep it from being mowed and being Grass will be very good, and it will scarce ever look handsome. In order to sow Grass seed, the ground should be first dug or broken up with a spade, and when it is desired and laid even, it must be very finely raked over, and all the clods and lumps taken off, and covered over an inch thick with good mould, to facilitate the growth of the seed; this being done, the seed is to be sown pretty thick, that it may come up close and short, and it must be raked over again to bury the seed, that if the weather should happen to be hot, it may not be blown away.

As to the best time of sowing, the latter end of August is a good time, because the seed naturally requires nothing but moisture to make it grow; if it be not sown in the latter end of February, or the beginning of March, if the weather proves dry, it will not so soon make the walks or plots green. It is also best to sow it in a mild day, and in sowing to rain; for that, by sinking down the seed in the earth, will cause it to shoot the sooner. But where Grass is sown in gardens, rather for lawns or walks, there should always be a good quantity of the White Trefoil or Dutch Clover sown with it, for this will make the turf much better than any other sown Grass, all continue a better verdure than any of the other.

After the seed is sown, and the Grass is very thick and of a beautiful green, it will require a constant care to keep it in order; this consists in mowing the Grass often, for the oftener it is mowed, the thicker and handsomer it grows; it must also be cut with a cylinder or roller of wood, as low as possible.

If Grass is sown in a field, it will run into Quick grass, unless it is cut; if it does so, there is no way to recover it, but either by sowing it, or laying it over again, but that once in every two years; but if the ground be well cleared from the roots of strong weeds, the turf be taken from a fine level common, it will continue handsome for several years, provided it be well kept.

In order to keep Grass-plant or walks handsome, and in good order, in autumn you may see some fresh seed over any places that are not well filled, and where the Grass is dead, to mow and furnish them again; but there is nothing which improves Grass so much as constant rolling and pulling it, to destroy worms, and to keep the turf so tender.

It is a general practice when turf is laid in grass, to cover the surface of the ground under the turf, either with sand or very poor earth; the design of this is to keep the Grass fine, by preventing its growing too rank. This is proper enough for very rich ground, but is not so for such land as is but middling or poor; for when this is practised in such places, the Grass will run to seed, and decay in numbers.

When turf is taken from a common or down, there should be regard had to the season of it, and not to take such as is full of weeds; for it will be a very unprofitable piece of work, to weed them out after the turf is laid; and unless this is done, the Grass will never appear handsome.

Where turf is designed to remain for years without renewing, there should be drinking laid upon it every year, either of very coarse dung, ashes, or straw; it can be easily procured, very common too, on a good deal of land; but these dressings should be laid on early in winter, that the rain may wash them into the ground, before the drought of the spring comes on; otherwise they will occasion the Grass to wither when the warmth of summer begins. When Grass is so dressed, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is not dressed or fed with dung, it will rarely continue handsome more than eight or ten years.

GRATIOLA. Lin. Gen. Plant. 17. Rad. Meth. Plant. 90. Digitalis. Toorn. Hist. R. H. 167. Hedge Hyssop.

The C. CHARACTER etc. The first is said to be a perennial cropment, which is cut into five parts; it has one part of the growing stalk, with a stalk longer than the peduncle, cut at the top; the other four parts are the upper leaves, which are small, narrow, and pointed at the end, and are upright; the lower leaves are oval and equal. It has five and six-petaled flowers, three of which are longer than the petals, and four, the other two are longer, and others in the tube of the petals; these are fruitful in their tops; they are terminated by roundish joints. In the center is situated a central column, supporting an oval disk, crowned by a figure with two lips, which rise after being fructified. The crown of the disk is filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's second class, entitled Dialectic Monogynia, which includes those plants whose flowers have but two stamens and one pistil; for he does not esteem the three last as having a staminal notice.

- The Species are,
 1. GRATIOLA (Coffinella) floribus pedunculatis, foliis lanceolatis serratis. Lin. Mat. Med. 17. Hedge Hyssop with flowers hanging on foot-stalks, and four-lobed leaves. Digitalis annua Gratiolosa Linn. Mar. Hist. 2. 479. Leafy Foxglove, called Gratiola.
 2. GRATIOLA (Fragrans) foliis lanceolatis ovatis, serratis. Flor. VIII. 6. Hedge Hyssop with straight peduncled leaves.
 3. GRATIOLA (Fragrans) floribus subsessilibus. Lin. Sp. Plant. 17. Hedge Hyssop with flowers sitting close to the branches. Gratiola latiore folio flore albo. Frull. Peruv.

The first sort grows naturally on the Alps, and other mountainous parts of Europe. The herb is thick, fleshy, fibrous, creeping root, which propagates very much when planted in a proper soil and situation, from which arise several upright square stalks, near a foot high, garnished with narrow spear-shaped leaves placed opposite; the flowers are produced on the side of the stalks at each joint, they are shaped like those of the Foxglove, but are small, and of a pale yellowish colour. These appear in July, but are seldom succeeded by seeds in England.

It is easily propagated by parting of the roots; the best time to do this is in the autumn, when the stalks decay; the plants should have a moist soil and a shady situation, in which they will thrive exceedingly; but in dry ground they often decay in summer, unless they are plentifully watered.

This stands in the list of medicinal iJ.ir.;, butij very rarely used in England, tlnun^li h i^ recommended by fame good writers as a purger of i^rious and choleric humuun.

The ficced fort grows naturally in North America, from whence I received the lcerfs. Thij grows naturally in moist place, wbcie it riles more than a foot high, but in England I have not seen it more than eight inches; the leaves are blunt, and indented at their ntremluq . the flowers; are white, utd come out from the fide of the (talk*, like thoir of" Uie other, but are not fuccerfeu I y feeds here. It may b.r propagated in the fame manner as the finV lbrt, and require the fame treatment.

The feeds of the third lbrt were frnt me from Carthagena, where it was found growing naturally in places where there had been a flat; waters, which were then dried tip. this plant grew about nine inches high, with it wscflUK, and the I was placed opposite; they were about three tuarler;. of a inch long, and half an inch broad, lawtrd un their edges; the Bower; came out fngle on each filc the ftilk; they wcrs wluu;. and much fmri^ than those of the first fort, but were not ficccicieti by feeds, fit d : plant was loft here.

GRAVEL and Grafs are naturally ornaments to a country-seat, and ilic glory of [lie linglilh gardens, and things in wh ch we excel all otht. nations, as France, Holland, Fianders, Sic.

[here are different forts of Gravel, liutfor thole who conveniently have it, I approve of that Gravel on acklicith, as preferable to most that we have in England; it confuting of linooih even pci bles, which, when mixed with a due quantity of I am, will bind extending . lofc, and look very beautiful, and continue hamlotnc longer ilum <ny other lbrt of Gravel which I luvc ve:.

Some recommend a part of iron-moud Gr.vvel, or Gravel with a little binding loim tvaogft i), than which not:;ng, they say, binds better when it is dry; but in wet weather it is apt to stick to the beds of one's shoes, and will never appear handsome.

Sometimes luam it m:..ed with Gravel that is over sandy or sharp, which must be very well blended u> cethtr, and lie in heapi, *fter which it *. ill bind like a rock.

There are many kind* of Gravel which do not bind, and thereby code u routinul trouble ot roilbg, to little or no purpoc •, as I or such,

If the Gravel be loofe .e sandy, you; should :ik« one luad ut' lbtmg loam, (two CH three of Gravel, and to cift them well icgether, and turn the mixture over three or four times, dial they may be ucll blended together; if this is done in proper porj* time, it wU bind well, am) nei thick to r-r vtd in uet weather.

There are many iirTent opinions about the choice of Gravel; some are for living the> gravel as i-httcaj possible, and in order tomak.: the walks more . i, they roll them well with tone rollers, which an often driven by the L mafon!, thu they may add a whistnet to the walk-; but this renders it very troublefome to the eyei, I reflecting the rays f' light to strongly, therefore T should ever be avoided; and loch Gravel as will be fine-oth, and teleci ihc leaft, ftould be preferred.

Some creer the Gravel too fine, which ii an error-, for if it be caft into a round heap, and ihc great llooc* only raised off, it will be the i-eltrr.

Some arc apt ro lay Gravel-ivalks too round, bur. thi* it liknvic an error, because the . are not fo good to walk upon, and besides, it makes them look surrow; one inch rise is enough in a crown for a walk of five feet; and it will be sufficient, if a walk of five feet wide, that it lies two inches higher in the middle than it does on each side; if fifteen feet, three inches; twenty feet, four; and so in proportion.

For the depth of Gravel-walks, fix or eight inches may do well enough, but a foot thickness will be sufficient for any; but there should always be a depth of rubbish laid vndef tru Gravel, especially if the

ground is wet; in which cift- there cannot be too much care to fill the bottom of die walks with large Qones, ilinii, brick rubbil n, chalk, or any other materials which Lin be beil procur, l, which will drain off the moilture from the (.i gravel, and prevent its being po.ithy in wet we.v^ter; but as it may be difficult in some places .o procure a sufficient quantity of these materials to lay in the bottom of the walks, so there may be a bed of Heath, or Furze, which ever can be procured at i: - least expence, laid under the Gravel to keep it dry: and if >ther of these are used jnms, they will be a long time, as they will be covered from air, and tht'ic will prevent: the Gravel from getting down into the i lay, and will always keep the Gravel dry; and where there is not this precaution in the first laying

• the Guvi! by the clay, willi..• the Gravel to be partly whenever there is much rain.

In ii'aking of Gravel-walks, there must be great regard had to the level nti he ground, so as to i y the walks with ealy dHtm toward the low parts of the ground, that the wet may be drained off easily; for when • is omitted, the water will lie upon the walks a considerable time after hard rains, which will render them unfit for use, especially when the ground is naturally wet or strong; but where the ground is level, and there are no i nclivities to carry off the wet, it will be proper to have fish-bones laid by the sides of the walks, at convenient distances, to lit off the we I; and where the ground is naturally dry, that the water r <:il loon l ak away, the drains of the fish-bones may be contracted so as to convey the water in fishpools, fnnnwliich i: - water will soak away iaa) hot time; but in wet land there should be under-ground drains, to convey the wet off, either into ponds, ditches, or the nearest place to receive it; for where this is not well provided for, the . *lks will never be jo handsome or so useful.

The month of March is the properest time for laying Gravel, it is not prudent to do it sooner, or to lay walks in any of tin winter months before that time. Some indeed! turn up Gravel-walks in ridges in December, in order to kill the weeds; but this is very wrong, for besides that it deprives them of the benefit of them all the winter, it does not answer the end for which it is done, but rather the contrary; for though it does kill the weeds for the present, yet it adds a fertility to them, so to the great future increase of both them and Gravel.

If constant rolling them after the rains and . It wit! not etR-aiully kill the weeds and moss, you should turn the walks in March, and lay them down at the same time.

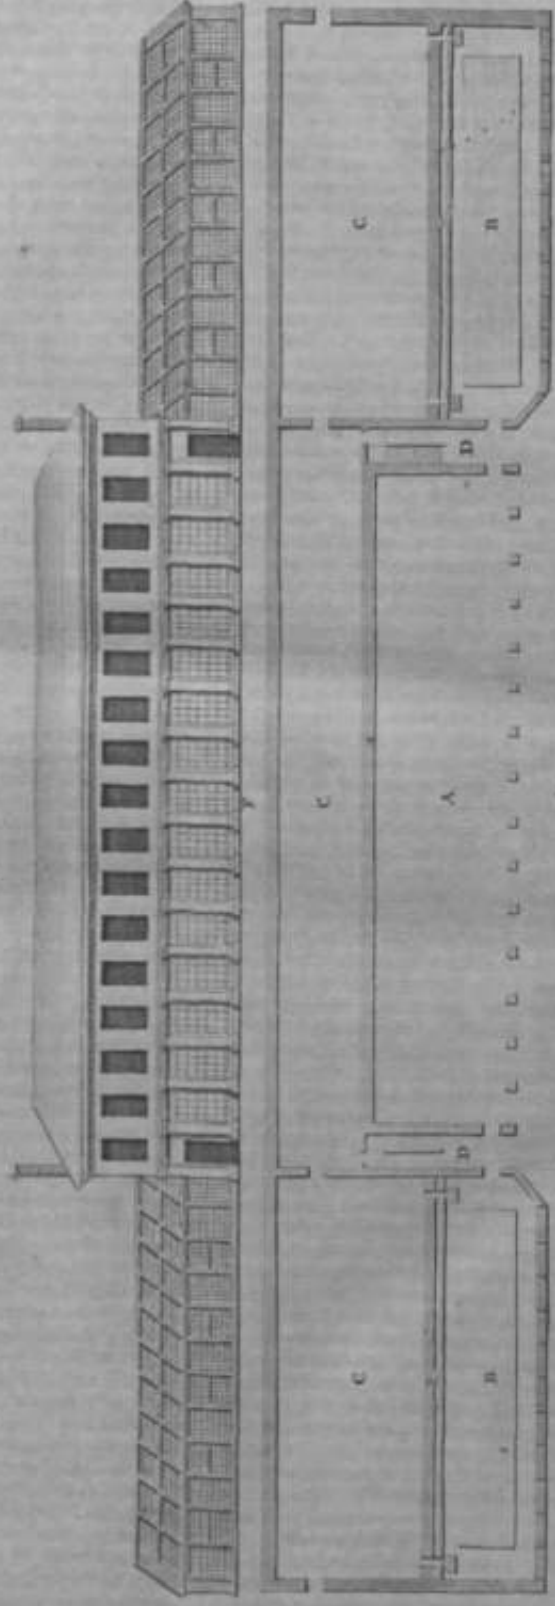

In order to deftro* worms that fpoil the beaury of Gravel, or Grass-walks, some recommended the watering them well with water, in which Walnut-tree leaves have been steeped, and made very bitter, especially those places most annoyed with them; and this they say, as soon as it reaches them, will make them come out hastily, so that they may be gathered; but if, in the first laying of the walks, there is a good bed of lime rubbish laid in the bottom, it is the most effectual method to keep out the worms, for they do not care to harbour near lime.

GREENHOUSE, or Conservatory.

As of late years there have been great quantities of curious exotic plants introduced into the English gardens, by the "iiiiiber of i. ren-houses, or Conservatories, li: .re increased; and not only a greater skill in the management and ordering of these plantias increased thereby, but also a greater knowledge of the nature and contrivance of these places, so as to render them both useful and ornamental, hath been acquired, and since there are many particulars to be observed in the construction of these houses, whereby they will be greatly improved, I thought it necessary not only to give the best instructions for this I was capable of, but also to give a design of one in the manner I would ciuue m erect it, upon the auocxeff cepp- . plant.

Plan of the Green-house.

- A. The ground-plan of the green-house.
- B. B. The ground-plan of the two Stoves.
- C. C. The Stoves behind the Green-house and Stoves.
- D. D. The passages of communication between the Green-house and Stoves where the Stairs are placed which lead to the Stoves over the Green-house.
- E. E. The Section of the Stoves in the back of the Stoves.
- F. F. The upright of the green-house and Stoves.

J. H. M. S. S. S.

As to the length of these houses, that proportion should be to the number of plants they are to contain, or the faculty of the owner, but their depth should never be greater than their height in the clear, which in small, or middle houses, may be six, eight, or ten feet, but for large ones, from twenty to twenty-four feet, is a good proportion; for if the house is long, and too narrow, it will have a cold within and without, nor

will it be proper to plant, if proper room be allowed on the back side of the house, and on the back side of the house which the plants are placed, and on the other hand, if the depth of the Green-house is more than twenty-four feet, there must be more rows of plants placed to fill the house, than can with convenience be reached in weeding and dressing; nor are houses of too great depth in proper for keeping of plants, as those of a moderate size.

The windows in a Green-house should be at least four and a half above the pavement, to within the front (lioultl Micn; from *br. of a cornice round the building, over the heads of the windows. As it is necessary to have these windows long, it will be impossible to make them in proportion as to their breadth, for if in the largest buildings the frames are more than seven, or seven feet and a half up and down, it is to be made it very difficult for one person to perform besides, their weight will occasion their frames to sink. It is also another inconvenience in having the windows too broad, which is that of being proper (hutters > them, in fidi a manner as ... they may fall back close to the piers, for as not ... be inwntm ... whieti open ...

... of the rays of light from reaching the plants. The piers between these windows should be as narrow as possible to support the building, for which reason I should think to have them of stone, or of hard well-burnt bricks; for if they are built with fine rubbed bricks, these are generally so soft, that the piers will require to be made thicker, and the building will be less strong, especially if there are any rooms over the Green-house, which a what I would always advise, as being of great use to keep the frost out in very hard winters. If they are made of stone, I would advise them to be two feet and a half in diameter, worked as columns cylindrical, whereby the rays of the sun will not be taken off, or obstructed by the corners of the piers, which it would be if they were square; but if they are built with bricks, it will be necessary to make them three feet in front, otherwise they will be too weak to support the building; therefore I would also advise to be sloped off towards the inside to admit the sun.

At the back of the Green-house there may be erected a house for mews, and for many other purposes, which will be extremely useful, and will also prevent the frost from entering the house on the back side, so that the wall between these need not be more than two bricks and a half in thickness, whereas were it quite exposed behind, it should be at least three bricks, or three and a half in thickness; and by this contrivance, if you are willing to make a handsome building, and to have a noble room over the Green-house, you may make the room over the mool-house, and carry up the staircase in the back, so as not to be seen in the Green-house, and hereby you may have a room twenty-five or thirty feet in width, and of a proportionable length, and under this staircase there should be a private door into the Green-house, at which the gardener may enter in hard frothy winters, when it will not be safe to open any of the glasses in the front. The floor of the Green-house, which should be laid either with Brecon Squares, Pitched Stone, or broad tiles, according to the fancy of the owner, must be raised two feet above the surface of the ground whereon the house is placed, which in dry ground will be sufficient; but if the situation is moist and springy, and thereby subject to damp, it should be raised at least three feet above the surface, and if the whole is encircled with low brick

... under the floor, it will be of great service in preventing the damp rising in winter, which are often very harmful to the plants, especially in great shades, when the air is often too cold to be admitted into the house, to take off the damp. Under the door, about one foot from the frame, I would advise a line of one foot in width, and two feet deep, to be carried the whole length of the house, which may be continued against the back wall, and carried up to proper benches adjoining to the front house, three inches over each other, by which the drafts may pass off. The simplest may be contrived at one end of the house, and the door at which the fruit is put in, so also the entrance may be contrived so open into the mool-house, so that it may be quite hid from the frost, and be in the day, and the food may be laid in the same shed, whereby it will always be ready for use.

I suppose many people will be surpris'd to see me direct the making of doors under a Green-house, which has been shew'd to be long, and by most people thought of ill consequence, as indeed they have often proved, when under the direction of mistaken managers, who have thought necessarily, whatever the weather was cold to make them tight, but however injurious doors may have been under such management, yet I have frequently look'd after they will be found of very great service; for though perhaps it may happen, that there will be no necessity to make any doors in them for two or three years together, as when the winters prove mild there will not, yet in very hard winters they will be extremely useful to keep out the frost, which cannot be effected any other way, but with great trouble, and difficulty.

Whithersoever of the windows, in front of the Green-house, you should have good frame shutters, which should be made with hinges to fold back, that they may fall back quite close to the piers, that the rays of the sun may not be obstructed thereby. These shutters need not be above six inches and a half thick, or little more when upright, which if made to joint close, will be sufficient to keep out our common frost; and when the weather is so cold as to endanger the freezing in the day, it is but making a bar in the over, which will actually prevent it; and without this contrivance it will be very troublesome, as I have often seen, where gardeners have been oblig'd to and men to shut their windows, or so that the hollow space between the shutters, and the glass work stays, which when closed, is completely sufficient to resist all the frost goes away, which if it should continue very long, the keeping the Green-house close shut up, will prove very injurious to the plants; and as it frequently happens, that we have an hour or two of the sun-shine in the middle of the day, in continued frosts, which is of great service to plants, when they can enjoy the rest thereof through the glasses, in when there is nothing more to do than to open the shutters, which may be performed in a very short time, and as soon shut again when the sun is clouded, the plants may have the benefit thereof whenever it appears; whereas, where there is so much trouble to uncover, and so much to cover again, it would take up the whole time in uncovering and shutting them up; and thereby the advantage of the sun's influence would be lost. Besides, where there is so much trouble required to keep out the frost, it will be a great chance if it be not neglected by the gardener; for if he be not as fond of preserving his plants, and as much in love with them as his master, this advice will be thought too great by him; and if he takes the pains to cover the glasses up with mats, &c. he will not care to take them away again until the weather alters, so that the plants will be shut up close during the whole continuance of the frost.

There are some people who commonly make use of peat filled with charcoal to sit in their Green-house in very severe frosts, but this is very disagreeable to the persons who attend their herbs, and I have sometimes known they have been almost suffocated therewith, and at the same time they are very injurious to the plants.

plmi; nor it. ihc trouble of tending upon ihc fmall and Uie many ha7ardi to which the ufe of ihc firrs U liable, havejuftly brought them into difufe with al fuHul perfons; and a^ ihc contrivances of fiici, am of the fires, arc bucfmail charges in their Sirl erecting, they arc much to be preferred to any other method for warming the air of the lieufr.

The wall on tht back part of the houfe fhould be either laid over with ftucco, or plaStered with mortar, and white-* afhed, for othefwift d* air in fuch ere frail wU penetrate through the walls, clpecial^ when [lie froft in attended wrii a Atoag wind, which is often the cafe in mod Seven; winter*. There arc ferae perfons who arc at [he expence of wainli:umng their Green-houfes, but whn this is done, it is proper to p (after the WJNJ with lime and hair behind ihc nemifcot, to keep out the cold *, and whert they are lined with wainfcot, they fhould be painted whije, as (ioulil the curling, and every part wiihinfiide of the houic *, for :ii reflects the rays of li^ht in • much greater quant:ty than any other colour, and is of iizul lc-vice to plants, rfpecialtj in the winter, when the huic is; pretty much dofctj, and bin a fmal ihare of light i admitted through the windows; for at fuch times I have obferved, that in ibme Green-houfes which have been painted black, or of a dark colour, the plants have call mo! of their leaves.

rWhere gern-lioufes arc built in filch places as will not admit of rootru over then), or the pertbii u unwilling to be at the expence of fi(ch buildings, there muft oe care mktn to keep out tie frofl from entering rough the roof. To prevent which it will be very proper to have a thkknfs of Rccds, Heath, or Fun, laid between the debug and ihc tiles y in the doing of which thicr tuft be tare taken in framing the iita, (b as io fupport thefc, that ihrir weight may not lie upon the ceiling, which might endanger it; for [hde fhould be laid a foot thick at leaf, Mid as ncuih as jrafTible, and Mrneci down well with Saths > prevent their riling, and iht-n covered over with a coat of lime anti hair, which will keep out the air, and alfo prevent mice and other vermin from harbouring i them, which, if left uncovered, they would certainly do. For wane of this precaution there we many Green-houfes • tilt, which will not keep out the froft i hard winters, and thii it many times attributed to the glafies in front admitting the cold, when the fault li in the roof; for where there is only the covering, either of tiles or (laces, over (he deling, every levtre iroB. will penetrate through thrm.

In this Green-houfe you fficuk have truffets, which may be moved out and into the houle, upon which you (hould tix rowi of plunks, fo «s to place the pens or tubs of plants in regular ruwi one above another, whereby the hi^cU of the pianis may be fo fitted, as not to iittrfctc with each other. The lowelt row of plants, which (houJd be the forwrtldt towardi the windows, fhould be placed about fo feet diftance, tli-it there may be a convenient brr ith left next the glafes to walk in front. aiut tie rowsot plants fhould rife gradually from the firft, in fuch a mner inerthatthc heads of the fecond row (houJd be mtireh/ ajvariced above the tirit, the ficms only being hid thereby; and at thr back fide of the houfe there (hould be allowed a fpace of at leaft five feet, -rthcconvnieny of watering the plants, as alfo to admit of a current of air roun J them, that the damp jccafioncii by the perfpiratioii of the plants, may be the better diflipated, which, by Staying pent in too clofely, often occafons i mouldineft i] on ihc tender (ho . and leaves, and when the hflufc L chafe ftup up, this dangerous vapour Li often very destructive to the plants; for which reafon alii- you fhould never crowd them too dole to each other.

Euphorbia, Torch Thistles, and other tender faculent plants, amongst Oranges, Myrtles, and other Evergreen trees; for, by an experiment which [•mde, anno I 750, I found that a Scedon placed in a Green-houfe amottg foch tr; , about daily increafed in weight, aithvHigh then ton BO WIICT givta to is the

whole linif; which increafe of weight WXM o wine to the moid tire imbibe*! from the air, which, bringV--plete with the tinnid vapours perijired from thc other plants, occaioned the lcavei to grow pale, * and in a (hort time they decayed and dropped ol', which I have often obferveri his been thecnie with nun] other fucculent plants when filacai in thofe houfes which were filled with many fort- of Evergreen trees, that required to be frequently watered.

Therefore, to avoid the inconvenience which attends the placing of" rjbuti of wry different natures in die fume houfe, it will be very proper to have two wings added to rhe main Grctn-houfrj which, if ula ed in the manner exprlFctd in the annexed plan, will greatly will (o the beauty of tl iv bnilding, and ilfo collect a greater (hare of heat. In this plan the Green-i. side is rilaredexiftly fronting the Ujuth, and oieut'tlir wings face the fouch-eaft, and the other the fouth-wd; fo that tram the time of the fun's firft ippralMC upon any part of the building, until it goes off a] night, it is conltimly reflected from one part to the other, and the LCIJ winds are all kept off from the front of the main Grten-houfe hereby; and in ilie area of this pbee you may contrive to place many or' the molt tender exotic planes, which will bear to be expufed in rhe fummer feafon -, and in the ipring, before the weather will permit you to fet out the jifonts, the beds and borders or' this area may br full of Aocmoniesj Rinunculufi;s, early Tulips, &c. whi^h will be pajt flowering, and the roots fit to tilke out of the ground by the time you carry out ihc plants, which will render this place very agreeable during thelpringfeafon, when the nowen arc blown: and here you may walk and divert yourRU" in a fuic day, when perhaps the air in TMft oihrt | of the garden will be too cold fur perfons not much usj thereto, u> ufcc pleajun: in being out of the hQufc.

In the center of this area may be contrived a fmall bafon for water, which will be very convenient for watering of plinu, and add much to the boury of the place; bides the water bring thus !; , will be fuffend by the heat which will be reflexd! from the glafes upon ir, whereby it «ll be re;;Jtred much better than raw cold water for thdc tender plants.

The two wings of the building fhould be contrived fo as to maintain plants of differing drgreei of ha: -; , which muft be effected by the firuation and extent trt' the fire-place, and the manner of conducting the flues, a particular account of which will be exhibited under the anid o(STOVES. But I would hen: obfrvr, that the wing facing the lbuth-eaft (hould always be preferred for the wirneft i; , as in :;tian being fuch, as that thr fun, upon its firft appearance in the mom- >ng, flüne* directly itpo: the glafes, which is of great lervtce in warming the i of the houfe, and adding life to the phn[5, alter having been (hut up during the long nights in the winter feafon. Thefe i-irgs being in the draught annexed, allowed fixty feet in length, may be divided in the middle by | of glafe, with glafe-doors to pifs from one t, the other. To each of thciethere flimild be afire place, with flues carried upa^ainft the back wall, through • hich the fluke (j, illdbe mniic'o . , as many tim <i the length of the houfe, as the height will admit of the numb: of flues; for the longer the fluke is in paffing, the more heat will br given [of the houfe, with a lefs quantity oi :uel, which is an article worth confideration, efpctially where fuel ii dear. By this contrivance you may keep fuch pUnti as require lit fime degree of heat in one pin of the houfe, am! hich will liinve in a much left warmth in the oilier part, but thiii will be more fully ratpUincd under the article of STOVES.

The other wing of the houfe, facing the South-weft, may illb be divided in die ti;ne unnce, and flues carried through both parts, which may be ufed according to the feafons, or the particular forts of plants which are placed therein; fo that here will be fuch difflont in the wngv cadi of which truly \x lcript up

to a different degree of warmth, which, together with the Grecn-houli^wiU be fulficient to miiituin plants from all the livcal countries of the world -, and without having ihcfc ll-icial uectrees of warmth, it will tin impofliukto pnHerve the various kind* of plants from the Gcvtta] piirts of A lica and richica, w are annually introduced into die linglifli garden for when i plants from ditiirrent countris are pbted in die lame hfufe, ionic are dellroytJror want of hex, while others are forced and (jioiled by tuo much of it; and this is often the cife in many places, where there ire Urge loMceimii of plants.

In the building thde wings, if there are not flieds running behind them their whole length, the wails lbrjuld not be left than three bricb thick; and if they are more, it will be ljetter, becaufe whic the wait are thin, and cXjvjLd to tlic open air, the cold will [(tetrac them, and when thi Erei arc mule, the heat will come out through the walk, lit that it will require a larger quantity of fuel, to mainuin a proper temperature (J! warmth in the houfe. Tie bick part of thefe boufi : having fluiiig roots, which are covered either with tiles or flanes, houkl illo be lined with Reeds, &c. uniii the evening, as it is lore directed for the Green-li'oufe, which -'li kvclj out iltc told air, and live a great xpence oi fuel j tot the dofer and Ut.c.r thefe lioules arc built, and the gliuuii of the lljpt, as ailb in front, ih' uitters, or Reeds in hard froll, ii • hls fuel • ill U" required to warm the Jioitlbfj ib that (tic firft expeticeiji building their houles properly, will be the dMMPeit, when tlie after-expence of fire is taken into conli- ration.

The ftoping glalles of thefe Louies ihuukl ht made to ilide and take off, fo that they may be drawn down more tr lefc in warm we.ither, to admit air to die plants; and the upright ghflej in front may be lb contrived, as that every ornat may open or be dixin iij>on hinges, and the ftoping glalles may be divided into two; the upper part of each fhould be covered d Co as to be drawn down like a lillie^, ib that citlitr of thrie may be ufed to admit air, in .. greater or l e6 propor- c may be occafion.

But beclde; the (. . . rriioncd, it will be p . . . ic a deep hot-bed iVape. Toth as is enm . . . raife l*g* annual* in the fpring, into which may be let pots of fuch plants as come from Carolina, Virginia, &c. while the plants are too small to plant in the open air, as alfo many other forts from Spain, &c. which require only to be freed from the violence of froft, and fhould have as much free air as poffible in mild weather, which ran IK no better effected than in one of thefe frames. litre the afles may be taken off every day when the fne weather permits, and put on every night, and when the fne weather glalles may be covered with mats, Seras, Peas-bauls, or the like, fo as to prevent the ftill from entering the pots to freeze the roots of the plants, which is all many times urefly deftroy them, though a light froft pinching the leaves or fhoots, very feldom does them much harm; if thefe pots are funk a foot or more, below the furface of the ground, they will be the better, provided the ground is dry, otherwife they fhould be built with bricks, with a curb of wood lwd round on the top of the wall, into which the gutters, the back wall of this frame may be four feet high, and two bricks and a half thick, the front two foot and a half; and the width of the inside of the frame about fix feet, and the length in proportion to the number of ljuAt-to be contained therein.

ST.

GREWIA. Lin. Gen. Plant. 474. This genus of plants was confidered by Dr. Linnæus, who gave it this name in honour of Dr. Grew, F. R. S. who published a curious book of the anatomy of plants.

The Character is, The flower hath a fmall hairy calycium, compofed of five fpear-shaped leaves, which are minorch, and spread open. The flower hath five petals of the fame form, but fmaller, and are inferted at their bafe, where is feated

a fmall yellowifh it iacob petal, teU. is thick and inward, which is ••£[oibt (nrdfT, ti. ii bettb m of ibt petals, term : by remtlijh fmaail the cat: i aiiflj g(rmc...

toritit; :bt gmm afterwarUt a fowf-temena ierry with four tllb, tmb itxkjingi iutiirftM.

This genus of jyltnts is ringed in the feveni fection of Linna:us'i twentieth dais, which indudei thofe pUnu whole iluwers have many ilimiiujoined to the ttyk, forming a colarnn of one body.

GREWIA (African) foliis ovato-lanct)lakis ft. Grewia with oval ;pcar-/bapid tcayti tohit art/ i the first sort has ixen long preferred in miny curioui garden*, both in England and 11 land, and ii • guied by Dr. Plukenet, by the tide gf Ulniifoliai bor Afric^na bacLifera, floribus purpiireii; but I Dr. Boer hi ave it MI liippoli'd to be one of i other Plum it's American pLin«, intitlcl Gui lousa Ulni folia, lure rofeo; but the diarafters of this do not at all agree with thole of the Guidonia, tla; p tpeciu of this genus being in die royal gal lra at Paris, which i i extremely different from tliis. It grow naturally at the Cape of Good Hope, from whence I liavc received the iveds, which have lucceded in r Chelca garden.

This will grow to ilie height of ten or twelve nuJ has a ftem jnd branches very like thofe of th small-leaved Elm, the Lurk being innooiii, and of th fame colour as that of Elm urticu young; the KAV ire ... to very li • tiofeof die Elm, and fall oB" i winter; the flower* arc produced fingly along th young brandies from the wing* of the leaves, whit are of a bright purple colour i ilicu- the end of July, and continue in Auguft, and the beginning of September, but are never fu- in this country.

This may be propagated from cuttings or I cuttings fhould be taken, i ult, and planted in April, before the buds fwil, for -iicy do no well after, their tinting* ihould be placed in fail] pou filled with loamy earth, and th pots fhould be plunged into a moderate bot-bed ofdooc bark, where, it" thq- are d ly watered, and in die I t of the day fhaded from the fun, they will take good root in ab'j at two months, and may th > be gr; uired TO beai the open air, into which they fhould be removed in Junr, and pbced in i : where they may warr • till autum! when they must be removed into • the grecn-houle-, tlit befi

liefon the buds tjnie out, and ihcfc will be rooted by tin (ame time the iblowin^ year, when they may be cut off from the oJ ptinn, and planted t.n:h into a f- parate pot fill' i with a lott loamy fail.

The bdt time to ; move or transplant this plant is, either in tlic (p ;ure the bu to fell, or in autumn, when the leaves begin to drop; for in fummer, when I c plants *re in faff Uaf, it will be very unproper to difturb them.

In winter thefe plants fhould be planted in • be green-houfe, but they are too tender to live abroad in Eng- land; but they fhould have as much free air as poffible in mild weather, for they only require to be protected from froft, and after their leaves are fallen, they will require very moderate watering; but in fummer they fhould be continually watered three or four times a week in dry weather, and placed in a fhaded fituation, with other hairy green-houfe plants, where they will add to the variety.

The feeds of the fecond fort: were fe-t me by i, mil. Richard, gardner to France at Mar- Sicut.

faller, which Btre brought from Senegal in Africa, by Monf. Admi. in this country with a shrubby bark 6 or fix feet high, lending out many lateral branches, which are covered with a brown hairy bark, and pruned with oval [pear-shaped] leaves, about two inches long, and one inch and a quarter broad in the middle, having fevct:il tranfverfc vcitw from the midrib to the fides, ivhere they are Gwed ; theft are :•aged alternately in the branches, hiving very short foot-ftalks, which continue in verdure through the year; the plants are yo^ngt fo have not as yet Rowel in England, therefore 1 cm give no further account of them.

This fort is tender, fo will not live through the winter in England, which it is placed in 4 warm stove; nor do those plants thrive well, which are placed on (helve; in the dry ivfive; therefore the only way to have them succeed, is to place them in the bark-bed in the tan-stove, where the plants have grown very well for some years. In furnishing these plants require a good share of free air to be admitted to them, and should have water thrice or four times a week in warm weather; but in winter they must be kept very watered, and require to be kept warm,

r. Lin. Gen. 659. Androvy Pear.

The CHARACTERS are,

The capsule is ovate, pale, of one leaf, cut into four equal segments; ikefcujtr has four kernels, the main part of the fruit is inserted into the capsule, and is defrried green when ripe, having nejt?; erxriud ha I

printed title

This genus of plants is ranged in the first order of Linnæus's thirteenth class, entitled Polyantha Vlonogyntia, the flower having many stamens and one style.

We know but one Species of this genus, viz.

- 1. GRONOVIA (Cassia). Lin. Sp. 771. f.chny Pear, Palcaudice non ramosa, foliis longifolius, flore tetrapetalo pallide luteo, fructu ex alboru truncu prodeunte. Sloan. Hist. Jam. 2. p. 122.

This plant grows naturally in Jamaica, and in many other warm parts of America, where it rises with a fruit undivided stem about twenty feet high, having a gray bark, marked with the veins of tin (often leaves, the top of the stem is greenish with leaves near two feet long and six inches broad. The fruit is without rib with five veins, and are of a lucid green; the lower part come out from the stem below the fruit, having no foot-stalk, in some places oval, and in others triangular, each having four thick yellow petals, and a great number of stamens which are fixed to the circumference of the flower; the pistil is included in the capsule, which afterward becomes a large oval fruit, which is a large pointed nut.

The fruit of this tree is by the Spaniards in the West-Indie pickled and sent to old Spain as presents, who eat them as Mango's, and some say the ripe fruit is eaten as a nut.

The fruit is planted by planting of the young, which should be put into the ground (bon ar) the fruit is gathered, and the plants must be constantly kept in the shade (in the stove, otherwise it will not thrive in this country.

GRONOVIA, Mart. Cent. ; Lin. Gen. Plant. 771. The name of this genus was given by the late Dr. Houllin, in honour of Dr. Gronovia, a learned botanist at Leyden.

The CHARACTERS are,

The flower hath a permanent envelope of one leaf, which is colored, and cut into the middle into four parts. It hath five small petals which are fixed to the centre of the capsule, and five hairy stamens the length of the petals, which are inserted into the capsule, and are placed alternately with the petals, terminated by two smaller which are oval. The germen is situated under the flower, fig-

psrtng s Jbnder Jyilt which is longer than the stem, crowned with a obtuse fruit a rousdijh-citmatd fruit a hrg < reuuiii/i feed.

This genus of plants is ranged in the first section of Linnæus's fifth class, entitled Penanthea Monogyntia, which contains those plants whose flowers have five stamens and one style.

We know but one Species of this genus, viz.

- GHONOVU (Sanidru). Mart. Cent. 2. Gronovia (Sanidru) lap pace; parrinca it-ndi. Houll. Catalogue of the Plants of the West-Indies.

This plant was discovered by the late Dr. Houllin at La Vera Cruz, from whence he lent the seeds to the late Mr. Knapp, which have succeeded in many gardens. It is an annual plant, which is like the Cucurbit, which are covered with broad green leaves, in the shape of the Vine; but the leaves are covered with small spines on both sides, which sting like the nettle; the branches have many tendrils or runners, by which they fall themselves to whatever plants they grow near, and will rise to the height of six or eight feet (cut; the flowers are of a yellow colour, and make a great appearance.

This being a very tender plant, must be raised on a hot-bed early in the spring, and afterward placed in the brick-stove, and treated in the same way as the Momordica; with proper management it will produce ripe fruit, but this having neither use or beauty, is rarely cultivated; it is used but in botanic gardens for the sake of variety.

GRO. SSUL. KIA. Km: Meth. Pbiir. 14°, Toutii. Lin. Gen. Pl. 401. Ribes. Lin. Gen. Pl. 401. Gro. SSUL. KIA. Km: Meth. Pbiir. 14°, Toutii.

of these trees more; whrtas in the irregular plantations, the t a berveue, and obtruiff the direct rays of the sun. When a person who is to lay out a garden, is 1b lappy as to mix with large full grown trees upon the spot, they should remain inviolate. ir' poffible v for it will be better to put up with many inconve... than to destroy them, which will ... in age to retrieve; so that nothing butthat oi'uftcudiny the habitations, by being so near as to occasion great 'Jjmsps or obfniffing fine vie-... should tempt the cutting Of' t lie ill ilown.

Mol' of the Groves which have been planted either in England or in [those cclrl'i. and gardens of France, are on a few regular lines of trees; many of which are avrn-Jcs ID the habitation, or lead to the I bttld- ing, or ...; but tilde do ntm appear fu g and, as these which have been made in wood; wlinv the trees have grown accidentally, and I at irregui. distances; and where the trees have large I reading heads, and are left at such a distance, as to permit the Groves to grow under them, then they afford the greatest pleasure: for nothing is more I We liim fine spreading trees with large stems, growing through Groves, especially if the Groves is well kept a good verdure; besides, most of these i lnted Groves have generally a gravel-walk n LJC in a Jlnic line between iJirm,

which greatly extends the light of persons who have true taste; therefore whenever a gravel-walk is absolutely necessary to a < dirriell tinough these Groves, it will be much better to t .ilt it about, according as the trees naturally stand, than to arrange regularly; but dry walks under large trees are not so useful as in open places, because the dropping of the trees will render these walks uilrb alter rjin, for a considerable time. Close Groves have frequently large trees standing in them, but the ground is filled under them ivicii fruite, or under-wood, so that the walks which are made in them are private, and secured from winds, whereby they are rendered agreeable for walking, at such times when the air is too violent or cold for walking in the more exposed parts of the garden. These are often contrived so as to bound th< open Groves, and frequently to hide the walls, or other inclosures of the garden; and when they are properly laid out, with dry walks winding through them, and on the sides of these trees-jimbling shrubs and flowers irregularly planted, they have a charming effect; for have a person may walk in private, sheltered from the inclemency of mild or violent winds, and enjoy the greater sweet of the agreeable kingdom: therefore where it can be admitted, if they are continued round the whole inclosure of the garden, there will be a much greater extent of walk; and these shrubs will appear to the best advantage, when they are not to be pruned.

These close Groves are by the French termed bosquets, from the Italian word bosquino, which signifies a little wood, and in most of the French gardens there are many of them planted; but these are reduced to regular figures, as oval, triangles, squares, and lines; which have neither the beauty or use which those have that are made irregularly, and whose walks are not that way on each side by hedges, which prevents the eye from seeing the squares; and these want the fragrance of the shrubs and flowers, which are the great delight of these private walks: add to this, the keeping of the hedges in good order is attended with a great expence, which is a capital thing to be considered in the making of a garden.

The bark and wood of this tree are much of the same nature, only the wood is accounted better; they are used in diet-drinks to purify and cleanse the blood, and to excite sweating; they are esteemed good for the gout and dropsy, the King's evil, and particularly for the French pox. The gum or resin, which is black, flaming, and brittle, and when dissolved, of a greenish white colour, of its aromatic smell, and pungent taste, is famous for cathartic, and a good purge in rheumatic cases, in the quantity of two scruples diluted with the yolk of an egg, and given in a convenient vehicle.

The wood of this tree is so hard as to break the tools in splitting them, so they are seldom cut down for fire-wood, being difficult to burn; but the wood is of great use to the sugar-planners, for making of wheels and craps for the sugar-mills, &c. It is also frequently brought to Europe, and wrought into bowls, and other vessels are made of the wood.

This tree can only be propagated by seeds, which must be procured from the countries where it naturally grows; these must be fresh, where in they will not grow, when they arrive, they should be sown in pots filled with light earth, and plunged into a good herb-bed; if the seeds are good, and the land is warm they are planted in of a proper temperature of heat, the plants will appear in six weeks by one month's time, and in six weeks will grow so big as to be of strength enough more

for transplanting them they should be cut full; rafen uuti.

the fresh ones, as in to preserve these roots as possible, and each planted in separate small pots filled with light earth, and plunged into a new hot-bed of tan, where they must be shaded from the sun till they have taken their root; then they must be treated in the same manner as other tender exotic plants from warm countries, admitting a large quantity of water to them when the weather is warm.

to be frequently refreshed with water in warm weather, but it must be given them with caution, for too much wet will inevitably destroy them. While the plants are young, they may be kept in a frame, but in the autumn they must be removed into the bark-ftovi, Mid plunged into the hot-bed of tan, where they liiukf l'oihihily rma and must be treated in the same manner as other trucker plants, be careful not to give them too much water in the winter, when it is very prejudicial to them, and in fismmr ilicj' fl; should have a large share of free air admitted to die in c the plants will thrive (low growth in their own country, is cannot be expected to msfcegr-

The leaves are many im: all leaves placed along the midrib by pairs, which are rounded and obtuse at their ends, but narrow at their bases; they are of the same form as those of the former kind, but of a darker green colour; the flowers are produced in loose clusters towards the ends of the branches, and are very large and showy.

The flowers are produced in loose clusters towards the ends of the branches, and are very large and showy. The fruit is a large, round, fleshy berry, which is very juicy and sweet.

from whence the seeds were brought to England. It is a native country plant to the height of twenty-five or thirty feet, with a flowing form, covered with a smooth bark, which in the young branches is green, but on the trunk it is of an Ash-colour; the roots grow knotted, and very thick. This, when young, is kneaded and used by the inhabitants in their country as a Liniment, having much the same efficacy; the branches are furnished with decomposed winged leaves; those which are situated at the base have but three leaves, but above the leaves are branched out into several divisions, which are again divided into smaller, having each two or six pair of oval lobes, terminated odd one; they are of a light green, and a little hoary on their under side. The flowers are produced in the bunches; the side of the branches; they are composed of an unequal number of petals, from five to ten; they have ten short stamens surrounding the germs, which afterward turns in a long taper pod, including several angular seeds, covered with a thin membrane. Their taste is like the sweet woodroot.

These five sorts are natives of warm countries, so will not live through the winter in England, unless they are placed in a warm flow, and the pots plunged into the hot-bed. They are propagated by seeds, but those of the two last sorts are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the hot-bed, they will not come up. The seeds of the first sort (ivtra, dity will remain years in the ground without vegetating; when they do come up, they will be fit to transplant in a fiun time; then they should be each transplanted into a small pot filled with light earth, and plunged into a moderate hooded of tanner bark, shading them till they have taken fresh root; then they must be treated in the same manner as other tender exotic plants, giving them a large share of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they must be removed into the back-stove and plunged into the hot bed, where they will make great progress, provided they have not too much water, especially during the winter season, for these plants are very impatient of moisture in cold weather.

The fourth sort requires the same treatment as those before-mentioned, but the seeds will grow without being steeped in water; and the plants are with difficulty shifted from one pot to another, for their roots are large, fleshy, and have but few fibres, so that unless great care is taken, all the earth will fall away from them, which often causes their stalks to decay almost to the root, and sometimes occasions the loss of the plants. This plant must be watered sparingly at all times, but particularly in the winter season, and will cause them to rot in a short time.

The fifth sort grows naturally in Canada, from whence the plants were brought to Paris, whence it has been long years cultivated; but about fourteen years past, it was first brought to England. This, in the country where it naturally grows, rises with an erect stem to the height of thirty feet or more, dividing into many branches, which are covered with a thin ash-coloured bark very smooth, and furnished with large decomposed winged leaves which are of the oval shape, very smooth and shiny, but are ranged alternate on the middle; these fall off in the autumn, and new ones come out late in the spring.

There are male and female of this sort in different plants, as their bark was at first observed in any of the English gardens; so I can give no farther account of them, but of the first, having never seen any of them. This sort here sinned in the year 1703, and if sown late by seed, it is propagated by cutting off some of the branches, which will send them to their upward, so may be taken from the old root, and placed in pots, where the plant may be multiplied, as by breakers from the root. It requires a warm soil, and the soil.

This plant was first named by Dr. Turner, in the honour of Dr. Gundelshamer, who found it in his travels in company with Dr. Tournefort in the Levant. The CHANACALERIA, It has an upright slender form, composed of many hermaphrodite flowers, which are supported by water. They have but one petal which is white at the bottom, and falls off at the top, where it is joined to the stem, forming a long, thin, fleshy peduncle, terminated by long cylindrical germs. The stem grows in clusters at the bottom of the flower, covered by small leaves, supporting a slender style which is longer than the petals, terminated by two roundish germs. The germs afterward become a roundish fruit, just lodged in the common receptacle, which is annual, and the seeds are separated by a fleshy skin.

This genus of plants is by Tournefort referred to his twelfth class, which contains the herbs with fleshy flowers. Dr. Linnæus ranges it in the fifth section of his nineteenth class, entitled Symplocia Polygamia corymbata, which includes those plants whose flowers have a common empalement, and each of whose flowers are included in another.

We have but one distinct Species of this genus at present in England, viz. GERANIUM. Lin. Sp. Plant. 474. There is no English title to this plant, but there are two varieties of it mentioned by Tournefort, which are supposed to be the same seeds, as they were found growing promiscuously together. These are, 1. GERANIUM (Toursforti) Otophila acutula aculeati folio, floribus incanis purpureis, capsis rotundis lanuginosis obtusis. TOURN. C. 31. *Geranium* with prickly leaf, several leaves, long purple flowers, and a round covered seed, a scarcely a nutlet.

2. GERANIUM (Galabri) Otophila, acutula aculeati folio, capsis pallide. TOURN. C. 31. *Geranium* with a prickly leaf, several leaves, and a smooth seed. This plant was discovered by Dr. Gundelshamer, in company with Tournefort, near Harboun in Armenia, but has since been found growing naturally in several places in the Levant, where it is generally found in dry, rocky land. The stalk of this plant seldom rises more than a foot and a half high; the under leaves are long, narrow, and fringed on their edges, their teeth ending in a spine; the other leaves are broader, which are irregularly curled to the middle, and armed at the points with sharp prickles; the stalk divides upward into several branches, which are armed with leaves of the same form, but are narrower; and each is terminated by a conical head of flowers, resembling those of Fuller's Thistle, being surrounded at the base by a circle of long, narrow, prickly leaves; these heads are composed of many hermaphrodite flowers, which are shut up in the scales, each having an empalement, and a group with five stamens surrounding it; but there are few of the seeds which rises perfectly in each head; in the natural places of its growth. If rain happens at the time when the plants are in flower, the germs rot, which is the case with several other of these plants whose flowers are collected into heads.

These plants are propagated by seed, which should be sown the beginning of March, in a warm dry border of earth, not too rich, in the place where the plants are designed to remain. When the plants come up, they must be carefully cleared from weeds, as they grow large, they should be thinned, leaving the plants which are designed to remain, about two feet distant, that they may have room to grow. After this there is no other culture required, but to keep them clear from weeds, and if the soil should prove severe in winter, the plants should be covered with straw or Peat-bark to protect them, but this covering must be taken off in mild weather; in one year they will produce their flowers, when they will make a fine appearance in a garden; when they come in the pleasy garden. They bloom in May, and the plants lose their bark, and leaves, in autumn, but they soon will be ready for the year.

GUNDELSHAMER. Tournefort, C. 31. Tab. 166. Lin. Gen. Plant. 474. Hæussl. Vahl. A. Rep. Scind. 1774.

GYPHOPHYLA. Lin. Gen. Plant. 498. We have no English title for this genus.

The CHARACTERS are, The flower has a permanent, angular, bell-shaped envelope, cut into five parts at the top. It hath five oval three parted, white broad open, and two oval shaped divisions, terminated by straight points. In the center is situated a tubular germ, supporting two slender styles, crowned by single stigmas. The perianth afterwards becomes a tubular corolla with six cells, opening with five valves, lined with small roundish seeds.

This genus of plants is ranged in the second section of Linnæus's tenth class, which includes those plants whose flowers have ten the stamens and two styles.

The Species are,

1. GYPHOPHYLA (Agrostoides) foliis multicaulis recurvatis, floribus aggregatis. Lin. Sp. Plant. 498. Gypophylla with several recurved leaves, and flowers gathered in a head. Lychmus Hispanica hali folio multicaulis. Tournef. Inst. R. H. 171. Spanish Lychnis with a Glasswort leaf and many flowers.

2. GYPHOPHYLA (Pulsatilla) foliis lanceolatis linearibus, orbiculatis truncatis, levibus obtusis secundis. Lin. Sp. Plant. 497. Gypophylla with narrow spear-shaped leaves, having three four eight, and smooth orbiculate leaves in clusters. Scapania cruce simpliciter, foliis linearibus ex alio foliolum concavis truncatis. Hort. Cliff. 166. Scapania with a single stalk, very narrow leaves, coming out in clusters from the wings of the stalk.

3. GYPHOPHYLA (Pulsatilla) foliis lanceolatis levibus, cuspidatis distichis, stipulis cordatis campanulatis longioribus. Lin. Sp. Plant. App. 1192. Gypophylla with smooth spear-shaped leaves, stipuled stalks, and the petals longer than the germ, which is bell-shaped.

4. GYPHOPHYLA (Pulsatilla) foliis ovato-lanceolatis, lemiamplexicaulis. Lin. Sp. Plant. 498. Gypophylla with oval spear-shaped leaves, half embracing the stalks. Lychmus Orientalis, leporum folio & facie, flore parvo & multiplo. Tournef. Cor. 41. Eastern Lychnis with the leaf and appearance of Scapania, having many small flowers.

5. GYPHOPHYLA (Pulsatilla) foliis lanceolatis levibus, floribus dichotomis cuspidatis revolutis. Lin. Sp. Plant. 497. Gypophylla with rough spear-shaped leaves, male and female in different parts, and the petals of the flowers recurved. Alina frutescens caryophylli folio, flore parvo albo. Geopb. Shewby's Chelidonium with a Glasswort leaf, and a small white flower.

The first sort grows naturally in the south of Spain, and Italy, upon the mountains. The second hath a perennial root, from which arise many narrow leaves

ending in acute points, which are recurved; the stalks rise about a foot high, garnished with narrower leaves placed opposite, and at some of the joints there are smaller leaves growing from the stalks in clusters; the upper part of the stalk divides into smaller branches, each being terminated by a choice bunch of small white flowers. These appear in July, and are scarce. It is by Innull ovd caput lra, Ijllt with six seeds.

1 EL keond for: i: hJicwliJt like tin: firV, but the leaves are much narrower, and almost three corners. cJi tfev are pitted in du lra, which come out from the side of the stalk; the bunches of the flowers are smaller, and not so closely joined. Tjiii hjtti a perennal root, and grows naturally upon the Helvetian mountains.

The third sort is in j^arciinJronr, from wliarharife smooth spear-shaped leaves in clusters; thieUk are near a foot long, but are purple on the ground, the flowers have a purple corolla, and the stamens much longer than the petals of the flower. This flowers in June and July, and the seeds ripen in autumn.

The fourth sort grows naturally in the Levant, and also in Spain. It hath a thick root, which strikes deep in the ground, leaving up several thick stalks, which rise near two feet high, garnished with several spear-shaped leaves, the upper part of the stalk divides into many smaller branches, which are terminated with loose bunches of small white flowers. Theft O[ti in Julf, and [lrc feeds ripen in autumn.

The fifth sort grows naturally in Siberia and Tartary, the seeds of it writ me from t'crerfmrgh. It hath a perennial root, from which arise many bunching stalks a foot and a half high, garnished with narrow smooth pointed leaves, impeded like thole of Gilliflowers; at the top of the stalks are produced loose clusters of very small white flowers, which appear at the same time with the first sort, and the seeds ripen in the autumn.

These plants have no great use, so are rarely cultivated; but in botanic gardens for the sake of variety.

They are propagated by Tsets, which (should be ibwn in a bed of light earth, and when the plants are fit to remove, they may be transplanted into the garden where they are designed to remain, and will flourish without other culture but to keep them clear from weeds; for the roots will continue to live many years, and produce flowers and seeds.

green-house, or in a dry place, which may be contrived to
as to be covered with glass in winter, in which the
roots, with i the African Garden's, **Irax's**, Persian
Cyclamens, &c. are planted in the full ground, they
will liowcr nmre constantly, and the foot stalks will
rife much higher than thole kept in pots.

The third fort is also **i** native of the Cape of Good
1 lope, t'mm when it was first brought to Holland,
where it ha: been propagated and dispersed over Eu-
rope; this may be **;**
the bed lin;it; **ibr** :!<• **i** in the spring, before the plants
puccut new folks, w which is also a right time to shift
and new-poc them **•** but as the roots do not multiply
very fast: in ofBets, the h; it may be to propagate them
from feets, which they **•** plentifully in England,
these should be lown soon after they are ripe, in pots
lilhd with light cirrh, and **i** put in the stove till rhe
winter; **il' j** these pots are planted into the tub-bed in
the ha it-stove, in the vacancies between the plants,
the ean'i will be **•** kept warm, and will not dry so fast,
as when they are plioed in a dry stove, so the seeds
will be sooner prepared to vegetate; in the spring the
puts; may be taken out of the stove, and planted into
a tub-bed, which will bring up the plants; these must
have **•** admitted to them every day in mild weather,
tn prt near their drawing up weak; and when they
are fit to remove, they may be each planted in a sepa-
rate small pot filled with light earth, and plunged into
the h it-bed again, to promote their taking new root;
then they must be gradually hardened, and alternated
may be removed into the dry stove, where they should
constantly remain, otherwise the plants will not thrive
and flower in this country. In the winter-season they
must not have too much wi t, for as dense roots are
fi-Oiy and fuccuint, sp tl,<• are apt to rot with
moisture. In the summCT **I** they must have a large
riare nf air in M tern weather, and require to be fre-
quently watered, especially during the time of their
blossoming.

nia, which incluJes thofe pi into whole flowers have
ten stamens and one style.

We has cl...
HÆMATOXYLUM (*Campechana*), Hort. Cliff. 161.
Linæus, *Systema Campechianum*, species quod-
dam. SloaruCnt, Jam 113. *Campechy Wood*.

This tree grows naturally in the Bay of Campechy,
at Honduras, and other parts of the Spanish West-
Indies, where it rises from six feet to twenty-four feet
hij'h. The i:ms are generally crooked, and very
deiorntd, **jtiui** are seldom thicker than a man's thigh.
The branches come out on every side; they are
crooked, irregular, and armed with thorns sharp,
garnished with winged leaves, composed of three or
four i air of lobes, which are obtuse, and indented at
the to]. The flowers come out in a racemus from the
wings of the leaves, standing erect; they are of a
pale yellowish colour, with a purple empalement,
and **1 -** succeeded by flat oblong pods, each containing
two or three kidney-shaped seeds.

The wood of this tree is brought to Europe, where it is used for cycling pumps, and for the best blacks, as it is a valuable commodity. The Spaniards, who claim a right to the possession of this plant, where it naturally grows, are for excluding all other countries from carrying of the wood, which has occasioned many disputes with their neighbours, but particularly with the English; this it is to be hoped will soon be over, as there are some of the planters in Jamaica, and the other Islands in America, belonging to the crown of Great-Britain, who have propagated this tree in its great plenty, so as to have hopes of supplying the demand for this wood in Britain in a very few years; for the trees grow so fast there, as to be fit for use in ten or twelve years after they are first planted, and as they produce great plenty of seeds in the British colonies, so that seeds scattering about, the plants come up in all the neighbouring lands, therefore 'till faun belik, an indigenous plant of the country.

Some of the planters in Jamaica have inclosed their estates with hedges formed of these trees, which are very strong and durable, but where the hedges are cut, it will greatly retard the growth of the trees, so that those who propose to make an advantage by the propagation of this wood, should sow the seeds upon beams of wood, which may be used for growing of sugar, and permit all their branches to remain, wnjch

It will be of great use in augmenting the bulk of these Jtoms; and if, while die JILLs are young, they are kept free from weeds, &c. it will be of great advantage in promoting their growth. I have been informed by some of the planters in Jamaica, that they have had some plants of this sort upon their estates, so that it requires but few seeds to raise a supply of this wood, sufficient to answer all the demands for it.

This plant is preserved in some curious gardens in England, for the sake of variety. The seeds are frequently brought from America, which, if fresh, readily grow when sown upon a good barbed seed; and if the plants are kept in a moderate heat, they will grow to be upward of a foot high the same year, and while the plants are young, they are generally well furnished with leaves, but afterwards they make but little progress, and are frequently but thinly clothed with leaves. These plants are very

ly kriji in 'e bark-th...; where, if they are kept watered, and the roots are kept in a good degree of moisture, the plants may be preserved well. Inhere are some of the plants now in the garden, which are of the first J-gji, and Mr Inwiig a

HALESTIA. Lin. Gen. Plant. 596.

The C... The flower hath a small permanent envelope of one leaf, inclosed in four parts; it hath a bell-shaped feeding funnel of one part, divided at the throat into four lobes, and from thence is formed a narrow tube, which is pink, terminated by a long oval funnel; the corolla is situated below, is white, supporting a smaller style longer than the petal, crowned by a single stigma; the germen afterwards becomes a thick nut, surrounded at both ends, having four angles, with two cells, inclosing a single seed in each. This genus of plants is ranged in the first section of Linnæus's eleventh class, inclosed Diocleandria Monogynia, the flower having twelve stamens and one style.

- The SPECIES are,
- 1. **HALESTIA (Tropæura)** foliis lanceolatis ovatis, petiolis glaberrimis. Lin. Sp. 654. *Halestia* with oval leaf-shaped leaves, whose petioles are glabrous. Præter Petioli foliis serratis, floribus monopetalis albis campaniformibus, fructu triloculari. Cassin. Hist. Carol. i. p. 224.
- 2. **Halestia (Diptera)** foliis ovatis, petiolis lobatis. Lin. Sp. 656. *Halestia* with oval leaves having lobed petioles.

fmfulr. The seeds of plants received by the learned and reverend Doctor Hales, of Toddington, near Hampton Court.

Both the trees grow naturally in both Carolina; the first on the banks of the river, where it frequently comes up with roots three fathoms from the shore, which rise from thence to twenty feet high, sending out branches toward their tops, furnished with oval lance-shaped leaves, which in the distance the flowers are produced on the sides of the branches in clusters, from one or three to six or seven in each; they are bell-shaped, hanging downwards of one period, when, when in inclosed in four parts at the top, they are surrounded by oblong nuts, having four wings and four cells, each containing one oblong seed.

The second tree hath much resemblance to the first, the leaves are oval, and the flowers are smooth; the fruit has but two cells.

These plants are propagated by seeds, when they can be procured fresh from the places of their natural growth. They should be sown in pots as soon as the seeds arrive, plunging the pots into the ground, in a situation where they may have only the morning sun. The seeds often require a year in the ground, therefore the earth in the pots should not be disturbed, until there is no probability of the seed growing. When the plants appear, they should be increased from the fan, and frequently, but not too plentifully watered, for while the plants are young, much moisture will rot their stamens. The following autumn, the pots should be placed in a common frame, where they may enjoy the sun in a mild weather, and be increased from root. The spring following, before the plants begin to shoot, they should be each put into a separate small pot, plunging them in a frame, where they should be shaded from sun, and in the summer placed in a shady situation, screening them from the sun, and the spring following they may be removed out of the pots, and placed in the full ground where they are designed to remain.

HALICACABUS PEREGRINA. See **CALYPTROGYNUS.**
HALIMUS. See **AMARANTUS.**
HALLERIA. Lin. Gen. Plant. 679. Caprifoliaceæ. Benth. Bot. Ind. alt. 2. p. 328. *Artemisia* by *Halleriæ*. The CHARACTER is,

The flower hath a permanent envelope of one leaf, which is cut into three parts at the top, the upper part being much broader than the other. It hath one petal of the growing kind. The bottom of the tube is rounded. The lobes are fleshy and reflexed, the bract is oval and oblique, cut into four segments, the upper being longer than the other, and is blunt, with one nectary at the tip; the tube falls out in four parts, and remains, the lower is very fast and white. It hath four stamens, which are long, and have longer than the other, terminated by two funnels. In the bottom of the tube is situated an oval germen, with a style longer than the funnels, terminated by a single stigma. The germen afterwards becomes a roundish berry with two cells, each containing one hard seed. This genus of plants is ranged in the second section of Linnæus's fourth class, inclosed Dielyniæ Angiosperma, which includes the plants with a flower, which have two long and two shorter stamens, and the seeds are inclosed in a capsule.

We have but one Species of this genus, viz. **HALLERIA (Lactis).** Hort. Cliff. 212. This plant has its name from Dr. Haller, who was professor of botany at Göttingen, in Germany. *Capsellidium Africanum* foliis pruinosis leviter serratis, flore subsericeo, laccis nigris. Benth. Bot. Ind. alt. 2. p. 328. *Artemisia* by *Halleriæ*, with a broad leaf finely serrated, a very red flower, and a thick berry.

The English name which I have here added, has been given to this plant by some gardeners, who observed that the shape of the flower had some resemblance to that of the Upright, or Fly Honey-suckle, and for want of an English name gave this to it; or they might take it from the Latin name, by which it was called by Dr. Boerhaave, who made it a species of *Huesyfuckle*.

This

This plant grows to the height of six or eight feet, having a woody stem, which is well furnished with brandies-, the hives oval faved L-JVC^, which are placed opposite, and commuc gfea through the year; the Bowers come out finally, and at- (if a red colour, but, being intermixed with the leaves, are not Lien untr ft they are looked after, for tin. eringty in the branches; these come out in June, s> the seeds ripen in September; the leaves are green in winter, in tin: plants make a variety in the given locale during that localbn.

It may be propagated by cuttings, which, if planted in pots filled with light earth in June, and plunged into a gentle hot-bed, will take root; the plants may be exposed in the open air, and will reinjoin: plenty of water in that season; in winter they will be housed with Myrtles, and odior hardy e*otk plants, which require a large space of air in mild weather.

This genus of plants is ranged in the first order of Linnaeus's sixth class, entitled Pentandria Monogynia, the flowers five Linn:: five (bunil it u named in honour of Monsieur de Hamelin Moncaux, member of the Academy of Sciences at Paris, and fellow of the Royal Society of London; a gentleman weU known to the learned, by the many useful books he has published.

We know but one SPECIES of this genus, viz. HAMMATA (Palm) racemosa erect. Jacq. Amer. t. HAMMATA (Palm) racemosa erect. Jacq. Amer.

HAIUWILIS (Lycium). Flac. Vir g. 139. 11- Hazel Hüzel Pilliifij Virginia nigr, uuryli fonia. luk. Aim. ig6. BUik I'irginia PifioMa will- Htzel hazel.

This plant grows naturally in North America, from the latitude of the Woods have been brought into Europe, and many of the plants have been raised in the English gardens, where they are propagated by cuttings, which are sold by the nursery gardeners. It hath a woody stem, from two to three feet high, sending out many slender branches, lined with oval leaves, indented in their edges, having great resemblance to those of the Nut, placed alternately on the branches, the bark is very in aUUm, and when the planware deftimt of leaves, the flowers come out in clusters from the joints of the branches, and sometimes appear the latter end of October, and often not till December, but are not succeeded by seeds in this country.

As the flowers of this shrub make very little appearance, it is only preferred in the gardens of the curious, more for the sake of its beauty.

This plant, propagated by cuttings, in the autumn, will take root in one year, provided they are duly watered in a dry weath; but many of the plants which are in the gardens, have been produced from seeds when carried from America; their seeds always remain a whole year in the ground, so they should be sown in pots, which may be plunged into the ground in the shady part of the garden, where they may remain all the summer, and require no other care but to keep the pots clean from weeds, and in very dry weather to water them now and then; in winter the pots may be removed to a warm place, and plunged into the ground under a warm hedge; and if the winter should prove very severe, they should have some light covering thrown over the pots, which will secure the seeds from being destroyed.

In the spring it will come up, therefore at the first growth, the pots may be removed where they may have the morning sun till eleven o'clock, and if they are duly watered in dry weather, the plants will have made good progress by autumn, when they should be transplanted, either into small pots, or in a nursery bed, where in one, or at most two years time, they will be strong enough to plant where they are designed to remain; they love a moist soil, and a shady place.

HAMELLIA. Lin. Gen. 231. X h C c T t t j arc.

The appearance of the former is small, greenish, and cut into five acute segments, the former is of one piece, having a long stalk, which when it is cut into five acute points, it has five small flowers inserted in the middle of the stalk, terminated by linear bracts the length of the stalk, and an oval germ, which lower part is tubular, supporting a slender style the length of the corolla, crowned by an ovate linear stigma: the former afterwards bears an oval serrated berry, with five cells, filled with small cylindrical seeds.

This genus of plants is ranged in the first order of Linnaeus's sixth class, entitled Pentandria Monogynia, the flowers five Linn:: five (bunil it u named in honour of Monsieur de Hamelin Moncaux, member of the Academy of Sciences at Paris, and fellow of the Royal Society of London; a gentleman weU known to the learned, by the many useful books he has published.

We know but one SPECIES of this genus, viz. HAMMATA (Palm) racemosa erect. Jacq. Amer. t. HAMMATA (Palm) racemosa erect. Jacq. Amer.

71. iismr&u with ertB ffikt: of flowers.

This plant grows naturally in America, and is found in the warm parts of America; it is brought from Paris, which were brought from Senegal by Mr. Adairton, with the title of Mortaria on the paper; and before that, I received a drawing of the plant in flower, from the late Dr. Houlston, who found it growing naturally in America, which it has since been found growing by Mr. Jacquin, who has figured it. It rises with a ligneous stalk, five or six feet high, sending out several erect branches toward the top, garnished with oval woody leaves, placed by threes round the branches, having red fleshy stalks; the flowers terminate in slender spikes; the bark is very in aUUm, and cut at their brims into live linear segments, standing erect, of a bright red colour; AKC are not succeeded by seeds in England.

This plant is propagated by seeds, when they are sown in the warm parts of America; it is brought from Paris, which were brought from Senegal by Mr. Adairton, with the title of Mortaria on the paper; and before that, I received a drawing of the plant in flower, from the late Dr. Houlston, who found it growing naturally in America, which it has since been found growing by Mr. Jacquin, who has figured it. It rises with a ligneous stalk, five or six feet high, sending out several erect branches toward the top, garnished with oval woody leaves, placed by threes round the branches, having red fleshy stalks; the flowers terminate in slender spikes; the bark is very in aUUm, and cut at their brims into live linear segments, standing erect, of a bright red colour; AKC are not succeeded by seeds in England.

As the seeds of this plant are brought to England, the plant may be propagated by cuttings, which if planted in small pots, plunged into a moderate hot-bed, and closely covered with either bell-glasses, will put out roots in about six weeks, and may then be treated in the same way as the seedling plants.

HAK M A L A. See FICUS. S E L Q U I S T I A. Lin. Gen. 241.

The CHARACTER is, It is an umbelliferous plant, whose marginal lobes are pointed at the spreading rays, they are for the most part double, the great: reticular lac. may. four leafly

leaves, the proper employment is very small, and both five
subulata, the former which is long cultivated; the latter
flowers are fruitful, but those in the disk are barren; they
have five petals, and five slender filaments longer than the
petals, terminated by exserted filaments: the undivided
germen is situated under the flower, supporting two slender
stamens, crowned by slender filaments; the germen
afterward becomes an orbicular fruit, composed of two seeds
having borders.

This genus of plants is ranged in the second or
third of Linnæus's fifth class, entitled *Peucedana*
Digyna, the flowers having five stamens and two
styles.

Its name is after Mr. Jussieu, who was the
inventor of the name.

- 1. *HEDERA HELIOPHILA* (Egyptiana). *Ann. Acad. Sci. Paris*,
1790. *Egyptian Hedera*. *Palinacæ Orientalis*, in
his elegantes insecta. *Bull. Cent.* 3. p. 16.

This plant is best preserved in England;
when the plants come up early in the spring, they
do not perfect their seeds the same year; and those
plants which sown in the autumn, seldom live through
the winter; therefore the best method to procure
good seed is to sow the seeds in pots
about the middle of August, placing the pots
where they may have the morning sun only, being
careful to water them daily, and as weeds will come
up in the pots, to take them out, and where the
plants are too dense, thin them; in October to
move the pots into a common frame, where they
may enjoy the free air in mild weather, but be screened
from frost: in the spring following, if the plants are
of the size of the pots, and planted in the
first ground, they will flower in June, and the seeds
will ripen in August.

HAWTHORN. See *MAYRUS*.

HAZEL. See *CORYLUS*.

HEDERA. *Linn. Gen. Plant.* 249. *Tournef. I. nil.*
R. H. 612, tab. 314. The Ivy-leaf.

The *Hedera* is a perennial, having a
stem which is woody in the lower parts. The
leaves are cut into five parts, and its roots are
flexible and
foetid

The germen is situated under the flower,
supporting a slender style, crowned by a single stigma. The
germen afterward becomes a globular berry with one cell,
encompassed by five or six large seeds, united by one stalk, and
situated in the disk.

This genus of plants is ranged in the fifth class of
Linnæus's fifth class, which includes those plants
whose flowers have five stamens and two or three styles.

THE SPERMATOPHYTES.

- 1. *HEDERA* (*Hedera*) *folia ovata lobulata.* *Flon. Lapp.*
95. *Ivy with oval lobed leaves.* *Hedera helix.*

- C. B. P. 305. *The Ivy.* and the *Hedera* common
Ivy. *J. B. 3. 141. Great common Ivy.*

- 2. *HEDERA* (*Convolvulus*) *folia ovata, ovata, serrata.*
Hort. Cliff. 54. *Ivy with leaves composed of five
lobes, which are round.* *Vallis cantuariensis* *Canadiana*
in Acadia. *Tournef. I. nil.* 614. *Climbing Convolvulus*
with five lobes, commonly called Virginia Creeper.

The first sort grows naturally in most parts of England,
where it meets with any neighbouring support. The
stalks will climb to it, and rise to a very great height,
sending out roots on every side, which get into the
joints of walls, or the bark of trees, and thereby are
supported; so that if there is no support near, the stalks
trail upon the ground, and when root all their length,
so that they only cover the surface, and are difficult
to eradicate; for when any small parts of the
stalks are left, they will soon spread and multiply.
While there are fixed to any support, or trail upon
the ground, their stalks are tender and flexible; but
when they have reached to the top of their support,
they become and become woody, turning themselves

into large woody stalks, and their leaves are larger,
more of an oval shape, and not divided into lobes like
the lower leaves, that is, both a different appearance,
which has occasioned some to take them for distinct
species.

In the latter part of the last century, when it was the
fashion to fill gardens with all sorts of flowered
greenery, there were many of these plants raised into
round heads, which were clipped into balls, or in form
of a cone, and as they were so easily injured by
weather, and would grow in any soil, so they
were then much esteemed; but since that
taste has been exploded, these plants are seldom
admitted into gardens, but to cover walls, or run over
grates, &c. for which purpose there is no plant so
well adapted.

There are two varieties of this, one with silver-striped
leaves, and the other with yellowish leaves on the top
of the branches; these are preserved in some gardens
for the sake of variety.

These plants are easily propagated by their trailing
branches, which when roots come their whole length,
which branches being cut off, and planted, will grow
up almost any soil or inclosure, and may be trained up
to them, or suffered to remain as climbers, to cover
walls, gates, &c.

They may also be propagated by seeds, which should
be sown soon after they are ripe, which is in the
beginning of April; if these are kept moist and covered,
they will grow the same spring, otherwise they will
remain a year in the ground; therefore few persons
trouble themselves to propagate the plants in this way,
the other being much more expeditious.

While the berries of this plant are on the
ground or upon walls, or other supports, they do
not produce any flowers, which has occasioned its
being called *fruitless*, or *barren Ivy*; but when the branches
get above their supports, they produce flowers at the
end of every shoot; these appear in September, and
are succeeded by berries, which turn black before
they are ripe, and are formed into round bunches,
which are called *myriads*, and from these the
essence of corymbin, is frequently used by botanists, is
taken.

The leaves of this plant are frequently applied to
wounds to keep them cool, and free from inflammation;
they are also used for curing of scabs, sores, and
scald heads. Mr. Jussieu, in his *Usefulness of Experi-
mental Philosophy*, commends a large dose of the
full ripe berries, as a remedy against the jaundice;
but Schroder says, they purge without and down-
ward. The gum of Ivy is viscid, but is recom-
mended by some to take spots and freckles out of the
face.

There is another species of Ivy,
which is called *Hedera Ponicæ*, by *Calpurnius*
Plinius, this grows in many of the islands of the
Archipelago, and produces yellow berries; but as I have not seen
this plant, I cannot determine if it is a distinct
species. Dr. Linnæus supplies it to be only a variety,
though he has not seen the plant; but *Tournefort*,
who gathered it in the Levant, puts it down as a dis-
tinct sort.

The second sort grows naturally in all the northern
parts of America; it was first brought to Europe
from Canada, and has been long cultivated in the
English gardens, chiefly to plant against walls, or
high buildings to cover them, which these plants will
do in a short time, for they will shoot almost twenty
feet high in one year, and will creep up to the top
of the highest building; but in the leaves fall off in
autumn, the plants make but an indifferent appear-
ance in winter, and as it is left before they come out
in the spring, they are somewhat obscured, unless it
is the full situation, where better views will not
show; for the plants will thrive in the middle of London,
and is not injured by smoke, or the cleanness of the
air, in any very proper for such situations. The stalks
of these plants put out roots, which fasten themselves

into the joint of the walk, whereby they are supported.

This may be propagated by cuttings, which if planted in KUtumn on a fhady border, will tak.; root, and by the following autumn will be 61 to plint where they are deligned to remain.

HEDE RA TERRESTRIS. See G L ECHOMA.

to Thorn So the Crab will grow much bigger than thofe of the White Thorn, fo that the Hedge will not be of equal ground; which is not near fo beautiful as ufeftil, as when the plants of a Hedge keep pace in

the growth. or Sloe, is alfo frequently planted for Hedges, and is a ftrong durable plant for that pur- pofe, rfyt e • by as it is ftrongly armed with thorns, that can le seldom care to leaze upon it, but where this is planted, the belt way is to raife the plants from the ftrout of the fruit; for all thofe which are taken from the roots of old trees, fprout, and put out fockers in fuch places from their apots, as to fpend over, and fill the neighbouring ground to a conider-

able diftance on each fide of the Hedge, ., frj the4 pleni' of fockers drawing aythenouti] occur from the o: plants (M be Hedge, they never grow to well as where there are I w or no uckcri pmjd thoJe plant. which are propagated from the ftockers fend not ibi'li, or at leaft but fparingly, therefore miy with Jittle trouble be kept dtiir : them. The belt me thud of raifing thde Hfde.> to low the flouers in the place where the Hfde is Inti; and where it Can be convcnii-ntly done, for then the plants will makr a much greater progreis, than thofe which are traififplanted-, but the objection ta • his method will arife from the difficulty of fecuring the Hfde from froi'ni the cattle; but this can have little force, when ; mull: be confidered, [hat if LIC i! the Hedge is planted, it muft be fenced for fome years, to prevent the cattle from d'roying - v cherciore the jarnc fence will do for ir whtn town, nor will thi^ requir a fence much longer than the o LIT. For the plants which ftand un- removed, w i! riakc i belter fence in G years years, than that which ii pbnted, though the plants fhould be of three or folir yen.- growth wh:n planted; which is what I have feen two or three times, where the experi- ment hjs btrn trk-d. The (boji) of this • nh ihou d be fo un cnily in Junoary, if the wearid will permit; but wu a they are kept out of the gn.unj It may, it will he proprr to mi* them wit! land, and keep them in a cuol place. The bifbes • : the black Thon are by much the btrdrf un r for making of dead Hedges, being of longer dui'ui'i, and having many thorns, neither the cattle nor the Hedge-breakers, will care to meddle with them j thefe bushes are alfo the belt to be ufil for under groui. ur they will remain found a long time when the air : excluded From them.

H E D

The Holly is sometimes planted for Hedges, and is a very durable ftrong fence; but where it is expofed, there will be great difficulty to prevent its being defroyed, otherwife it is by far the moft beautiful plant, ii being an Evergreen, will afford much better shelter to cattle in winter, than any other ;

as of Hedges, and the leaves being armed with thorns, the cattle will not rjre to bronze upon it. Anodic objection to this plant is the low grow b, ID that Hedge; plant with this planr, rctquire to be fenced a much longer time than moft others. This is a reafon which muft be admitted, to prevent this being generally prafticed; but in fuch grounds as be contiguous to, or in fight of gentlen

houl good (ifrv! . hen they ar

the Spring of the year, when die il

it unpleasant to walk abroad in expofed places, thefe Hedges will afford good fiicler, A tiitj^l will

one year before fey lie luu: by which method they will be j

The way of doing this is, to gather the berries about Christmas (which is the time they are usually ripe,) and put them into large flower-pots, mixing fome fand with them; then dig holes in the ground, into which the pots muft be funk, covering them over with earth about ten inches thick; in this place they may remain till the following Octobr, when the Hedge is intended

up, and low in the place where the Hedge is intended. The ground for this Hedge fhould be well trenched, and cleared from the roots of all bad weeds, bushes, trees, &c. Then two drills fhould be made at about a foot diftance from each other, and about two inches deep, into which the feeds fhould be fow- bered pretty clofe, left none fhould fail, for it is bet- ter to have too many plants come up, than to want.

The reafon of my advifing two drills is, that the Hedge may be stuck to the bottom, which is a fup- pofe row rarely happens, efpecially if there is not great care taken of them in the beginning. When the plants come up, they muft be carefully weeded, for if the

weds

H E D

weeds are permitted to grow among them, they will soon destroy them, or weaken them so much, that they will not recover [their strength in a long time. This should be commonly observed, by every person who is desirous to have good Hedges of either sort, for when the weeds are suffered to grow near the plants, they will rob them of a great part of the nourishment they are capable of receiving, and will also prevent their putting out flowers, which will occasion the bottom of the Hedges to be thin and naked.

When the Holly Hedges are drunged with water, they will be kept very neat, and they will be only defaced at the end of a year, in May and August, but they are only defaced at the end of a year, which (however) is about the latter end of June, or the beginning of July; and if they are not cut, they will be very beautiful.

The fences which are made from the Holly Hedges, should be contrived so as to admit as much fresh air as possible, which is absolutely necessary for the growth of the plants; for when they are crowded on each side with dead Hedges, the plants seldom thrive well. The best sort of fence for this purpose, are those which are made with posts and rails; or instead of rails, three ropes drawn from post to post, and holes made in the posts to let the ropes through; this

is the cheapest sort of fence, and will appear very handsome; but if sheep are not admitted into the fields, there will be occasion for two ropes only, which will be enough to keep off larger cattle; and if the ropes are painted over with a composition of melted pitch, brown Spanish colour, and oil, mixed well together, they will last found several years, and these sort of fences never obstruct the air, and the plants, at the same time being open to view, the weeds will be better discovered than when the fences are close.

In the latter case, the Hedges are to be covered with weeds, by which they are excluded from the light, and are frequently forgotten, especially in winter, when the weeds grow more luxuriant.

There are some persons who intermix the Holly with the White Thyme in making their Hedges, which if rightly managed, will have a good effect, especially when young; but when they are advanced, the Holly should be planted by itself, so that the Hedge may be entirely formed of it as it grows up, when the White Thyme should be quite rooted out; for as they advance, they will not keep pure in their growth, so that they will not appear beautiful when intermixed.

When the Holly is intended to be made by plants, the ground should be well trenched, and watered, especially when the ground is very wet; the plants should be set in October, but, in wet ground, March is preferable. The plants should not be taken from a better soil than that in which they are to be planted; for when it is otherwise, the plants are much weaker before they recover this change, than those which are taken from a better soil.

If the plants have been before removed two or three times, they will have heavy roots, and will be in less danger of miscarriages; besides, they may be removed with balls of earth to their roots. When the frost comes on, it may be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may thus have been put out, from being destroyed by the cold. I would never advise the painting of Hedges with Holly plants, of above five or six years growth from the berries; for when the plants are older, if they take to grow, they are longer before they form a good Hedge, than when they are much younger; and if the plants have been twice before transplanted, they will more certainly grow.

I shall next treat of Hedges for ornaments in gardens; these are sometimes planted with Evergreens, especially if they are intended to grow very high, in which case, they are planted with Deciduous trees. Evergreen Hedges are planted with Holly, Yew,

H E D

Laurel, Laurestinus, Phillyrea, and Atamurus, (Evergreen Oak, and four others of less note. The Holly is peculiar to any other, for the reason before given. See the article on this subject, in the account of the Yew, on account of its growing very close; for when these Hedges are well kept, they will be so thick, that a bird cannot get through them; but the dead colour of the Yew, renders these Hedges less agreeable. The Laurel is one of the most beautiful greens of any of the evergreen trees, but then it shoots so luxuriant, as to render it difficult to keep the Hedges which are planted with it, in a desirable shape; besides, the leaves being very large, if the Hedge is clipped with shears, the leaves will be cut through, which gives them a bad appearance; therefore where there are Hedges of this kind, it will be the best way to prune them with a knife, cutting the shoots full down to a leaf.

And although by this method the Hedge cannot be rendered so even as when cut with shears, yet it will have a much better appearance than that of most of the others, the leaves being cut through and the wood being exposed, in the winter time they will be when flowering.

The Laurestinus is also a very fine plant, but the same objection may be made against it as against the Laurel; and as one of the great beauties of this plant is in its flowers, which are produced in the winter time, so when these are desired, the flowers are generotly cut off, by which their beauty is lost. Nor can this be avoided, where the Hedge is to be kept in close order, therefore this plant is not so proper for the purpose, but in such places where walls or other fences are designed to be hid, there is not any plant better adapted than this, provided it is rightly managed; for the branches of this plant are slender and pliable, so may be trained up close to the fence, whereby it may be entirely covered; and if, instead of clipping these with shears, they are pruned with a knife, they may be so managed, as to have them full of flowers from the ground upward. This may be effected by pruning them in April, when the flowers are going off, cutting them so that they have flowered, or pruned them so that they are always cutting close to the leaf, that they may be kept in the best shape, and that they may be kept in the best shape, and that they may be kept in the best shape.

There are some persons who intermix the Holly with the White Thyme in making their Hedges, which if rightly managed, will have a good effect, especially when young; but when they are advanced, the Holly should be planted by itself, so that the Hedge may be entirely formed of it as it grows up, when the White Thyme should be quite rooted out; for as they advance, they will not keep pure in their growth, so that they will not appear beautiful when intermixed.

both they may remain until Michichmas, when they should be transplanted into the large borders of a parterre or pleasure-garden, allowing them at least three feet distance from other plants, amongst which they should be interspersed, to continue the succession of flowers; when they will make a fine appearance, especially the red sort, which produces very beautiful flowers.
 As these plants decay after they have perfected their seeds, so there should annually be a fresh sowing of plants raised, when they are desired, for the old roots seldom continue longer. They are very proper ornaments for large borders, or to fill up vacancies among shrubs, but they grow too large for small borders, unless they stalks are pruned off, leaving only two or three on each plant, which, if kept upright

with sticks, will prevent their haingine ovr other floweri. They arc propagated for i:iplytn^ the markets with plants to adorn the London gardens arid balconies, by the gardeners in the neighbourhood (j'Lt-

The ibeund lott Li an annuul plant, which grows naturally in Spain and Portugal, the leaves of this are nit rowan d oblong, four or five pair being piao along the midrib, with an odd Ode at the end; [lie fitalcs i terminated by I mall fpikw of purple Mowers, which are succeeded j by filial! rough pods, fhiipitd like those of the former fort. This pUni is preserved in be;unit gardens for die fake of variety t it is j propagated by feeds, winch mould be fown the beginning of April, in the place v. here the plants are to remain, and will require no other culture but Co thin them where they arc too near, and keq> them clear Iron W(-uls. Tl is flowers in July, "W the seeds ripen in Autumn.

The iliird fort hath a perennial root, which will stand many years if planted in l dry foil. I his is propagated by (owing the feeds in the manner directed for [he former; but when the plans arc come up two inches high, thry fnoiid IM [ranf plan red where IM arc to remain for pond; but if they are not too thick in th^ seed-bed, they may be suffered to remain there until the following autumn, at which time they should be carefully taken up, and transplanted into the borders where they are designed to stand; for their root; generally run down a very deep, so that it is necessary to remove ilitci ol them. This plant produces its flower; abuc dll same time as the former, and if the season proves favourable to its growth, it will be in the open air very well, re lifting the fevetell coldj provided they are planted in aatj foil.

The fourth fort is an annual plant, which grows naturally in the Levant. This iuth one re-embles that of the foil, but is much smaller, and its flowers are a foot high, and nre [jnmilled with win; compofrdcif two or ihn • pair of oval lobes, terminated by an oblong spike at the top of the stalk, which are of a pale red intermixed, with = little bios. TheTc appeafinju! and are fucceeitd by jointed pods which are waved en both ficlc3, forming an obtusc angl' ar each joint; the (ieds ripen in the autumn. I'lii.i u propigaiet in the fmc way us the U-cond fort, and u equally hardy.

The fifth fort grows naturally in boili i fides; the feeds of tfik were fent inc from La Veru Criti. by the late Dr. Houlloun. Th't* i» an annuul plant, with a long tap mot which runs deep in the ground. it-njing out one or two ft.ilks, whitfi rift about pine inches high, the lower part being gumfithed with oval leaves by pair in on cadl foi-iMfci but titir upper part of the stalk where die flowers come uuc, is giium; with fmail leaves, ending in acute pomts, fitting close to the rtallu, and Jt eadi of thec is litLaicd a little, small, yellow flower, inclofd by the two leaves. These are insikc but little appearance, and are fact by oblong pods, e containing me kidney-limpe d f«xi. The fwtri fort wiS lent me by the the late Dr. I foot-toun from La Ve

This is an annual naturally, a* ii alii* docs in Jamaica. Italk upward of four feet high, dividing into fev branches, which are garnished with oblong oval cr.il bn that are trifoliate, standing up long foot-stalks, and die lobe an inch beyond the other; the branches are terminated by long look panicles of purple flowers, which are succeeded by narrow pointed pods which are twisted. The plants flower in July, and their seeds ripen in the month of August. The two last mentioned J arc tender pkmu, fo thir feeds must be sown in the spring upon a hot-bed, and when the plants are fit to remove, they should be planted in a separate small pot filled with light earth, and plunged into a hot-bed, keeping them shaded from the sun till they have taken new root; when

 indm;: an inch beyond the other
 • v.inate
 le mid
 i ntmtn.

H E D

then they must be treated in the same way as other tender plants from hot countries, always keeping them in the stove or glass-case, otherwise they will not flower or produce seeds in the winter.

The eleventh fort grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houlton. This is a shrubby plant, which rises about five feet high, and divides into several branches, which are garnished with trifoliate leaves, which are oval, the middle lobe being much larger than the other two (the stalks are terminated by long spikes of small purple flowers, which are succeeded by narrow pods, jointed on one side, but jointed on the other.

The eighth fort was sent me from La Vera Cruz by the late Dr. Houlton, who found it growing (here naturally. This rises with a shrubby (talk six or seven feet high, dividing into several branches, which are garnished with trifoliate oval leaves, silky and white on their under side, but of a pair green on their upper side; the flowers come out in long narrow spikes from the wings, and at the end of the branches, fitting close to the stalks, they are small, of a bright purple colour, and are succeeded by flat, smooth, jointed pods, about one inch long, each joint having one kidney-shaped seed.

The two other forts will continue two or three years, if the plants are placed in the bark-stove. They are propagated by seeds, which must be sown upon a hot-bed, and the plants treated in the same manner as those just before-mentioned; and when they have obtained height, they should be removed into the bark-stove, where they should continue to remain, allowing them a large share of air in warm weather. These plants seldom flower till the second year, when they will produce seeds which ripen in the autumn.

The ninth fort is an annual plant, which grows naturally at La Vera Cruz, from whence it was sent me by the late Dr. Houlton. This seldom rises more than eight or nine inches high, sending out several branches from the root, which are diffused and hairy; they are furnished with small, oval, trifoliate leaves, a little woody. The flowers grow in small spikes; they are purple, and have very hairy empalements.

The tenth (on potatoes naturally in Jamaica. This hath ligneous trailing (stalks a foot and a half long, sending out several branches on each side, which are garnished with small, round, trifoliate leaves, of a pale green colour; the flowers are produced in very long spikes at the ends of the branches; they are small, and of a pale purplish colour, succeeded by narrow twisted pods which are jointed, each joint being four cornered, containing a single, small, compressed seed.

The two hit forts being annual, require the same treatment as the fifth and sixth forts before-mentioned, with which management they will flower and ripen their seeds in this country.

The eleventh fort is a shrubby plant, which rises with triangular stalks live or six feet high, dividing into several branches, garnished with heart-shaped trifoliate leaves, and sending out at the points of the flowers are produced in very long spikes at the end of the branches, which are of a pale purple colour, and are succeeded by narrow jointed pods which are variously twisted; the seeds are small and compressed.

This plant grows naturally in Jamaica, from whence the seeds were sent me by the late Dr. Houlton. It will continue three or four years, if the plants are treated in the same manner directed for the seventh and eighth forts, and will produce seeds in the winter.

The twelfth fort is annual, the seeds of it were sent me by the late Dr. Houlton from Campechy. This hath a slender stalk, which rises about two feet high, garnished with heart-shaped trifoliate leaves, the upper part of the stalk branches out into panicles of flowers, which are of a pale purple colour, these are succeeded by narrow jointed pods, which are variously twisted, and contain one or two seeds.

The seeds of this plant were sent me by the late Dr. Houlton from Campechy. This hath a slender stalk, which rises about two feet high, garnished with heart-shaped trifoliate leaves, the upper part of the stalk branches out into panicles of flowers, which are of a pale purple colour, these are succeeded by narrow jointed pods, which are variously twisted, and contain one or two seeds.

H E D

prefixed kidney-shaped seeds. This is propagated by seeds, and requires the same treatment as the seventh and eighth forts.

The thirteenth fort was sent me from La Vera Cruz, by the late Dr. Houlton. This is a shrubby plant, which gets round the trees and shrubs which grow near it, and climbs to the height of ten or twelve feet, garnished with oblong, oval, trifoliate leaves, (landing upon pretty long foot-stalks, the flowers are introduced in long narrow spikes, and are of a tincture purple colour, and (it is said) to the stalk. This is an abiding plant, which requires a (love to produce it in this country, so the plant should be treated in the same manner as the seventh and eighth forts.

The fourteenth fort is an annual plant, which grows naturally in both Indies. The seeds of this were sent me from the Havannah by the late Dr. Houlton. It hath trailing branches more or less long, which are garnished with round trifoliate leaves, a little indented at the top, very like trifoliate leaves of the Strawberry Trefoil, flat, stalks and under side of the leaves are hairy in the rows are produced in long narrow spikes at the end of the stalks, they are of a purple colour and small, these are succeeded by narrow jointed pods, which are variously twisted, and contain one or two seeds. This flowers the end of July, and produces perfect seeds here.

The fifteenth fort is a low annual plant, having slender stalks a foot long, their upper part being garnished with trifoliate leaves, sending out (Tender trifoliate leaves their upper part is adorned with flowers, which come out by pairs above each other, to the end of the stalks, they are small, and of a reddish yellow colour, these are succeeded by jointed narrow pods, which are variously twisted, and are kidney-shaped. The two other forts are annual plants, which require the same culture as the fifth and sixth forts.

The fifteenth fort was sent me by the late Dr. Dalrymple, from South Carolina. This hath a slender stalk, from which arise two or three (shrubby hairy stalks near two feet high, branching out on every side near the top, garnished with oval, pear-shaped, trifoliate leaves, which are hairy on their under side, and stand upon short too-tended stalks; the flowers are produced at the end of the branches in long spikes; they are of a purplish yellow colour, and small, these are succeeded by narrow jointed pods which are variously twisted, and contain one or two seeds. This is propagated by seeds, which should be sown upon a hot-bed in the spring, and the plants are fit to remove, they should be planted in (a moderate hot-bed, obfervitig to (have them until they have taken new root; then they should have a large share of air admitted to them in warm weather, and in summer they may be exposed to the open air, but in the autumn they must be placed under a frame to screen them from frost, the following spring some of these plants must be taken out of the pot and planted in a warm border, where, if the summer proves warm, they will flower, but these should be planted in their feeds; therefore two or three plants should be put into larger pots, and plunged into a moderate hot-bed, which will bring them early into flower; so that if the glass is kept over them in bad weather, these will ripen their seeds in autumn, and the roots will ripen the following year, if they are kept from frost in winter.

The seventeenth fort was sent me with the last, from the same gentleman, it is an annual plant, which rises about two feet high, garnished with long trifoliate leaves, which are rounded at their base where they are inserted, and are of a pale purple colour, these are succeeded by narrow jointed pods, which are variously twisted, and contain one or two seeds.

The seeds of this plant were sent me by the late Dr. Houlton from Campechy. This hath a slender stalk, which rises about two feet high, garnished with heart-shaped trifoliate leaves, the upper part of the stalk branches out into panicles of flowers, which are of a pale purple colour, these are succeeded by narrow jointed pods, which are variously twisted, and contain one or two seeds.

He onr fits upon a foor-flilk an inch long ; tlic Bowers arc produced in long lpik« from the wings of the (talk, growing ereft-. the lower pan of ihr fpike is but : thinly fet with flwuer!, but on the upper pnn I they are : foaled very dote ; tiitli; are (mail, and of a : bright yellow colour, fitting very : ofe nUKUttUu, and are fuccceded (by juinteJ pods ill .it on one lide. The HELIUM (Aconitum) is radiis bnceobtb-lir, integerrimis glabris, pedunculis acutis unifloris. Helianthum with floure narrow leaves, which are fouth, male, and axial feet-falls with fingle flouers. Helianthum folio lincolor & anguftiore. Vaill. Aft. R. Pai. 1720. Helianthum has floure with a longer and narrow haf-

HELIVUM (Lactuca) folio lanceolatis acutis serratis, pedunculis breviteribus, calycibus multinerviis. Helianthum with pointed, four-fingered, fround leaves, fower feet-falls, and a many-jointed empolument. Helianthum folio brevior & latiore. Vaill. Aft. R. S. 1720. Helianthum has floure with a broader and fower haf-

These plants rife to the height of fix or feven feet in good ground; the roots, when large, fend up a great number of ftalks, which branch toward the top; thofe of the firft firtare gamid ed with fmooth leaves, which ,iir three indies anJ » half long, and half an inch broad in the middle, with thort edges fitting clofe to the ftalks, and from their bafe is extended a leafy border along the ftalk, fo as to form what was generally termed a winged ftalk, but Linnæus calls it a running leaf; the top or part of the ftalk divides, and from each division arifes a naked foot-ftalk about three inches long, fufifting one yellow flower at the to], fhaped like a Sun-flower, but much (mailer, having long rays, which are r and pretty deep

deep inca four or five segments which appear in August, and there is a tuft of flowers on the plants till the frost puts a stop to them. The flowers are not thin, the leaves are more than an inch broad in the middle, ending in acute points, and are flurpily laved on their edges. The flowers stand upon a stalk, growing together, but they do not branch near so much as the other, they both flower at the same time.

There is also another sort which tares as narrow as the first, which are acutely pointed on the edges. The italics branch in the copious manner, but the middle flowers have smaller stalks than those which branch on thin stalks, and are provided with small leaves, almost to the top, but I am not certain if they are the same, or only a variety which has accidentally risen from the seeds of the other.

These are both natives of America; the first was first received from Virginia and New England, where they grow wild in great plenty in the woods, and often in places where the ground is moist. They may be propagated by seeds, or by jointing their roots; but the latter is generally practised in this country, because they seldom perfect their seeds here, but if the seeds are procured from abroad they will be the beginning of March on a border of high earth, and if the seeds should not come up the first year, the ground should not be disturbed, because they often remain in the soil for several years, and then come up.

When they first appear, if the soil is dry, they must be often watered, which will greatly forward their growth; and where the plants come up too close to each other, they should be thinned, and transplanted out into beds a foot asunder every way, being careful to shade them until they have taken root, as if you water them in dry weather. In autumn they may be transplanted where they are to remain, and the following summer they will produce their seed, which will continue till the frost prevents them; and their roots will produce many years, and afford many offsets, which they may be removed.

The bed of the plants should be kept clear of weeds, and to part them for the first time, in the end of October, when their flowers are just beginning of March, but before they begin to shoot; but if the spring is dry, they must be duly watered, and they will produce many plants the same year. These plants should not be removed every other year, if they are expected to flower; if they do not flower in a soil rather moist than dry, they may be divided in the wet in winter, but if they are planted in a dry soil, they must be often and plentifully watered in dry weather, to make them produce plenty of flowers.

HELIANTHEMUM, ELEGANTIS. Sec 15, 16.

HELIANTHEMUM, TOURNEFORTII.

Tab. 118. Cibus. Lin. Gen. Plant. 598. Dwarf Cibus, or Sun-flower.

The CHARACTER is, The flower has a three-lobed calyx, which is persistent, which afterwards covers the seed vessel. It has five round petals which spread open, with a great number of small stamens, which are terminated in final/ rounded points. In the center is situated an oval germ, supporting a style to the length of the filament, crowned by an oblong stigma. The perianth afterwards becomes a receptacle, or oval capsule, and then divides into three parts, each with three rough seeds.

This genus of plants is joined by Dr. Linnaeus to that of Cibus, and is ranged in the first section of his third class, which includes those plants whose flowers have many stamens and one style. As the empurment of the flower has but three leaves, and

those of Cibus, the flowers are of the Helianthemum habit, but the three calyx, and that of Cibus, (the characters are sufficient to distinguish them) separated into different genera, and as there are a great number of species of both sorts, so by this comparison they may be better ascertained.

THE SPECIES ARE,

1. HELIANTHEMUM (Germanicum) caulibus procumbentibus suffruticulis, foliis oblongis subpinnatis, stipulis bracteolatis, Dwarf Cibus with trailing fleshy stalks, along hairy leaves, and four-lobed petals. Helianthemum vulgare flore luteo. J. B. 2. 15. Gemma Dwarf Cibus with a yellow flower.

2. HELIANTHEMUM (Germanicum) caulibus procumbentibus, foliis trifloris, ramulosis, juncis floribus simplicibus. Uvrruf 1. Cibus with trailing fleshy stalks full of branches, and large petals in the flowers. Helianthemum album Germanicum. Tab. (con. 10G1. White German Dwarf Cibus.

3. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

4. HELIANTHEMUM (juncifolium) caulibus suffruticulis, foliis lanceolatis linearibus, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

5. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

6. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

7. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

8. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

9. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

10. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

11. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

12. HELIANTHEMUM (Panicum) caulibus suffruticulis, foliis lanceolatis obtusis, nervis reflexis, Dwarf Cibus with hairy fleshy stalks, linear four-lobed leaves, and reflexed petals. Helianthemum foliis linearibus. Son-albo. J. H. 1. 16. Dwarf Cibus with linear leaves. <d a vskiltfm

24. **HELIANTHEMUM** (Marsiliense) caule herbaceo procumbente, foliis ovatis serratis lobatis. Dwarf Cistus with an herbaceous trailing stalk, and small hairy leaves finger-shaped at the base. **Helianthemum Alpinum,** foliis pilosella minoris Fockell. I. B. 2. 141. Hoary Dwarf Cistus of the Alps, with large leafy joint leaves.

The fifth sort grows naturally on the chalky hills and banks in the plain of England; the stalks of this plant are ligneous and slender, trailing upon the ground, extending themselves near a foot each way; these are furnished with small oblong leaves, of a dark green on their upper side, but of a smoky colour on their under. The flowers are produced at the ends of the stalks in loose pikes; the petals are of a deep yellow colour which is more evident in the day, but (but) in the evening, these appear in rose and purple, and are succeeded by capsules, including angular seeds, which ripen in August and September, and the root is bituminous.

The second sort grows naturally in Germany in the hills of the Rhine, and is much larger, and several times taller than those of the first; the leaves are longer, and are of the lower part of the stem are erect. The flowers are much longer than those of the first; the petals are white and larger. The empalement of the flowers are hairy and whitish; these differences are arising from the soil.

The third sort grows naturally in the mountains of France, in Italy, and Germany. The stalks of this plant are either of the farmer, and are more ligneous. The joints are farther asunder, the leaves are longer and hoary, in the spite of the lower are generally reflexed; they are white, and the flowers of the second sort are of a very narrow.

The fourth sort grows naturally on the Apennine mountains, and is much more erect than those of the first. The leaves are not so long, the stipules are very small, and the whole plant is very hoary. The flowers are white, and the spikes are shorter and more compact than either of the former. The fifth sort grows naturally in the south of France, in Spain, and Sicily, from the last country I have received the seeds; this is a low trailing shrub, which are hoary, but of a branched, and are more than four or five inches long. The leaves are narrow and hoary, and there are no stipules at their base. The flowers are white, and are in small clusters at the end of the stalks; this sort seldom continues longer than two years.

The sixth sort has trailing (Jirubby) stalks, which extend a foot in length, and are furnished with very narrow smooth leaves placed alternate; but their short stalks bear flowers, which do not flower, have shorter and four-leaved growing in clusters, these have no stipules at their base. The flowers are placed singly toward the end of the branches, they are yellow and striated; this sort grows in the south of France and Italy.

The seventh sort has very long, trailing, ligneous stalks, which are furnished with four-fingered leaves placed opposite, which are very hairy, and grey on their under side, having at their base three long narrow stipules. The spikes of flowers are near a foot in length, but grow singly; they are large, and of a deep yellow colour, with very hairy empalements; this sort grows naturally in the south of France and Spain.

The eighth sort has very shrubby crooked stalks, covered with a purplish brown bark like the common bush. The branches are slender, and furnished with narrow leaf-like leaves like those of Thyme, which stand opposite, having no stipules at their base. The flowers are produced on naked four-fingered, which terminate the branches in a sort of umbel; the petals are of a pale yellow colour, and a little smaller than those of the common sort; this grows naturally on the hills near Fontaine, in France.

HEL

The ninth fort grows naturally in Germany, from whence the feedi were fem to the Into Pr. Burchaavc, in uhufi; curious gard near Leyden I gared the Irrds; ihi- fends out from root biproous a great number of triliti" ftjls, which are fmoorii, artd ex-mud more than a foot -ich way, girmilhd with oval, fpoji -faped, fmooth leaves, placed J rcjipofire, having at their bafe three fpear-fhaped fl-pula. The flowers are i -rge, yellow, and grow in fhort clufters at the end i - the branches, the -w**s continue the fame from feeds.

The tenth fort grows naturally in Spain, from whctite I received it i this hath alhort, tvcl;, woolly ftalk. •ime -hich out fever.U (hurt fidc-branches, which are garnifhed with aviwoodJr leaves, havi: three long-euina! veins. The flower-felk which arifes from •i the main Hem grows about nine inches high, hav:;g tvraor three narrow leaves placed alternate. The flowers are produced in pretty longpe-dicles toward the ••; of the flaik, and hav' very finifh compen -nts.

The ele•vem U fan was fent ilc from Verona, where it grows naturally, this has ii •! luw ilirtibhy (UJk, from which come out s icw lhort brunches, garnifhed with fmall woolly fpears [Imped leaves, plictl oppofite. The fiower-ftalk riles amin fix uichi bigh, and branches toward the top, where the fle*CTS ire produced on jireny lunjj; 'tooE-falks; they are white, and fmaller than thoti; of the common lurr.

The twelfth ilii t hath long lhmbby flilks which trail on the ground, and divide into many branches, •which arc garnifl. A veined leavi

green on ihciruppiT fidc, but of agrayilh colour below, with three narrow crrel Ltiupit at their bife. Thy flowers are pretty large, whitt, mul gfuw in clivifcerst <t tht r<J of the hriiiches.

The fourteenth fort Inili Bin bby ftalks which grow pretty upright, garnifled with narrow IpL-ir-flupal leaves placed oppofite, w•••)- un thier und: fide, and three very narrow fl-pula growing II their bfc. The flowers are . I lite, growing in long (pikes at the end of the branches; thu grows naturally in the foutli of France.

The fourteenth fert hath in erect (hrubby (hik, which fends out many fide branches, whole joints are pretty clofe, and arc gara'Oied with vrry narrow leaves, placed oppoCtte, wiiofe borders are PC-flexed -, their up^er fide is of a lurid green, and their undfr fide hoary. The (lowers arc pretty Urge, white, and grow in final]ctuften sr the tndot the branches; thir: ows naturally in Spain, from whence (he roots were limr me.

The •tenth fert was found by Mr. F.dmund Du Itoij, near Chydon, in Surry, and was at Sft iup]>ofed to be ••ly an accidental variety of the common - fort, but the feeds of this always produce the f •if- I hive ••ltivated this above thirty years, and never • have found it vary from feeds, this is very like the corn-mon fort, but the leaves are hairy. The petals if the Bower imed, and fmaller than iliofc of the tmrmin CJTL

The fifteenth fert hath upright ftEabb: * ftaliti, which rife a foot and a half high, fending out branch?! the whole length; they are garnifhed with •:nall fpear-flaped livery leaves, placed oppofite, which arc ("moot). The flower-falks branch, and the flowers, • li:; are white, are produced in Ciort fpikes »i the rod of the branches.

The fixteenth fert was found growing ranjrally by the late Dr. William Sherrard, near Sayrus, w^ofenc the feeds to England; this hath flubby ftalks which do not trail on the ground, garnifhed with oblong oval leaves placed oppofite, but thofe toward the top are narrow and placed alternate. The flowers are produced at the end of the branches in long loofe fpikes; they are of a pale colour, and the fize of thofe of the common fert.

The eighteenth fert is annual, this grows naturally in France, Spain, Italy, and in Jerkey, where the late Dr. William Sherrard found it, and fent the feeds to

HEL

Eng; ihs hiA i branching herbaceous ftalk, whic! riles •• or fire inches high, garnifhed with narrow fpear-fhaped leaves, placed oppofite, which are ctx ••od with hairs; thofe •• the upper j •• of the ftalk-t arc placd akernare, -ird are narrowci. The flowers jrc prpdurd in loofe fpikes at the end of the branches, tending upon long tocc-ilalk; they are final), and i -ppofed of five yellow petals, with a dark purp'••: fpoe at tilt baft i' each; the flowers are very fugacious, for they open early in I the morning, and their petals drop off in a ft-w hou-. ten of the dock the llowfnjre all Bellen.

The nineteenth fert grows niuirtly u< on Mount !!;Jiis, from wjrnce the feeds were fent me; this is an annual jil'in', whir: fends out many herbaceous flails from the mot, gamiied with i oval leaves, which are hairy. The Howert arc i i produced in loofe fpikes at the end of the hraiKhes; th ey are of a pale yellow colour, and very fiteii i •• seldom lasting two hours before the petals fall o(T' ihi t thii which gfowi abdiit Vcron is another variety of ••, with upright ftalks. The twentieth fun grows naturally in the fouth of France and ttdy, and v

was found by the late Dr. Wil-

liam Sherrard, growing near Sni)rnj; who li-nt die feeds to ttlgland ami Holland by a new tale, fuppofing it to be a different plant; I when it was cultivated here, it proved to bL the limew" that growing in the

ibutli of France; far this plant puts on different appearance, according to the foil and fituation where it grows; tor, in a good foil, where the plant * land Itngle, and are not injured by weeds, aj will rife near J foot and a hair liii'li, the leaves will be two inches and a half long, and ric-r ball' an inch broad in the onddle; but in a poor foil, or where th; plants ttand too clof', or arc injured by weeds or neighbour- ing plants, they do not rife more than 1 1/2' thac height. The leaves are much narrower, and the feed- vels not half fo large; fo that any perfon finding ihclc plants in twu diffrent fituations may be deceived, and take them for (different - I feeds; but when they are cultivated in a garden in the fame foil and fi- LUitjrn, they do not diner in any particular. This is an annual plant, which pennies loou after ilie leeds are ripe.

The twentj-Srft (on is an ann:il vl:int, which grows nmirilly in Spain and ! orugal; this hath branching ftalks, wh< h rife a foot high, garnifhed with oval oblung lean •• placed oppofite on the lower part of the ftalk -, t out on the upper part they are alternate and ll crow, a fingle leaf being placed between each (lower, which oc -cations the title of Solitary Flowers, for they grow in loofe fpikes at the end of the branches, in the fame manner as the other fertes.

The twenty-second fert was fent me by Dr. Adriano Van Royer, who received the feeds from the Cape of Good Hope. This rifej with a flir bby ftalk about nine' < inches high, garnifhed with very narrow fine leaves, growing in clufters; the flowers arife out from the fize and at the end of the ftalks, ftanding oppo- fiender fbot-ftalkj; they are •• of a pale fcarc colour, unJ x very fugacious, seldom continuing longer than tfo >Du^ before the perils till GIV. "The seldom continues longer than two yfors.

The twenty-third fert grows naturally in Egypt; this is an annual plant having threuby erect ftalks, garnifhed with narrow fpear-fhaped leaves, ftanding on too: -ftalks; the upper part of the ftalks are adorned with white flowers, whole petals are not fo large as the crnpalcnKiu. and being very fugacious they make but litt! appearance; it flowers in July, and the feeds rife in September, foon after ••• the plants decay.

The twenty-fourth fert grows naturally about Ken- TV I dali^ Weftmoreland, and in fome parts of Lanca- (hire, i upon rocky fituations. This hath trailing her- baceous ftalks, which feldom extend more than three or four inches, garnifhed with oval leaves, which are v< ry woolly, and fit clofe to the branches; the flowers are produced at the upper part of the branches; they are white and fmall, to make no greff appearance.

Most of the perennial forts of Dwarf Ci (tus are hardy, fo will thrive in the open sir in England i they are propagated by feeds, ^takh may b^ lwn in ptacci where the plants are to remain, and I will require no other care but to keep them dran from weeds, and thin them where the>art too dole, always obll-rving to leave those forts at a liirthei dilbmce, wio ... ill on the ground, ami gruw to the grejtcfst length. Tholl-plants will continue fevcral years, cfpecfolly in a poor dry foil; but in rich grounj or moilt fitujtkins, they felJom lad long: but as they ripen feeels in plenty, lbtthey may be eafly repaired. They ail fWer about the lame time as the common Ion, am! thdr feeds ripen in (lie iimutut.

The annual forts maybe propagated with as great facility i for if their feeds are ibwn iupon a bed of common earth in April, th plants will come up n May, and require no other culture, but to thin them where they are too dof, and keep than dear from mii:.. Tilde will flower in July, and the feeds ripen in the autumn. The twenty-fceond fort will thnvr in the full ground in the fame manner as the other; but unleft the iummer proves favourable, the seeds ;, ill not ripen : thernots have lloud through die winter when the feason ... proved mild, without any fbeli have flowered the following fiiinmf.

The (weiry-fourth fort requires a lhatly Tuuition, orhcrwile it will nut thrive here,

- The first fort grows an rally in the south of FtSnec, in Spain, Italy, and molt of the warmer countries in Europe. It is an annual plsnat, which fuccei; bcter fion fecdi which /carter in the autumn, tr Jbwn at thar leafon, than in the fpring; for whin tl. are Town in [he fprini;, they fdtiom come up the lame year; but if the plant h once obtaint-d, and the feeds iififered to fhed, it will maintain kclct without any trotable, requiring no other culture but to keep it clean from weeds, and thin the plants where (hey are too clofe.
- This rifers about seven or eight inches high, dividing into twt) or three branches, garnilhed with ovnl rough leaves, two inches long and fine broad in the middle, of a light green, Handing upon preclly long ibot-ftaiki alternately; the Howrs arc protlucrd at thr end of the brinchca in doubL fpikes, jcticat the bottom, which are about an inch and i luit kmg, turning backward like • fweep's tail. n, e flowc3 are white, and appear in June mil July •, the ten's ripen in autumn, loon after which tl: r l'; •
- The fecond Can grows naturally in the West-Indies. This ii annual l the rt;ik rifes 3 foot uu) a half, or two feet high, branching out toward the top: the leaves are rough and hairy. Handing upon pren long foot-flalks; they are two inches and .1 hail long, and nne and a half broad in the middle, cnd ing in acute points; the flowers are produced tow?.. the •! the branches in fingle fpikc=, which ate li\ incttea long, turning backward M the top like the other ippecies. The fiowera are blue, and appear in July and Auguft, the fteds ripen in September and October.
- The third fort grows naturally in the Weft-Indies. This is 3 fmailer plant than the former, feldom growing above two feet high -, the leaves are one inch and a half long, and about half an inch broad; the fpikes of flowers arc very (lender, and not more than two inches lonR; the flowers arc fmall, and of a light blue color-. They appear at the fame time with the former, and the leeds ri; in a sum >n.
- Thek rch, l-[snluftbefownon a hot- bed> in thr tyring, and when the plants ant fit to remove, they muft be tranfplanred on another hot-bed to bring them forward, treating them in the Umc way as the Billaminic, and other tender annual plants; and in June they may be ufcen op with balls of earth, am! planted in the borders of the fiWrr-garden, where they will flower, and in warm feifbn* produce ripe feed):
- The fourth fart rifes with a (hrubby ihlk fix or seven • whichjtheyoungbranchM; re dazily o wored with a white itewn, anil the lwv« on thole arcvery hoary and entire, but thole on thr older branches >re gref ner, .md fome of them an- m'ufian their etige? j at each joint of th« stalks come out nre floirt bwsht* oppofuc, which >rc usinillied with fmall hairy leaves plant oppofite: thole, when branhd, emit a ilrcm^ odot'r which to fome perfons is very difagreeable, biit others are pleafed with it. The plants rarely flower in England, but in Di in fifty years which I have cultivated them, I have but once fern them in flower. The flowers are white, collected in roundish heads, which turn backward, and fit clofe to the branches

illie !•oves continue all the year, for which the plants are j•ferred in green-houses. li) Lld W (lit Vji I in winter.

The sixth sort grows naturally in the Country of Peru. It rises with a woody stalk three or four feet high, dividing into many branches, which are garnished with oval leaves branched on their edges, growing opposite upon long foot-stalks; they are hairy, and of an Ash colour on their under side; the flowers are produced from the side of the branches on peevy long foot-stalks, each containing four short roundish spikes or heads, which divide by pairs, and spread from each other. The flowers are white, and appear in June and July, but are not succeeded by seeds in England. The leaves of this plant, when bruised, emit an agreeable odour, for which it is by some persons much esteemed; the gardeners have given it the title of Madam M liaicnoa, but for which I know not

TJje [wo lail for: are too tender to live through (W water r in the open an in this country. It is raised in a green-house during the season, but they require to be brought from fruit, so may be planted with Myrrils and the other hardy green-plants, where they may have a large share of air in winter, and be treated in the same way, as usually propagate eggs during any of the months of the year, which, if put into a tub of water, will be ripe in six weeks; then they may be planted in a pot, and placed in a fi•ti*1' fivation till they have taken new root, after which they may be transplanted into the old plants.

The sixth sort grows naturally in Peru, from whence the seeds were first by the youngicer lulleu co die Royal Garden at Paris, where the plants produced flowers and fruit; and from the curious garden of the Duke of Arco, at St. Germain. I was supplied with some of the seeds, which were sown in the Chelsea garden, where the plants have flourished and perfected their stalks for some years.

This rises with a fleshy stalk two or three feet high, dividing into many small branches, garnished with oval leaves flapped, rough leaves, set on without order; they are three inches long, and one inch and a half broad in the middle, standing on short foot-stalks; they are hairy, and greatly veined on their under side, which is of an Ash colour. The flowers are produced at the end of the branches in short reflexed spikes, growing in clusters. The foot-stalks divide into two or three, and their shrift again into six, each containing a spike of pale blue flowers, which have a strong sweet odour. The plants continue in flower great part of the year, and those flowers which come out in summer, are succeeded by ripe seeds in autumn.

It may be propagated either by seeds or cuttings. The seeds should be sown upon a moderate hot-bed in a glass, and when the plants are fit to remove, they should be transplanted into small pots filled with light earth, and plunged into a hot-bed, where they should be shaded till they have taken root, after which they should be brought to the open air by degrees, into which they should be removed in summer, placing them in a sheltered situation; and in autumn they may be headed with other exotic plants in a good green-house, where they will flower great part of winter, so will make a good appearance among the Orange-trees, and other green-house plants, whose culture this plant will thrive. If the cuttings of this plant are put into pots filled with light earth, during any of the summer months, and plunged into a moderate hot-bed, they will take root very fast, but these do not make so good plants as those raised from seeds.

The seventh sort grows naturally in the sea-shore in the West Indies; this is an annual plant, whose branches rise upon the ground, and grow a foot long; they are garnished with narrow grassh leaves, which are smooth. The flowers are produced in double spikes

from the side of their branches, they are white and small, and have a great appearance. It is propagated by seeds, and requires the same treatment as the second and third sorts. The eighth sort rises with an upright woody stalk six or seven inches high, with a hoary bark, full of marks where the leaves have grown; the upper part of the stalk divides into two or three strong woody branches, which grow erect, and are very closely garnished with long, narrow, woolly leaves, which stand on every side of the branch without order. The flowers come out from the side of the stalks, to which they sit close; they are short and reflexed, and of the colour of the Oiwmare purple, sitting in very regular order. The whole plant is very white and woolly, like the Sea-Cudweed, so makes an odd appearance when intermixed with other exotic plants; this is propagated by seeds, which must be produced from the places where it naturally grows, for it never produces any seeds in Europe; it is raised in a tub of water in the country, for when the dried seeds come over they seldom grow, and if they do, it is not before the second year; and from several parcels of the seeds which I have received from the West Indies, I have not raised more than two plants, and they came up from the seeds which had been sown more than a year; so that if the seeds are sown as soon as they are ripe in a tub of water, when they arrive in England, they will be plunged into a hot-bed of tanners bark, which will bring up the plants, and when they are fit to be removed, they should be each planted in a separate small pot filled with earth, composed of sand and light undressed earth, with a little lime rubbish well mixed together, then plunged into a hot-bed of tanners bark, and shaded until they have taken new root; after which, they must be treated as other tender exotic plants, always keeping them in the tub-bed by the roots, giving them but little water, especially during the winter season.

The ninth sort is a native of the West Indies, where it grows plentifully on the sea-shore; it rises with an upright shrubby stalk a foot and a half high, garnished with small spear-shaped leaves, scarce one inch long, and one-third of an inch broad in the middle, ending in acute points, sitting close to the stalk; they are hairy on their under side, but smooth above. The flowers are produced in single slender spikes, which come out from the side, and at the top of the stalks; they are but little increased, especially those on the side, but those at the top are more turn; they are white, so make but little appearance.

The tenth sort was sent me from Carolina, where it grows naturally on the sandy soil. This is an annual plant, with trailing stems, which grow six or seven inches long, garnished with small oval leaves, which are woolly and entire. The flowers are produced at the end of the branches, in single short spikes, which are reflexed; they are small and white, so make but little appearance.

The eleventh sort is by the late Dr. Houston from La Vera Cruz, where he found it growing in plenty; this rises with a fleshy stalk three feet high, dividing into slender branches, which are closely garnished with oblong, oval, woolly leaves, placed without order. The flowers are produced at the end of the branches in double spikes, which are slender, short, and fruit, not removed to the other species. The flowers are small and white, and the plant is perennial.

These three last mentioned are propagated by seeds, but the difficulty of getting them from America, and the uncertainty of their growing, which they are too slow, and brought over in earth, has rendered them rare in Europe; and as they are plants of little beauty, so few persons have taken the trouble to procure them; besides, as they require a slow and prolix culture in this country, and must have a peculiar soil

from the side of their branches, they are white and small, and have a great appearance. It is propagated by seeds, and requires the same treatment as the second and third sorts.

The eighth sort rises with an upright woody stalk six or seven inches high, with a hoary bark, full of marks where the leaves have grown; the upper part of the stalk divides into two or three strong woody branches, which grow erect, and are very closely garnished with long, narrow, woolly leaves, which stand on every side of the branch without order. The flowers come out from the side of the stalks, to which they sit close; they are short and reflexed, and of the colour of the Oiwmare purple, sitting in very regular order. The whole plant is very white and woolly, like the Sea-Cudweed, so makes an odd appearance when intermixed with other exotic plants; this is propagated by seeds, which must be produced from the places where it naturally grows, for it never produces any seeds in Europe; it is raised in a tub of water in the country, for when the dried seeds come over they seldom grow, and if they do, it is not before the second year; and from several parcels of the seeds which I have received from the West Indies, I have not raised more than two plants, and they came up from the seeds which had been sown more than a year; so that if the seeds are sown as soon as they are ripe in a tub of water, when they arrive in England, they will be plunged into a hot-bed of tanners bark, which will bring up the plants, and when they are fit to be removed, they should be each planted in a separate small pot filled with earth, composed of sand and light undressed earth, with a little lime rubbish well mixed together, then plunged into a hot-bed of tanners bark, and shaded until they have taken new root; after which, they must be treated as other tender exotic plants, always keeping them in the tub-bed by the roots, giving them but little water, especially during the winter season.

The ninth sort is a native of the West Indies, where it grows plentifully on the sea-shore; it rises with an upright shrubby stalk a foot and a half high, garnished with small spear-shaped leaves, scarce one inch long, and one-third of an inch broad in the middle, ending in acute points, sitting close to the stalk; they are hairy on their under side, but smooth above. The flowers are produced in single slender spikes, which come out from the side, and at the top of the stalks; they are but little increased, especially those on the side, but those at the top are more turn; they are white, so make but little appearance.

The tenth sort was sent me from Carolina, where it grows naturally on the sandy soil. This is an annual plant, with trailing stems, which grow six or seven inches long, garnished with small oval leaves, which are woolly and entire. The flowers are produced at the end of the branches, in single short spikes, which are reflexed; they are small and white, so make but little appearance.

The eleventh sort is by the late Dr. Houston from La Vera Cruz, where he found it growing in plenty; this rises with a fleshy stalk three feet high, dividing into slender branches, which are closely garnished with oblong, oval, woolly leaves, placed without order. The flowers are produced at the end of the branches in double spikes, which are slender, short, and fruit, not removed to the other species. The flowers are small and white, and the plant is perennial.

These three last mentioned are propagated by seeds, but the difficulty of getting them from America, and the uncertainty of their growing, which they are too slow, and brought over in earth, has rendered them rare in Europe; and as they are plants of little beauty, so few persons have taken the trouble to procure them; besides, as they require a slow and prolix culture in this country, and must have a peculiar soil

from the side of their branches, they are white and small, and have a great appearance. It is propagated by seeds, and requires the same treatment as the second and third sorts.

The eighth sort rises with an upright woody stalk six or seven inches high, with a hoary bark, full of marks where the leaves have grown; the upper part of the stalk divides into two or three strong woody branches, which grow erect, and are very closely garnished with long, narrow, woolly leaves, which stand on every side of the branch without order. The flowers come out from the side of the stalks, to which they sit close; they are short and reflexed, and of the colour of the Oiwmare purple, sitting in very regular order. The whole plant is very white and woolly, like the Sea-Cudweed, so makes an odd appearance when intermixed with other exotic plants; this is propagated by seeds, which must be produced from the places where it naturally grows, for it never produces any seeds in Europe; it is raised in a tub of water in the country, for when the dried seeds come over they seldom grow, and if they do, it is not before the second year; and from several parcels of the seeds which I have received from the West Indies, I have not raised more than two plants, and they came up from the seeds which had been sown more than a year; so that if the seeds are sown as soon as they are ripe in a tub of water, when they arrive in England, they will be plunged into a hot-bed of tanners bark, which will bring up the plants, and when they are fit to be removed, they should be each planted in a separate small pot filled with earth, composed of sand and light undressed earth, with a little lime rubbish well mixed together, then plunged into a hot-bed of tanners bark, and shaded until they have taken new root; after which, they must be treated as other tender exotic plants, always keeping them in the tub-bed by the roots, giving them but little water, especially during the winter season.

The ninth sort is a native of the West Indies, where it grows plentifully on the sea-shore; it rises with an upright shrubby stalk a foot and a half high, garnished with small spear-shaped leaves, scarce one inch long, and one-third of an inch broad in the middle, ending in acute points, sitting close to the stalk; they are hairy on their under side, but smooth above. The flowers are produced in single slender spikes, which come out from the side, and at the top of the stalks; they are but little increased, especially those on the side, but those at the top are more turn; they are white, so make but little appearance.

The tenth sort was sent me from Carolina, where it grows naturally on the sandy soil. This is an annual plant, with trailing stems, which grow six or seven inches long, garnished with small oval leaves, which are woolly and entire. HEMEROCALLIS. Lin. Gen. Plant. 391. Lilio-Aphodelus. Thurn. Inft. R. H. 344. tab. 179. Liliaftrum. Tourn. Inft. R. H. 369. tab. 194. Lily Aphodel, or Day Lily \ in French, *Us de Saint Bruno*.

The CHARACTERS are,

The flower has no empalement; in fome [peeks the flower is of one petals cut into fix parts \ in others it hath fix petals, with a fhort tube, fpreading open at the top, which is reflexed. There are fix awl-jhaped declining ftamina furrotnding the ftyle, terminated by oblong prostrate fummits. The roundijh furrowed germen is fituated in the middle, fupporting a flender ftyle, crowned by an obtufe three-cornered ftigma. The germen afterward becomes an oval three-cornered capfule with three lobes, opening with two valves, filled with roundijh feeds.

This genus of plants is ranged in the firft fection of Linnaeus's fixth clafs, which includes the plants whose flowers have fix ftamina and one ftyle. Tournefort places the firft in the firft fection of his ninth clafs, which includes the plants with a Lily-flower of one leaf, cut into fix parts, whose pointal becomes the fruit; the fecond he places in his fourth fection of the fame clafs, with the flowers of the fame form which have fix petals.

The SPECIES are,

1. HEMEROCALLIS (*Flava*) corollis flavis. Lin. Sp. 462. Hort. Upfal. 88. *Day Lily with a yellow flower.* Lilio-Aphodelus luteus. Park. Par. 148. *Yellow Aphodel Lily.*
2. HEMEROCALLIS (*Minor*) fcapo compreffib corollis monopetalis campanulatis. *Day lily with a compreffed ftalk, and a bell-shaped flower of one petal* Lilio-Aphodelus luteus, minor. Tourn. Inft. R. H. 344. *Smaller yellow Aphodel Lily.*
3. HEMEROCALLIS (*Fulva*) corollis fulvis. *Du> *-~. -J:b a copper-coloured flower.* Lilio-Aphodelus phoenicius. Pack. Par. 148. *Aphodel Lily with a reddifh flower.*
4. HEMEROCALLIS. (*Liliaftrum*) fcapo fimplici, corollis hexapetalis campanulatis. Hort. Cliff. 128. *Day Lily with an unbranched Jingle ftalk, and beU-jhaped flowers with fix petals.* Liliaftrum Alpinum majus. Tourn. Inft. R. H. 369. *Greater Alpine Bafiard Lily, called Savoy Spiderwort-9* and in French, *Lis de Saint Bruno, i. e. St. Bruno's Ufy.*

The firft fort grows naturally in Hungary, Dalmatia, and Iftria, but has long been an inhabitant in the Englifh gardens 5 this hath ftrong fibrous roots, to which hang knobs, or tubers, like thofe of the Aphodel, from which come out keel-shaped leaves, which are two feet long, with a rigid midrib, the two fides drawing inward, fo as to form a fort of gutter on the upper fide. The flower-ftalks rife two feet and a half high, having two or three longitudinal furrows; thefe are naked, and at the top divide into three or four fhort rbot-ftalks, each fupporting one pretty large yellow flower fhaped like a Lily, having but one petal, with a fhort tube, fpreading open at the brim, where it is divided into fix parts, thefe have an agreeable fcent, from which fome have given it the title of yellow Tuberoft. It flowers in June, and the feeds ripen in Auguft; this plant is commonly propagated by offsets, which the roots fend out in plenty, thefe may be taken off in autumn, that being the beft feafon for tranfplanting the roots, and planted in any fituation, for they are extremely hardy, and will require no other culture but to keep them clean from weeds, and to allow room that their roots may fpread; they may alfo be propagated by feeds, which, if Town in autumn, the plants will come up the following forms, and thefe will flower in two years; but if the feeds are not fown till fpring, the plants will not come up till the year after.

The fecond fort grows naturally in Siberia, this hath roots like thofe of the former fort, but are fmaller: The leaves are not near fo long, nor more than half the breadth of the former, and of a dark green co-

lour. The flower-ftalk rifes a foot and a half high, is naked and compreffed, but has no furrows 5 at the top is produced two or three yellow flowers* which are nearer the bell-fhape than thofe of the other fpecies, and ftand on fhorter foot-ftalks; thefe flower the beginning of June, and the feeds ripen early in Auguft. It is propagated by offsets from the root, or by feeds, in the fame manner as the former, but the roots do not increafe fo faft; it fhould have a moift foil and a fhady fituation, where it will thrive much better than in dry ground.

The third fort is a much larger plant than either of the former, and the roots fpread and increafe much more, therefore is not proper furniture for fmall gardens -, the roots of this hath very ftrong flefhy fibres* to which hang large oblong tubers. The leaves are near three feet long, hollowed like thofe of the former, turning back toward the top. The flower-ftalks are as thick a man's finger, and rife near four feet high; they are naked, without joints, and branching at the top, where are feveral large copper-coloured flowers, fhaped like thofe of the Red Lily, and as large. The ftamina of this fort are longer than thofe of the other, and their fummits are charged with a copper-coloured farina, which fheds, or being touched, or if a perfon fmells to the flowers, it will fly off and fpread over the face, dyeing it all over of a copper colour, which is a trick often played by fome unlucky people to the ignorant: thefe flowers never continue longer than one day, but there is a fucceffion of flowers on the fame plants for a fortnight or three weeks; this fort flowers about the fame time as the former, and the roots propagate too faft for thofe gardens where there is but little room. It will grow off any foil or in any fituation * the beft time to tranfplant the roots is in autumn.

The Savoy Spiderwort, or, as the French call it, St. Bruno's Lily, is a plant of humbler growth than either of the former: there are two varieties of this, one is titled Liliaftrum Alpinum majus, and the other Liliaftrum Alpinum minus by Tournefort; the firft of thefe rifes with a flower-ftalk more than a foot, and a half high; the flowers are much larger, and there is a greater number upon each ftalk than the fecond; but as there is no other effential difference between them, I have not put them down as different fpecies; but the firft is by much the finer plant, though not common in England, for the fecond fort is what I have always obferved in the gardens here. I received fogie roots of the fecond fort from Monf. Richard, gardener to the King of France, which continue their difference in the fame foil and fituation with the firft, which fflowers earlier in the year; the leaves of this fort are fomewhat like thofe of the Spiderwort, are pretty firm, and grow upright; the flower-ftalks grow about a foot and a half high, and have feveral white flowers at the top, fhaped like thofe of the Lily, which hang on one fide, and have an agreeable fcent; thefe are but of fhort duration, feldom continuing in beauty above three or four days; but when the plants are ftrong, they will produce eight or ten flowers upon each ftalk, fo they make a good appearance while they laft.

This fort is ufually propagated by parting the roots; autumn is the beft feafon for doing this work, as it alfo is for tranfplanting the roots; for when they are removed in the fpring, they feldom flower the fame year, or if they do, it is but weakly: thefe plants fhould not be tranfplanted oftener than every third year, when the roots may be parted to make an increafe of the plants, but they fhould not be divided too fmall for if they are, it will bg. two years before they flower: thefe plants delight in a light loamy foil and in an open expofure, fo muft not be planted under the drip of trees; but if they are planted to an eaft afpedt, where they may be protected from the fun in the heat of the day, they will continue in beauty longer than when they are more expofed.

HEMIONITIS [*He*wk, of H'otas a.Mule, q. d. Mulewort, becaufe ihis plant was believcd to be as barren as a mule.*] Moonfern.

Tlii? : a plant whi is fridoni p:rp.i:- LI id in gardens, therefore 1 •' all not r...ible the a-ader with any account of it more than this. Tjtai whoever liati a mind 10 or 11... of the sort, must procure the plants from the •>m tries wt v: they naturally grow, there are iwo lbr» which art natives of th= warmer part; •. Europe, but in America •••re is a great number of very different kinds, these iimft be planted in pots filled with loamy undruggd, 1 iiii, 1lm [uch tit them as art natives of hot countries, must be placed in thi flower; the others may be sheltered i ;ider it common franc in winter, and during iJic lumail-r they must be 1 1 cjucndf watered, but in winter they will require but little. In summer they lliould alfo have plenty of free air admitted to them; with this manner • merit the plants will rflit.

HEPATICA • A. Boerh. Ind. Plant. Ranunculus. TERN. Inf. R. Fl. 150. American. Linl. Gen. Plant. 614. [Hepatica, or Hepas, the liver, is called, because the leaves of this plant are divided into lobes, like the liver (but it does not at all take its name from its ufi for it is of no virtue against the diseases of the liver, us many have croutoudly imagined); and trissha, iiom iti uuil made thereto.] Hepatic >> of Noble Livci..

The Jharr hath a ti-t-ltaoed cmpnlrmt. Is hath for petals, which are oval, and expand to the bottom, with a great number of slender filamentous flowers. km tl<t petals, surrounded by single lamina; and several forms collected into a head, supporting accumulated stamens, crowned by white filaments. The perianth consists of five acuminate pale fleshy scales the styles.

This genus of plants is by Tournefort ranged among the Crisifoots, and by Linnaeus it is placed under American; but as the flowers of American have no enfilaments, and the Hepatica hath a three-leaved one, it may be separated from that genus \ and ai C it is well known in the garden by this title, so should we range it with the American, it might occasion confusion. This is ranged in the Systema section of Linnaeus's thirteenth class, which includes the herbs with flowers having many laminae and styles.

The VARIETIES of this plant are,

1. HEPATICA (Nobis) trifolia, circulo RCB◀. CM. 71M *Jugh the Hepatica, or Noble Liverwort.*
2. HEPATICA (Pisa) trifolia circulo p.'no. Cluf. fir *Askle the Hepatica, or Noble Liverwort.*
3. HEPATICA (Alta) trifolia, flore alba i implki. Boerh. Ind. *The pale white Hepatica, or Vait IJi'truwt.*
4. HEPATICA (Pulchra) trifolia • mbroflora. Clu.: *Single red Hepatica, or Noble Liverwort.*
5. HEPATICA (Rubra) trifolia St. flore rubra Nle-na. Boerh. Ind. *Double red, or Ptaib-idkurdt Hpa-tica.*

Theic plliir are some of the g-iteft bea' •ers of the fp'ng; thic t'uwcis arc produced in Febrii.

In great plenty, before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight long in flower than the single kinds, and the flowers are much fairer, I have seen the double white kind ofttn mentioned in books, but could never see it existing, though I do not know but such a flower might be obtained from seeds of the double white, or blue kinds. I have sometimes known the double blue sort produce some lowly; in autumn, which were inclined to white, and thereby Ionic pwijlle Juvc b«n ikcciv«l, who have procured tr roots at •itat feafon, and planted them in their gartiwi: but the spring following their Sowers were blue, ai before t and this is what frep. A illy happens, »! i in the autumn is so mild as to cause them to flower, but whether the double white sort, mentioned in the books, was only this accidental alteration in the colour of the flower, I cannot say, though it seems very probable it was. I see not could hear of any person who >ever £1* the double white sort grows in the f

The single sorts produce f... r-ryycar, whereby

they are easily propagated, and alfo new flowers may be raised; ii way t)bt...ed. The brtftcfcon i or lowering of the let-dsii in ihc begitnir^ pi August, either in pots or boxes of Hgln earth, which should be placed in a to luvc onl) the morning sun until October, when they Qwuld be removed into the full sun, to remain during the winter leaf inij but itt March, when the young pbnt: will begin to appear, they must be removed again to a shady situation, nil in t.r) weather should be frequently watered, and about the bfjjiit- r^N^ of August they w!! Lr in inij [jt tr,tninUnted; ac which time you (huuM ijrff]arc a border lacing the Mil, of good, frech, loamy earth, into wiiidi you (liould remove the p'am., ;lacing iima about fAK inches • difUrcc t... way, closing the earth pretty fast 0 thcir roof, to prevent the worms from drawing iheni out 01 the ground, which they are very apt to do at that season; and, in the spring following, they will begin to show their flowers, but it will be tiit, two years before they flower freely, and till then you cannot judge of their goodness; when, if you find any double flowers, or any of a different colour from the common sort, they should be taken up, nnet I: and planted into the borders of the flower-garden, where they should continue at least two years before they are taken up or parted; for it is remarkable in this • plant, that when they are often removed and parted, they are very subject to die; whereas, when they are permitted to remain undisturbed for many years, they will thrive l exceedingly, and become very large.

The double flowers, *1 which never produce seeds, are propagated by parting their roots, which lliould be done in M.;; ch, at the time. Ion tiey arc in 1lt/weij but •! lliould be careful not to separate them into very [i small heads, nor should they be parted •-iienter than every third or fourth year, if you intend to j]it... them thrive, for the reason before given. They delight in a strong loamy soil, and in an eastern position, where thejr mny have only the morning sun, (houg; they will grow in almost any aspect, not too warm, and are ; ever injured by cold.

HEPATICA TORFI. M. See ERYTHRODIA. 11.

Hi-ITAPHYLUM. See POTTIA IU-A.

HER. • CLEIM. Lm. Gea, 3+5. Sphonjylium. Tourn. Inf. 1. Cow ParCncp.

The CHARACTERS are,

The calyx of the greater united is large, composed of many smaller, which are plain; the general involucre is composed of many leaves which fall off; the partial united have involucrems of three to seven leaves, the outer being the longest. The general involucre is deformed, the furrows are mostly pentafid; each of the lobes have five equal petals, which are reflexed; Most of the rest have the same number of unequal petals, the outer being the largest; they have each five filament longer than the petals, surrounded by a single lamina. The perianth is fringed with the leaves, and is almost oval, supporting four styles, crowned by simple stigmas. The perianth of several becomes an elliptical fruit, composed of two oval compressed seeds.

This genus of plants is ranged in the second order of Linnæus's sixth class, under Pentandria Digynis, the flowers having five Stamens and two styles.

The SPECIES are,

1. HERACLIS (Sponjylium) foliis pinnatifidis. Hort. Cluf. 303. Cow Parjog with white pointed lobes. Sphonjylium vulgare hibernum. C. B. P. 157. Cow-parjog.
2. HERACLIS (Pinnar) foliis pinnatis, foliis quibus, intermedia trifidis, floribus radiatis. Hort. Lugd. 69. Cow Parjog with orange lobes longer than the, and radiated flowers. Petax Sphonjylii rad. in Hieracium. C. B. P. 157.
3. HERACLIS (Sponjylium) foliis simplicibus, floribus radiatis. Lin. Sp. 359. Cow Parjog with large white and radiated flowers. Valant from Sponjylium glabrum. C. B. P. 157. Double Spun Cow Parjog.
4. HERACLIS (Silybum) foliis pinnatis, foliis quibus, intermedia trifidis, cordatis uniformibus. Hort. Uplid. 69. Cow Parjog with orange lobes, having five

lobes and a uniform corolla. Paftinaca foliis fimpliciter pinnatis, foliolis pinnatifidis. Flor. Siber. i. p. 218.

The firft fort grows naturally in moil parts of England, fo is rarely admitted into gardens; there is a variety (if not a diftinct fpecies of this) with narrower leaves, which are more divided than thofe of the firft; however, as they are feldom cultivated, I fhall not trouble the reader with their defcription.

The fecond fort is placed in moft of the Pharmacopoeias as a medicinal plant, but is rarely ufed as fuch, efpecially in England. This rifes with a tall ftalk near fix feet high, which is embraced by the bafe of the leaves 5 thefe are winged, having generally five roundifn lobes, whofe furface is rough, of a dark green colour: the flowers are produced at the top of the ftalks, being clofely inclofed by the empalement when they firft appear 5 but this afterward burfting, the umbel expands, having large petals on their exterior row, which are almoft heart-fhaped, and are fucceeded by flat compreffed feeds like thofe of Parfnep, but larger, having black ftreaks on their outfide. This grows naturally on the Appenines.

The third fort grows naturally on the Alps, as alfo in Siberia: the ftalks of this rife as high as thofe of the former, but the leaves are fmooth. This is feldom cultivated.

The fourth fort grows naturally in Siberia and Tranfylvania; in the former country, the inhabitants eat the ftalks and leaves of the plant for want of better food.

As thefe plants are rarely cultivated, unlefs in botanic gardens, fo I fhall recommend to thofe who are defirous to propagate either of the fpecies, to fow their weeds in the autumn; and in the fpring, when the plants are up, to hough the ground, cutting up the feeds, and thinning of the plants, in the fame manner as is direfted for Parfneps, with which culture the plants will thrive.

HERBA GERARDI. See ANGELICA SYLVESTRIS MINOR.

HERIBALIST, HERBARIST, a perfon who is fkilld in diftinguifhing the kinds, natures, or virtues of herbs or plants.

HERBA PARIS. See PARIS.

To HERBARIZE, to go abroad in the fields in queft of different or new herbs or plants.

HERBIFEROUS fignifies bearing or bringing forth herbs.

HERBIVOROUS, i.e. devouring or feeding on herbs or Grafs.

HERBOSE, graffy, or full of Grafs or herbs.

HERBOSITY, graffinefs, or abundance of Grafs or herbs.

HERBULENT, graffy, full of Grafs or herbs.

HERMANNIA. Tourn. Inf. R. H. 656. tab. 43*. Lin. Gen. Plant. 74a. The title of this genus was given by Dr. Tournefort in honour of that great bo-Lift, Paul Herman, M. D. Profeffor of Botany at Leyden.

The CHARACTERS are,

The flower bath a pitcher-fhaped permanent empalement, divided into five parts at the brtm. It bath five petals, which are narrow at their bafe, and twijt agatnjt the fun within ibe tubulous empalement, but fpread open above, where they are broad and obtufe. It bath five broad ftamina, which are joined in one body, terminata by pointed fummits, which are joined. In the center is fituated a roundijh five-cornered germen, fupporting an owl-toaped fyle which is longer than the ftamina, crowned with five fpikelets. The germen afterward becomes five-lobed.

The germen is ramred in the firft feftion of This gemis or F T X h includes the plants Lmnaeus's fixteentn crais, * < ^ . 5, ^ whose flowers have five ftamina joined in one body to the fyle.

The SPECIES are, >. Itawu c***) * & % ? £. Hermannians, crenato-emarginatis. Hort. ^ u ^ 3+

ma with wedgefhaped folded leaves, which are crenated and indented. Hermannia frutescens, folio oblongo ferrato latiori. Boerh. Ind. Shrubby Herinnannia with a broader, oblong, ferrated leaf.

2. HERMANNIA (Grossularidfolia) foliis obovatis acutè incifis, pedunculis bifloris, Prod. Leyd. 347. Hermannia with oval leaves acutely cut, and foot-ftalks bearing two flowers. Hermannia frutescens folio grossulariae parvo hirtuto. Boerh. Ind. Shrubby Hermannia with a fmall, hairy, Gooseberry leaf

3. HERMANNIA (Althaeafolia) foliis obovatis plicatis crenatis tomentosis. Hurt. Cliff. 343. Hermannia with oval, folded, woolly leaves, which are crenated Hermannia frutescens, folio ibifci hirtuto molli, caule pilolo. Boerh. Ind. Shrubby Hermannia with a soft, hairy, Mershmallow leaf, and woolly stalk.

4. HERMANNIA (Hyjlopifolia) foliis lanceolatis obtusiferratis. Hort. Cliff. 342. Hermannia with obtuse fpear-fhaped leaves, which are fawed. Hermannia frutescens, folio oblongo ferrato. Tourn. Shrubby Hermannia with an oblong ferrated leaf

5. HERMANNIA (Trifolciato) foliis oblongo-ovatis crenatis tomentosis flore mutabili. Hermannia with oblong, oval, crenated woolly leaves, and a changeable flower. Hermannia frutescens, folio oblongo molli cordato hirtuto. Boerh. Ind. Shrubby Hermannia with a soft oblong, hairy, beard-fhaped leaf.

6. HERMANNIA (Pinnata) foliis tripartitis, media pinnatifida. Hort. Cliff. Hermannia with tripartite leaves ending in many points. Hermannia frutescens, folio multifido tenui, caule rubro. Boerh. Ind. alt. Shrubby Hermannia with a narrow multifid leaf, and a red stalk.

7. HERMANNIA (Lavendulifolia) foliis lanceolatis obtusis integerrimis; Hort. Cliff. 342. Hermannia with obtuse fpear-fhaped leaves, which are entire. Hermannia frutescens, folio lavendulae latiori & obtuso, flore parvo aureo. Boerh. Ind. alt. Shrubby Hermannia with a broad, blunt, Lavender leaf, and a fmall golden flower.

8. HERMANNIA (Hirtuta) foliis fimplicibus tematicis hirtutis feffilibus. Hermannia with fingle and trifoliate leaves which are hairy, and fit clofe to the stalk.

The firft fort rifes with a fhubby ftalk fix or eight feet high, dividing into many eredt irregular branches, covered with a brown bark, garniied with wedge-fhaped leaves, which are narrow at their bafe, but broad and round at the top \ they are about an inch long, and three quarters broad at the point, where they are indented and crenated. The flowers are produced in fhort fpikes on the upper part of the branches; they are of a pale yellow colour, but fmall; thefe appear in April and May, and are often fucceeded by feeds, which ripen in Auguft.

The fecond fort is a fhrub of lower ftature than the firft, but fends out a great number of branches, which fpread wide on every fide, garniied with fmaller leaves than thofe of the former, which are rough, and fit clofe to the branches. The flowers are produced in fhort clofe fpikes at the end of every fhoot, fo that the whole fhrub feems covered with flowers; they are of a bright yellow, and appear toward the end of April, but are not fucceeded by feeds in England.

The third fort is a plant of humbler growth than either of the former, feldom rifing more than two feet and a half high ; the ftem is not fo woody, and the branches are foft and tender, garniied with oval woolly leaves, which are plaited and crenated on the edges; the flowers are produced in loofe panicles at the end of the branches ; they are larger than thofe of the other fpecies, and have very hairy empalements. This fort flowers in June and July, and frequently puts out more in the autumn.

The fourth fort has been longer in the European gardens than either of the other. This rifes with a fhubby upright ftalk to the height of feven or eight feet, fending out many ligneous branches from the fide, which alfo grow ipore eredt than any of the other; thefe are doathed with obtufe fpear-fhaped leaves,

ahair an inch and a half long, and hilt' mmch broad, lawed on (he edges towir l the end. [he flower* come out in linull buncim from ilv lido of the *Cniki* ihey *MC of v.* pale Straw colour, ami appear in May and June; tiicie arc frequently luccccited by lccds, which jil ripen lhc latter psn of Augult.

The fifth • rt kidom nfes more thin two feet high, with * fort Ligneous (ULk, lending out llcndcr irregular brarKh-s, garniihed with oblong, oval, woolly leaves, ftandir r. up n pretty long foottalks; the low produced in Joofc fpikes it the end or the bran thefe arc, al rheir firft appearance, of a gold colour, but after they have been lomc days open, they change to yellow. Th(S flowers in Jurw and July.

Th* fufth fort hfes with a. Ihrubby llalk near three feet high, fending out many lknder branches, covered with a rrdiJh bark, garnifhed with narrow wing-pomted leaves ; the flowers come out from the fide of ih: branches in fmall clufters; ihey are ii.iall, <nd of a deep yellow colour. This flowers in June and July.

The feventh fort hath ftrubby branching ftalks, which arc very bufiiy, bur {*Adam* rife more than a foot and s half high •. the branches arc very fender, Mid garni[hed with hairy, paic, green leaves of different lizes -, *fame* of them are two inches long^ and one bioad at their ends •, but their common fric is felclom more dun one inch long, and half an inch broad at their points; they are entire, and fit pretty close to tilt branches -, the (lowers come out from the fiJe of the il alls fitgly, they are fmatl, a;id of .l yellow colour. This fort flowers molt [urr of Kimmer.

The eighth fort I raifrd from feeds n-hldi came from ihe. Cape of Good Hope. This r.--^ with * ihrubby hairy Halk about two tccr iii^n. It-tiding out many fide branches, which grow more atEt tfu of tie former, gamifhed with oblong, Veined, hairy leaves, wliich arc fomctimes Qrglc, and at oit times come out by thrcci, the middle one bring die large! j the flowers arc produced toward t^ end of the branches; they are large, and of a deep yellow colour, with large, iwollen, hairy ejnalcments. Thii fort continues flowering mulV part 01 furmncr.

All the fpecies of thi) genci yn known, are natives of LHC country about tht- Cape of Good Hop. from whence moft of them were brought to the gardens in Holland, where they have been propagated and lprrad through moil parts of Europe.

The plants are all propagared by planting cui. of them during any otihc lummer month*, in a bed of frith earth, obferving to water and iludc them until they arc well rocurd, which wil be in sbfil wrtks after planting; then you fhouid rake diem up, pidrrvtag a ball of tanh to ilicir roots, and pl:n: them into pots filled with light frith earth, pljcinf; ihem in .l Cwdy fituation until they have taken freili root; after which (hey may be ejtpofed to tin open air, with Myrtles Geraniums, See. until (he middle or latter end of October, when chry mull be removed into ilic greca-houfe, obfervin^ to place them in the mokflpart of the houfe, where they may l> nmcti free air as poffible; ior if they arc too much drawn in the houfe, they will appear very faint and fieldy, imdfeldoni produce many flowen; whereas, whn they arc only preferved iroin [he fruft, => a great fl. r, they will .ippr.ir ft rang ar.d healthy, and produce Urge qvsniities of flowers in Apr: and May, during which tcurytialic a very hirullomc appearance in the grern bout: rticj mult alio be frequently waii red, and w. I require to be pew potica at leaft twice every year, i. e. in May and Scptember; otherwife fhdrn>ti will be ib rnmtdtd, 3\to it their growth.

These plants rarely l produce good fruct with us, except the fourth and eighth forts, which ripen their fructs every year in England; the • other tart: productiis any, t Iippoic tlui nuy be their).

Having been long purpofed from couages, for thofe plants which I have raded from feeds, have been fruful two or three years after, but I have always

found thole plants which have been prop snared by cuiinjptaken from thefc, luyc four tecmnc barren: the lame thing I have ubicrved in n any other plants, tEic^elueie Lhole who arc dTiru'ji to continue tluir plants fruitful, (liquid cortljtitly reite them from iceds. Theft-, as alfo thole which arc gbtained troiu abroad, muft be lown upon a molLer^te hoi and when the pUnts come up, they mult be trtnl-planted into finsUpocs, am: abanqued into anucher very tnodernte hot-bed, in offio to pntow their rooting •, after which they mull be hardened by de-prcccs, to endure the open air in fuminci and may then be treated us the old pkots.

Ij fix M O D A C T Y L U S, the HefmodaSy], commonly called Snake's-head Iris.

This genus is by Dr. Ltnn:eus joined to Iris, the characters of the flower agreeing pretty well wit at thm gL-nus; from which Toura it has feperand it from the difference of ihe root, which is .jt ai; COTdiog to his own fylleii, wliere i be lhfpe of the petals with their nuhier ami pofition, the principal chrn.ictcriitics in diftmguifliing die clsfils and genera ; but as this plant rquires a particular treatment, Jo J have continued it under Tournurfurt's title.

The CIMKVK-TERS are, *It beth a Lsty-jbaped jlrarr, wtfijtini tf cm lajf, end Jhopti rx.kify likt an bit, tut has a txbema* rwi, Ji -l iwte t'jjs or tbrte dags, like ol/txg LuH'S.*

We have but one Snoui of this plant, HatwoDACTVLUS [*TuhmiNi*] foliu quad ran 511 St C. B. P.

Snekti-besd Iris, vul^o. "iliiis is alio called Iris tu-be noth Belgarum, i. c. *fuixroii Iris* if lite iitiitib.

'iliii plant u eaCty propiflfted Ly hi tubers, whkh lhottld be cackit off soon after the green leaves decay, but they fhould not be kept long out of the ground, left they fhrink, which will caufe them to .l wken they are planted. They ihould have a loamy Jbil, nor too Jtrong nor deep, and muft be planted to or caft afpect, where they wil flower very weli.

The roots fhould not be removed (-fctner thia: onct three years, if you detign to iooMls ilirfij but then mey ihould be planted at 3 farther L:ftance from each other, thari if they were to remuj) but one years and the beds fhould be kept cleir from Weeds, and at Michaelmas ilicre fhould be (one line earth laid over the beds, which will greatly ltingthen their roots.

The diftance which thrfr plants ihould be allowed is fixinchesfquire, and they ihouldbt. placed three, inche> deep to the duce U jeir fy •• rrs in M ay, and their feeds arc ripe in Auguft ; but as tley multiply pretty fa& by thier TOOLS, tew people are it the tremble of roofing them from fecdj \ buc rhofc who havean inclinai on to do, muft m:; them in the man: or directed for the bulbous Iritb.

The roots oi this plant are very apt u> wn deep into the ground, and then rhyr lldum product llovers; and many times they ihoot fo deep as to lce foil, elpcciiily where the foil b very li;:tii; [ht-reibre to pccr ont tho, it will be proper to lay a ftack of tubbiih under the beds where thefc lre planted, to hinder them from getting down. This fhould al-ways be pradifed in light i round, bu; in ftrong land ihe're will be no occafwn'io maJ.: uie of this precaution, becaufe they do n< flioot downward io freely in that.

This plant has by fome botanic writers been fuppofed the true Hcrtnodactyl, but w] as has been long whd in Europe for thtat ia the root of a Colchicum.

H. E. R. S A N D I A. Plum. Nov. Gm. j. 1737. 47. Lin. Gen. Plant. 431. jack-in-a-Box, vulgu.

The CHAÏAOTIXI (IC,

It hath male and female flowers on l. lant, the male flowers have a partial corolla.

*b*ra titter i&JbmtJ trnfaitmnu*

are shaped like the male, but want stamina, they have a rounded germen, supporting three slender styles, crowned by acute stigmas. The empalement afterward becomes a large, swollen, oblong fruit, perforated at each end, inclosing one hard globular nut.

This genus of plants is ranged in the third section of Linnaeus's twenty-first class, entitled Monoclea Triandria, which includes those plants which have male and female flowers in the same plant, whose male flowers have three stamina.

We have but one SPECIES of this genus in England, viz.

HERNANDIA (Sonora) foliis peltatis. Hort Cliff. 485. tab. 13. Hernandia amplo hederæ folio umbilicato. Plum. Hernandia with a large umbilicated Ivy leaf, commonly called in the West-Indies, Jack-in-a-box.

This plant is very common in Jamaica, Barbadoes, St. Christopher's, and many other islands in the West-Indies, where it is known by the name of Jack-in-a-box. The fruit of this plant when ripe, is perforated, and the nut in the inside becomes hard; so that when the wind blows through the fruit, it makes a whistling noise, which may be heard at a distance, from whence, I suppose, the inhabitants gave this name to the plant. It grows in the gullies, where there are rills of water.

In Europe this plant is preferred in curious gardens, with other tender exotic plants. It is propagated by sowing the seeds in a hot-bed in the spring; and when the plants have arisen two inches high, they should be transplanted each into a separate pot, filled with rich earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root, after which time they must have air admitted to them, (by raising the glasses) in proportion to the warmth of the air, or the heat of the bed in which they are placed, and should be frequently watered, otherwise they will not thrive. As the plants advance, they should be removed into larger pots, which should be filled with rich earth, but in doing this, you should be very careful not to break the roots, as also to preserve a good ball of earth to them, and if their leaves should hang after being removed, the plants must be screened from the sun until they have taken new root. The best time to shift these plants is in July, that they may be well rooted before the cold approaches; the plants must be constantly kept in the bark-stove: in winter they should have a moderate share of heat, and in the summer they must have plenty of air in hot weather. With this management, the plants will grow to the height of sixteen feet or more, and the leaves being very large, will make a beautiful appearance in the stove. It hath not as yet flowered in England, though we may expect some of the large plants to flower in a short time.

HERNIARIA. Tourn. Inft. R. H. 507. tab. 228. Lin. Gen. Plant. 272. [of Hernia, Lat. a rupture.] Rupturewort.

The CHARACTERS are, The flower hath no petals, but a coloured empalement of one leaf, cut into five parts when spread open. It hath four small unequal styles situated on the division of the empalement, terminated by acute stigmas, five others which are shorter, placed alternately between them. In the center is an oval germen with two stigmas, which have acute points; the germen afterward turns to a small capsule included in the empalement, having one unequal-pointed seed.

This genus is ranged in the second section of Linnaeus's twenty-first class, entitled Pentandria Diogynia, or the whole flower alive.

- The SPECIES are, 1. HERNIARIA (Glabra) glabra herbacea. J. B. 3. 378. Smooth Rupturewort. 2. HERNIARIA (Filifolia) * * herbacea. J. B. 3. 379. Rough or hairy Rupturewort. 3. HERNIARIA (Alba) alba herbacea. Tourn. Inft. 507. Rupturewort with a Chickweed leaf.

4. HERNIARIA (Fruticosa) caulibus fruticosis, floribus quadrifidis. Amoen. Acad. 4. p. 369. Rupturewort with ligneous stalks and quadrifid flowers. Herniaria fruticosa, viciculis lignosis. C. B. P. 382.

The two first sorts grow naturally in England, but not very common; they are low trailing plants, their branches lying on the ground, and extend seven or eight inches each way; they have leaves like the smaller Chickweed, the first is smooth, and those of the second are hairy; the flowers come out in clusters from the side of the stalks at the joints; they are small, and of a yellowish green, to make no appearance.

The fourth sort hath shrubby stalks which trail upon the ground, garnished with small hairy leaves like the second sort; the flowers are all very like that.

The third sort is an annual plant, which grows naturally in France and Italy. This doth not spread so much as either of the other sorts, but the flowers and leaves are somewhat like the first, but larger.

These plants are seldom cultivated, but in botanic gardens for the sake of variety. The three first are annual plants, seldom continuing longer than one year, and must be permitted to shed their seeds, whereby they are better preserved than if sown with art. The fourth sort is an abiding plant, which may be propagated by cuttings; but as they are plants of no beauty, they are rarely preferred in gardens.

The first sort is what should be used in the hops, but is rarely seen in London, the herb-women commonly bringing the Parsley Breakstone to the markets, which is sold instead of this plant.

HESPERIS. Tourn. Inft. R. H. 222. tab. 108.

Lin. Gen. Plant. 731. [some derive the name of this plant from Heperia, Italy, from whence the people were anciently called Heperides; but it is pretty plain, that the name was taken from Ἑσπερίς, because the flower commonly smells most in an evening, either of these may be admitted. It is called Viola Matronalis, because it resembles the Violet, and was at first cultivated by women.] Dame's Violet, Rocket, or Queen's Gilliflower, in French, Juliane, or Juliene.

The CHARACTERS are,

The flower is composed of four oblong petals in form of a cross, whose base or tails are narrow, and are situated in a four-leaved empalement, which falls away. It hath six unequal styles, four of them as long as the tube of the flower, and two much shorter, terminated by narrow crescent-shaped stigmas, reflexed at their points. It hath a honey-gland situated between the two short styles, and a four-cornered germen the length of the styles, but no style, the oblong erect stigma fitting on the germen; the stigma is divided into two parts, which join at their points, the germen afterward becomes a plain, long compressed pod with two cells, divided by an intermediate partition, inclosing many oval compressed seeds.

This genus of plants is ranged in the second section of Linnaeus's fifteenth class, entitled Tetrastemonia Siliquosa, the flowers having four long and two short stamina, and are succeeded by long pods.

The SPECIES are,

- 1. HESPERIS (Matronalis) caule simpliciter erecto, foliis ovato-lanceolatis denticulatis, petalis mucrone emarginatis. Lin. Sp. 927. Dame's Violet with a single upright stalk, oval, spear-shaped, indented leaves, and the petals of the flowers indented at the top. Heperis hortensis, flore purpureo. C. B. P. 202. tem
The fecond fort grows naturally in India, from
whence tin French first carried the feeds to
the Weft-Indies; and the inhabitants of
theBriiilli colons there have been fupplied with the
; and from them, fo have given it the title of Maracoon
; and there are the double and fingle flower-
ing, which from the feeds of the double the fingle is
frequent!) produced, but the feeds of the fingle plant
differ in the double. The ilowcrs i of these plants
alii: their colour, before their full opening they are
white, tin they change to a bluish Rose colour, and
as they decay they turn to a purple. I ithcWeft-In-
dies, a: their alterations but n the hmc day, a; I
fuppofe the flowers in thofe hot countries are not of
longer duration; but in England, where •• the Qowert
last near a week in beauty, the c changes arc not fa
fudden.

I III: plant has a soft spongy stem, which, by age,
becomes lignous and pulpy. It rises to the height of
twelve or fourteen feet, branching out
every III* toward the top, which art hairy, gar-
nished with bran-fhaprd leaves; that into five acute
angles on their bndr.Tf, and are fightly f: wed on their
edges, of a hieit rjrem on their upper fide, but pale
below ftanding alternately upon pretty logg foot-
rtiJk:. The flowers are produced: ?fin the wig j of
the fljlk, I in thofe of the firl fort, the flomc one
is compofed of v.ry large petals, which spread open,
and are tidl white, but afterward change in the man-
ntr before-men trailed •, thec are fucceeded by short,
ihkk, blunt omfbitt, whki. are very hairy, having
five cells, which contain irony fir.all kidney fhaped
feeds, having ^ line plume of fibroul down adhering
to them.

This fort is propagated by feeds, wiiith wuft be
(own upon a hot bed in the fpring, and when the
plants are fit to remove, they fhould be planted
in I feparate fmall pot filled with litcher-irden
earth, and plunged into a moderate hut-bed, when:
ilicy mull l • fhaded till they have takci new root,
then they mull be treated si u:her pl:its from wann
countries, but not too tenderly, for thec require 3.
large pure of air in warm weather, othenwfethey
vili draw up very w<ak: thi I plants fhould not be
quite expofed to the open air the firl feafon, and
the firl winter will require the warmth of a
rate flovey; but as they get more through, they mxy
bt treated v. I In a cave, for they will bear the open
nil in fummer, in a warm fhaded fiteuation, and will
liw through the winter in a very good green-houfe,
provided they have not too much wet, but the plants
thus hardly treated, will not make: i freat prugreft,
nor fhower fo well as w: h t little additional warmth i
and if the are not fo ierly managed, they will .lrj-
up weak, fo will be less likely to flower. This fort
usually Q'ears in England: November, ft that it
keeps... the vint •• cffloweing in its native
country.

The third fort ••fl« naturally in the Weft-Indies,
where it is commonly known by the title of Mufk,
the French cultivate great quantities of these plants in
their American Iflands, the feeds of which are usually
lent to KrJncr in great quottii; fo that they
certainly have loilli way of rendering it: [u); it
feems to be a considerable branch of trade. It
rises with an herbaceous -Ijlk 3toviit threecor four feeti
lending out ruw of three lide brinchr=.. (• milled with
large leave) nut fmo fx or fewn any lei, which are
acute, and dwell tj] their ed(" they stand on long
foot-(talks, ititi are placed altnately. The stalks and
leavr^ > this are very hairy. The flowers come out
front the wings of the stalk upon pretty long foot-
stalks, which stand erect; they are large, of a sulphur
coltL, with dark purple bottoms, and are fucceeded
by pyramidal five-cornered caufules, which open in
fi™ cell, filled with i Urge kidney-limped leedi of a
vcj™: mufky odour.

Tfm fort fddom lives more than one year in England. bin in it-native century will Lift two years, [it propagat... d by fertls, which, if own on a good hot bed in the fpring, and the plants afterward plantet in pots... I with lip lit earth, and plunged mtoafrelh hot bed, treating... ifterwjrjd i... the same way as the Amar...tkus, they will Rower in July, ar.d their ii-cl- will ripen in IUCUI.

The fourth ii ion grows naturally In both the I... with ;n jjerbaseoui... I ilk. three tir feet high, garnifhed with leaves which aiv divided into... Segments a] molt to the bottom; the middle segment being four inches long, and the an inch broad, tin- 'upper later I Eegmcim abotil three inches long- and the fame breadth; theft a<- in... at their ex;... the lower feginems arc not much man... than an :LClI long, and have... flowers are produce! from the wings of the ftalk?- towird ilie top, Handing on Ihott foot [talks] they are compofed of rive large tujpbur... ired petals, which, when open, fprecd five inches wide, they have i ih.ik JH:l[... bottom, with a column of... in ins ami liyl.c i riling in the center, and an... ceded by large, pyramidal, live-cornered, creel... opens rig i n five cells, < led with pretty large kidney-itaped feeds, ivhich have little Jim-U or ufte.

It is propagated by feeds in (he fame manner A- the fornir Ibn, and if fo managed, will pnotiL flowers and perfect fctda the fame kafon; bin the plants may be continued through the winter in a moderate warmth, though few perfons are at the trouble of preserving the plants after they have ri- j:rntt their feeds, becaulb the young plants make a better appearance.

The fifth fort grows naturally in die Wefl-loci, where it riles with a v... ody flalk lbven oreighbfct high, fi nil ing out many fide branches toward the top, which are covered ! with a whitifh bark, and garnifhed with angular heart-lhaped leaves, which are wixilly ; they are about iuur inches long, and three broad toward their tafc, ending in acute poieKSt and have 1c-v;ral longitudinal veins. Xhe ftowers are produced from the... of the flalk upon long foot ihllki ; (he) arc compofed of five roi... petals, which are joined at their bafe, but fpread open above, and are of a yellow colour, turning to a red as they decay ; theft arc licceeded by large, obtufr, five-romered, tmiry ftd-veOe's, which open in five ctk, liiltl with large Udney-fturx-d fctclj.

Thits is propagated by liedts, which muft be (own upon a hot-bed in the fpring, and the plants afterward irtated in the lame way as the two lift m?n-tionri, during he firll fumrncr, but in the autumn (hey mult be plunged into the un-bed in the ftove, where they fiouulul conftantly remain, and be i... in (he lame way a^ other tender plants from ci'. (ame counir)', giving them but little watef in winter ; the fecond yeji tht plants will flower, but they have not as yet perfected... in England.

The fifth fort grows naturally in both Indies; thu riles with i woody pithy fem eight or ten teet high, dividing into feveral brandies toward the cop, which are covered uith u woolly down, and garnifhed with round heart-flujxd leaves, ending in acute points ; they are of a lucid green on their upper fide, and hairy on their unlet, full of large veins, and are placed alternately on the ftalks. The flowers are produced at the ic end of the brandies in loule fpik<; they are of a whitifh yellow colour, and are Tu<ctciid by fevee acuminate capsules, opening iF five cells, filled with large kidney-lhaped teeds.

This fort is p... d in die fume way, and the plants require the lame treatment aa D)C fi'f', and I flower the fecond year, provided they are brought forward, otherwife the... will not fluer before the third or fourth kafon i, but they will bear the open uner, in a wjrm fituation, though ti... will not make great progref there.

The feventh Tort grows naturally on the toaft of

MnTabar, from whence I received ihc rVUni... this rife with a WJLU... flalk twelve or fourteen feet high, dividing into nuny fmal I branches toward the top, which are gainiix'J with oval fawed leaves, ending in acute points ; the ; arr tit i mciil gR-tu abovx; ; b'L are pale on that under lidc, and arc placed without order.

The ; lowers come out from the fide of the branches, at the wings of tin: leaves, on ptettj... rbrly arc com poled of many obl'i... - - J's of 3 red colour, whi... expand like the Rofe, the flowers being its lurge whe fully blovm, as the oosunoo red Rofe, and as durable. This is a perennia 'uui, which is propagatiii by cuttings -, and the plants mud continue to be kept in tin- (tove, giving them a larjc lharc of air in warm weather, and but little water in winter. There is a variety of this with wfiitt flowers, but I have not f<n any of the piano in the Engtlb. gardens ; nor I have feen... flowering kind, for the inhabit'...

of India propagate that with >oubc fio*cri by tmtingi, which put out roots freely ; this they do rorthelale of flowers, which the wafenof that country make ule ut to colour their hair and eye-brows black, which will not wa/h oG": the F.ng-lifti thiere ufe it for... it Hiuti, and from thence have called it Shoe-flower.

Xhe eighth fort is an annual plant, which riles with an upright folk feven or eight feet high; the lower leave; are oval, lcrated, and entire, but the upper leaves are divided aUnoi... to the root-ftalk, in to five fpcar-flaped fegimets, like the fingers of a hand, ftarding on very long foot-ftalks, which have thorii at their bnfe, and are ihu-ply lawed on their edge.

The flowers come out from the wings of the flalks ; they are large, of a pale fulphur colour, with a dark purple bottom, and are fucceeded by oval, acuminate, prickly capsules, which open in five cells, filled with large kidney-shaped feeds.

This is propagated by feeds, which muft be fown upon a hot-bed, and the plants treated in the lame way as the third fort; and when they are grown too full to Hand under ilte 6 times, they muft be planted in the lltive, where they will flower in Aug. ii, and die feeds will ripen in autumn.

The ninth fort is fcarcely known in the eighth, bin the (btlki do not grow fo tall; the lower leaves are licait-liaped and entire, the middle leaves are divided into three and ii. upper into five fegments, almost as the foot-ftalks; they are fawed on their edges. The Italli ii prickly. The ftowers come out tram the wings of the lliil... they are of a very pale bluphr colour, with dark buttonis, but not fo large as the feeds of the lad.

This is propagated by iet'ds in die fame way as the eighth, and die plants require the fame treatment. It Rowers in July in England, and the feeds ripen in autumn.

The bark of both ihrfe plant- is full of drop fibres, which I have been informed the inhabitants of the Malab... are and make into a strong curdage i and b\... that I have observed, it may be wrought into His firoig thread of any size, if properly manufactured.

The tenth fort grows naturally in the Weft-Indies, where the inhabitants use the green pods to add an acid taste to their victuals; there are two varieties of this, one with a light green, and the other a deep red pod, which ; ways maintain their difference; but as there is no other difference but that of the colour of the pods, they do not deserve feparate titles. The riffs with ai; herbaceous stem about three teet high, sending out feveral lateral branches, which are furnished with Gnoot... leaves divided into five lobes. The fl'jweti... come out from the fide of the branches; they are of a dirty white, with dark purple bottoms, and are fucceeded by obtuse heart-ftalks, divided into five cells, which are filled with kidney-shaped feeds.

This fort is propagated in the lame way as the third, and will flower and perfect feeds the fame year, in a feldom peiturbed longer in England.

The eleventh sort; baaiur; i (Ceylon; his lifts^.... an herbaceous stalk, which is prickly, from 3 to 4 feet high, dividing upward into small branches, which are garnished with hand-shaped leaves, divided into five segments. The flowers come out from the wings of the leaves; they are small and white, with purple bottoms, and are succeeded by short oblong capsules with five cells, filled with kidney-shaped seeds. The seeds of this sort were first sent me by Dr. Sprengel of Dant.

This plant is an annual, and is to be treated in the same way as the third.

The twelfth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort.

The seeds of this were sent me by Dr. Joffea, from Paris. This thirteenth sort was discovered by the late Dr. Houffton on the island of Cuba, from whence he sent me the seeds. This rises with a woody stalk twelve or fifteen feet high, sending out many lateral branches, garnished with hairy heart-shaped leaves, from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The fourteenth sort was discovered by the late Dr. Houffton on the island of Cuba, from whence he sent me the seeds. This rises with a woody stalk twelve or fifteen feet high, sending out many lateral branches, garnished with hairy heart-shaped leaves, from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris. This fifteenth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The sixteenth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The seventeenth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The eighteenth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The nineteenth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twentieth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-first sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-second sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-third sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-fourth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

rising sun, but long before noon in warm weather. These are succeeded by capsules of very different forms, in the different varieties; in some the capsules are not thicker than a man's finger, and five or six inches long; in others they are very thick, and not more than two or three inches long; in some plants they grow erect, in others they are rather inclined; and these varieties are common in the country; I have many years cultivated these plants, and have not found them vary.

This sort is propagated by seeds in the same way as the first; and the plants are the same as the first; but they are too tender to thrive in the open air in this country; I have often transplanted the plants into warm borders, after they have acquired proper strength, and have sometimes in very warm seasons had them thrive for a short time, but the first cold or hard weather their leaves have all dropped off, and the plants have decayed gradually, so that they have but rarely flowered, and have never in the best seasons perfected their seeds; therefore those who are inclinable to cultivate these plants, must constantly shelter them in bad weather.

The sixteenth sort grows naturally near Venice, in moist land, this has a perennial root, and an annual stalk, which rises from three to four feet high; the lower leaves are regular and heart-shaped, but the upper are spear-shaped, and slightly indented on their edges; the flowers are produced from the wings of the stalk, upon long foot-stalks; they are small, and of a purple colour with a dark bottom, and are succeeded by five-celled compressed capsules. The seeds of this sort are propagated by seeds, which are to be sown on a hot-bed, and the plants should be treated in the same way as the thirteenth sort, otherwise they will not flower; for although the roots will live in the full ground here, yet the summers are not warm enough to bring them to flower. I have found the roots which have remained three years, putting up many stalks, which rise upward of three feet, and have the flower-buds formed on their tops; but these appear late in the season, that they are not so common.

The seventeenth sort grows naturally in North America; this has a perennial root and an annual stalk; the roots of this sort will live in the full ground, but unless the summer is warm, the flowers seldom open. It rises with single stalks from the root, two feet high or more; the leaves are oval and broad, the flowers are large and purple.

The eighteenth sort grows naturally in North America, in moist ground. This has a perennial root, and an annual stalk like the former, which is herbaceous and never branches; the leaves are oval, with three lobes which are not deeply divided; they are of a bright green on their upper side, but woody on their under; the flowers are produced from the wings of the stalk; they are of a purple colour. The sort, like the former, will not flower in this country, unless the summer proves very warm, but the roots will live in the full ground, if they are placed in a sheltered situation. The only way to keep these plants flower in this country, is to keep the roots in pots, and shelter them under a frame in winter, and in the spring plunge them into a hot-bed, which will cause them to put out their stalks early; and when the stalks are so high as to reach the glasses, the pots may be removed into a glass-case; where, if they are duly supplied with water, and have plenty of air in hot weather, they will flower very well in July, and in warm seasons will ripen their seeds.

The nineteenth sort is an annual plant, which grows naturally in some parts of Italy, and has been cultivated in the English gardens, by the name of Venice Malva. Gerard and Parkinson call it Alcea Veneta, and the Italians call it Fiore di an hour, from the short duration of its flowers, which in hot weather conanue but few hours open; however, in the country, they are not so common.

The twentieth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-first sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-second sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-third sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-fourth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-fifth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-sixth sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

The twenty-seventh sort is also annual with us; this rises with an herbaceous stalk three feet high, chiefly fit with prickly hairs, and divides into branches upward, garnished with hand-shaped leaves, divided into five lobes, which are spear-shaped, ending in acute points; they are hairy, and creased in their edges, standing upon very long foot-stalks; the flowers come out from the wings of the stalk, and are very like those of the third sort. The seeds of this were sent me by Dr. Joffea, from Paris.

h ft u«STinn of Bowers which op- n daily for a conf- d crniifi time, fo that a few of thie plants may be allowed a place in every curious garden. It ril's with a branching iblk a time and a half high, having tnanj* thi r stems which are soft, and do not appear unlefti (ndey viewed: the les-!! *rc divided into thrc lobes, which ai deeply jagged almost to the midrib: il:rn-jag are opposite, and the segments are obtuse; the (lowers come from the jjiots erf the ftalki upon pretty lon; foot-stalks, having a double empalcment, the outer being composed of ten long narrow leaves, which join at their base; the inner n of one thin leaf, swollen like a bladder, cut into five acute fi'gmeiui at the top* Having many longitudinal l! purple ribs, and in liniry. I both these are permanent, und inclofe the capfui after the flower is paf. The flower is composed of; five obtufe petals, which

ad open .it thir top, the lowci an open bcll-Qiaped flower j thefe have dsrfe purple bottoms, but are of i pale fulphur colour above, having • the ftamina and apices joined in a cmlmm m the center-, artw tht flo-wcr is paf, the ^er.Ticn tunii to a blunt Cjiplule opening in five cells, which nre Elled with (mall kidnry-thapwl f«ds. It flowers in June, July, and Anpuft, and the feeJs ripen about ;i month alter. Tliis ion is propagated by fecdi, which Jhould be Town «»efe tht plants are defigned lo r?-miiiji, for they tio not bear tra? plants well; if the feeds are Yown in autumn, the plant* will come up early in the fpring, i; will be per in the fdmner, and dicfe innch arc fbwn carly in the fpring will fdceele them ; fo that by fowing them I! three diftrent fefons, th ey may be continued in fcccEftion liH the froft (topi then-.

These require no other culture but to kucp them clean from weeds, and thin them where they are too clofe; an if the feeds are permitted to fcatter, the plants will come: up fjill ai well as when fown, fu that it will maintain its Groa-tion tiiolefi it is weeded out.

The rwentie-th fort grows heturaily at the Cape of Gtxxl Hope j this is alib an annual plant which ricim- bks the former, but li • plants grow more erect, are of a purple h colour, and very hairy, the leaves are compolci! of three lobr . which are divided almost to the root-lik ; tlelc are narrow, the middle • lobe freaching out more thn twice the l< length of the two fide lobes, and they are but flightly indented on i their ed^ci, wht?; at thole of the former are cut almost to tht middle; the flowers are larger, and their colour deeper, rhi thole of the other.

The k of the twenty-fecnd fort •vere Cate me from the Cape of Good Hope, a few years I id This is alfo an annual plant, having at firft light fome re- femblance of the other forts before-mentioned.

It is with ftrong hairy brufching ftalks; d; but it wih much hr. : leaves thin either of the former, the tower being di vided into three, and the upper five • wide lobes, which are crested on th ; per into the (• other. This has maintained the difference ten

years, fo liwt thcie is no doubt: of its bdng ddititid

All thefe aye *s hardy «s ihc nineteenth fort, fo may The twenty-third fort grows naturally at Cunpeachy, from whence the late Dr. Houflon's fort are the feeds. This differs fo essentially from the other fpecies in its fructification, as to derive another title, for all the have dry capfules with five cells, including many kidney-fhaped feeds, but this hath a fift vil-cous berry, with a hard fhell-lucdot, containing five roundish feeds: it riles with a flrabby ftalk ten or twelve feet high, dividing into many branches, which are garnifhed with fmoth, heart-fhaped, angular leaves, which are crested on their edges; the flowers come out from the wings of the ftalks fingly, fanding on them heart-ftalks; they are compofed of five oblong petals, which are twisted together and never expand; they are of a fad colour, and are fucceeded by rwadifil tc-ncj uf c fcarlet colour when ripe, in-

doling a harri (he'l which opens in five ecil) each containing a tingle rutindilh feed. This ibrt is generally piopsp.ned here hi-r . strings, bee.icik«the feeds do not often ripen IUT. if the cut-tinga arc planted in trots fsilcJ with Hjjb plunged into a gt'nllc hot bed, !tceping the air from them, they will foon take root, and : . will gradually inureu to benn the ope:: . These plants require amodmteftoveroprefcrvrthem ti; . though the winter; aiui if thr." are kept in warmth in . . winter, they will flower, and fomerimes ripen fruit, thoi. if they may be placed abroad in a fhctted fituation foj two or thrcr months in fume.xr, hu: tht p«nUB lo treated lel-dom flower fo well.

HIERACIUM f. Lin. Cen. PUni. B18. Toum, Intl. R. 11. 469. tab. 207. [oCtiffu, (.IT. a hawk; fo called, beexufe hawki as -well as eagle, have i ftning anil quick Gght; anJ it is reported, that if by mafon of I the heat of the air, a filus grows over the evtsof this.bird, then the parent let fall a drop of the juice MI n in its eye, which takes it off, and that, in Iw manner, it is good w dear the iuntra fight.] Hawkwctd.

The t CHARACTERE etc, It hath a flower composed of :'.any herm«pbreMli with, viitb arc included in one common juft empalcment, Vih&fi fidlri art :: and very crowded in their top > ondpejilknl \ the flowers are small and unopen, they have CXipftui -L- is fuppl'd like a tongue, indented in five segments at the point, placed vertically near each other; there being each five joint hairy funnels, terminated by cylindrical funnels. In the bottom of the petals fl-aiiti the supporting a slender style, crowned : h *TM the perianth of several leaves a four-angled peduncled with down, fitting in the empalcment.

This genus of plants • is ranged in the first section of Linnæus's nineteenth class, which includes the plants with a L-ompouitd fisma, composed only of fruitful florets.

There nrr a great number of species of this genus, many of which grow naturally in woods in England, am! thcotlr are fo in different countries, therefore I Oiall only I clect thole which are the most beautiful, and beftwonli cvivating from the number, which in enumttnte, wouU well thin work greatly beyond its bourula.

1. HIERACIUM (Astrucianum) foliis integris caule fib- nudo simpliciflmo pibulo corymbifero. Hort. Cliff. 308. Herbaceous with entire leaves, and a fingle, hairy, naked stalk, terminated by a corymb of flowers. Hieracium i orientale, floribus atro purpureis. C. B. P. tie. G

J. HIEKACIUM (Cristatulum) foliis radicalibus obovatis demicubtis caulibus obliquis semierectis. Hort. Cliff. 124. Herbaceous with heart indented leaves at the base, the stem in the flalks oblong, and half embracing them. Hieracium Pyrenaicum folio cristatis. Schreb. Bor. Arm

3. HIERACIUM (Bismoridum) foliis lanceolatis amplic- caullibus dentatis, floribus fistulatis, calycibus laxis. Hort. Cliff. 187. Herbaceous with spear-shaped indented leaves embracing the stalks, flowers growing singly, and half embracing the stalks. Hieracium Pyrenaicum, latius folio minus fistulatum. Toum. Ind. 472. Bismorid Herbaceous with a Milk Milkish leaf, leaf hairy.

4. HIERACIUM (Asperifolium) foliis amplicaulibus cordatis subdentatis, pedunculis unifloris fistulatis, caulibus nudis. Hort. Cliff. 187. Herbaceous with heart-shaped indented, hairy leaf stalks, leaves embracing the stalks bearing one flower, and a terminal stalk. Hieracium Pyrenaicum rotundifolium amplicaulis. Schreb. Bor. Pyrenaicum Herbaceous, with round leaves embracing the stalks.

5. HIERACIUM (Salsolium) caule erecto simplicifloro, foliis ovatis lanceolatis dentatis semierectis. Hort. Cliff. 124. Herbaceous with an oval leaf hairy, by many flowers, and oval spear-shaped leaves half embracing the stalk. Hieracium Salsolium oblongifolium foliis ovatis brevibus, crebris marginibus. Mart. Hill. 3. p. 71.

&, HiiRACiuM (*UmbeUatum*) foliis linearibus fubdehatis pparfis, floribus fubumbellatis. Flor. Lapp. 287. *Hawkweed with linear indented leaves placed thinly, and flowers almoft in an umbel*, Hieracium fruticosum, anguftiffimo incano folio. H. L. 316.

The firft fort grows naturally in Syria; this fends out from the root many oblong oval leaves, which are entire and hairy; from between the leaves arife a fingle ftalk, little more than a foot high, covered with hairs \ the flowers are produced in a corymbus at the top \ they are of a dark red colour, compofed of many florets, which are fucceeded by oblong black feeds, crowned with a white down, which, when ripe, by the elasticity of the down, is drawn out of the empalement, and by the firft ftrong gale of wind, are wafted to a confiderable diftance. The flowers appear the beginning of June, and the feeds ripen in about five or fix weeks after, but there is frequently a fucceffion of flowers till the autumn.

It is propagated by feeds, which fhould be fown on an eaft appe&ed border in March; and when the plants come up, they muft be kept clean from weeds, till they are ftrong enough to remove, which will be by the beginning of June; then they fhould be tranfplanted to a fhady border of undunged ground, at fix inches diftance, obferving to water them if the weather fhould prove dry, till they have taken new root, after which, if they are kept clean from weeds, they will require no other culture: in the autumn they fhould be tranfplanted where they are defigned to remain; the following fummer they will flower and produce ripe feeds, and the roots will continue fome years, if they are not planted in a rich moift foil, which frequently occafions their rotting in winter.

The fecond fort grows naturally on the Pjrrean mountains. It is a perennial plant, whole lower leaves are oval, indented, and of a grayifh colour; thofe on the ftalks are fmaller, but of the fame fhape and colour, and half embrace the ftalks with their bafe; the ftalks rife a foot high, branching out in feveral divifions, each being terminated by one yellow flower. This is propagated by feeds as the firft fort.

The third fort grows on the Pyrenees; this hath a ~~perennial~~ root, which fends up feveral ereft ftalks, ~~garnifhed~~ with fpear-shaped leaves which are indented; the flowers are produced from the wings of the ftalks, upon fhort foot-ftalks, each fuftaining one large yellow flower, having a loose compofition; ~~the flowers in June; it is propagated by parting of the roots in autumn, and will thrive in any fituation.~~ The fourth fort rife with a branching ftalk a foot and a half

high \ each divifion of the branches terminate in a foot-ftalk, fuftaining one large yellow flower, which appear in June and the feeds ripen flower, when it is a perennial plant, which is

indented leaves, half embracing the ftalk, with a large yellow flower, the flowers are pretty large, or a deep yellow colour, terminating in a double, in flowers in July. The fecond fort grows naturally in Holland, it is a perennial plant, rifing with three or four fender ftalks, garnifhed with hoary linear leaves, and terminated by yellow flowers. This rarely produces feeds in autumn, fo is propagated by parting of the roots in autumn; but the fifth may be propagated either in the fame manner, or from feeds at the firft fort, as it produces plenty of feeds here.

HILLS have many ufe, of which I fhall only mention three or four. They ferve as greens, to keep off the cold and fift, they ferve as greens, to keep off the cold and fift, clipping blades of the northern and eastern winds. adly, The long ridges and chains of lofty mountains,

being generally found to run from eaft to weft, ferve to ftop the evagation of thofe vapours toward the poles, without which they would all run from the hot countries, and leave them deftitute of rain.

3dly, They condense thofe vapours, like alembic heads into clouds and fo by a kind of external diftillation, give origin to fprings and rivers; and by amaffing, cooling, and confpitating them, turn them into rain, and by that means render the fervid regions of the torrid zone habitable.

4thly, They ferve for the produ&ion of a great number of vegetables and minerals, which are not found in other places.

It hath been found by experience and calculation, that Hills, though they meafure twice as much as the plain ground they ftand upon, yet the produce of the one can be no more than the other; and therefore, in purchafing land, the Hills ought not to be bought for more than their fuperficial meafure, i. e. to pay no more for two acres upon the fide of a Hill, than for one upon the plain, if the foil be equally rich.

It is true, that thofe lands that are hilly and mountainous, are very different as to their valuable contents, from what are found in fiat and plain ground, whether they be planted, fown, or built upon, as for example:

Suppofe a Hill contains four equal fides, which meet in a point at top; yet the contents of thefe four fides can produce no more grain, or bear no more trees, than the plain ground on which the Hill ftands, or than the bafe of it; and yet by the meafure of the fides, there may be double the number of acres, rods, and poles, which they meafure on the bafe or ground-plot.

For as long as all plants preferve their upright method of growing, hilly ground can bear no more plants in number than the plain at the bafe.

Again, as to buildings on a Hill, the two fides of a Hill will bear no more than the fame number of houfes that can ftand in the line at the bafe.

And as to rails, or park pailing over a Hill, though the meafure be near double over the Hill to the line at the bottom, yet both may be inclofed by the fame number of pales of the fame breadth.

HIPPOCASTANUM. See ESCULUS.

HIPPOCRATEA. Lin. Gen. Plant. 54. Coa; Plum. Nov. Gen. 8. tab. 35.

The CHARACTERS are,

// bath a large fpreading empalement of one leaf, cut at the top into five figments \ the flower bath five oval petals, which are indented at the points. It bath three awl-fhaped flamina, terminated by broad fummits, and an oval germen fituated below the petal, with a fnyl the length of the flamina, crowned by an obtufe ftigma. The germen afterward becomes a heart-fhaped capfuh winged at the top, mclofing five feeds.

This genus of plants is ranged in the firft fe&ion of Linnseus's third clafs, intituled Triandria Monogynia, the flowers having three ftamina and one ftyle.

We have but one SPECIES of this genus, viz.

HIPPOCRATEA (*Volubilis*.) Lin. Sp. 50. Plum. Gen. 8. *Hippocratea with a triple roundifh fruit and a twining ftalk*. Coa fcandens, fru&n trigemino fubrotundo. Plum. Nov. Gen. 8. *Climbing Coa with a triple roundifh fruit*.

The feeds of this plant were fent me from Campeachy by Mr. Robert Millar, and feveral of the plants were raifed in England, which continued two years in feveral gardens, but not one of them lived to flower, they grew to the height of eight or ten feet, twining round ftakes, but their ftalks were very tender, and decayed at the bottom, probably from their having too much wet.

It is a very tender plant, fo muft be constantly kept in the bark-bed in the ftove, and fhould have but little wet in winter.

HIPPOCREPIS. Lin. Gen. Plant. 791. per* rum equinum. Tourn. Inft. 400. tab. 225. *Horfe-fhoe Vetch* \ in French, *Fer de Cheval*.

This* genus of plants is ranged in the third faion of
 Linnæus's recent method, intitled Diodoriana De-
 candra, which includes the plants with a leguminous
 Bowel, having ten flamina joined in two bodies.

- The SPECIES are,
 1. HIPPOCRATIS (*Urtica*) leguminibus full ubu fa-
 lincis Hort. Cliff. 364. *Horse-foot* with single
 pods growing close to the stalk. Petrum equinum, filiqua
 triangulari. C. B. P. 349. *Horse-foot* with a single
 pod.
 • HIPPOCRATIS (*Crepis*) leguminibus pedunculiciCon-
 fertis, marginibus ciliatis repandis. Prod. Leyd. 384.
Horse-foot with pods growing in clusters upon
 foot stalks, which later border is turned inward. Petrum
 in Germanicum, filiqua in ciliatis. C. B.
 P. 346. *Gtruwti i* - *Horse-foot* with pods on the top
 of its stalks.

- I. HIPPOCRATIS (*Urtica*) leguminibus peduncu-
 latis ciliatis, marginibus alatis. Hort. Cliff. 364.
Horse-foot with pods growing in clusters upon foot
 stalks, the border of which is later. Petrum equi-
 oum filiqui muiiiplci. C. B. P. 34. *Horse-foot*. • *Vilth*
 with • *IQ P&I*.

The first Ion grows naturajly in Italy and Spain.
 This is an annual plant, which sends from the root
 tvcr... trailing stalks a foot long, that divide upwird
 into 1. other branches, garnished with winged leaves,
 compoled 1. four or five pair of narrow small lobes,
 terminated by an odd one. 1. liidi arc oli1... and in-
 dentated at their ftltii from the wings of the stalk
 come out fingle Bowen of the butterfly kind, which
 »rc yellow, and luce ceded by single pods fitting clofc
 to the stalks, which are about two... long, and
 1 third of an inch broad, heading inward like a
 fickle... This flowers in June and July, and the
 seeds ripen in the autumn. Jban if... which the plants
 do.

The second sort is found growing naturally in Jbmc
 of England, upon chalky hills, partic:drtly -M
 on the hilly near Cambridge, this is 1 fl.mllcr
 plant than the former, and hath a perennial root, send-
 ing out slender trailing stalks about six inches long,
 which are garnished with narrow winged leaves; the
 flowers grow in clusters on the top of long foot-
 stalks; these are succeeded by pods which are shorter,
 and twisted inward in roundish curves, but have joints
 shaped like those of the former sort.

The third sort grows naturally in the fouth of Lancf,
 Germany, and Italy. This is an annual plant, with
 trailing stalks greatly resembling the first, but the
 flowers are produced in clusters on the top of pretty
 long foot-stalks; they are shaped like those of the
 other sort, and the pods are jointed in like man-
 ner, but the joints are fixed in the opposite border.
 Their plants flower in June and July, and the seeds
 ripen in August and September.

These plants are propagated by seeds, which should
 be sown in the autumn, when the plants are designed
 to remain; and when the plants come up, they must
 be kept clear from weeds, and thinned where they
 are too close, which is all the culture they require.
 The two annual sorts will decay in the autumn after
 they have perfected their seeds, but the roots of the

H I P

either will continue two or three years, provided they
 are not in too good ground.
 HIPPOLAPATHUM. & ; F. Mix. .
 HIPPOMANE. Lin. Gen. 30. 20. 30. The Man-
 chinchil.

The CHARACTERS are,
 It hath male and female flowers in the same spikes, the
 male flowers come out in small clusters, from a small
 cup-shaped receptacle; they have no petals, from the
 center of each receptacle arise a few styles, surrounded
 by five stiff bracts. The female flowers have no petals,
 but an oval stigma wrapped up in a star-shaped receptacle;
 they have no style, but are crowned by a trifurcate
 style figure. The stigma after it becomes a roundish
 fruit with a fleshy cover, which is rough hard shell
 with several seeds, each inclosed in a woody husk.

This genus of plants is ranged in the ninth section of
 Ljni. Lin's twenty-fifth class, which includes the plants
 with male and female flowers, which have but one
 flar.

- The SPECIES are,
 1. HIPPOMANE (*Mangifera*) foliis ovatis serratis Hort.
 Cliff. 484. *Hippomane* with oval serrated leaves. Man-
 tanelU [the tree. Plum. Nov. Gen. 30. Mandarinal
 with the appearance of the Palm tree.
 HIPPOMANE (*Engelhardtia*) foliis ovatis serratis, hull
 violola. Lin. Sp. Plant. 1431. *Hippomane* with
 oval serrated leaves, which have glands at their base. Man-
 ganilla laevi foliis oblongis. Plum. Nov. Gen. 30.
 Mandarinal with oblong leaf leaves.
 3. HIPOMANE (*Stemona*) foliis subovatis dentato fpi...
 Lin. Gen. Plant. 1431. *Hippomane* with oval leaves
 which have pretty indented. Mangonilla nigra 1051
 foliis. Plum. Nov. Gen. 30. Mandarinal with lilly
 leaves.

The first sort grows naturally in all the islands of the
 West-Indies. This is a very large tree in its native
 soil, almost equalling the Oak in size; the wood is
 mud l efteci... for making of canisters, book cases,
 &c. being very durable, and taking a fine polish; it
 is also said, that the worms will not eat it; but as the
 trees abound with a milky exudate juice, in before
 they are felled, they make fires round their trunks to
 bum • out their juice, otherwise they who fell them,
 would be in danger of losing their sight, by the juice
 Bying in their eyes; and whenever this falls on the
 skin, it will raise blisters; and if it comes upon linen,
 it will immediately turn it black, and on being washed
 will come into holes; it is also dangerous working
 of the... It is fown out, for if any of the dew-
 doft happens to get into the workmen's eyes, it causes
 inflw. mations, and the loss of sight for some time;
 to prevent which, they generally cover their faces
 with fine linen, during the time they are wuriifig the
 wood.

This tree hath a smooth brownish bark; the trunk
 divides upward into many branches, which are
 garnished with oblong leaves about three inches long,
 and at an inch and a half broad, ending in acute points;
 they are tightly fixed on their edges, and are of a
 lincid green, standing on short foot-stalks. The flowers
 come out in thick spikes at the end of the branches,
 being of both sorts in the same spike, but having no
 petals they make but little appearance; these are suc-
 ceeded by fruit, about the size and the same shape
 as the Golden Pippin, turning of a yellow colour when
 ripe, which has often tempted strangers to cut
 them to their cost, for they inflame the mouth and
 throat to a great degree, causing violent pain in the
 throat and stomach, which is dangerous, unless re-
 medies are timely applied.

The inhabitants of America believe it is dangerous
 to sit or lie under these trees, and affirm, that the rain,
 or dew, which falls from the leaves, will raise blis-
 ters, but it is very certain, that unless the leaves are
 broken, and the juice of them mix with the rain, it
 will do no injury.
 The second sort grows naturally at Carthagena in
 New Spain, and the third at Compechy, from which

but as there are many species of each genus, so it is better to keep them asunder, whereby their oldities, by which they have always been known in the fiops and market will be retained, though there is no very essential difference in their characters.

The SPECIES are,
i. HORMINUM (Ferknacea) Mis finuatu ferraus, corollis calyce angustioribus acutis. Claty with finuated fawedleaves, and the petal of the flower narrower than the cup. Horminum sylvestre lavender flore. C. B. P. 2/0. Wild Oary with a Lavender flower.

2. HORMINUM (Lyrata) foliis pinnato-finuatis rugosis. ZU Angioribu, < A E E E % S 1 3 1 1 ro B, Indtbe n's W than the petal of the flower, Horminum folio Volk. Oak-leaved Clary.

3. HORMINUM (Verticillatum) verticillis subnudis, stylo collato in labio inferiore incumbente. Clary with heart-shaped, crenated, indented leaves, naked whorls and the style rises under the lip of the petal. Horminum sylvestre laciniatum verticillatum. C. B. P. 283. Broad-leaved wild oary, with flowers growing in whorls.

4. HORMINUM (Napifolium) foliis radicalibus pinnato-verticillis, crenatis cordatis crenatis, fummis femipennatis radicalibus. Clary, whose lower leaves are cut and the upper ones are broad and crenated, and SKZopbls tracing the stalks. Horminum napifolium Mor. Hort. R. fatt Clary with a Navev leaf.

5. HORMINUM (Salsum) foliis obtusis crenatis, bracteis fummis (terribilibus majorebus coloratis. Clary with obtuse crenated leaves, the bracts at the top of the stalks large, colored, and barren. Horminum comit purpureo-lanceolatum J. B. g. 309. Clary with a purple flint top. The first fort grows naturally on sandy and gravelly JrSunds, in rainy parts of England. Thus a perennial plant, the lower leaves grow upon pretty long foot-Mks, and are near four inches long and two broad; they are finuated on their borders and blundy

ground; raised on their edges; the flowers grow in a whorled manner at the top of the stalk, each with two spikes; one on each side; the flowers are small and blue; these are sweet to the taste; they have but one petal which is longer than the under lip; the upper lip is a little longer than the under. and almost the same as the feel stamina in each flower, and after supporting a little while the seeds fall down. This fort propagates itself in plenty, if the seeds are permitted to scatter, and requires no other care.

plants clean from the garden. This fort propagates itself in plenty, if the seeds are permitted to scatter, and requires no other care.

Jut. The virtues of this are J3 fnnowerful. The second fort grows naturally in the south of France and Italy; the lower leaves are upward of four inches long, and not more than one broad, regularly incised on both sides, in form of a winged leaf; the stalks rise about the same height with the former, but all the leaves upon the stalks are finuated in the same manner as the lower; the flowers are smaller than those of the first, but grow in whorled spikes like them. This is a perennial plant, which is very hardy, and will propagate itself in plenty by the scattered seeds. It is seldom kept in gardens but for the sake of variety. The third fort is a perennial plant, which grows nat-

H OS

urally in Auftria and Bohemia. This fends out from the root a great number of heart-shaped leaves; which are fawed on their edges and deeply veined. Handing upon pretty long foot-stalks which are hairy, the stalks arise from between these, which are square, and grow two feet and a half high, which are garnished with two heart-shaped leaves at each joint, whose base fits close to the stalks, half embracing them; the stalks at the two or three upper joints, put out on each side a long foot-stalk; these, and also the principal stalk, are garnished with whorls of small blue flowers, not much unlike those of the common fort, but larger; the spikes are more than a foot long, and toward the top the whorls are nearer together. It flowers in June, and the seeds ripen in August.

The fourth fort grows naturally in the fourth of France, and in Italy. This is also a perennial plant, which has some resemblance of the third, but the lower leaves of this are cut at their base to the midrib, into one or two pair of ears or lobes, which are but small, and are often at a distance from each other; the leaves are not fawed, but are bluntly indented; the stalks of this are flenderer, and do not grow so tall as those of the third, nor are the spikes of flowers so long. This flowers and feeds at the same time with the third.

Both forts may be easily propagated by seeds, which, if sown in the spring on an open spot of ground, the plants will come up, and require no other care but to keep them clean from weeds, and allow them room to grow; for the plants should not be nearer than two feet apart, for they grow very large, and will last several years.

The fifth fort is an annual plant, which grows naturally in Spain, of this there are three varieties which are constant, one with purple tops, another with red tops, and a third with green tops. As they differ in nothing but the colour of their bracts on the top of the stalks, so I have not put them down as different species, though from more than thirty years cultivating them, I have not known them alter.

These plants have obtuse crenated leaves, shaped like those of the common red Sage; the stalks are square and grow erect, about a foot and a half high; their lower parts are garnished at each joint with two opposite leaves of the same shape, but gradually diminishing in size toward the top: the stalks are garnished upward with whorls of small flowers, and are terminated by dufters of small leaves, which in one are red, in another blue, and a third green, which make a pretty appearance, and are preserved in gardens for ornament. They flower in June and July, and their seeds ripen in the autumn.

The seeds of these are sown in the spring, in the places where they are designed to remain, and require no other care but to keep them clean from weeds, and thin them where they come up too close.

Garden Clary. See SCALARIA. HORNBEAM. See CARPINUS. HORSE CHESTNUT. See ESCULUS.

HORSE DUNG is of great use to make hot-beds for the raising all sorts of early garden crops, as Cucumbers, Melons, Aparagus, Sallading, &c. for which purpose no other sort of Dung will do so well, this fermenting the strongest, and, if mixed with long litter, and fea-coal ashes in a due proportion, will continue its heat much longer than any other sort of Dung whatsoever, and afterwards when rotted, becomes an excellent manure for most sorts of lands, more especially for such as are of a cold nature; and for stiff clayey lands, when mixed with fea-coal ashes, and the cleansing of London streets, it will cause the parts to separate much sooner than any other compost will do; so that where it can be obtained in plenty, I would always recommend, the use of it for such lands.

HOSE IN HOSE, a term used in gardening, to signify one tube or petal within another, in the Polyanthus,

of thus, where there are in some varieties two or three.

HOT-BE1>S are of genml use in ricfc northern part* of Europe, wtv i ... In the making of these hot-beds, it must be i v,fully observed to make us dung close with a fork; and if it be full of long litter, it should be equally trod down close in every part, otherwise it will be subject ro htiti too violently, and consequently the heat will be much sooner spent, which is one of the greatest dangers these sort of beds may be liable to. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and in the day time carefully raise them to let out the steam, which is subject to rise very copiously while the dung is fresh; but as the heat abates, so the covering should be increased; otherwise the plants in the beds will be blasted in their growth, if not entirely destroyed. In order to remedy this evil, if the beds be very cold, you must put a pretty good quantity of fresh horse manure, and cover it up the next a confiderable time after; and as the spring advances, the sun will supply the lack of the dung's heat; but then it will be advisable to lay some mowings of straw round

lite GdM of itir bed, especially if the night should prove cold, as it often happens in May, which is many times, even if thou liL ... very harmful to tender plant on I IMI-1'-1-

But although the Hut-bed I have described is what the gardeners commonly use, yet those made with tonntrs b<k are a much preferable, especially the alt tender CKOf- plants or fruits, which require an even degree of nmrnth t j l. continued for several months, which h wfial cannot be effected by heating ciung only. The manner of making these beds is as follows:

There must be a trrndi dug in tdt earth about three feet deep, if the (ground be dry, but if wet, it must rot be above a toot or fin tnchei deep. The dung must be r.iiftd in projn ... above ground, so as to iidmit of die nih being laid thtm; ... The length mi; be proportioned to the frames intended to cover ii, bu: (hoold nvrer fxc li-li ilun rk or twtlvc feet -, buiifitb twice lhar Jm'f. it will be better, and the v ... iliiin fij. ^

Such is the best use of these beds for ... round the beds above mentioned ticifthio! tirtf fci ... paying the bottom with bricks to prevent tticem! ... on, m< \ fir and be tiled in the space with trenchers bark (i. e. such as the tanners have lately drawn out ofvhc:!

• T >ave used it for tanning leather) which should be laid in a round heap for a week or ten cays before ii is put iii the trench, that the moiflure may be better strain out of it, which, if detained in t;tgreat » quantity, will pn-nt its ferment-itioti; then; put it into the trench, and gently beat it down equally with a dung-fork; but it must not be trodden, which would also prevent its heating, by fitting it too close; then you must put on the frame over the bed, covering it with the glasses, and in about six days or a fortnight it will begin to heat; at which time you may plant your pieces of plants or fruit. into It, ObiCTVJJIE IIII i> : read down the back in doing it.

A Boi thus prepared (if the back be new and not ground too flint) will continue in a good temper of warmth for two or three months; and when you find the heat decays, if you stir up the back again pretty deep, and mix a load or two of fresh bark amongst the old, it will cause it to heat again, and preserve its warmth two or three months longer. There are many ways for some hot beds in the bottom of [p] the trench, to cause it to heat; but this I would never practise, unless I wanted the bed sooner than the bark would heat of itself, and then I would put but a small quantity of dung at bottom, for that is subject to make it heat too violently, and will occasion its being the best sooner than ordinary; and there will never be any danger of the bark's heating if it be new, and not put into the trench too soft, though it may sometimes be a fortnight or more before it acquires a sufficient warmth, but then the heat will be more equal and lasting.

The frames which cover these beds should be proportioned to the several plants they are designed to contain: for example, if they are to cover the Apples or Pine-apples, the back part of the frame should be three feet and a half high, and the lower part fifteen inches, which will be sufficient depth to carry off the wet; and the back side will be high enough to stand in the large framing plants, and the lower side will be sufficient for the smaller plants; so that by placing them regularly according to their heights, they will not only have an equal distance from the glasses, but also appear much handsomer to the Eye. And although many people make their frames deeper than what I have advised, yet I am fully persuaded, that where there is but height enough to contain the plants, without breaking their leaves, it is much better than to allow a larger space; for the deeper the frame is made, the less will be the heat of the air included therein, there being no artificial warmth but what the back affivti, which will not heat a large space of air, and

We Know but on. Species of this genus, viz. **HURA** (CrcpHsm.) Hon. Cliff. 286. Sord-ho-tro ; Hv r» Amencana, Abutil., Indiol palm. Hort. Amt. 2. 111. • ib. 66. American (huiss, wot

This i -rows rawrally in the Spanilh Wefl-Indics, J from whence it has been inw-ered into the Brit', cok nies of America, where some of the plants are pntferve d by way of curiosity. It rises with a fast lignon, is fier to the height of twenty-four feet, dividing! into many branches, which abound with a milky juice, and • luvc firm on their bark, where the leaves luvt fallen off. The brindies fu-egwmi; od with heart-shaped leaves, three which are the broadest are eleven inch: long and nine inch: it u^d in it. middle, indented on r' or tdgw, hating a prominent middle, with several transverse veins from i Oiai totlic ljes, which are ^alternate-

these stand upon long slender foot stalks. the male flowers come out from between the leaves, upon foot stalks which are three inch: long; they are formed into a cluR- fpik, or hacket, forming a column, lying over each other like the scales of fish. The female flowers are situated at a distance from the male, they have a swelling cylindrical empanumet, which rises the petal of the flower, which hath a long funnel shaped tube, spreading at the top,

object C which rises the petal of the flower, which hath a long funnel shaped tube, spreading at the top,

top, whisre it is divided into twelve parts, which are rncxed. Alter the fn«cr » paf, the germen [wells and become a round, ci... ligneous r... having twelve deep furrows, each being i dutinf, ctll, containing one large round comprefed feed; when the pods ate ripe, the/ burft with an claffitiry, and throw out their feedi to a confiderabli. du-rance.

It is I ropagated by feeds, which (hould be fown rnrly in the (pring, in pan tiled with light rich earth, and plunged into a hot-bed of rannm bark. If the feeds are frclh, die plants will appear in about five or fix weekj after ihe feeds are lbwn. AS the plants will advance very faft, where due care is taken of ihem, fo they fhould have i large (hare of fxfch air admitted to them in warm wearier, otherwife tiify will draw up too weak. When (lie plants are about two inches high, they (hould be rranrtianted «c!i into a fepatare fmall pot filled with lipht rich earth, and plunged again into the hot-bed of miners bark, being cieriul to lhadc them from the heat of the fan, until they ha vi ukenncw root; after which time they mult have free air admitted to them, by railing of the glalles in proportion to the warmth of the featbn, and Inould be foquenily, but gently, watered. When the plants have filled thefe {mall pots with their roots, they mult behakenour of them, and their roots trimmed, and then placed in larger pots, which (hould be filled with the like: rich earth, and plunged again into the hot-bed, where they Jlwuld remain rill Michwlm, provided the pLms have room, without tquthmg of the gjaffes, at which time they mult be removed into the tmrk-ftove, and plunged in the warmed pirt thereof: during the winter ieafon they mud be Iparmgly watered, for as the plants have focculrm Hulks, much mifiture v.itl rot them \ they mud life be kept very wirm, oilierwic they will not live iit this country. In fummer they mult have a large Jhare of frfh air in warm weatlicr, but they mult not be removed into th: open air, for they arc too lender to live abroad in the warmed pan of the year in this country.

This plant is now pretty common in the Englifh gardens, where there are collecfions of tender plants prderved, lbzne of which are grown ro die he... of twelve or fourteen feet, and many of them have produced fkiwers, but there has not btxn »ny of their fruit produced as yet in England.

As thrc plants have ample leaves, which are of a beautiful green colour, they afford an agreeable variety among other tender exotic plants in the ftove -, for where they are kept warm, and duly rcfrelhed with water, xhep retain their leaves all the year in verdure.

The fruit of this plane is, by the inhabitants of the Weft Indies, cut open on the iide where tht- tbot-ftlck grew, and the feeds carefully Likim out, after which the (hells are ufal to contain land for writing, which gave rife to the name of Sand-box. "When thefc Iruirare brovgh; entire into England, it is very difficult to preferve i hem; for when the hea; of the fummer comes on, they usually burft with an expjofion, *nd t... their feeds about, and from the noile nude

O cnumcraw thdc vark-tie* here, would lwell this work to very little purpofc* as every year produces neu- | ends.

The firft fort grows naturally in woods anrl near hedges, in hind? which have htely been w> : , I many parts of Hngbnd, lo i> iel.ion; admitted ir.(J gardens; but the poor people, who nuke it their hufinc& to gather the wild flowers of the LLJ M^O^ woods for nolcgays, &c> b: ing great quantities of thele in the Iprirtg ro Lonion, and fell them about tlic ftreets.

There i a variety of this with white flouen, wl ich id kept in !... gardens, whic b only differ* in the colour of their Jcwens from the other.

The fecond fort is preferred in tornr few gardens for the fake of variety, but as it hath as little beauty astlielirft, (b is li kdom allowed a place in the flower-garden. The Sen ers of this are narrower than thofe of the firft fort, and feem as if their petals were divided to the bottom, thofe of the fecond legments being fe-parated from the other, ftanding as a fmall diftance from •... three intervals, but they are all feinet redde blue colour, but before they decay, they take to a worn-out purple colour. This flowers early in the Ijiring, and yrowt natura [y in SpaLn and Mau-ritania.

The ihtRJ fwt grow* natur. ly in Spain and Italy: the haxh biue lki«m of the open ijtrcad b«df.* with b ^rt? tivided in:...

m, m. r-f disposed on every side the stalk. The stalks rise about nine inches high, and when the roots are strong; ilic tlyrfe of ; roots are large. This flower about the same time with the first fore, and was formerly preferred to gardeners, but since there have been io many finer Bow . raised from the seeds of the Eastern Hyacinth, these have been almost totally neglected, so that they are seldom seen but in old gardens.

The fourth sort seems to be a variety of the first, the flowers brint; ranged t'nrjhe m of part upon one lid; y| ilc lbik, and the top of ; . The flower is always bent on one side. The iloft ers are of a bluish peach coloir, am! appear abo at the Ihmci

The fifth sort grows naturally in Spain; this hath a smaller root than either of the former sorts, and comes earlier in the stabn. The petals rise into five parts liah I The length of the stem is referred, at the bottom, the lower part is L-cylindrical, a lie in tweling at the base. The stem is of a deeper blue ilun tintier of ihe for nitr. Thii is usually qjlltid by the gwdenrj die CeivCH: y blue Hyacinth.

This is the E-farli Hyacinth, of which we formerly h'td no otrirr vani l in the English gardens, it is the single and double white .mil li flower raised in England; and also by the L:1710D girtteners, it came over annually with their flowers to vend in England; but the gardeners in Holland have within the last fifty years raised so many

to render [lie formr (brs t-l) or no vi] . The roots propagate in great plenty in any soil or situation, and will require no other care but to take up their roots every other year, and plant them again m nuti; for if they are left longer in the ground, their roots will be spoiled to great a degree, so as to render their flowers very small and weak, so of little worth.

All the different sorts of Hyacinths are propagated by seeds or offsets >m thi old bulbs; the former method has been used in England till very lately, but in Holland and Flanders it hath been followed for many years, whereby they have obtained a very great variety of the most beautiful flowers of this kind; and it is owing to the industry of the florists in those countries, that the lovers and delighters in gardening are so agreeably entertained, not only with the curious variety of this, but of most other bulbous rooted flowers; few other plants thinking it worth their trouble to wait four or five years for the flowers of a plant, which when produced, perhaps there might not be one in fifty that may deserve to be preserved; but they did not consider that it was only the loss of the four or five first years after sowing, for if they continued sowing every year after they began, there would be a succession of flowers annually, which would compensate at least some sorts that might be different from what they had before seen; and new flowers being always the most valuable and useful sorts, provided they have good properties to recommend them, it would always be a sufficient recompence for their trouble and loss of time.

The method of raising these flowers from seed is as follows: having provided yourself with some good soil (which should be saved from either from double, or such single flowers as are large, and have good properties) you must have a parcel of square shallow boxes or pots, with holes in their bottoms to let off moisture, which must be filled with fresh light sandy soil, laying the surface very level; then sow your seeds thereon as equally as possible covering it about half an inch with the light earth; the time for this work is about the middle or latter end of August. These boxes or pots should be placed where they may enjoy the morning sun only until the latter end of September; at which time they should be removed into a cooler situation, and towards the end of October they should be placed under a common hotbed (i.e. where they may remain during the winter)

in a cooler situation, for the heat of the sun at that season would be too great for these tender plants, causing their blades to decay much sooner than they would naturally do, if they were screened from its violence. In this shady situation they should remain during the heat of summer, observing to keep them constantly clear from weeds; but you must not place them under the dropping of rain, for you should you give them any water over their blades are decayed, for that would infallibly rot the roots. About the latter end of August you should lift a little light rich earth over the surface of the boxes, and then remove them again into a warmer situation, and sow them, during the winter, spring, and summer months, as was before directed: and about the middle of August following you should prepare a bed of light rich sandy soil, in proportion to the quantity of your sowing plants, and having levelled the surface very even, you should take the earth from the boxes in which your plants were raised, and mix it with the soil of the new bed, which by this time, if they have grown well, will be about the thickness of a small quill; these roots should be placed upon the bed at about two or three inches asunder, observing to set the bottom part of their roots downwards; then cover them over two inches thick with the same light earth; but as it will be impossible to get all the small roots out of the earth in the boxes, you should spread the earth upon another bed equally, and cover it over wide flat earth, by which method you will not lose any of the roots, if they ever be found.

These beds must be covered over with hoops, and in very hard frosty weather they must be covered with manure, to prevent them from frosts; and in the spring, when the green leaves are above ground, if the weather should be very dry, you must water them with water; but do this sparingly, for making a more vigorous in these bulbs than use great quantities of moisture. During the summer season you must constantly keep the beds clear from weeds; but after the blades are decayed, you must never give them any water; and in autumn you should lift the surface of the bed with a very heavy tined fork, being extended circular not to thrust it so deep as to reach the roots, which, if hurt, are very subject to perishing after. Then lift a little light rich earth over the bed

about an inch thick, or somewhat more, and in winter cover them again (as was before directed.) In this bed the roots may continue two years, observing to treat them, both in summer and winter, as before; then the third year the roots should be carefully taken up a little before their leaves decay, laying the ends horizontally in the ground proper for their growth, after which they may be kept out of the ground all the end of August, when they should be planted in new beds prepared as before, placing them at the distance of six inches asunder; in these beds the roots may continue, till they flower, during which time they should be treated as before, with this difference only, that instead of covering them with manure in the winter, the surface of the bed should be covered with tanners bark, which will keep them from being scorched by the sun, and should be covered with tanners bark.

When the roots are taken up, they should be carefully examined, and the decayed ones should be burnt, and the good ones should be preserved in a cool dry place, till they are wanted for sowing.

When their flowers begin to liew themselves, you should mark all such as appear to have good property, by thrusting a small flick down by each root; which roots, at the time for taking them up, should be selected from the rest, and planted by themselves though I would by no means advise the rejecting any of the other roots, until they have blown two years, before which you cannot be ascertained of their value. When the green leaves or three plants begin to decay, their roots must be taken up, and a bed of tight earth, in a shady situation, should be raised into a ridge, the better to protect the moisture, the roots should be laid into the earth again in an horizontal position, leaving the green leaves hanging out of the ground from the roots, whereby the great moisture contained in their very succulent leaves and flower-stalks may be exhale, and prevented from returning to the root, which, when suffered to rot, is very often the cause of their rotting after they are out of the ground. In this ridge the roots should remain until the leaves are quite dried off, when they must be taken up, and after being cleared of all manner of filth, which would be hurtful to them, they must be laid up in boxes, where they may be preserved dry until September, which is the proper season for planting them again. The method of doing this is all but the same as after mentioned, when we treat of the management of old roots.

I shall now proceed to the culture of lily Hyacinths which have either been obtained from Holland, or are of our own product from the seeds of such flowers as were very beautiful, and worthy to be preserved in collections of good flowers: and it is indeed the want of skill in the management of these noble flowers, which has occasioned the ill success most people have had with them in England, whereby they have been neglected, supposing their roots to degenerate after they have flowered in England, which is a great mistake; for were the roots managed with the same care as hath been practised in Holland, I am fully convinced they would thrive near as well in England as there, or elsewhere, as I have experienced for, from some hundreds of roots which I have received from Holland at two or three different times, I have had a very great increase of their roots, which were at first scarce, and produced as many flowers upon their stems, as the same sort generally in Holland.

The soil in which these flowers are sown, should be a rich, sandy, freestone, rich earth, which may be computed after the following manner: take half the earth from a common, or pasture land, which is chiefly of a sandy loam; this should be sifted, and not taken above eight or nine inches deep at most; and if you take the turf, or green (Ward with it, it will be better, provided you have time to let it rot before it is used; to this you should add a fourth part of leaf-mould, and the other fourth part of rotten cow dung; mix these well together, and call it into a heap, where it may remain until you use it, observing to turn it once in three weeks or a month, that it may well mature. If this compost is made two years before it is used, it will be much the better; but if you are obliged to use it sooner, then it should be frequently turned, that the pans may the better unite, this soil should be hid two feet deep on the beds which are designed for Hyacinths, and if you have a little rotten cow dung, or tanners bark, at your command, which may be within reach of the filth, you may touch the bulb, it will be better, especially if the soil is very wet where these beds are made, you may raise them ten or twelve inches above the surface of the ground; but if it be dry, they need not be raised above three or four inches.

The manner of preparing the beds is as follows: first, take all the former old earth out of the bed to the depth you intend, which should be not more than three inches (prod fame rotten new turf, or tan, in the bottom about six inches thick, laying it very close upon the surface of the above-mentioned earth two feet thick, levelling it very even; then

scour out the differences for the roots, which should be eight inches square, in straight rows each way; after which, place your roots exactly in the squares, observing to set the bottom part downward; then cover the roots six inches deep with the same prepared earth, being very careful in doing this not to displace any of the roots, and if the tops of these beds are made a little rounding, to protect them from the wet, it will be of service in moist ground, provided the middle of the beds are not made too high, which is a fault the other way.

The best season for planting these roots is the middle or latter end of September, according to the condition or situation of the soil, or the weather when it happens; but I would advise you never to plant them when the ground is extreme dry, unless there be a prospect of some rain soon after; for if the weather should continue dry to a considerable time after the roots will receive a mouldiness, which will certainly destroy them. The *Ufa* will require a farther cure until the fruit comes on very leisurely, at which time they should have some rotten tan spread over them, about four inches thick; and if the alleys on each side of the bed are filled up, either with rotten tan, dung, or sand, it will prevent the frost from penetrating the ground on each side to the roots, and secure them from being destroyed; but when the winters prove very severe, it will advise to have some Peas-hair, Straw, or such like covering laid over them, which will keep out the frost better than mats; and lying hollow, will admit the air to the surface of the ground, and allow permit the exhalations to pass off, whereby the earth will remain dry, and prevent the roots from rotting, which has often happened when the beds have been too close covered. But you should observe to take off this light covering whenever the weather is mild, and only let it continue on in very hard frosts; for when the beds are covered with tan or sea-coal ashes, so common a soil to penetrate through, the coverings are necessary, except in very severe frosts; for a small frost cannot injure the roots before the green leaves appear above ground, which is seldom before the beginning of February, at which time the beds must be arched over with hoops, that they may be covered either with mats, canvas, or some other light covering, to prevent the frost from injuring the buds as they arise above ground; but these coverings must be constantly taken off every day when the weather is mild, otherwise the flowers will be drawn up to a great height, and become very weak, and the stalks of the flowers will be long and slender, and rendered incapable of supporting the bells; which is a great disadvantage, to the flowers, for one of their greatest beauties consists in the regular disposition of their bells. When three hoops are fixed over the beds, the rotten tan should be most of it taken off them; in doing of which, great care should be taken not to bruise or injure the inclosed Hyacinths, which by that time will be breaking out of the pound with the flower-stem, therefore the tan should be removed by the hands; or it may be made use of in the doing of it, there must be great caution how it is performed. When the stems of the EOWIM are advanced to their height before the flowers are expanded, you should place a hoop (lick, down by each side, to which a wire formed into a hoop, the stem of the flowers should be fattened, to support them from falling; otherwise, when the bells are fully expanded, their weight will incline them to the ground, they are not screened from the wind and rain. During their season of flowering, the plants should be covered in the heat of the day from the sun from all heavy rains, but they should be left to receive all gentle showers, and the moisture of the evening sun; but if the night is frosty, they should be covered with mats, or such like covering, to be constantly kept on. The Hyacinth in bloom should continue your Hyacinth in bloom at least one whole month, and during that time should be kept in their strength, or the favourableness of the season.

H Y A

When their flowers are quite decayed, and the tops of their leaves begin to change their colour, you must carefully raise the roots out of the ground with a narrow spade, or some other handy instrument; this is what the Dutch gardeners term lifting of them: in the doing of this, the instrument must be carefully thrust down by the side of the root, being careful not to bruise or injure it, as also to put it below the bottom of the root; then by the forcing of this instrument on one side, the fibres of the root are raised and separated from the ground. The design of this is, to prevent their receiving any more nourishment from the ground; for by imbibing too much moisture at this season, the roots frequently rot after they are taken up: about a fortnight after this operation the roots should be entirely taken out of the ground, and then carried to beds situated where the morning sun only shines upon them; the earth of the beds should be loose and raised into a sharp ridge, laying the roots into it in a horizontal position, with their leaves hanging out, by which means a great part of the moisture contained in their thick succulent stalks and leaves will evaporate; which, if it were permitted to return back to the roots, would cause them to rot and decay after they are taken up, which has been the general defect of most of the Hyacinths in England.

In this position the roots should remain until the green leaves are entirely decayed, which perhaps may be in three weeks time. This is what the Dutch gardeners term the ripening of their roots, because by this method the roots become firm, and the outer cover is smooth, and of a bright purple colour; whereas those roots which are permitted to remain undisturbed, till the leaves and stalks are quite decayed, will be large, spongy, and their outer coats will be of a pale colour, for the fibres of many of these flowers are very large, and contain a great quantity of moisture, which, if suffered to return into the roots, will infallibly cause many of them to perish. After they are so ripened, you must take them out of the ground, and wipe them clean with a soft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie singly, and be exposed to the air, but they must be preserved carefully from moisture, nor should they be suffered to remain where the sun may shine upon them, in this manner they may be preserved out of the ground until September, which is the season for planting them again, at which time you must separate all the strong flowering roots, planting them in beds by themselves, that they may make an equal appearance in their flowers; but the offsets and smaller roots should be planted in another separate bed for one year, in which time they will acquire strength, and by the succeeding year will be as strong as the

~~old roots~~
The single and semi-double flowers should be planted also in a bed by themselves, where they could be carefully flickered (as was directed before) from the frost, until the flowers are blown; at which time their covering should be entirely removed, and they should receive the open air, but one HUUU-IMUM *W__ be supported with flicks; which, though the weather may soon deface the beauty of the flowers, yet is absolutely necessary to promote their feeding; and when the feeds are quite ripe, you must cut off the vessels and preserve them, with the feeds therein, until the season for sowing it. But you must observe, that after these flowers have produced feeds, they seldom flower so well again, at least not in two years after, so that the best method to obtain good feeds is, to plant new roots every year for that purpose. Although these roots are, by most persons, taken up every year, yet if the beds are well prepared for them, they may remain two years in the ground unremoved, and the roots will increase more the second year than the first, though the flowers are more liable to degenerate, therefore those who cultivate these for sale, take up their roots annually when

H Y D

they are large and saleable; but the offsets and final roots, they usually leave two years in the ground.

There are some persons who let their Hyacinth roots remain three or four years unremoved, by which they have a much greater increase of roots, than when they are annually taken up* but the roots by this great increase are frequently degenerated, so as to produce single flowers; therefore I should advise the taking up of the roots every year, especially those of the most valuable kinds, which is the most certain method to preserve them in their greatest perfection, though the increase may not be so great; and if these roots are planted a fortnight or three weeks earlier in the autumn than is before directed, it will cause them to produce stronger flowers, and those roots which are annually removed, will be rounder and firmer than such as stand two years unremoved.

For the other sorts of Hyacinth, see MUSCARI and ORNITHOGALUM.

HYACINTHUS TUBEROSUS. See CRINUM and POLYANTHES.

HYDRANGEA. Groo. Flor. Virg. 50. Lin. Gen. Plant. 492. We have no English title for this genus.

The CHARACTERS are,

The flower hath a small permanent empalement of one leaf indented in five parts, and five roundish petals which are equal, and larger than the empalement. It hath ten stamina which are alternately longer than the petals, terminated by roundish Juments. Under the flower is situated a roundish germen, supporting two short styles set a distance apart, crowned by permanent obtuse stigmas. The germen afterward turns to a roundish capsule, crowned by the two horned stigmas, divided transversely into two cells, filled with small angular seeds.

This genus of plants is ranged in the second section of Linnæus's tenth class, intitled Decandria Dygynia, which includes the plants whose flowers have ten stamina and two styles.

We have but one SPECIES of this genus, viz*

HYDRANGEA (Arborescens.) Gron. Flor. Virg. 50.

This plant grows naturally in North America, from whence it has been brought within a few years past to Europe, and is now preserved in gardens for the sake of variety more than its beauty. It hath a spreading fibrous root, from which is sent up many soft, pithy, ligneous stalks, which rise about three feet high, garnished at each joint with two oblong heart-shaped leaves placed opposite, standing upon footstalks about one inch long; the leaves are three inches long, and two broad near their base, fawed on their edges, and have many veins running from the midrib upward to their borders; they are of a light green, and fall away in the autumn; the flowers are produced at the top of the stalks, in form of a corymbus; they are white, composed of five petals, with ten stamina surrounding the style. These appear toward the end of July and in August, but seldom perfect their feeds in England,

This is easily propagated by parting of the roots; the best time for this is the latter end of October, which is also the best time to transplant them: the plants should have a moist foil, for they grow naturally in marshy places; they require no other culture but to keep them clear from weeds, and dig the ground between them every winter. The roots are perennial, and if in very severe frost the stalks are killed, they will put out new ones the following spring.

HIDRRASTIS. See WARNERIA,

HYDROCOTYLE, [of ftp water, and water, a cavity* because this plant has a cavity in the leaves which contains water, and the plant grows in marshes.] Water Navelwort,

This plant grows in great plenty in moist places in most parts of England, and is never cultivated for use, so I shall pass it over with only naming it.

HYDROLAPATHUM. See RuMEX.

HYDROPHYLLON. Lin. Gen. Plant. 187. Hydrophyllon, Tourn. Inf. R. H. 81. tab. 16. Water Leaf.

HYDROSTATIC

Hydrostatics (Species, of the, water,
and cases, of conf. flanding, of Love, I fluid or fup.
Hydrostatics being conceived as the doctrine of the
equilibrium of liquors,) or the doctrine of the gra-
vitation of fluid, or it is that part of the mechanics
which confiders the weight or gravity of fluid bodies;
particularly of water, and of folid bodies immerged
therein.
To Hydrostatics belongs whatever relates to the
gravitates and equilibria of liquors, with the art of
working bodies in water, in ordtr to
Of the use of this Science in horticulture, the Rev.
Dr. Hales, in his excellent Treatise of Vegetable Statics,
has given many examples, by experiments,
knowing the quantities of moisture imbibed and per-
fpired by plants and trees, necessary to be known, in
order to produce the best effect of vegetation.
Some of the most useful heads of this Science are:
1. That the upper parts of all fluids press upon the
lower.
2. That a lighter fluid may rife upon or press upon a
heavier.
3. That if a body that is confidered to the water,
be the same, or is just, lower than the upper furface
of the water, the lower part of the body will be
pushed upwards by the water which touches it
beneath.

4. Tiine nctds only a compemir tciEht of an x-
ternal fluid, w account for the vSw^ oi waier in

Qed, they are puffed

How far the knowledge of any of these properties
of fluids may conduce to the philosophical improve-
ment of gardening, and the husbandry of vegetation,
will be more clearly perceived when well confidered
by the ingenious reader, than being set forth by words.

HYGROMETER (Species, of the, moist, and
f 50 meaiun-J
liicw or

These are divers kinds of Hygrometers; for what-
ever body either ferile or ferrous by drench or moi-
sture, is capable of being formed into an Hygromete-
ter; fuch are the woods of most kinds, particularly
Ash, Deal, Poplar, &c. fuch also is a cord, cat-
gut, &c.

Stretch a brazen cord or fiddle-string along a wall,
bringing it over a trussel or pully, and to the other
end tie a weight, unto which fit a scale or index;
on the fame wall be a piece of wood, divided into
any number of equal parts, and the Hygrometer is
complete.
For it is a matter of undoubted observation, that
moisture ftrips the length of cords and strings; and that as the moisture evaporates, they re-
turn to their former length, mid th(like may be said
of a fiddle string.

The weight therefore, in the perfect state, upon an
increase of the moisture of the air, will descend, and
upon a diminution of the same will ascend.

Hence, as the index will show the spaces of ascent and
descent, and these spaces are equal to the increments
and decrements of the length of the cord or gut, the
instrument will discover whether the air be more or
less humid now, than it was at another given time.

The ordinary contrivance w: : whip-cord is one of Jki: shell, for that will infall Wy (horten andlcr then as the air grows moifrrr atul drier. Some recommend a cat-gut.; the bed, which may be 3 yard in length fulpended, having a plumber on piece olead, with an index or (jointer hanging ar ric lower end, by means of which the w-gai will twill will as the air dries ormoiftw and from en and Jen«he» fo ns to raise and sink the plumb: with the index, uid this We* will point out in* degree lughl for.

The weigh! of this lead ur plumber, hould be about two ounce. Some perlbru who approve a fine whip-cord, ntoad of Mi sur, use a greater weight of lead, thewnftuig andunWwifring ofthe cat gut or whip-cord, will make the lead with the index turn round, as well as nic sndfall. The degrees may be made up^n an Open pJumbet^{all} screw of brass within, will which the pJumbet^{all} tncxx has its m! jn_ i ..

The first ... is very common in England, growing upon the fides of banks and old dunghills. Imoft evtry where. It is i biennial plant with long fleshy roots, which (bake deep into the ground, fenf ing out fevtrll large loft leaves, which ore deeply frashed on their edges, and fpread on the ground; the following prinTM the folks come out, which rile about two te« high, garnitbed with leave: of the fame ftiape, buc fmallr, which embrace the folks with thieir bafc i the upper part >.. garnificd with flowers lUndtng om one fide in a double row, Erring dole to the llalki alternately j thele are of a dark purplih colour with » black bottom, and arc (ieeceedk by roundilheapfules, iurring within the em-palemsr i thelc open wih a lid at the tup, and have two cells filled wim lciull irrrguar feeds. This u i very poibnous plant, and Hi>util be roowd out in ail plbcei where children arc iuficrcii to come j tor in the year 1720, there were three children puilbnvd with eating ihe fecdi of (his plant, fleir lottcnhtun-tourr; (wo of which (kpt two day* and two nightu before they could be awakened, and were with difficulty recovered; but AK third being older and llrongcr, efcapec better.

The rout; of this plant arc iifed for anodyne neck-laces to hang about children's necks, being cat to pieces and frung like beads, 10 prevent fie and caule n eafy breeding of their teeth, but thty arc veiydan-eroui to ufc inwardly. For fomL' years pift there was a mixture of thele roots brov; ih Gentian, and ufed as fuch, which was anened with very bad effects, u hath been mentioned under the irucle of Gentian, fo I ihall not repeat it here.

The fecond fort grows naturally in the tflands of the Archipelago. This luth rounder leaves, which arc obtufcly Graated upon their borders, and thud upon foot-fUlks j die Balks branch more than thofcof the first, and the wen grow in clulUrs toward the end of the branis iVanJint: upon (Hort foot-iblk; j they «re ut" a pale yellow colour, with very dark purple bottoms.

The third fort is much tike the feeond, bur die (lowers arc in larger bunches, fitting very dole on the end) of the branches! they are of a greenilh yellow colour, K-itj green bottoms. It grows naturally in the warm parts of Europe, an, ii3the fort whose feeds should be used in medicine, living the white Henbane o: tile ..

The fourth fan was brought from the Levant by Dr. l ... Thii hith n GrsaDet italic than either or the former, whose joints are further diftant; the leaves arc roundiil, and deeply indented in ob> tvjfc fepTienn, Handing upon prrny long foot-ftaUu % the flowers come out singly from the fide of che (falks, at a fmall diftance from each other; they arc of a cycl-cotein-wit dk bx

'Joe fifth (on grows naturally in Syria; this riles with a branching stalk two feet high, gvnilhcd with long spear-shaped leaves having two-balks, tli: lower leaves are regularly cut on both fides in ladDte figments which are oppofit, fo are fhaped like the winged leaves, but the upper leaves are ... the flowers grow at the end of the stalks in ii bunches; ; they ur: of t wgn-out red colour, and fhaped like

of the common fort, but their tube* are fata,

All thefe are biennial plants, which perish soon after they have perfected their feeds. They flower in June and July, 2nd their feeds ripen in the autumn, which, if permitted to scatter, will produce plenty of the plants the following spring; or if the feeds are sown in the autumn, they will succeed much better than in the spring, for when they are sown in the spring, the plants themselves come up the same year. They are all hardy except the fifth one, and require no other culture but to keep them clean from weeds, and thin the plants where they are too close. The fifth one should have a warm (it is a double and a dry soil, in which it will live much better through the winter than in rich ground.

The sixth one grows naturally in Candia, this is a perennial plant with weak stalks, which require a support; the leaves are roundish, and acutely indented on their edge; standing upon pretty long four-sided stalks; the flowers come out at each joint of the stalks, they are large, of a bright yellow, with a dark purple bottom in the middle or this lobe is much longer than the petal. It bears a soft part of summer, and sometimes ripens seed in the autumn. If their seeds are sown in pots as soon as they are ripe, and put under a hot-bed frame in winter, the plants will come up in the spring. But if they are sown out of the ground till spring, they rarely succeed. This one will continue several years, if they are kept in pot? and (sown in winter, for they will not live in the open air that (eafan, but it only requires to be protected from frost; if they are placed under a common hot-bed in winter, when they may enjoy as much free air as possible in mild weather, they will thrive better (when they are more tenderly treated. This one may be easily propagated by cuttings, which, if planted in a shallow box during the winter of the summer months, will take root in a month or six weeks, and may be afterwards planted in pots, and treated like the old plants.

The first one has many winged leaves of a grayish colour, which grow near the ground, and slender blanching stalks, which lie parallel to the surface of the ground, the art naked below, and the top ere gsnuQied with two or three small leaves of the lame size and colour: the flowers come out from between the leaves, and are yellow, each finishing or ... yellow flower with ...

HYP

petals, 2nd a pointal stretched out beyond the petals, which afterward turns to a jointed compressed pod about three inches long, which bends inward like a bow, having one rotundish compressed seed in each joint. This flowers in June and July, and the seeds ripen in August.

The second sort hath slender stalks which stand more erect, and the segments of the leaves are longer and much narrower than those of the first; the flowers are smaller, and come out at the division of the branches, these are succeeded by narrow taper pods, which hang downward. It flowers and feeds at the same time with the first.

The third sort grows in the east; Dr. Amman received the seeds from Dauria, and I received the seeds from Istria, where it was found growing naturally. This hath much the appearance of the second sort in leaf and flower, but the pods grow erect, and are wreathed and twisted about. It flowers and feeds at the same time with the others.

These plants are all of them annual, so their seeds should be sown soon after they are ripe, otherwise it will be a year before the plants will appear, on a bed of light fresh earth where they are to remain, for they seldom succeed if they are transplanted. When the plants are come up, they should be carefully cleared from weeds; and where the plants are too close, they must be thinned, leaving them about six or eight inches apart; after this they will require no other culture, but to keep them constantly clear from weeds. In June these plants will flower, and their seeds will be ripe in August.

When the seeds are sown in the spring, and the season proves dry, the seeds will not grow the first year; but if the ground is kept clear from weeds and not disturbed, the plants will come up the following spring. I have known the seeds of these plants remain in the ground two years, and the plants have come up the third spring very well; so that it will be very proper to sow some of the seeds in autumn, soon after they are ripe, in a warm border, where the plants may come up early the following spring; and these will be stronger, and more likely to perfect seeds, than those sown in the spring, by which method the kinds may be preserved.

If the seeds of these plants are permitted to scatter, the plants will come up the following spring without any care; and if they are treated in the same way as the others, they will thrive equally, but when the seeds are sown in the spring, they should be taken out of the pods, and divested of their fungous covering, which adheres close to them, so prevents their growing, till that is rotted and decayed.

These plants are seldom propagated but by those who are curious in botany, though for the sake of variety they may have a place in large gardens, because they require very little trouble to cultivate them; and as they take up but little room, so they may be intermixed with other small annual plants in large borders, where they will make a pretty appearance.

The juice of these plants is of a yellow colour, resembling that of Celandine, and is affirmed by some eminent physicians to have the same effect as opium.

HYPERICUM. Tourn. Inst. R. H. 254. tab. 131. Lin. Gen. Plant. 808. St. Johnswort; in French, *Mfflepertuis*.

The CHARACTERS are,

<The flower hath a permanent empalement, divided into five oval concave segments-, it hath five oblong oval petals which spread open, and a great number of hairy stamina, which are joined at their base in three or five distinct bodies, terminated by small summits. It hath in the center a roundish stem, supporting one, three, or five styles, the same length of the stamina, crowned by single stigmas. the stem afterward becomes a roundish capsule, having the same number of cells as there are styles in the flower, which are filled with oblong seeds

This genus of plants is ranged in the third edition of Linnæus's eighteenth class, entitled Polyadelphia

HYP

Polygynia, which contains the plants whose flowers have many stamina joined in distinct bodies, and several styles.

The SPECIES are*

8. **HYPERICUM** (*Balearicum*) floribus pentagynis, caule fruticoso, foliis ramisque cicutariatis. Lin. Sp. Plant. 783. St. Johnswort with five styles to the flower, a shrubby stalk, and scarified leaves and branches. *Afcyron Balearicum*, frutescens, maximo flore luteo, foliis minoribus, subtus verrucosis falvad. Boerh. Ind. alt. 1. 242. Shrubby Balearick St. Peterwort with a large yellow flower, and small leaves wadded on their under side.

9. **HYPERICUM** (*Androsium*) floribus trigynis pericarpis baccatis, caule fruticoso ancipiti. Hort. Upfal. 237. St. Johnswort with three styles to the flower, a fleshy seed-vessel, and a shrubby stalk with two sides. *Androsium maximum frutescens*. C. B. P. 280. Common tutfan, or Park-leaves.

10. **HYPERICUM** (*Bartramium*) floribus pentagynis calycibus obtusis, staminibus corollâ sequantibus, caule erecto herbaceo. St. Johnswort with five styles to the flower, obtuse empalements, stamina equalling the petals, and an erect herbaceous stalk.

11. **HYPERICUM** (*Monogynum*) floribus monogynis, staminibus corollâ longioribus, calycibus coloratis, caule fruticoso. St. Johnswort with one style to the flowers, stamina longer than the petals, coloured empalements, and a shrubby stalk.

There are some other species of this genus, which are preserved in botanic gardens for the sake of variety, but as they are seldom admitted into other gardens, I have not enumerated them here, lest the work should swell too large.

The first joint feeded sorts are both very common plants, growing in the fields in most parts of England; the first is used in medicine, but the second is of no use: these are rarely propagated in gardens, but I think to mention them, in order to introduce the other sorts, which deserve a place in every good garden.

The first sort has a perennial root, from which arise several round stalks four and a half high, dividing into many small branches, which are furnished at each joint with two small oblong leaves, standing opposite, without foot-stalks; the branches also come out opposite. The leaves have many pellucid spots in them, which appear like so many holes when held up against the light. The flowers are numerous on the tops of the branches, standing on slender foot-stalks; they are composed of five oval petals, of a yellow colour, with a great number of stamina, not quite so long as the petals, terminated by roundish laminae. In the center is situated a roundish pistil, supporting three styles, crowned by single stigmas. The pistil afterward becomes an oblong angular capsule, with three cells, filled with small brown seeds. It flowers in June and July; and the seeds ripen in autumn. The root is perennial, so will continue many years; and if the fresh are permitted to remain, the plants will come up in too great plenty, so that they will be very troublesome weeds. The leaves and flowers of this are used in medicine; it is esteemed an excellent febrifuge plant, and of great service in wounds, bruises, and contusions; there is a compound oil made from this plant, which is of great use in the foregoing accidents. From the stamina of the flower is expressed a red juice, which is sometimes used in colouring, but fades very soon.

The second sort hath square stalks, which rise above the first height with the first, but do not branch so much. The leaves are shorter and broader than those of the first, and have no pellucid spots. The flowers are short foot-stalks at the end of the branches, which are shaped like those of the other. This sort and feeds at the same time with the other, and will propagate in as great plenty if the seeds are permitted to remain.

The third sort grows naturally in Sicily, Spain, and Portugal; this rises with slender stalks about three feet high, sending out small branches at each joint opposite, which are furnished with oblong oval leaves, placed by pairs, fitting close to the stalks, which have a rack smell like a goat. The flowers are produced in clusters at the end of the branches; they are composed of five oval yellow petals, with a great number of stamina which are longer than the petals, and three styles which are longer than the stamina. The pistil which supports these, afterward becomes an oval capsule with three cells, filled with small seeds. It flowers in June, July, and August, and the seeds ripen in autumn.

The fourth sort grows naturally in the Canary Islands, it was formerly preserved in green houses during the winter season, but is found to be hardy enough to resist the general cold of this country, so is now cultivated in the gardens as a flowering shrub; this rises with a shrubby stalk six or seven feet high, dividing into branches upward, which are furnished with oblong leaves, set by pairs close to the branches. The leaves of this have also three sides, but are quite so hard as the former. The flowers are produced at the end of the stalks in clusters, and are very like those of the former sort, having a great number of stamina which are longer than the petals; this flowers at the same time with the former, and perfectly ripens in autumn. Both these plants have a very strong odour like that of a goat; so that when the plants grow in large quantities, the smell is carried by the wind some yards distance; or if the leaves are kindled, they emit the same odour.

These two sorts are propagated by cuttings, which are to be made in the first of the old plants. The best season for taking of the former is in March, just

before they begin to shoot, they should be planted in a light dry soil, in which they will endure the general cold of our climate very well. The second sort is propagated by cuttings, which should be planted at the same season or by roots, which may be taken in August or September, which is as soon as they are ripe and ready to be planted.

The first sort grows naturally on Mount Olympus, where it was discovered by Wheller, who sent the seeds to the Oxford garden; this rises with many upright linear stalks about a foot high, terminated by small spear-shaped leaves, fitting close to the stalks opposite. The flowers are produced at the top of the stalks, three or four together; they are composed of five oblong petals, of a bright yellow colour, with a great number of stamina, which are of unequal lengths, some being longer, and others shorter than the petals, terminated by small roundish laminae. In the center is situated an oval pistil, supporting three slender styles, which are longer than the others. The pistil afterward becomes an oval capsule with three cells, filled with small brown seeds. This flowers in July and August, and in winter ripens its seeds in autumn.

This plant is usually propagated by parting of the roots, because the seeds seldom ripen in this country; the best time for doing of this is in September, that the plants may have time to get root before winter; this will live in the open air, if it is sown in a warm situation and a dry soil, but it will be proper to keep a plant or two in pots, to be flickered under a frame in winter, lest in very severe winters, these in the open air should be destroyed. If this is propagated by cuttings, they should be taken from after they are rooted in pots filled with light earth, and placed under a frame in the winter, to shelter them from frost; when the plants are taken up, some of them may be placed in a warm border, and others in pots, and treated in the same manner as the old plants.

The fifth sort rises with a shrubby stalk about eight feet high, with a reddish bark, and many small branches, which have small oval leaves, which are placed by pairs, fitting close to the stalks; they are produced opposite. The flowers are produced at the end of the stalks in clusters. They are composed of five oval petals, with a great number of stamina which are longer than the petals, and three styles which are longer than the stamina. The pistil which supports these, afterward becomes an oval capsule with three cells, filled with small seeds. It flowers in May, June, and July, and the seeds ripen in autumn. This is now propagated in the gardens as a flowering shrub. The flowers are of a purple red colour, and are composed of five oval petals, with a great number of stamina which are longer than the petals, and three styles which are longer than the stamina. The pistil which supports these, afterward becomes an oval capsule with three cells, filled with small seeds. It flowers in May, June, and July, and the seeds ripen in autumn. This is now propagated in the gardens as a flowering shrub. The flowers are of a purple red colour, and are composed of five oval petals, with a great number of stamina which are longer than the petals, and three styles which are longer than the stamina. The pistil which supports these, afterward becomes an oval capsule with three cells, filled with small seeds. It flowers in May, June, and July, and the seeds ripen in autumn.

The sixth sort was first brought to England from Constantinople, but has long been very common in the English gardens, for the roots spread and increase very fast, when it is permitted to stand long unremoved. The stalks of this are slender, and incline downward; they are furnished with oval, spear-shaped, smooth leaves, placed by pairs, fitting close to the stalks. The flowers are produced at the end of the stalks; these are very large, and of a bright yellow colour, with a great number of stamina, which stand out beyond the petals; there are five styles in each flower, which are of the same length with the stamina. The flowers are supported by pyramidal foot-stalks with five cells, containing many small seeds. It flowers in June and July.

This plant is easily propagated by parting of the roots; the best time for this is in October, that the plants may be well established before the drought of spring; otherwise they will not produce many flowers. As this will grow under trees, so it is a very proper plant to place under trees and trees to cover the ground, where they will make a good appearance during the season of their flowering.

1. JACQUINTA (*Rufifolia*) foliis lanceolatis acuminatis. Jacq. Amer. 15. Lin. Sp. 271. *Jacquinta* with four-angled acute-pointed leaves. Fruticulus foliis rufis fcl- latis. Hort. Elth.
2. JACQUINTA (*sermifolia*) foliis obtusis cum acuminis. Jacq. Amer. 15. Lin. Sp. 272. *Jacquinta* with blunt leaves ending in acute points. Chrysiophyllum Barbato. Linn. h. 204.
3. JACQUINTA (*Linnæi*) foliis linearibus acuminatis. Jacq. Amer. 15. Lin. Sp. 272. *Jacquinta* with linear sharp-pointed leaves.

The first fort grows naturally in the island of Cuba, and in fome other warm parts of America; it riles with a shrubby stalk about a foot high, which is ligneous at the bottom, and about the size of a swan's quill, covered with a dark brown bark, fend- ing out a few slender branches, garnifhed at inter- vals with hand-shaped Bfl leaves, placed in whorls round them; thefe are stiff like thofe of Butcher's Broom, ending with fharp points, of a deep green on their upper fide, but pale on their under; the flowers are (according to Plumier's figure) produced from between the leaves on the top of the branches; but having been no flowers in England, I can give no farther account of them.

The second fort grows naturally at Carthage, Mez- itimus, and other parts of South America, where it riles with a shrubby stalk four or five feet high, di- viding toward the top into four branches, which are furnished in whorls round the principal stalk, garnifhed with oblong blunt leaves, placed alfo in whorls, having a fharp Denier apex. The flowers are produced in a racemous at the end of the branches, each containing five or fix white flowers of a thick confiftence, which

J A S

hive i ktax. like Jafmincflowers, whi I they remain after they decay, (o are worn by the lidita of thofe: toutburys Air ornament.

The third fort grows naturally on the borders of the fea, in the island of Domnita; this is an utKkr-lhml¹, of a very low growth, rarely riling about two feet high, di- viding into feveral branches, garnifhed with linear stiff leaves, ending with a thorn; thefe are placed in whorls round the branches and from the middle of the whorls come out the foot-ftalks otche flowers, each being ter- minated by one lnaU white flower withsux (cent,

As thefe plants are natives of thefe parts, they will not live in England, inlefc they are planted in a wanti ilove, and treated in the manner commonly ufed for uilicr plants from the Rime countrie; giving them tirtje water in winter, and in warm in-n. ltr pices of frelhair. They are rjiied from feed, when thicj can be procured from the countries where tinnat- ural¹ grow; iikh mull be lbwn on a fv-bed, and may afterwards be propagated by cuttings, though it is with difficulty they take root.

The CHARACTERS are,
The flowers have a tubular empalment of the leaf, which is permanent, and cut into five segments at the base, which are oval. The stem is of two sorts, having a long cylindrical stem, which is cut into four segments at the top, which grows open. It hath two sorts of leaves, which are terminated by small junipers, and are furnished with the side of the petal. In the center is situated a round- ish racemous, supporting a slender style, crowned by a leaf- like stigma. The racemous afterwards turns to several berries, with a soft fleshy pulp, which are flat on their flat sides, and convex on the other.

This genus of plants is ranged in the first section of Linnæus's second class, intitled Diandria Monogynia, in which I have placed those plants which have two imina and "n" f.

if permitted to stand, will produce flowers; and these often starve and kill the grafts, so that there will be only the common fort left; and this has been the case with some plants which he examined, therefore supposed the difference of the other sort was wholly owing to culture; whereas, if he had only observed the difference of their leaves, he would have certainly made two distinct species of them, which he has now done in the last edition of his species.

This plant is propagated by budding or inarching it upon the common white Jasmine, on which it takes very well, and is rendered hardier than those which are upon their own stocks. But the plants of this kind being brought over from Italy every spring in so great plenty, they are seldom raised here: I shall therefore proceed to the management of such plants as are usually brought into England from the place above-mentioned, which are generally tied up in small bunches, containing four plants, and their roots wrapped about with moss, to preserve them from drying; which, if it happen that the ship has a long passage, will often occasion them to puff out strong shoots from their roots, which must always be taken off before they are planted, otherwise they will exhaust the whole nourishment of the plant, and destroy the graft.

In the making choice of these plants, you should carefully observe if their grafts are alive, and in good health: for if they are brown and shrunk, they will not puff out, so that there will be only the stock left, which is of the common sort.

When you receive these plants, you must dear the roots of the moss, and all decayed branches should be taken off; then place their roots into a pot or tub of water, which should be set in the green-house, or some other room, where it may be screened from the cold; in this situation they may continue two days, after which you must prune off all the dry roots, and cut down the branches within four inches of the place

Where they were grafted* and plant them into pots filled with fresh light earth; then plunge the pots into a moderate hot-bed of tanners bark, observing to water and shade them, as the heat of the season may require. In about a month or six weeks after they will begin to shoot, when you must carefully rub off all such as are produced from the stock below the graft and you must now let them have a great share of air, by raising the glasses in the heat of the day; and as the shoots extend, they should be topped, to strengthen them, and by degrees should be hardened to endure the open air, into which they should be removed the beginning of June, but must have a warm situation the first summer; for if they are too much exposed to the winds, they will make but indifferent progress, being rendered somewhat tender by the hot-bed. If the summer proves warm, and the trees have succeeded well, they will produce some flowers in the autumn following, though they will be few in number, and not near so strong as they will be the succeeding years, when the trees are stronger and have better roots.

These plants are commonly preserved in green-houses, with Oranges, Myrtles, &c. and during the winter season, will require to be frequently watered; which should be performed sparingly each time, especially in cold weather, for too much wet at that season will be apt to rot the fibres of their roots, they should also have a great share of fresh air when the weather will permit, for which purpose they should be placed in the coolest part of the green-house, among plants that are hardy, where the windows may be opened every day, except in frosty weather; nor should they be crowded too close among other plants, which often occasions the tender part of their shoots to grow mouldy and decay. In April the shoots of

these plants should be raised down to the roots, and all the weak branches should be cut off; if you have the convenience of a glass-house, or a deep frame, to place the pots in at that season, to draw them out again, it will be of great service in forwarding their flowering; yet still you should be careful

not to force them too much; and as soon as they have made shoots three or four inches long, the glasses should be opened in the day time, that the plants may, by degrees, be inured to the open air, into which they should be removed by the latter end of May, or the beginning of June; otherwise their flowers will not be so fair, nor continue so long. If the autumn prove favourable*, these plants will continue to produce fresh flowers until November; and sometimes when they are strong they will continue flowering later; but then they must have a great share of air when the weather is mild and will admit of it* otherwise the flower-buds will grow mouldy and decay. But notwithstanding most people preserve these plants in green-houses, yet they will endure the cold of our ordinary winters in the open air, if planted against a warm wall, and covered with mats in frosty weather; they will also produce ten times as many flowers in one season as those kept in pots, and the flowers will likewise be much larger; but they should not be planted abroad till they have acquired strength, so that it will be necessary to keep them in pots three or four years, whereby they may be sheltered from the frost in winter; and when they are planted against the wall, which should be in May, that they may take good root in the ground before the succeeding winter, you must turn them out of the pots, preserving the earth to their roots; and having made holes in the border where they are to be planted, you should place them therein, with their stems close to the wall; then fill up the holes round their roots with good, fresh, rich earth, and give them some water to settle the ground about them, and nail up their shoots to the wall, shortening such of them as are very long, that they may puff out new shoots below to furnish the wall, continuing to nail up all the shoots as they are produced. In the middle, or toward the latter end of July, they will begin to flower, and continue to produce new flowers until the frost prevents them; which, when you observe, you should carefully cut off all the tops of such shoots as have buds formed upon them, as also those which have the remains of faded flowers left; for if these are suffered to remain on, they will soon grow mouldy, especially when the trees are covered, and thereby infect many of the tender branches, which will greatly injure the trees.

Toward the middle of November, if the weather proves cold and the nights frosty, you must begin to cover your trees with mats, which should be nailed over them pretty close; but this should be done when the trees are perfectly dry, otherwise the wet being lodged upon the branches, will often cause a mouldiness upon them, and the air being excluded therefrom, will rot them in a short time: it will also be very necessary to take off the mats as soon as the weather will permit, to prevent this mouldiness, and only keep them close covered in frosty weather, and in the nights; at which time you should also lay some mulch upon the surface of the ground about their roots, and fatten some bands of hay about their stems, to guard them from the frost; and in very severe weather, you should add a double of treble covering of mats over the trees; by which method, carefully performed, you may preserve them through the hardest winters. In the spring, as the weather is warmer, you should by degrees take off the covering; but you should be careful not to expose them too soon to the open air, as also to guard them against the morning frosts and dry easterly winds, which often reign in March, to the no small detriment of tender plants if they are exposed thereto; nor should you quite remove your covering until the middle of April, when the season is settled; at which time you should prune the trees, cutting out all decayed and weak branches, shortening the strong ones to about two feet long, which will cause them to shoot strong, and produce many flowers.

There is a variety of this with semi-double flowers, which is at present more rare in England, and only to be found in some curious gardens; though in Italy it is pretty common, from whence it is sometimes

brought over amongst the fingle ; the flowers of this kind have only two rows of leaves, so that it is rather cultivated for its curiosity, than for any extraordinary beauty in the flower. This may be propagated by budding it upon the common white Jasmine, as has been directed for the fingle, and must be treated in the same manner.

The fifth kind grows naturally in India; this rises with an upright woody stalk eight or ten feet high, covered with a brown bark, lending out several branches which want no support; these are closely garnished with trifoliate leaves of a lucid green, which are placed alternate on the branches; the two upper lobes of the leaves which grow opposite, are much less than the end one; they are oval and entire, continuing green all the year: the flowers are produced at the end of the shoots in bunches, which have long slender tubes, and are divided at the top into five oblong lobes of a moderate width spreading open; these flowers are of a bright yellow, and have a most agreeable odour. They come out in July, August, September, and October, and continue to the end of November they are frequently succeeded by oblong oval berries, which turn black when ripe, and have each two seeds.

This sort of Jasmine is propagated either by seeds, or laying down the tender branches; if you would propagate them by seeds, which they sometimes produce in England, you should make a moderate hot-bed in the spring, into which you should plunge some small pots, filled with fresh light earth; and in a day or two after, when you find the earth in the pots warm, you should put your seeds therein; about four in each pot will be sufficient, covering them about an inch thick with the same light earth, and observe to refresh the pots with water as often as you shall perceive the earth dry, but do not give them too much at each time, which would be apt to rot the seeds.

They will appear above ground, at which time it will be necessary to remove the pots into another fresh hot-bed, of a moderate temperature, in order to bring them forward; you must be careful to water them as often as is necessary, and in the great heat of the day the glasses should be tilted pretty high, and shaded with mats, to prevent the plants from being scorched with heat. About the middle of May you should begin to harden them to the open air, by taking off the glasses when the weather is warm, but this must be done cautiously, for you should not expose them to the open air in a very hot day at first, which would greatly injure them; rather take off the glasses in warm cloudy weather at first, or in gentle showers of rain, and so by degrees temper them up to bear the sun; and in June you should take them out of the hot-bed, and carry them in some well sheltered situation, where they may remain until the beginning of October, at which time they must be carried into the green-house, observing to place them where they may enjoy as much free air as possible when the windows are opened, as all to be clear from the branches of other plants.

During the winter season they will require to be often watered, but you must be careful not to give them too much at each time; and in March you must remove these plants each into a separate pot, being careful not to shake them from their roots; and if at this time you plunge them into a fresh hot-bed, it will greatly facilitate their rooting again, and be of great service; to the plants, but when they are rooted, you must give them a great deal of air, for if you draw them too much, they will become weak in their stems, and incapable of supporting their heads, which is a great defect in these plants.

You must also harden them to the open air, in which they should be removed about the middle of May, observing, as was before directed, to place them in a situation that is defended from strong winds, which are injurious to these plants, especially while they are young. In winter house them as before, and

continue the same care, with which they will thrive very fast, and produce annually great quantities of flowers.

Theft plants are pretty hardy, and will require no oilier care in winter, than only to defend them from hard frosts; nor do I know whether they would not live in the open air, if planted again. It will not, which in what I have said by planting for a new sinfi a wall for that purpose, and I think we have no reason to doubt of the success, since they are much harder than the Spanish; but there is the difference between them, viz. these plants have large, thick, Evergreen leaves, so that if they were covered with mats, as was directed for the Spanish Jasmine, the leaves would rot and decay. It is however, but as they will only require to be covered in extreme frost, so if their roots are well mulched, and a mat or two loosely hung over them in ordinary limits, it will be sufficient; and the method here is to roll them up, or taken quite off in the day, there will be no great danger of their being hurt, which only can proceed from being too long dole covered.

In the spring these should be pruned, when you should cut off all decayed branches; but you must not shorten any of the other branches, as was directed for the Spanish sort, for the flowers of this kind are produced not only at the extremity of the branches, but also in the axils; and therefore they would be cut off, and their growth of a more vigorous substance than the other, will not produce shoots strong enough to flower the same year.

If you would propagate these plants from layers, the best method is to lay down in March, and if you give them a little care, as is practised in laying down Carnations, it will promote their rooting; you should always observe to refresh them often with water, when the weather is dry; which, if carefully attended to, the plants will be rooted by the succeeding spring, and may be transplanted, when they must be planted in pots filled with light earth, and managed as was before directed for the Spanish Jasmine.

This sort is frequently propagated, by inarching the young shoots into (locks of the common yellow Jasmine, but the plants so raised do not grow so strong as those which are upon their own (lock; besides, the common yellow Jasmine is very apt to send out a great number of suckers from the root, which renders the plant, unless they are constantly taken off, as they are produced, they will rob the plant of their nourishment.

The sixth sort grows naturally in the Azores; this hath long leaves, which require little care, and may be trained twenty feet high; they are gamished with trifoliate leaves, whole lobes are large and heart-shaped, of a lucid green, and are placed opposite on the branches, they continue all the year. The flowers are produced at the end of the branches, in loose bundles; they have long narrow tubes, which at the top are split into five spreading open; they are of a clear white, and have 3 veils of agreeable scent. This is the same time with the former, the gardener call it frequently the Ivory Jasmine.

The seventh Jasmine is also pretty hardy, and requires no more care than the former; and I am apt to think, if this sort was planted against a warm wall, and managed in the same manner as the yellow Indian Jasmine, it would succeed very well; for I remember to have seen some plants of this kind grow against a wall in the garden at Hampton Court, where they had endured the winter, and were in blossom in June, and I have never seen any of the kind in pots, and I produce a Rattrerqua of flowers. These plants are propagated in the same manner as the yellow Indian, and require the same management.

The plants are deserving of a place in all green-houses, in any which are there preserved; for their leaves being of a shining green, make a good appearance all the year; and their flowers having a fine scent, and continuing so long in succession, renders them very valuable.

The first fort was brought from the Cape of Good Hope, by Captain Hutchinbn of the Godolpliin, who discovered it growing naturally, a few miles from the land from the sea, being drawn to it by the fragrance of its flow. L.T.S. which he found it to be different from the plant, which was then in full flower; and after having viewed the plant, and remarked the place of its growth, he returned thither the following day with proper help, and a tub to put it in, and caused it to be carefully taken up, and [itemed in the tub with some of the earth on the spot, and conveyed on board his ship, where it continued flowering.

Rose, and Twigs, in the curious garden of the Duke of Devonshire, at Woburn, in Effix, who is obliged to favour me with branches of this plant in the month of June, of the number of which I have been informed in the description of it to have been known to the first discoverer, for I have not met with any figure or description of it in any of the books; (her fort which is figured in the book of the plants of Ceylon, and also in the book of the plants of Nandi evatum, Lujur. Hort M., in having longer and narrower leaves, the tube of the flower is larger, and the segments do not spread so much as this; the flowers also of the Cape Jasmine are white, and the leaves are dark green, there is no doubt of its being a different species from that of Dr. Uurnarii but it is surprising to find that it should be unknown to the people at the Cape of Good Hope, for there is a plant of it in the curious garden, nor can I find any other plant of it but that which he brought away.

The stem of this plant is large and woody, becoming green by pairs of opposite leaves, which are first green, but afterwards become yellowish.

The leaves are five linear, and are terminated in a point, they are of a reddish green, having a venal traofveile vclus from the middle to the borders; they are round, and of a thick confidence. The flowers are produced at the end of the branches, they are of a tubulose emulose, and are deep red, the segments, ending in a but one petal.

Segments at the top, yet the all joined in one tube below; some of these are much more double than others, having four or five orders of petals; these which have so many, have only a bifid stigma, but those which are less double have trid stigma. All these flowers which I have examined have but one or two stamina, which may be occasioned by the fulness of the flowers; as is often observed in many kinds of plants, whose flowers have a greater number of petals than usual, many of which want both parts of generation, and are therefore sterile. This flower is fully down, as large as a middling Rose, and some of them are as double as the Damask Rose; they have a very agreeable odour, on the first approach it is like that of the Orange flower, but when more closely touched, has the odour of the common double white Narcissus. The season of this plant flowering in England, is in July and August, but in its native country it is supposed to flower great part of the year; in Captain Hutchinbn, who brought the plant over, said there was a succession of flowers on it, till the ship arrived in a cold climate, which put a stop to its growth.

Dr. Linnaeus has been induced from what has been printed in the Transactions of the Royal Society, to alter the title of this plant to Gardenia; but as the description of the plant with its characters as there printed, wsi taken from a double flower by some jicuple, who thought have innibrrd what Linnaeus has written to call Joci perjb., against regarding the double flowers of all kinds, in ranging them in their classes: nci generS, which if they had adhered to, they would not have made this mistake. For I have found several of these plants from Kr. Some of which have produced flowers which visit Tingle, having all the marks of the double, the flower is white; "to » the colour befoit they faded, and all the flowers had such but five funina and i trid it: whereaj in Ae thai is own by Linnaeus, there h no famiia, but Five linear anthera, by which it u plain from the increale uf the number of petals (or ivirher their Jegutent^ hit occufun an alteration in the parts of generation, which is also very conspicuous in the double flowers of Dianthus, where some flowers have but two or three stamina, when the same species with mynrl Qowe have usually ten. Linnaeus atlu fuppofe the capsule of the Rose to have two full of equal seeds; but the person who told him this mistake, have since suppi the figure given by Dr. Plukeiet in his +4Bill plate, under the title of U-11-ky, to IK* the fruit of this plant, whereas this has three cells lilkil withi angular ferec-fected feedi, as the specimen: I have of that demonstration, by which it is certain they are the fruit of a different plant; for the seeds, which I found of this Jasmine, were a berry composed of two seeds is like the Jasmine; therefore I have continued it under the name ^cnus, with an add id an to the title of its h: :lif«ftamina.

This plant is easily propagated by cuttings, or by the inner scason i tic cuttings Short be planted in pots, and phingtdintoamudcratc I ilum clofc with either bell or band-j

the external air, being careful to screen them from sun in the day time, when they have taken root they should be carefully parted, and put each into a separate small pot, planted again into the bed, and fitting them until they have taken new root, atkr whk& they should be gradually raised to the open air.

Though the cuttings of this pbnt take root freely, and make a strong shoot a year or two after. Yet in the first or four years they are very apt to stint in their growth, MB, tfeir kara turning pale and licky, and frequently die soon after; this has happened ever, where within my knowledge, although the plants have been kept in various degrees of heat in winter, and in fomrotr when they tavi beta differently managed, they have frequently faild. I have also been informed by a gentleman who lived fomr yvars in India, where he had the plants in his garden, they frequently went oil in the same manner. This has been the case of the plants in England.

TheCiUR*c<i are, h IKUSI and female fruits in the same plant; the flowers have a faint odour, they are pale, edged, of the petal, with a short tube, whose base is cut into five roundish segments which spread them; they have ten oval-shaped stamens, the long alternately shorter than the others, and are joined with together, pushing well to the center of the flower, terminated by rounded long filaments. The female flowers which are situated in the same whel have no segments, but have five points spread out like a Rose. In the center of a roundish greenish tube long forams, supporting these styles, crowned by single stigmas. The points afterward become a roundish capsule with three cells, each containing one seed.

This genus of plants is ranged in the ninth section of Linnaeus's twenty-first class, intuled Mosceria Mosceridiphia,

nodolphia, which includes thrift plants which have male and female flowers ort the fame plant, and the ilanuiii «re collected in one body.

The GXEII fon v as discovered by the lat. Dr. Houftoun at La Cruz where it is frequently permitted to grow as a way of ornament; it lives with a strong, white, lignous stalk, ten or twelve feet high, covered with a gray bark, and divides into many branches, which are garnished with leaves that are serrated with small prickling spines like those of the Nettle; at the end of these branches come out the flower-stalks, which are five or six inches long, resembling an umbel of white flowers. The male flowers are of one petal, having a tube, which is divided into five parts like those of the common M. that are ilividi

form of a Koff, having the general m the centfr, which afterwards becomes a prickly fruit with three lobes, growing in three ccUs, <ch conuining >

is introduced from the continent, first into the West-Indies, where it is called French Poytic Nut, is distinguished from the following sort, which is called Poytic Nut, from its pungent quality.

This rises with a stiff thick stem eight or ten feet high, dividing into several branches, covered with a grayish bark. The leaves come out on every liJe of the branches on strong foot-stalks, which are five or eight inches long; they are divided into three or four parts, which are joined together at the base.

The upper side of the leaves is of a lush green, but their under side gray, and a little covey. The flowers come out upon long foot-stalks from the end of the branches, formed into an umbel, in which there are male and female flowers, as in the other species; these umbels are large, and the flowers being of a bright scarlet, they make a fine appearance; and the leaves being very remarkable for their beauty, has occasioned the plant being cultivated for ornament in most of the West-Indies.

The eighth sort grows IK; usually in all the idintlj of the West-Indies; this rises with a strong tall stem, or fourteen feet high, which divides into several branches; these are garnished with angular heart-shaped leaves, which end in acute points. The flowers come out in umbels at the end of the branches; they are male and female, of a L herbaceous colour, the male flowrs are succeeded by oblong oval capsules, the female cells, each containing one oblong black seed.

The seeds of the two last sorts have been used as a purgative by the inhabitants of the West-Indies, but they operate so violently, that now they are seldom used; three or four of the seeds have worked upward and downward near forty times, on a person who was ignorant of their effects; but it is affirmed that this purgative quality is contained in a thin film, seated in the center of the nut, which, if taken out, the nuts are harmless, and may be eaten with safety. The leaves of the tall sort are used in baths and fumigations.

The ninth sort grows naturally in all the islands of the West-Indies, where it is sometimes called wild

Cassida, or Cassava, and at others Belly-ach Weed, the leaves of this plant being accounted a good remedy for the dry belly-ach. This plant rises with a stiff herbaceous stalk to the height of three or four feet, covered with a purple bark, and at the joints have branching scabry hairs rising in small bunches, not only upon the principal stalk, but also on the branches, and the foot-stalks of the leaves. The stalk divides upward into two or three branches; these are garnished with leaves standing on very long foot-stalks, divided into hVc k l e s which are oval, entire, and end in acute point. The flowers are produced at the end of the branches, upon slender stalks called foot-stalks, in small umbels; they are small, of a dark purple colour, having male and female flowers in the same umbel; the female flowers are succeeded by oblong triangular vessels, smooth, and covered with a dark film, when ripe, in each of the cells is lodged one oblong brown seed.

All these plants are natives of the West-Indies in America, but some of them are now cultivated in England. The best sort is cultivated in the West-Indies for food, where it is propagated by cutting the stalks into lengths of seven or eight inches, which, when planted, put out roots; the method of doing this having been mentioned in various books, I shall not repeat it here.

The other sorts are easily propagated by seeds, which should be sown on a good hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot filled with light earth, and then plunged into a fresh hot-bed of tanners bark, carefully shading them; after which they must be treated in the same manner as other tender plants from hot countries, admitting fresh air as their daily proportion in the warmth of the Stove; but as many of the sorts have succulent stalks, some of which have a milky juice, they should have but little water given them, for they are soon destroyed by wet.

The fourth sort is an annual plant, to if the feeds are sown early in the spring, and the plants are brought forward, they will perfect their seeds the same year; but the other sorts are perennial, so do not flower till the second or third year; therefore the plants should be plunged into the water in the Stove, where they should constantly remain, giving them a large flow of air in warm weather, but in winter they must be tenderly treated, and in that season must have very little water. With this management the plants will continue several years, and produce their flowers, and frequently perfect their seeds in England.

THE BERRY. Dillen, Nov. Gen. 6. Lin. Gen. Plant. 721. Thisopodium, Tournef. Inf. R. H. 214. tab. 101. Scitica Cistis. The CHARACTERS are, The flower stalk an enlargement of four oval leaves, which spread open, are bell-shaped and fall away. It hath five unequal petals, which are oval, sharp, and spread open, having along with each, the two outer petals are longer than the other. It hath six oval sepals with flammets, the two on the sides being shorter than the rest, terminated by rounded flammets. In the center of the tube is situated a round compressed germin, supporting a first single lobe, enclosed by an acute stigma. The germin afterwards becomes a roundish compressed vessel, having two cells, each containing one oval seed.

This genus of plants is ranged in the first section of Linnæus's fifteenth class, entitled Tetradynamia Siliculosa, which includes those plants whose flowers have four long and two short Stamens, and the seeds grow in their pods.

The SEEDS are, The seeds of the first sort are small, oval, and have a smooth surface, with a small point at the end. The seeds of the second sort are larger, oval, and have a rough surface, with a small point at the end. The seeds of the third sort are small, oval, and have a smooth surface, with a small point at the end. The seeds of the fourth sort are small, oval, and have a smooth surface, with a small point at the end.

This first ibn here mentioned is a low Jh: bby plant, which ill'tiom rifa above 3 foot and a h: high, having many tender branches, which spread on every fide, and the ground if they are not kept paired. Theft branches are well furnished with leaves toward their extremity, which continue grKTrall the year; and in Tummer the Sm are as p... it the end of the Ihooi, which are white, and grow in an umbel. Theft Dower, continue long in beauty, and are succeeded by otbors, ft thu the pbna arc rarely defitute of flowers for near fight months, from the end of August to the beginning of June, wltich ft>- dery 1 hi plant valuable.

This ptinr it fomewnt tender, therefore is gencll:- pric. .ftl in green-houfes in winter, where, bdn^ placed imor.s other low plants tow^rd the Iioiir of the houfe, it mate) act agreeable variety, as it com fawning all thc winter. But I though it s conunply to be •tcd, y« in mod crate winter] this plant will live in ihc open air, if t be pUnu in a warm situation •od on a dry hill; and if, in very hard frost, they arc cot red either widi nuts, Reah, Sera», or Pcas-haulm, cte may be . fen'ed very wr!¹. and these plants which grow in the full ground, will thrive better, and produce a number of flowers, than those which are kept in pots; but the soil in which these are planted, should be: be over rith, nor 100 w«.

for in either of these they will grow too vigorous in summer, so will be in greater danger of suffering by the frost in winter; but when they grow on a gravelly soil, or among lime rubbids, their flowers will be show, strong, and not so expicte with moisture, so will better resist the cold.

This plant very rarely produces seeds in England, therefore is only propagated by cuttings, which, if planted during any of the summer months, and shaded from the sun, and duly watered, will be rooted in two mon: j, lid may afterwards be either •, planted

IB E

in pea, or into die borders where &cy are drfigntd to (land. There ia a varirty of this with variegattd Icai-fs, which is prefervei in some of the gardens where perfoni dtli(jlic in chcl- ti ped-leaved plants. This is not fo bard] as the plain sort, therefore must be treated more icn. rly in winter; thins is also increased by- tutLJigs in the fame niui! , or as the caler.

The feontl frt is a j.l.itit of humbler growth than the firil •, this feldotn rifes more than six or eight Liches high, nor du the brc; ches grow woody, but are rather fierbaci out, the leaves of this plant continue green through iht year, and the flowers are of as long duration as 1 title of the first sort, which renders it vihttbi*. : a rarely produces seeds in England, but 1 propagated by slips, which in summer easily take 1 «t, and tt: plants may be treated in the same manner M kith iorn directed for tin; (:it fort, and will thrive in the open air.

The third fore is a low annual plant, the sedj of which were formerly town to make edgings for boxes in the pleasure-garden, for which purpose all the low annual: flowers are very improper, because they do not answer the intent, which is to prevent the earth of the borders falling into the walks, which these plants never can do and though they make a pretty appearance during their 1 continuance in flower, which is seldom more than a fortnight or three weeks, yet after their flutters are , all they become very unsightly; therefore all these sorts of flowers should be kept in Iniall patches in the borders of the flower-garden, where, if they are properly mixed with other Bfiacn, Ln • will have a very good effect; and by having uf trirrii at three or four different seasons, there may be a succession' : n of [hcin t continued in flower till autumn.

There arc two different varieties of this third sort, one with red, and the other hath white flowers; but the white is DOTcomm on in the gardens, but the best of the IV th sort are generally sold for it, and is seldom dltfinguilhed bui by those who are skilled in botany; tilts plant fdiu... rises more than five or six inches high, and • they have room will branch out on every fide, but when they are left too close, they draw each other up, and are weak; as these do not bear transplanting well, so the seeds should be sown thin in patches, and when the plants are grown pretty strong, they should be thinned, leaving but six or eight in each patch to flower; and by this means them, they will put out side branches, and flower much stronger, and continue longer in beauty than when they are left close together; these plants will require no other culture but to keep them clear from weeds.

The fifth sort seldom grows so large as the third, and [he flowers are much smaller, but have an agreeable colour. It grows naturally in Helvetia, and is preferred in botanic gardens for variety. It is rampant, and requires the same treatment as the third. The fifth sort grows on shady and rocky places in several parts of England, but rarely succeeds in gardens. The leaves of this are small, and cut to the middle into many juze; these are spread on the ground, and between them will a naked stalk two or three inches long, supporting small umbels of white flower. This is an annual plant, whose seeds should be town in Jutumn where the plants are desired to nrmiin, and require no odicr : are but to keep them clear from weeds.

The sixth sort is very like the third, but differs in the shape of the leaves. The flowers of this are white, ib may be sown to make a vi :!* red. It requires the same treatment.

The seventh sort grows naturally on the Alps, from whence it was first sent; this is a perennial plant, which roots pretty deep in the ground. The lower leaves which rise from the root, are round, fleshy, and rounded on their edges. The stalk rises four or five inches high, and is garnished with small oblong leaves which half embrace the stalk with their base. The flowers resemble the stalk in a round cov-

prft umbel i thty <r of a purple colour. -A sp-
pear in June, I in are seldom exceeded by '• in
England.

It is propagated by seeds, which firmbl be lwo on
dry borders in autumn, and when the plants are
strong enough to remove, they should be transplanted
on a shady border where they are designed
and will require no other care but to keep them clear
from weeds.

The eighth fern grows naturally in Spain and Portugal;
it has a great resemblance of the former, but
the stalks do not spread so much; they grow erect,
about seven or eight inches high, are lignous and per-
ennial. The leaves are very narrow, and seldom
more than an inch long, bending thinly upon the
stalks, having no foot-stalks. The flowers
row III nemifchrri. It flowers in May and June,
but seldom produces good seeds.

They are propagated by cuttings, in the same way as is
the case with the former. Some of the plants may
be ordered in a dry soil, where they
will be better than in ordinary winters very well.

It will be proper to have two or three plants in
each pot, which may be inclined under a frame in winter,
to preserve the kind, or by severe frost. In
the open air it should be destroyed.

IBIS - U.S. - See HISTORIC.

ICAC - O. - See CHRYSEALAC.

ICE is a hard transparent body, formed from some
liquid condensed, or fixed.

Ice is said to be the natural state of water, which re-
mains firm, and not liquid, when the external
force upon it.

The true cause of the congelation of water into ice,
is not to be the introduction of frigid particles into
the pores of water; but the particles of wa-
ter, in the ordinary winter season, to near them, & to

the open air should be destroyed.

water, by cold should imagine, that being cold.
Denser water, is ought to be more condensed, and
consequently heavier; but it is to be considered, that
there are always four bubbles of air interperled in
ice. It is certain, by the experiment, of ice upon wa-
ter, that it is specifically lighter than the water, out of
which it is made by freezing; and it is aⁿ amin.
The height of ice proceeds from the numerous
cubbies that are produced in it by congelation.

Water, when it is frozen into ice, it loses imp more
space than it did before it was congelated. This is very
fible, the fibres of water are increased by
freezing, its particles being kept at a distance
the one from the other, by the intervention of the
frigidific air.

Anil- Besides the air, there are many little volumes of air
included at several distances from the surface of the
water, and in the pores of the ice, both in the pores of die
spherical figures. Now, by the intervention of the frigidific
air, the volume of air is driven out of the
watery particles; and many of the air, being united, form
lorgi bubbles, by a greater force
to ex) and themselves than water, which they displace,
and to both enlarge their diameter, and to rise up
specific gravity of water than that of ice, which is
l into Ice.

It seems very probable, that cold, and consequently
the air; in that lilt, sail
more eminently these particles are driven out of
with ice or snow, do wonderfully increase the force
and effects of cold.

It is a visible, that all these bodies cause a
nests a: a frigidicy in the air, which they enter.

It is manifest, by observing that the air is by
that the Bguntt of the air, is by the miaofcope,
fan. - d*y & ° < »

ICE

tnaflw, nrc thn double wedge-like particles, which
have abundance of surface in respect to their fluidity,
and this is the reason why they begin in water, when
once they are raised in it, although they are specul-
cally heavier, their small pores are driven into
the pores of the water, whereby they are, in some
measures, suspended in the water, when the water
is not ordered to be frozen; but when it is ordered to
fall into fluid, to break their points, and to keep
them in perpetual motion, which being left disturbed,
are more at liberty to approach one another, and by
floating into chrysalis, of the form above-mentioned,
do, by their extremities, infuse themselves into the
pores of water, and by that means freeze it into a
solid form, called Ice.

Mont. Marston, in his Treatise of Hydrostatics, gives
the subsequent account of what happens to water in
freezing, which he discovered by the following experi-
ments.

Having filled a cylindrical vessel, of about eight
inches high, and six inches diameter, with water
eight inches high, and six inches diameter, and
two inches of the top, with cold water, he exposed it to
the open air in a great frost, and observed exactly the
whole progress of the congelation.

The first congelation was in the upper surface of the
water, in little long water thons, or masses, which
were jagged like a saw. In the same manner the re-
maining still water, though the top of the water
was already frozen to the bottom of the vessel, was
found in the ice, that began to form on the bottom
and sides of the vessel; and others
remained entangled in the ice, which made him un-
agine that these bubbles taking up more space in the
water, than when their matter was, as it were, dis-
solved in it, they pulled up a little water through
the hole at the top, after the same manner that new
wine works out at the bung hole of a small when it
begins to heat, and the little water that oozed out at
this little hole in the ice, spreading itself upon the
upper surface of the water, which was already frozen,
became ice also, and there began to form a little
ice in that hole continuing open, by reason of the
water which passed successively through it, and
pushed up by the new bubbles which formed them-
selves in the ice, which continue to increase about
the sides and bottom of the vessel, he observed that
the lower surface of the ice water re- frozen above an
inch thick water in the vessel, and
above an inch more a hole round about the little
hole, before the water that was contained in it, as
in a pipe, became frozen, but at last it was frozen,
then the middle of the water remaining unfrozen,
and the water which was compressed by the new
bubbles, which formed themselves for two or three
lines, which rose up at the little hole, the ice broke
at once towards the top, by the forcing of the
included air.

In the manner the frost acts upon vegetables, by
the frigidific particles cutting the tender shoots of
plants, and infusing between the pores of the top,
thereby increasing its bulk, so that the tender vessels of
the plant are broken, and those parts of the plant, are
(MII killed; ami tl) greater the quantity of the air
is in vegetables, the more they are in danger of being
destroyed, but we frequently see many plants which
grow on the top, and from the joints of walls, escape
the severest frosts, when those of the same kind are
all destroyed which were in the ground, which is en-
tirely owing to their vessels being stronger and more
compact, and not so full of water, so when
the autumn proves cold and moist, whereby the ves-
sels of plants are not properly hardened, and are re-
plete with moisture, a small frost will do great mis-
chief to them, whereas when the autumn is dry and
warm, the tender shoots of trees and shrubs are har-
dened, and trained of their vessels, so are not li-
able to the like accidents.

ICEHOUSE is a building contrived to preserve ice
for the use of a family in the summer season.

This

I CE

Tisti: are more generally used in war*ci* cuumnes, than in kngland, but particuliy in Italy, where tin: meanrft prfbn who tons a hemfe, a not widi on a vault or cellar for keeping of ILC, but »i [he ufe of kx in En^lind. is much greater ot' late than it was forniefly, <> the number oi Ice-houfes fw been i-re.itij' n. ... Etoi ol'ihelc ... he, lei ... subject, yet if it is conidred, that theft buiking» »re generally creffleJ in gardens, and as often put undo¹ tiic LJFC of ganicnen, it may nut be amft for me to give fome general dircifvions tor the choice of ilie Jiuuation jmi ltruaurc of the building, as .illb for the management of the ice.

In the choice of : fnuwion for MI Ice-houfe, the principal regard : Iould be, thit of a dry fjot of ground, for wherever there is moisture, the ice will melt; therefore in all i'ong land, which detain : wet, there cannot be ri much care taken to make drains all round the building to cany off all ii moisture: for when this a lodpd nnr tUe building, it will occiUoij adamp therct which will always be jinrjudid.il to the keepin;: ol the ice.

Thit next consideration must be, to have the place in elevartii, that there may be dclene CIHJUJII tocairy orFwrldivi; wet may happen near iht huilit: or from the ice melting, abo, that the place be .lll much expoed to the [un *nd air as pofftblc, and r.o: phto i ntlr thcilrip, or in the Diace of trees, ai liatii been too often profbiid, under a t, ... lid be txpoed to :hc fun, th imcr, whit.

In the next consideration must be, to have the place in elevartii, that there may be dclene CIHJUJII tocairy orFwrldivi; wet may happen near iht huilit: or from the ice melting, abo, that the place be .lll much expoed to the [un *nd air as pofftblc, and r.o: phto i ntlr thcilrip, or in the Diace of trees, ai liatii been too often profbiid, under a t, ... lid be txpoed to :hc fun, th imcr, whit.

It is necessary that the place should be so situated, that it may be exposed to the sun, and wind, all iamps and vapours will thereby be removed from about the building, which can never be kept too dry, or free from moist vapours. As to the figure of the building, this may be according to the fancy of die owner; but for the well into which the ice is to be put, a circular is the most convenient; the depth of the well, as also the diameter of it, must be proportioned to the quantity of ice wanted, but it is always best to have enough; for when the hoick is well built, it will keqj the ice for mo or three year •, and there will be this advantage in having a large enough to contain ice for two years consumption, that if a mild winter should happen, when there is not ice to be had, there will be a stock to supply what is want.

If the quantity wanted is not great, a well of Sixfeet diameter, and eight feet deep, will be large enough; but for large consumption, it should not be less than nine or ten feet diameter, and as many deep; where the situation is either dry chalk gravel, or sand, the pit may be entirely below the surface of the ground; but in strong loam, clay, or moil ground, it will be the best way to raise it so high above the surface, as due there may ix no dampness from the wet.

At the bottom of the well, there should be a iucc 1ft, about two feet deep, to receive any moisture which may drain from the ice, and a small underground drain should be laid from this, to carry off the water; over this space of two feet, should be placed a strong grate of wood, to let the moisture fall down, which may at any time happen, from melting of the ice. The sides of this well must be backed up with a wall, at least two bricks and a half thick; but if it is yet thicker, it will be better, because the thicker the walls are made, the less danger there will be of the well being affected by any external cause. When the well is brought within three feet of the surface, there must be another cover such as wall began, which must be carried up to the height of the top of the intended arch of the well; and if there is a second such cover over from this well, it will add to the goodness of the hoick; but this must be fabricated to the

turn of the well, and if there is a second such cover over from this well, it will add to the goodness of the hoick; but this must be fabricated to the

J E Iⁿ

perfun wlio build:, i he will be at the expense, but it cot, then the plain into which the roof is to be fram: 1. must be laid on this outer wall, which should be carried high enough above the inner such, to admit of a door-way in, tugecaut the ice.]] the building u to be cov. ... should be ti thick:) ... the fun and external air, if these floods are but two feet thick, and plastered over with lime and hair, there will be no damage of the heat getting through it.

The external wall need not be built circular, but of any other figure, either square, hexagonal, or octagonal; and where this stands much in sight may be so contrived as to make it a good object. I have seen an ice-house built in such a manner as to have a front porch above that in the front, and behind this porch was contrived a passage to get out and put in the ice; and by having the entrance behind, to the north aspect, a small passage being next the porch, through which a jicilun might enter to take out the ice, and a large door being contrived with a porch, wide enough for a small cart to back in, to drop down the ice upon the floor near the mouth of the well, where it may be well broken, before it is put down. The aperture of this mouth of the well need not be more than two feet diameter, which will be large enough to put down the ice, and if it was greater, it would be inconvenient; there should be a stone fixed to stop this aperture, which must be cleft up as secure as possible, when the ice is put in, and all the vacant space above and between this and the outer door, must be filled close with barley straw, to exclude the air; for the door to enter for taking out the ice should be on the opposite side, immediately behind the above door, as was before mentioned; and this door should be no larger than is absolutely necessary for the passing of the ice, and must be strong and close to exclude the air; it should be at five or six feet distance from the outer door, which should be contrived, which should be easily dim when the inner door is opened, whenever the ice is taken out.

The building being finished, should have time to dry before the ice is put into it; for when the walls are green, the damp of them imparts to the ice. At the bottom of the well, upon the wooden grate, should be laid some small ragged, and if upon these a layer of straw is placed beneath for the ice to lie upon. It will be better than straw, which is commonly used, and in the corner of the pit, the diameter is, the better it may be broken to powder, for the smaller it is broken, the better it will come when put into the well; in putting of it in, there must be care taken to ram it close, so close to allow a vacancy all round next the wall, of about two inches; that it may give passage to any moisture, which may be occasioned by the melting of some of the ice on the top, which, if pent up, will melt the ice downwards; when the ice is put into the well, if there is a little salt-petre mixed at every six inches or a foot thickness, it will cause the ice to join more closely into a solid mass. The instructions here given, being carefully observed, will be sufficient to guide persons wholly ignorant in their manner.

JET D'EAU is a French word, which signifies a Fountain that casts up water to any considerable height in the air. Monsieur Mariotte, in his Treatise of Hydrostatics, says, That a Jet d'Eau will never rise so high as its reservoir, but always falls short of it by a space which is in a subduplicate ratio of that height; and this he proves by several experiments; that though Jets ought to rise to the height of the reservoir, yet the friction of the sides of the spout, and the resistance of the air, are the causes that in Jets do not have very high reservoirs, the height of the Jets does not come up to that of the reservoir, by a great deal.

He adds, That if a greater quantity of water is sent in smaller cases, or is distributed through several Jets, the square of the diameter of the main pipe must be proportioned

to the height of the reservoir, and if the diameter of the main pipe is to be the same, the height of the reservoir must be the same. He also says, That if the diameter of the main pipe is to be the same, the height of the reservoir must be the same.

JET D'EAU is a French word, which signifies a Fountain that casts up water to any considerable height in the air. Monsieur Mariotte, in his Treatise of Hydrostatics, says, That a Jet d'Eau will never rise so high as its reservoir, but always falls short of it by a space which is in a subduplicate ratio of that height; and this he proves by several experiments; that though Jets ought to rise to the height of the reservoir, yet the friction of the sides of the spout, and the resistance of the air, are the causes that in Jets do not have very high reservoirs, the height of the Jets does not come up to that of the reservoir, by a great deal.

He adds, That if a greater quantity of water is sent in smaller cases, or is distributed through several Jets, the square of the diameter of the main pipe must be proportioned

portioned to the sum of all the expences of its branches; fciat if the refervatory be fifty-two high, and the ajutages half an inch in diameter, the pipe ought to be three inches in diameter.

He fays. That the beauty of Jets of water confifts in their uniformity and tranfparency at the going out of the ajutage, and fpreading but very little, and that to the higheft part of the Jet.

That the worft fort of ajutages are thofe that are cylindrical, for they retard very much the height of the Jets, the conic retard it lefs; but the beft way is, to bore the horizontal plane, which fhuts the extremity of the pipe, or conduit, with a fmooth and polifhed hole, taking care that the plate be perfectly plain, polifhed, and uniform.

Thefe fpouts of water are fome of the greateft beauties of the Italian gardens, and are certainly better adapted for gardens in thofe warm countries, than they are for our climate, becaufe, in the great heats of fummer, the fight of thefe water-fpouts is cooling and refrefhing to the imagination, and they certainly add a real coolnefs to the air; but in cold countries they cool the air too much, therefore fhould not be erected -, or if they are, they fhould be placed at fuch diftances from the habitation, as that the damp may no ways affeet it.

Where thefe Jets are contrived, if there is not a conflant fupply for a large column of water, they fhould by no means be made, for nothing can have a meaner appearance, than thofe pitiful piffing fpouts, fo frequently to be feen in England, which perhaps have not a fupply of water to play above an hour or two; therefore where there is not a natural body of water, to fupply thefe Jets, without the expence of raifing ir, there fhould never be any of thefe contrived in gardens.

I L E X. Lin. Gen. Plant. 158. Aquifolium. Tourn. Inf. R. H. 600. tab. 371. The Holly-tree, in French, *Houx*.

The CHARACTERS are, they have male, female, and hermaphrodite flowers on different plants. The male flowers have a fmall permanent empalemt of one leaf which is indented in four parts; they have but one petal, which is cut into four fegments aUmeft to the bottom; they have four awl-Jbaped ftamina, which are Jhorter than the petal, and are terminated by fmall fummits. The female flowers have their empalements and petals the fame as the male, but have noftamina 5 in their center is placed the roundifh germen, having four obufefigmata fitting on it. The germen afterward becomes n roundifh berry with four cells, each containing a fingle hard feed.

This genus of plants is ranged in the third lection of Linnaeus's fourth clafs, intitled Tetrandria Tetraoyonia, which includes thofe plants whofe flowers have four ftamina and four ftyles; but according to his own fyftem, it fhould be placed in the third fection of his twenty-fceond clafs, with thofe plants which have male and hermaphrodite flowers on different plants.

The SPECIES are,

1. ILEX (Aquifolium) folus oblongo-oyatis, undulatis, fpinis acutis. Holly-tree with oblong leaves which are waved, and have acute fpines. Hex aculeata ~~Waldst. & Schmidt.~~ C. B. P. 425. Prickly berry-bearing Ilex; and t ~~The com-~~ folium five agrifolium vulgo. J. B. 1. 114.
2. ILEX (Echinata) folis ovatis, undulatis, marginibus aculeatis, paginis fuperne fpinofis. Holly with oval, waved leaves, whole borders are armed with fpines above, and their upper furface prickly. Aquifolium echinatum folis fuperficie. ~~Comar. Canad. 180. Holly-tree with a upper furface of the leaves are prickly, commonly called Hedge-hog Holly.~~
3. ILEX (Caroliniana) folis ovato-lanceolatis ferrugineis. ~~Hoet. Chiff. 40. Holly with oval, fpear-shaped, fawed leaves. Aquifolium Carolinense, folis dentatis, baccis rubris. Catesb. Carol. 1. p. 31. Carolina Holly with pointed leaves and red berries, commonly called Dabber Hc'Jj.~~

There are federal varieties of the common Holly with variegated leaves, which are propagated by the nurfery gardeners for fale, and fome years palt were in very great efteem, but at prefent are but little regard, ed, the old tafte of filling gardens with (horn Evergreens being pretty well libolifhed; however, in the difpofition of the clumps or other plantations of Evergreen trees and ihrubs, a few of the moil lively colours may be admitted, which will have a good effect in the winter feafon, if they are properly difpofed. As the different variegations of the leaves of Hollies, are by the nurfery gardeners diftinguifhed by different titles, fo I fhall here mention the moft beautiful of them, by the names they are generally known: Painted Lady Holly, Britifh Holly, Bradley's beft Holly, Phyllis, or Cream Holly, Milkmaid Holly, Pritchett's beft Holly, Gold-edged Hedge-hog Holly, Chcyney's Holly, Glory of the Weft' Holly, Broad-erick's Holly, Partridge's Holly, Herefordfhire white Holly, Blind's Cream Holly, Longftaff's Holly, Eales's Holly, Silver-edged Hedge-hog Holly.

All thefe varieties are propagated by budding or grafting them upon (locks of the common green Holly: there is *lib a variety of the common Holly with fmooth leaves, but this is frequently found intermixed with the prickly-leaved on the fame tree, and often on the fame branch, there are both forts of leaves.

The common Holly grows naturally in woods and forefts in many parts of England, where it riles from twenty to thirty fcephigh, and fometimes more, but their ordinary height is not above twenty-five feet. The ftem by age becomes large, and is covered with a grayifh fmooth bark; and thofe trees which are not lopped or browsed by cattle, are commonly furnifhed with branches the greateft part of their length, fo form a fort of cone *, the branches are garnifhed with oblong oval leaves about three inches long, and one and a half broad, of a lucid green on their upper furface, but are pale on their under, having a ftrong midrib: the edges are indented and waved, with fharp thorns terminating each of the points, fo that fome of the thorns are railed upward and others are bent downward, and being very ftiff, renders them troublefome to handle. The leaves are placed alternate on every fide of the branches, and from the bafe of their foot-ftalks come out the flowers in clutters, Handing on very fhort foot-ftalks *, each of thefe fuftain five, fix, or more flowers. In fome plants I have obferved the flowers were wholly male, and produced no berries; in others I have obferved female and hermaphrodite flowers, but upon fome large old trees growing on Windfor foreft, I have obferved all three upon the fame trees. The flowers are of a dirty white, and appear in May; they are fucceeded by roundifh berries, which turn to a beautiful red about Michaelmas, but continue on the trees if they are not deftroyed, till after Chriftmas before they fail away.

The fecond fort grows naturally in Canada, from whence it was brought to Europe. The leaves of this fort are not fo long as thofe of the common Holly, and their edges are armed with ftronger thorns ftanding clofer together *, the upper furface of the leaves is fet very clofe with fhort prickles, from whence the gardeners have given it the title of Hedge-hog Holly. This fort is ufually propagated in the nurseries, by budding or grafting it upon the common Holly *, but I have railed it from the berries, and found the plants to be the fame as thofe from whence the feeds were taken, fo make no doubt of its being a diftint fpecies.

There are two varieties of this with variegated leaves, one of which is yellow, and the other white. There is alfo a variety of the common Holly with yellow berries, which is alfo accidental, and is generally found on thofe plants which have variegated leaves, and but feldom on plain Hollies.

The common Holly is a very beautiful tree in winter, therefore deferves a place in all plantations of

the three first sorts grow naturally in Spa³l. Perin-
palk and the fourth of France; the
stalks about a foot high, garnished
with trail leaves

Theft hwecrewn then to the ground in their native
soil, whereby they spread to a great distance; and
in this country, when they are plunged into a
tan-bed, they will multiply as fast, by taking root in
tan, or any of the other pots of plants which are near
them.

The flowers of the fourth sort are
ance, therefore the plant is easily pro-
cept in botanic gardens for variety; but are pointed in
and first sort have dry heads of flowers, resembling
the of ilic Ainaraothoides, under which genus they
tt'ercioni" ¹ are placed.

These three sorts are tender, so wil| noi thrive in
the open air in England; therefore they should be
be sown on a v-bxU in the i< ring, at th< r lime time as
the Ananthis, Gompilens, and other tender planwi
and afterward, if they are plunged in othe: ran- b d
in the stove, their branches will put out roots, whereby
they may be propagated in plenty.

MPATIENS. Rivin. Oul. 4. Lin. Gen. Plant.
100. Balsamina. Tournef. Inst. R. H. 218. tab. 235.
"lisle Balfuwin^, w French, Balsamine.

The Characters are,
The flower has a two-lobed small empaleum, which
is tubular, and placed in the side of the petals. It hath
five petals which are unequal, and shaped like a lip-
flower. The petals are roundish, the upper is oval, slightly
cut at the point into three parts, where it is sharp-pointed,
forming the upper lip; the two lower petals are broad,
obovate, irregular, and reflexed; these comprise the lower
lip; the intermediate pair are small, and are placed oppo-
site, joining at their base. It hath a callicum in the
bottom of the flower, shaped like a hood or oval, which
is oblique to the mouth, rising on the outside, whose edge ends
in a tail or spur. It hath five short stamens which are
narrow twrsd tkir lft and tubular, terminated by

stamens, which join at the top round the flower, but are
divided at their base. In the bottom is situated an oval
sharp-pointed ovum, having no style, but a single stigma
shorter than the stamens. The genus is of several kinds
it agrees with one another, agreeing with an equality in five
calves, tubular petals, and certain stamens reaching
into half to a crown.

This genus of plants is ranged in the fifth section of
Linnæus's nineteenth class, which includes those plants
which have single flowers in the compound, while
Linnæus was in number and in rank.

The SPECIES are,

1. IMPATIENS (Nig. tanger) pedunculata multiloba foli-
oformis, foliis ovatis, petalibus corollæ tubularibus.
Flor. Suec. 702. Balsamina with five petals following
more single flower, oval leaves, and stalks being
January 1000. Balsamina lutea, five. Non me tan-
gere. C. B. P. 1206. Yellow Balsamine, or Touch me
not.

2. IMPATIENS (Balsamina) pedunculata uniflora aggre-
gata, foliis lanceolatis, archam floribus tubularibus.
Hort. Upsal. 270. Impatiens with five petals following
single flowers, which rise in clusters, spear-shaped leaves,
and tubular which are shorter than the flower. Bal-
samina formosa. C. B. P. 1206. The French Balsamine.

3. IMPATIENS (Fragaria) pedunculata uniflora foliolata,
foliis angustis lanceolatis. Flor. Zeyl. 215. Impatiens
with three flowers in a just-pink, and narrow spear-
shaped leaves. Balsamina erecta, in formis, Petalibus
angustis foliis Zeylonica. Hort. Par. Bat. 104. Upright,
or French Balsamine of Ceylon, with a narrow spear-shaped
leaf. There are several other species of this genus, which
grow naturally in India, which are plants of little
beauty, so have not been introduced into the English
gardens; the first sort mentioned, are all I have
yet seen growing here, except one tall sort from
North America.

The first sort grows naturally in several parts of
West-India and Yucatan, but is frequently in-
tro. I

It is an annual plant, which rises about a foot or a half
high, with an upright succulent stalk, whose joints are
fleshy, garnished with oval smooth leaves, which
stand alternate on every side the stalk. The flowers
come out from the joints of the stalks upon long
tender foot-stalks, which branch into several other
smaller, each sustaining one yellow flower, composed
of five petals, which in youth are shaped like the lip
or grinning flowers, but as their base have a tubu-
lar with a long tail like the flowers of Indian Cress;
these are succot... and by taper pedic, wllii is, when ripe,
bunt open upon being touched, and curl spirally
like a screw. Ring out il: seeds with great elac-
ticity. If die > tal of this plant are pointed in
fe<ier, th, generally succeed better than when they
ate fewn; but unless they are sown in the autumn soon
after they are ripe, they very rarely grow. The plants
require no are lux to keep them clean from weeds,
and thii them where they are too close. It flowers in
June, ami "e I seeds ripen about a month or five weeks
afters diis ddigi at in a shady situation and i moili
fall.

Tiie. Seam I sort is the female Balsamine, of which
there are several varieties; the common sort has been
long "l inhabit-
is th: white, the red, and striped flowered, and the
Wiiir: in single and double flowering, with variegated
flowers of two colours. Their seeds are so hard as
to rise in (he lull ground; and when the seeds are
rider, i the plants will come up the following spring;
but such self-sown plants do not come to flower so
early as those which are raised upon a hot bed, how-
ever, they generally are stronger plants, and continue
much longer in the autumn in flower than the others,
so are MI ornament u* ihe garde. when there is a
meattr feircity of r' flowers.

T)ib ion ril is a foot and a half high, dividing into
many succulent branches, which are garnished with
long, spear-shaped, serrated leaves. The flowers come
out from the joints of the stalks, upon slender foot-
stalks.

IMP

i about an **Itch bug**, each **iuftaining a fingle**
flower, but **! there are two, rhree, or four o:** these
 foot-stalks arising from the same joint. **The Awers**
 ate **CMT!** out of five larger uncles: **petal***, which jre
flia-; **!**; **!**; **!** **former** **t!**; **!**, but **!** **larger**,
anil f!>reil' open mini wider-, **these are white, Jiur-**
ple, and red of this sort, as also **fingle and double**
flowers. If the feeds of these are sown on a moderate
 hot-bed in the spring, the plants will flourish in **Jiir;**
best table which are sown in the **full ground**, will
 not flower before the middle of **Jy**; **ly; and thiffe will**
 continue flowering till the first of **lit puti £** (top to them in
 the autumn.

There are two other varieties of this, **! no* Jittincl:**
 species, one of them grows naturally in the East, and
 the other in the West-Indies; that is from
 the East-Indies, by the name of Immortal Eagle Flower,
 is a most beautiful plant, the flowers are double,
 much larger than those of the common sort; they
 are **coral and white variegated, and purple and**
white in others, and the plants producing **mm**
 flowers, **render them very valuable**; and if the feeds
 of these are carefully sowed, the feeds may always
 be preserved; but I have raised some **plant* from**
 foreign feeds, whose flowers **ere !u very Jouble**
 as to take these male parts, **i !lid nor produce any**
 feeds.

The feeds of these plants; **i fliouU be sown on a mode-**
rate hot-bed in the spring, the plants are
 commonly **up about** an inch high, they **lliiiiild be trinf-**
 planted on a moderate hot-bed at about **lit four**
 inches distance each way, observing to shade them
 from the sun till they have taken new root, after which
 they should have a large share of free air admitted
 to them, in all times when the weather is favourable,
 to prevent their drawing up tall and weak; they
 will require to be often watered with water, but as
 much not be given to them in too great plenty,
 for as their stems are very succulent, **i ihty are apt**
 to rot with much moisture. When the plants are
 grown to large as to touch each other, they should be
 carefully taken up with balls of earth in their roots,
 and each planted into a separate pot filled with light
 rich earth, and plunged into a very moderate hot-bed
 under a deep frame, to shade the plants to grow,
 shading them from the sun until they have taken fresh
 root; then they should have a large share of air ad-
 mitted to them every day, and by degrees hardened,
 for **a wbcirifie open atr, into which pare of iht pUius**
 may be removed in July, placing them in **.. warm**
 sheltered situations; where, if the season proves favour-
 able, they will flower and make a fine appearance;
 but it will be proper to keep part of the plants
 either in a glass case or a deep frame, **in order to**
 get good feeds, because those in the open **lit will**
 not ripen their feeds unless the summer prove **as AT!y**
 and the plants in shelter must have a good
Hun of free air every day, otherwise they will grow
 pale and feeble; nor should they have too much of the
 sun in the middle of the day, in very hot weather,
 for this occasions their leaves hanging and their re-
 quiring water, which is often very **iunful - , ifn**
 if the plants are shaded in the middle of the day for
 three or four hours, the plants will thrive better, and
 continue longer in beauty than when they are exposed
 to the heat of the sun. Those who are curious to preserve
 their plants in perfection, pull off all the single and
 plain coloured flowers from the plants which they pre-
 serve for feeds, leaving only those flowers which are
 double and of good colours; where this is carefully
 done, they may be continued without the least depre-
 cation constantly.

The last which grows in the West-Indies, is there
 called Cochian. This is a plant as large as the
 last-mentioned one, but I never saw any of them
 more than half double, **md oni**; with white and red
 stripes: the plants are very apt to grow to a very large
 size before they produce any flowers, so that it is late
 in the autumn before they begin to flower; and some-
 times in bad seasons they will scarce have any flowers,

 part are immortelles, but the feeds are here, which
 are - J-ipilfMcf f.
 ill umhf; (the principal word is mofura, the feeds
 have four-angled petals, which are round and in-
 feid. They last for long times, terminated by
 round feeds. The period is finished under the pe-
 tals, separating the vertical fibres, enclosed by white sig-
 nals. The period afterward becomes a round, un-
 proved fruit divided in two parts, containing two and
 lateral feeds.

This genus of pbnti i in the second section of
 Linnseus's liriih cL wh
 flowers have **e to-**
 rriii: and two styles.

We have of the Species of this genus, viz
 IMPERATORIA (Qbrafiam.) Mart. Cliff. 109. Aghy-
 wort. Imperatrice major. C. R. P. 156. Grand
 Mofure, and the Admirals of Dodonaeus. Impat.
 200. Mofure, or the Palmyra of Spain.

This plant grows naturally on the Apennine and Sep-
 timan Alps, and upon other mountainous places in Italy;
 the root is as thick as a man's thumb, running uni-
 formly in the ground; it is fleshy, acorned, and has
 a **ihong ac;** **!** rills, biting the tongue and smooth
 like Primula of Spain, the leaves arise **nmedtai**
 from the root; they have four-stalks seven or eight
 inches long, dividing into three very blunt ones at the
 top, each sustaining a trilobate leaf, indented on the
 border; the foot-stalks are deeply compressed, and
 when broken emit a rank odour. The flower-stalks
 rise **&b** not two feet high, and divide into two or three
 branches, each ter-
 minated by a pretty large um-
 bral of white flowers, whose petals are faint; these are
 five-angled b<, oval compressed feeds, somewhat like
 thole of Dili, but larger. It flowers in June, and the
 feeds ripen in August.

This plant is cultivated in gardens to supply the
 markets. It may be propagated either by seeds, or
 by putting the roots; if you would propagate it by
 feeds, they should be sown in autumn upon a hot
 bed or border, on a bed or border, in a shady situ-
 ation, observing not to sow the feeds too thick;
 nor should they be covered too deep. In the spring
 the plants will appear, when they should be carefully
 weeded; and if the season should prove very dry, they
 should be now and then refreshed with water, which
 will greatly promote their growth. Toward the be-
 ginning of May, if you find the plants come up too
 close together, you should prepare a small fresh bed
 (and thin the plants carefully, leaving them about
 six inches distance;) and plant those which you draw
 up into the border about the same distance apart every
 way, being careful to water them daily, if the feeds
 should prove dry, and they have taken root, they
 which time, these plants (as also those remaining in
 the hot-bed) will require no other culture but to
 keep them clear from weeds, which may be easily ef-
 fected, by holding the ground between the plants now
 and then in dry weather, which will destroy the weeds
 and by thinning in the ground, will be of great service to
 the plants. The following manner these plants should
 be transplanted, where they are designed to remain,
 which should be in a rich moist soil and a shady situa-
 tion.

tion; where they will thrive much better than if too much exposed to the sun, or in a dry soil, for they delight in shade and moisture; so that where these are wanting the plants will require a constant supply of water in dry weather, otherwise they will thrive but feebly. The distance which these plants should be placed, must not be less than ten feet every way, for where they like their situation, they will spread and increase much. When their plants are rooted, they will require no other culture but to keep them clear from weeds; and in the spring, before they shoot, the ground should be every year yearly dug between the plants, in doing of which great care should be had not to cut or break their roots. These plants, with this management, will continue several years, and will produce seeds in plenty.

If you would propagate these plants by offsets, their roots should be parted at Michigama, and planted in a shady situation, at the same distance as has been directed for the seedling plants, observing to water them well they have taken root, after which it time thw

The roots of this plant are used in medicine, and are greatly recommended for their virtue in contagious distempers, or the bites of venomous creatures; they are alexipharmic and sudorific; by some they are recommended for cholera and asthma, for the cramps, and all cold distempers of the nerves.

INARCHING is a method of grafting, which is commonly called grafting by approach. This method of grafting is used when the stock you intend to graft on, and the tree from which you would take the graft stand so near (or can be brought so near) that they may be joined together. The method of performing it is as follows: take the branch you would attach, and having fixed it to that part of the stock where you intend to join it, take away the rind and wood on one side about three inches in length. After the same manner cut the stock or branch in the place where the graft is to be united, so that the end of both may join exactly together, at least on one side, then the top may meet; then cut a little trough upward in the graft, and make a notch or slit in the stock downward to admit it, so that when they are joined, the rind will prevent their slipping, and the graft will more closely unite with the stock. Having thus placed them exactly together, you must be them with some lute, or other hot humours; then cover the place with grafting clay, to prevent the air from entering to dry the wound, or the wet from getting in to rot the stock; you should also fix a stake into the ground in which that part of the stock, at the graft should be fastened, to prevent the wind from breaking them asunder, which is often the case when this operation is not observed.

In this manner they are to remain about four months, in which time they will be sufficiently united, and the graft may then be cut from the mother tree, observing to dig it off close to the stock; and if at this time you cover the joined parts with fresh grafting clay, it will be of great service to the graft. This operation is always performed in April or May, that the graft may unite with the stock before the succeeding winter, and is commonly practised upon Orange, Myrtle, Juniper, Walnut, Fir, Pine and several other trees, which will not succeed so well by common grafting or budding. But although I have mentioned Orange trees among the rest, yet I would by no means advise this practice when the trees are clipped to grow large, which in this method they rarely ever will do; and it is chiefly practised upon those trees only as a curiosity, to have a young plant with fruit upon it, in a year or two from seed. Inarching is a tedious, yet these plants are seldom long lived.

INDIGOPERA L. G. G. 186. Indigo.
The *Crotalaria tinctoria* L.
The empurple is a tree leaf, spreading almost flat
but into four points; the flower is of the lavender kind.

... being a smooth spreading fluted, which is indented at the point and returns; the wings are oblong, striate, and their angle border spreading; the tail is striate, ... and acute pointed. It has the flowers double in a corolla, which points upward, terminated by smooth ... and a cylindrical ovary, supporting a four lobed crown by an oblong stigma. The crown is formed by a long taper pedicel, including thick fluted stalk. This genus of plants is raised in the third edition of Linnaeus's seveneenth class, entitled Diadelphia Decandria, from the flowers having ten stamina joined in two bodies.

- The Species are,
1. *INDIGOPERA* (Tinctoria) *lymniscus arcuatus incanus*, racemosa foliis serratis. Flor. Zeyl. 173. Indigo with leaves divided into five, and the branches of flowers from the joints. And see Indigo Americana, filiquis in foliolarum modum contractis. Acad. R. Scien. 1735. Guineale Indigo.
 2. *INDIGOPERA* (Tinctoria) *lymniscus arcuatus incanus*, vixle fraxinea. Indigo with a fluted stalk, and leaves divided into five. Cochlearia affinis fraxinea argentea. Etonius spiraeae vixle purpurea, filiquis lobatis. Sloan. Cat. Jan. 1722.
 3. *INDIGOPERA* (Tinctoria) *lymniscus arcuatus incanus*, quibus spinis longioribus spiculis, radice perennante. Indigo with longer stalk, leaves with five lobes, long leaf stalks of flowers, and a perennial root.
 4. *INDIGOPERA* (Tinctoria) *lymniscus arcuatus incanus*, communis, foliis pinnatis. Indigo with widely compound, long leaf stalks, and several leaves.
 5. *INDIGOPERA* (Tinctoria) *lymniscus arcuatus incanus*, foliis trifloratis. Indigo with rounder stalk, and triflorate leaves.

The first and fifth sorts are common plants with us; the seeds of these must be sown on a hot bed early in the spring of the year, and when the plants are come up to two inches high, they should be transplanted into small pots filled with good rich earth, and the pots plunged into a box full of sawdust, which the plants have obtained time through, they must have a great deal of fire-heat, by raising the glasses in the day time; and in June they may be exposed more to the open air, by which time they will begin to produce their flowers, which will be succeeded by seeds in a short time after, and in August these seeds will be perfected, if the plants are brought forward in the spring.

The second sort grows to the height of five or six feet, and will abide some three years, if it is preserved in a very warm stove in winter; this produces stalks of flowers from the wings of the leaves on the sides of the stems of the plant, and long stipes will produce seeds in England. This must be raised in a hot bed, as was directed for the two former, but must not be wholly exposed to the open air, even in the hottest weather.

The fourth sort is supposed to be particularly adapted to make the Indigo, but the first is the commonest which is cultivated in the English plantations in America; but I have been informed by a person of great credit, that he has made a great Indigo from the second sort, as may also be produced in our plantations; and this being a much higher plant, will afford a greater quantity from the same compass of ground, than any one of the other species, especially if cut before the stalks grow lignous; and this sort will grow on poorer land, so may be cultivated in such places where the first sort will not thrive so well, by which means great improvements may be made with this plant in our American plantations. There are some other sorts of this plant which are natives of India, from which the Indigo is made; two of which, viz. the fourth and fifth sorts I have had growing in the garden at Chelsea, both which are very different in their leaves and seeds from either of the American sorts which have been cultivated. I have also received seeds from India of the third sort, which is the true mother of Indigo which grows naturally in South Carolina, and which was greatly esteemed

John v tutt a goby the Iniligo planters of that cecuniry. for the beauty of the color: iio:Jily chilli it [tftnlucN] ; but the plants beinn lkn<ler>nd thinly garni tiled with leaves. whil i wen (hull, they ; did not furnish a quantity of i:ill'Ci ill [HXipOfwi pa their bold. loot late this lurt. but I Jjpt I an M'utii cwuwa:=ii there; though the account I rec'd with tile feeds was. (hai ii t<u >liar the bt& Indigo or." InJU was made from.

The whole process in making the Indigo 0 being exactly described by Fern Labat in his voyages, I think >uuah it would not be unacceptable to the English reader, to translate his account in this place, which is as follows.

There was formerly a great deal m Indigo made in the parish of Macouba: there is JOE a l'revn nor river in it, where one does not meet with S'tl'ligu wwl. that is, beds or vats of stave work w' ll ce- imented, in which the plant that yields the dye itipui to digest: there are usually three of these vats IB OQC above another, in the manner of a cascade, so that the second, which is lower than the bottom of the first, may receive the liquor contained in the first, when the beds which are made in the bottom of the first are unstopp'd, and that the third may in it. run receive what was in the second.

The first, largest, and highest of these vats is called the flarger or vat; it is usually made twenty feet long, twelve or fifteen feet wide, and three or four feet deep. The second is called the beauty, it is about half as small again as the first: and the third, which is much less than the second, is called the desiviling.

The names of the two last perfectly agree with their uses, for the plant is laid to steep in the first, where it ferments, is macerated, and becomes like green dung: after that the juice and substance of the leaf are separated and dissolved in the water by the fermentation, which the heat and vapors of the plant has excited in it. It is in the second that they agitate and beat this water, impregnated and loaded with the juice of the plant, till having collected it, re-united, and, as it were, coagulated them with one another, they form the 1 species which compose the dye.

As for the name of the third, I do not see how it agrees with it, which it is because this vat is deeper coloured than the others, for the Indigo already formed remaining in it, consequently dyes a I U CO lump it much deeper than the others.

To which I should add, that it is only at St. Domingo that they make use of this name. In the Windward Islands they call this last vat the levery, and this name fits it perfectly well, because it is in this, that the Indigo begins to be deeper, and perfected at the bottom: it never grows into a mass, separates itself from the particles of water which remained in it, leaves them at top, and settles at the bottom of the vat; whence it is taken out to be put into little bags, and then into the boxes, as I shall mention hereafter.

Nothing could be so equal in the building and making these vats substantial, the strength of the construction is so great, that unless the floor-work and pillars be very well done, and the mortar carefully chosen and wrought, they crack; and a very moderate daily infiltration to let out a vat of Indigo, and cause a considerable loss to the owner.

When this misfortune happens, the following is an easy and infallible remedy, which I can answer for, as having experienced it. Take some six beds of any kind whatsoever, spread them without burning staves, powder them, and fit them through a fine sieve. Take an equal quantity of quick lime and fill it up with water enough to make a stiff mortar, and in quick it you can, dip the sides of your vat with it. This mortar impregnates, cracks, and does in a moment, and immediately prevents the water's running out of the vat.

It is very hard to say, or should know, that Indigo is a dye used in dye wood, silk, cloths, and stuffs, that the Spaniards call it Anil; the French they make it call in New Spain, comes from Guatemala, which makes

I N D

a great many people call it birry Gi animalo. il b made also in the East Indies, particularly in the dominions of the Great Mogul, the kingdom of Golconda, and other places thereabouts, as Mr. Tavernier rtijti'i in his voyages. This last is in Europe otherwise called: India 11441 lad -J O. Anil, peopl

ii? proper a Some audio of our oider, having fancied that the Indigo which comes imni the L:IU-1IH;IC^ h tnor.

and vicriTh ttian tint wltidi comes from the West-Indies. wht< li they all flat Imligo, wliile th; call that from the East ii batvly IiwBt They would have Ipokt- pttyi if tjitry haj call the latter round India; for, by rhiir h.ivr, all the difference between the two Indias, or Indigos, is that that made in the East Indies, for as for goodness and a Itujx'i! likr kill' eg di the West like cases, for as for goodness and b^iuiy, the one will i be a whit superior to the other, if both are wrought with exact care and fidelity.

The shape of the Oriental Indigo obliges the merchants who would carry it into Europe to pound it, that they may get the more into the chests, or barrels rirey put it up in. It is certain, that being thus pounded, its grain having been broken under the pebble, ground, and reduced to powder, makes it firu- than the West-Indian Indigo, which coming in cakes): as it was dried, there is grain entire, and CCofccjuently i must appear coarser; but what is that to the mini l products of the commodity. I maintain it is the same in both, though there seems to be a dd.

To be con i tQed of iliU truth, uke a lump of fudge equally white throughout, break it in two, pound one part of it, and reduce it to powder; this will look fair and white, though there is a waste, which proceeds only from this, that the grain of the one has been separated and divide into a greater number of parts, which, though very small, and almost imperceptible, yet have a greater number of surfaces, and consequently reflect more light; whereas the other or-tnau ting coarse, presenting to the eye only a liige grain, which has but little surface, of course reflects less light, and by a necessary consequence must appear less white; which is the same as appearing less beautiful, since the beauty of sugar consists in its whiteness. Methinks we may reason in the same ma: ore upon Indigo, and say, that coarser puribus, the West-Indian Indigo is as beautiful as the East-Indian, when they are both wrought alike.

I think I should add, that the American Indigo is better for use than the other; for who does not see, that there is no powdering this dye, without the most filthy parts being dissipated in the air, as Mr. Tavernier allows? And who can doubt that these pans are the best, and th-JIC thai fu tirtheft when it is used?

I guess that the Indigo which comes from the East-Indies, is coarser than that which is made in the West-Indies; the reason is plain, it comes farther, runs greater risks, and those who bring it would not find their account in selling it, at the same price with that which comes from a much nearer place; but that does not at all prove it to be more beautiful, or better.

Indigo is composed of the salt and substance of the leaves and root of a plant of the same name, so that naturally say, it is a dissolution or dispersion of the plant, caused by the fermentation it has excited in the water it was laid to steep in. I know some writers pretend, that the substance of the leaves does not penetrate the Indigo, which, as they would have it, is only a violent texture, or colour, which the fermentation of the plant diffuses in the water: but before I take their words for it, I desire they would tell me what becomes of the moisture of the plant; for when it is taken out of the flarger, it is certain that it has no longer the same weight, consistency, nor colour, as had before. The leaves, which were very plump,

I N D

plump, juid very full of juice, are light, flabby, and withered, and Luk m-*re* like dung than any illing elc, which jtniks thri- frequently give the name of rot to the deeper. It then we no longer find in the leaves, and the rest of the plant, the time fulfiance that was obierable in it before irwas laid to lleij>, as it not weat ;:Urai to be' here, that it is the same

(hey weed and dtjuvlie the ground where they plant it, five times. "Vtr- should think they mi ulJ Vail it fowing, but the ferns of planting is conf. i: ited in our illes, ntn dank I oop it fiir rhloi. e of a word to fall out with our phnr.-rs *!, . . . ir tltwm HI iboufatid :-:oum, th"tigh they have pot n h

of manuring the French language. They sometimes carry their weatels in such a pitch, that they liveep the pecc of ground as they do a rooth. After that rfiy mal e the holes whereas the seeds are to be put for this purpose, lic flave,<, nt . others, who are to work at it, range the :nfi:l<5 in die Gune line, at the top of ie piece of ground, and going in kwanis they mak

little drills the breadth of their hoe, or the depth of two or three inches, at about a foot distance every way, and as much as possible in a line it inc.

When the weat come to the end of the ground, t'icli furnishes himself with a little bar of seeds, and returning that way they came, they put eleven or thirteen seeds into each of the holes they have made. A mistak of superstitio has taught them that the number must be odd. They so meanly approve of this practice, but I shall take care not to endeavour to show them the usefulness and folly of u, being satisfied I shall only kill my time and labour.

This work is the most noblest of e; in tic manu- facture of Indigo; for those who plant it must be always slooping, without rising up, at the planting of the whole length of the pecc is ended, (o that wten that is large, which almost always happens, they are obliget to rcnW. two hours, and other must, in this rolhire.

When they come to the top of the pecc, they go back again, and cover the holes where they have put the seed in, by shuffling in with their feet tit nrnth they had taken out of them, and to the feet covered with about two inches of earth.

The culture of this plant may be rent.-ed very easy, provided the inhabitants of our colonies in America could be brought to make use ct' rhe drill | though, for with this instrument two persons and a horse or mule will dig more land with h Indigo in one day, than twenty persons can perform in the same time, in the method now practised; for the plough makes the drill, and the harrow which is fixed to the plough covers it, and frames the seeds at equal distances in the drills; and an instrument behind the harrow covers in the drills, whereby the whole operation is performed at the same time, and with great ease. Indeed the use of this machine must be understood by the persons who are to perform it, otherwise they will do it in a bad manner, but a little practice will bring any person to the right use of it.

As the Indigo is sown in rows, a hoeing plough may be made of a proper dimension, in order to clear the ground from weeds, and to make the soil more loose. It may be performed in this manner, and the method now practised. But in doing of this, I would advise the stirring of the ground, soon after the Indigo plants are come up, because the weeds have got much strength, in which time they are best destroyed, and by stirring of the ground ;: plains will be

EH rher ñ
<nd beiwfen the ro<; *ith
m.o, h fcS time than.int..

plains will be

I N D

encouraged; and the strongest and most thriving plants will always make the best Indigo.

When the best ways of cutting the plants before they are too old, in order to have the Indigo of a better colour, is certainly right. Therefore as soon as the flowers begin to appear, it should be cut; for if it stands much longer the stems of the plants will grow hard and stringy, and the lower leaves will change to a yellowish colour, which will render the Indigo less valuable; as will also the plants being too close together, which will I occaffii* th bottom leaves to decay for ivanr of I see air, the same will happen if weeds are suffered to grow among the plants. Therefore there must be great regard to their being kept always eloni.

Thenjj all seasons are good for the planting of Indigo, yet care must be taken not to put it in the ground in a dry time: it is true, the seeds may keep a wh'.k' iLLHh in the ground, without being sowed; but when k ð pl:ed to, one runs the risk of having it eaten up by vermin, or carried away by the wind, or choked by the weeds that rising up with it, so that the prudent planter never runs the risk of planting it dry, &c. at a time when rJicj do nor probably expect rain in two or three ty after the planting is ended; they chuse therefore usually, a moist season, which promises rain, and then ifie: . . . fear of seeing the plant rising up in three or four dayi nfttr iti being pl.intcl.

Notwithstanding all the care that has been taken in clearing the ground where the seeds have been planted, the planter must be careful when the Indigo is got above ground; because the goodness of the soil, joined to the moisture and warmth of the climate, and the plentiful dew that fall every night, makes a prodigious quantity of weeds spring up, which would choke and absolutely kill the Indigo, if extreme care was not taken to weed them up as soon as they appear, and to keep the plant extraordinary neat, and very often the weeds are partly the cause of the withering of a kind of cancrulars, which devour all the leaves in a short time.

From the time of the plants rising above ground, to its perfect maturity, it but two months, and then it is fit to cut; if not cut by this time it would blossom, its leaves would grow stiffer and harder, and consequently they would yield less substance, and the colour would not be so beautiful.

After this best cutting, the new branches and leaves which the plant produces may be cut again every six weeks, provided the leaves be dry, and this care be taken not to cut it in a time of drought, because then we should inevitably kill the plant, or, as they call it there, the Champans, and be obliged to plant again; but all things being rightly managed, the plant may last two years; after which it must be plucked up, and new ones planted.

When the plant is ripe, which is known by the leaves, which grow brittle and less supple, they cut it three inches from the ground. They use for the cutting of it great crooked knives made like sickles. Some planters make it into bundles like double hoes of hay, but a negro may easily carry them to the harrow, but most people put it into large pieces of coarse cloth, which they tie by the four corners, and this is more convenient, the plants less handled and spoiled, and the seeds are carried away as safely as the great and bundles the work goes on quicker this way, than in making bundles, and as new is pretious every where, and especially in America, there cannot be too much care taken not to kill any.

Whether in twenty weeks of plants, each about the size of two bottles of hay, are sufficient to fill a harrow of the other mentioned size. When it is filled with water, so that it covers the plants, they put pieces of wood on the top, that the plants may not rise above the water (much after the manner as they do upon the Grapes that are put into the press), and let all ferment. According as the heat is greater or less, or the place niort 01 less ripe, the fermentation is called faster or

TheC.eneralD'; history praised it Tn •oux, rrim very seriously, upon the credit of father Plomer a mission, that the Indigo-makes having taking up some of the water of this battery in his cup, dips in it, and that if the Indigo be formed, the fibres immediately sink... of the cup, and that then he makes them leave off beating, if not, he makes them continue. This is not the only incident in which people have imposed upon father Plomer's credulity and simplicity. I have been a witness of it upon other occasions.

When they have left off beating they let the... latter... boctom oi... the vat, and gather together like a kind of mud, and the water freed from all the laka it was impregnated with, swims above it, and grows clear. Then they open the cocks, which are placed in the battery at different distances from the bottom, and let the water run away, and when they come to the surface of the fibres, they open the cocks of the bottom, that the fibres may all fall into the screwing or fether. Then they let it settle a little while longer, after which they put it into linen bags, fifteen or eighteen inches long, made with a pole, where it perfectly purges itself from the rest of the water, which remained among its particles. When that is done, they spread it in little boxes three or four feet long, six broad, and about three inches deep, and expose it to the air to dry it perfectly. They observe not to expose it to the sun, because it would flave the colour, by drying it; and they take a great deal of care to keep it from the rain, because it would destroy the colour.

When that is done, they spread it in little boxes three or four feet long, six broad, and about three inches deep, and expose it to the air to dry it perfectly. They observe not to expose it to the sun, because it would flave the colour, by drying it; and they take a great deal of care to keep it from the rain, because it would destroy the colour.

It ; imrtimes happens (ha; the water pillars get among the Indigo, and if they are let alone they will settle a while they eat all the leaves, and often the very thick nml end' of the branches, and kill the stocks; it is but a loft time to i... endeavour to destroy them, or hinder than from •... a whole piece, by flopping them with a stick. The usual way is to cut down the Indiguwith all luci: let its age be what it will, and as tlirow bail; plants and waterjules together into the fiteperi there th... and part with... they had devoured, and i'i... Indigo is not the best beautiful til i... It is true, when the plant is not come to its perfect matur: it yields much less, but many have thought so, that the colour it yields Mcperimen!- tsmuchnwir beautifuU fit tl... what is full one way is greater another.

I would not wait for its perfect maturity before I cut the plant. Perhaps all the leaves of these whole Indigo is so much scattered beyond ours, but only in cutting the plant when it yields the lowest colour. I have experienced that in having some excellent files upon some Indian figs, which were too ripe, instead of being red, they grew of a firmest colour, like the fruit they fed upon. The same thing might happen in Indigo, but I have supposed it not a ground-kfi doubt, hence it is backed by the experience I have jutr rcbtai... which plainly proves, that the same plant, cut at different ages, produces colour different in beauty. I would not venture to give this advice to the Indians, who value the quantity rather than the quality of their commodity; but I believe it will do nothing so far from our islands, who are generous and so confident, sometimes even beyond their abilities; I shall then therefore propose different trials, as to the soil, the water, the age of the plant, the water they steep it in, the point of dissolution, &c. and I am sure, with a little care, labour, and patience, may still make things that will equal, and even excel, the most beautiful Indigo of foreign countries.

The planters of St. Domingo have that in 1701 their cochinele sugar was very bad, and was nm made without infinite trouble, and at present every body allows, that by their labour, industry, and enquiry, it is grown much more esteemed than that of the Windward Islands; why may not the same be hoped for in Indigo?

Mr. Pomet, author of the General History of Drugs, says in his first part, chap. 20. That the Indians of the village of Sanguin, near Antioch, use only the leaves of the Indigo, and throw away the plant and branches, and that it is from thence the most esteemed Indigo comes.

I am pretty much of his opinion, for we see, that those who take the pains to strip off the Grapes from the branches, before they put them into the vat, and then wash the stalks carefully, make much the best wine, because the stalks always contain an acid, which mixes with the juice of the Grapes in the pressing and peeling them both together, and for the same reason, the stalks of the Indigo plant much contain a kind much less perfect in colour than that of the leaves; but one ought to have the labour and patience of the Indians in undertaking such a work, and have workmen as cheap as they are in that country, supporting the fact true, as Mr. Pomet delivers it from the relation of Mr. Tavernier.

Though I am a great friend to those improvements which may carry our manufactures to a greater perfection, yet I dare not propose this, because of the expense they must be at, who should try it; and because the profit arising from it would not perhaps equal what, however, I have here given the method of the Indians of Sanguin, that I may have no reason to reproach myself with having advised a thing which may be of some use to my country.

Good Indigo ought to be so light, as to swim upon water; the more it sinks the more it is to be suspected of being mixed with earth, either, or produced from its colour ought to be a deep blue, and to be a Violet, brilliant, lively, and bright; it ought to be

When that is done, they spread it in little boxes three or four feet long, six broad, and about three inches deep, and expose it to the air to dry it perfectly. They observe not to expose it to the sun, because it would flave the colour, by drying it; and they take a great deal of care to keep it from the rain, because it would destroy the colour.

more beautiful within than without, an! •ok •ning, and as it were filverd,

If it is too heavy in proportion wit'. bulk, i; ought to b; suspected, and its quality examined into; for as it is in price, it is fit that those who buy it, should be acquainted with the fraud:

It may be committed by the following: . i in it. the plant too much I the beating I the kind of it may be the li that the li certain that the quality of the matter is considerably increased by this distillation, but the Indigo is a great deal lighter II. beautiful for it, ii w bbeckifh, thick, heavy, and cuter -> b= thrown away than usual.

The second is the mining of the earth, or a certain brown filir, no land (which is pretty commonly found in th; bays by the sea side) and especially powdered KMC, wk'li die facts, stirring all well together, that it may incorporate, and the fraud not appear; and this fraud is much more easily committed in the powdered Indigo, than in that which is in cakes; because it is very difficult for those heterogeneous bodies to unite so well together, as not to make in many places, as it were, beds of a different nature, and thus, by breaking the piece of Indigo, the fraud is easily perceived.

The two following expedients may be used = ulc of, in wder 10 know the goodnet* or b*Jne& of InJig*

The first is to distill it in a glass of water. If it is pure and well refined, it will dissolve; but if it is adulterated, it will sink to the bottom of the glass. The second is to burn it. The good Indigo will burn all awi/, wher as the other, it rut, and flaw, lemoi after the true Indigo is consumed.

In itti, Indigo was sold at the Windward Islands, from three to four sols, no four sols per pound, according to its beauty, and the number of vessels to be freighted with it. I have known it sell at a much lower price; however, the planter would see fit of making a very considerable profit of it. [though he should sell it for no more than forty sols per pound, because it is commonly requires fewer vessels: iild lttf charge than a sugar-work.

Since the cultivation of Indigo in the West Indies has been brought from thence to England; and it may be hoped that the management granted by parliament to the proprietors, will enable them to procure this branch of commerce with such success, as to be a great advantage to the country, and of equal advantage to the colonies: but as yet the planters have not arrived at so much perfection as to be able to raise the quantity of it for most of the islands; so that I have seen of that country, has been to lurd as to render it almost insupportable, occasioned by the quantity of lime-water into the vat, in order to it; jkc ihc ta

As to the culture of the plant, by all the information I have been able to procure from thence, they commit a great error in sowing their seeds too thick, whereby the plants are drawn up with slender stems, which are not sufficiently garnished with leaves; nor are the leaves so large and succulent as they would naturally be

grow with the plants allowed a greater share of room, so that the stalks consist of little else but stringy vessels which are not dissolvable by the fermentation, and it is only the upper parts of the plant which are furnished with leaves; the young stems growing close together which are drawn up with slender stems, having no lateral branches, nor leaves, but at their tops; therefore it is not to be supposed, a great quantity of Indigo can be produced from plants so managed; for it is a common observation of the cultivators of Wood, that when their plants thire, and have narrow, thin leaves, they produce but little of the dye; so that they make choice or take strong land for sowing the seeds of this plant, and are careful to thin them, that they may have room to spread, and produce large succulent leaves, from which they always receive the greatest profit. If the planters of Indigo in America would but imitate the cultivators of Wood in the particular, [ny wwife certainly find their advantage in so doing.

Another thing in which they err is, letting the plant stand too long before they cut it, supposing from the height of the plant to procure a great quantity of the dye; but in this they are greatly mistaken, for the older the plant is before it is cut, the dirt and filth will be the thicker; therefore the best time of the plant will be dissolved by fermentation, nor will the leaves of the old plants be near so beautiful as that of the young. Therefore it is to be wished, that they would try some few experiments in the culture and management of the plant, by sowing thin, and keeping the plants perfectly clean from weeds, as also to cut them while young and full of juice, and hereby they will be better informed how to improve it to the greatest advantage. Not as labour is dear in that country, so many persons probably object to the expense of cultivating the Indigo in this method; therefore, to avoid this, I have before proposed sowing the seeds with a drill plough, whereby the soil appears will be greatly loosened, and the seed more equally sown; and by the use of the horse plough, ten acres may be kept clean from weeds with as small expense, as one when managed by the hand hoe, and by liring, of the ground often, and casting up the plants. not bind round ;: the eye of the bud, which should be
left apt n.

Wlwii your buds have been inoculated three weeks
or fi : month, you will see which of them have taken ;
ihdc of th which appear discolled and black, being
dead . but those which remain fresh and plump,
you may depend are joined, and at this time you
muu look to the lardage, which, if not done in
timi. will pinch the flock, and greatly injure, if not
destroy, the bud.

The March full iwine Jou moft tut oi the flock
about three inches above the bud, hoping it that the
wv may pass off, and not enter the flock, to this
part of the flock left above the bud, it is very proper
to fisten ti. float which proceeds from the bud, and
would be in danger a.
veoii being blown out, if not pre-
vented, but this must continue no longer than one
year, after which it must be cut off close above the
bud, that the flock may be covered thereby.

The time for inoculating is, from the middle of
Junt I into the middle of August, according to the
for : rdodi of the fisifc, and the particular sort of
tree* to b< propsgatnf , but the time may be easily
known, by trying the buds, whether they will come
off well from the wood. I However, the most gen-
ericd rule is, when j ou observe the buds formed
at tin : extremity of the time year's shoots, which
is a fl ; of these having finished their spring growth,

The : if first commonly inoculated is the Apricot,
Md tie nail the Oringe-trrrt, which should never be
done until die n : of the month of August, and in doing of
this work, JOJ fioulti : always make choice of cloudy
wcafter ; •: if it be done in the middle of the day, in
very hot weather, the shoots will perforce fall, as to
l<ve the bud : distance of moisture, nor should you
t*kc off ih : cuttings from the trees long before they
ait u . . : if it be done in the middle of the day, in
dng) from some distance, as it often happens, you
hould then be provijrd with a tin box or case, hav-
ingaf< ; set about ten inches long, and a cover - the
cop, . : which must have five or six holes, in this fucket
you J'ould put as much water as will fill it about
two or three inches high, and place your cuttings
therein in ai : upright position, so that that part which
•wasr, it from the tree may be set in the water, and is
taken down the cover to keep out the air, and the
holes in the cover will be sufficient to let the respira-
tion of these branches pass off, which, if pent in,
would be very harmful to them; you must also be
careful to carry it upright, that the water may not
reach to the buds ; for it is a very wrong practice in
those who throw their cuttings all over in water, which
is saturates the buds with moisture, that they have no
straining force left to insulate the tip of the flock,
whereby they very often miscarry.

But before I leave this head, I beg leave to observe,
that though it is the ordinary practice to divide the
bud of that part of the wood which was taken from
the shoot with it ; y^{rs} in many sorts of tender trees,
it is best to preserve a little wood in the bud, with-
out which they often miscarry. - The not observing
this, has occasioned some people to imagine, that some
sorts of trees are not to be propagated by inoculation;
whereas, if they had perceived it in this method,
they might have succeeded, as I have several times
experienced.

II. CHARACTERI GEN.

It hath a spatulate compound flower, made up of indicated
impulses, composed of 12 rays, spreading from base,
the outer being the longest. The disk, or middle of the
flower, is composed of 40 or more fertile, and the fer-
tile, or ray of the female, and fertile, together, and set
a torus. The hermaphrodite flowers are funnel-shaped,
crisp, and set into five segments at the top; these have
five long slender stamens, terminated by cylindrical an-
thers, which stand up at the top: they have an anther-
mon, crowned with hairs, together a female five the
length of the stamens, •**JJL** by an upright leaf sig-
na. The female half forms a narrow concave torus,
or stigma, and a long crowned germ with a hairy style,
and an upright stigma. The pericarp is tubiform be-
come a single, narrow, four-cornered leaf, crowned with a
down, being as a solid receptacle.

This genus of plants is ranged in the •• fecotid feffior
of Linnæus's nineteenth class, intitled Syngenesia
Polygamia superflua, which includes the plants with
a cen : compound flowers, made up of hermaphrodite flowers
in 11 : iiiile, intl female halt' :oi : for the rays, which
are fringed.

The Species are,

1. **INULA (Helicium)** foliis amplexicaulis ovatis, ri-
gulis, lobis tomentosis, calycum squamis ovatis.
Amar. Arab. 1. p. 410. Eleagnus with erect rays,
fertile, which enclose the buds, singly in their under side,
and the fields of the uppermost row. Alter monachum
maximus, Helicium dictum. Tourc. Inf. 432. The
great Eleagnus, called Helicium.
2. **INULA (Oera)** foliis amplexicaulis dentatis, hirsu-
tibus, radice tuberosa, calycibus lanceolatis acute
pinnatis, Lin. Sp. Plant. 1236. Inula with long es-
serted rays, entering the buds, singly at the bottom row,
but none on the buds, four-angled, which have but few
flowers. Alter Inula radice odora. C. B. P. 266.
Yellow Mountain with a sweet root.
3. **INULA (Salsica)** foliis sessilibus lanceolatis retuseis
serratis scabris, floribus inferioribus sterilibus, ramis
sub-angulii : Amar. Arab. 1. p. 410. Inula with
four-angled, serrated, rough, pointed leaves, sitting close
to the buds, and the under flowers growing taller than
the upper, and singular branches. Alter montana lo-
tris, foliis glabro folio. C. B. P. 266. Yellow Moun-
tain Mountain with a smooth Yellow leaf.
4. **INULA (Germaria)** foliis sessilibus lanceolatis serratis,
scabris, floribus subsessilibus. Lin. Sp. Plant.
113. Inula with four-angled serrated leaves sitting close
to the buds, which are rough, and flowers growing in
clusters. Alter Thuringicus alpinus hirsutus,
montanus, flore luteo parvo. Haller. Jen. 132. Yellow
head-headed Mountain Mountain of Georgia, with a
small yellow flower.
5. **INULA (Crotonea)** foliis hirsutibus cordatis trian-
gulatis. Lin. Sp. Plant. 843. Inula with narrow fully
erect rays in three rows. Alter maximum flavis
crithimum chrysanthemum dictum. Raii Meth. Ed. 3.
p. 174. Yellow mountain Mountain, called Golden Sam-
ple.
6. **INULA (Montana)** foliis lanceolatis hirsutis integris-
simis, caule unifloro calyce brevi subulcano. Lin. Sp.
Plant. 124. Inula with long, four-angled, entire leaves,
one flower on a bud, having a short stalk ray. Alter
montana luteo magno flore. C. B. P. 267. Moun-
tain Mountain with a large yellow flower.
7. **INULA (Oera Gled)** foliis amplexicaulis oblongis,
hirsutibus hirsutis, caule pinnato, corymboso. Lin.
Sp. Plant. 1237. Inula with oblong, entire, hairy leaves,
and flowers growing in a corymb. Contra Panagæa
longiora. C. B. P. 265. Mountain with 5 flowers.
8. **INULA (Africanus)** foliis amplexicaulis lanceola-
tis, distinctis serratis, subna villosis, caule ramoso
villoso crasso. Flor. Ind. 720. Inula with four-
angled leaves, entering the buds, none on the
under side, and an oval branching leaf. Alter palustris
hirsuta, foliis longiore longioribus. Tourc. Inf. 432.
Yellow Mountain with a large smooth leaf.

decays; these should be planted in rows about a foot
apart, and nine or ten inches distance in the rows;
the spring following the ground must be kept clean
from weeds, and in autumn it is slightly dug; it
will promote the growth of the roots; there will be
fit for use after two years growth, but the roots will
abide many years, if they are permitted to stand; how-
ever, the young roots are preferable to those which are
old and thrifty. It loves a gentle sandy soil, and a
dry.

The second sort hath a perennial root, from which
arise several stalks, about two feet high. The leaves
at bottom are oval, adpressed, and hairy; those above
embrace the stalks with their base. The stalks are
divided into several branches, garnished with
flourishing yellow flowers. It bears but a very short
colour when broken. It flowers in July, but rarely
ripens seeds here.

The third sort hath a perennial root, from which
arise many spear-shaped leaves, which are smooth
and incurved. The stalks rise near two feet high,
they are angular, and branch at the top into several
foot-stalks, each sustaining one yellow radiated flower.
It flowers in June, July and August, and the seeds
ripen in September.

The fourth sort rises with an upright stalk between
three and four feet high, with spear-shaped leaves,
which are turned backward, indented on their edges,
and rough on their upper side. The flowers are col-
lected in close bunches on the upper part of the stalks;
they are small and yellow. It grows on the hills, and
other mountainous parts of Europe. It flowers in
June, and the seeds ripen in autumn.

The fifth sort grows naturally on the sea-coast of many
parts of England. I have seen it growing plentifully
near Sheerness, in the life of Sherry, in 1660. It
rises with an upright stalk a foot and a half high,
garnished with spear-shaped leaves, which are erect
in clusters, and are shorter on each and a quarter
long, and one eighth of an inch broad, ending broader
toward the top. The flowers come out at the top of the
stalks in small umbels; they are yellow, and have a
bunch of rays; this flowers in July, and the seeds
ripen in autumn. The younger branches of this
plant are frequently sold in the London markets
for Saffron; but this is a great mistake, because this
plant has none of the warm aromatic taste of the true
Saffron.

The sixth sort grows naturally in Germany; it rises
with upright stalks a foot and a half high, garnished
with spear-shaped leaves which are covered with soft
hairs, and are erect. The stalks each support one
large yellow flower, which appears in July, but rarely
ripens seeds here.

The seventh sort hath a perennial root and an aerial
stalk; this grows naturally in Hungary. The leaves
are oval and hairy; the stalks branch at the
top into several smaller branches garnished with
oblong oval leaves, which are indented on their edges,
and end in acute points. The flowers terminate the
stalks, each branch ending with one large, yellow,
radiated flower, sitting in a leafy empulment, whose
leaves are oval, and placed like the scales on fish over
each other. The flowers are succeeded by narrow
four-cornered seeds crowded with down. It flowers
in June and July, and the seeds ripen the latter end
of August.

This sort may be propagated by seeds, which should
be sown in autumn soon after they are ripe; for if
they are kept till the spring, they seldom grow; but
where they are permitted to stand, the plants will
come up the following spring without any care, and
may be either transplanted the following autumn, or
if they are designed to remain, they should be
hoed out to the distance of ten inches, or a foot each
way, and constantly kept clear from weeds; their
roots will be fit for use the second year.

But most people propagate the plant by offsets, which
if carefully taken from the old roots, with a bud, or
eye, on each, will take root very easily; the best time
for this is the autumn, as soon as the leaves begin to
fall.

The eighth sort grows naturally in the town of France,
Spain, and Italy; it hath a perennial root, from
whence arise several stalks about one foot high; the
lower leaves are spear-shaped and prickly; the upper
half embrace the stalks, which divide into several
branches, each being terminated by one yellow flower,
which appears in July, but seldom perfect seeds
here.

The ninth sort rises about a foot high, dividing into
many branches, which are garnished by oval hairy
leaves, which half embrace the stalks with their base,
and are smooth and shining.

each of the branches is terminated by one Urge yellow (lower, who' emralctnetn ij compofed of oval feals. li (lowers in July, and I Auguft, but never perfects feeds

The eleventh fort grow* naturally in I lungfry i tti: rils with feuple ftraight flalks near two feet high, garnifhed with oval fpear-fhaped leavts, which are flighly indented on the edges, and fit clofe to the ftilli', wrsiuh arc hairy, and divide in form of a corymbu at the top. The flowers are irepretty Urge, of a pjlt yellow colour, and appear in July, but a« not fucceeded by feeds in this country.

The twelfth fort growi J. naturally in the Canary [dandjs this rils with feveral flubby flalks near four feet high, which divide into feveral branches, t, gsniihrd with clufers of narrow feble leaves, which are Ji-vided into three fegments at the joints. The flowers conic our on the fide of the branches at the top of the ftiiik-, they are fmall, and of a pole yellow to- low, appearing in Augoft.

Th. twelfth fort, firth, fixth, feventh, tight!), nll. ninth fort are abiding filing, which vll tiiriv and flower in the open air in England i they may be all propagated by parting their roots. The belt time for doing of this is in autumn, it which time the plint: may be removed, they may be in'enTii*ed with oth.: flowering plants in the borders of large gardens, v. here they will make an agreeable variety during the continuance in flower. As their roots multiply precily flit, they ihould be fifted more than LWO feet fr)m other ah. and if they ut removed every third year, it will be often enough, provided the ground between them is dug every winter, and, in flummer, if they are kept clear from weeds, they will require no other care.

As fow of these forts produce good feeds in England, they may be propagated by lowering of the feeds in the fpring, when the plants appear, they fhould be kept clean from weeds till they are fit to remove, when they fhould be transplanted on a fandy foil, fix inch; funder, obferving to fhade and water them till they have taken new roots, and digging them up in autumn they may be transplanted into the borders where they are to remain.

The thirteenth fort grows naturally in thci'onthof Francr. And on the Pyrenean mountains. Kbit lath a thick fibre in a root, which is perennial, sending out many trailing indented leaves, whole bulk runs along the flalks from one joint to another: from the root arife three or fiir flalks about two feet high, which divide each into three or four fmall branches, which are terminated by clufers of fmall yellow flowers, fitting clofe between the fmall leaves, thofe appear in June and July, and are fucceeded by narrow leavts, crowned with down, which open in the autumn. It is propagated by feeds, which fhould be fown in a bed of light earth early in the fpring, in May the plants will appear, which fhould be kept clean from weeds till they are fit to transplant, when they fhould be planted in an ead bedden, at about fix inches diftance each way, watering and fhading them till they have taken new roots, after which they will require no other culture but to keep them clean from weeds till the autumn, when they fhould be planted where they are defigned to ftand.

The eleventh fort grows naturally near Montpellier, and rife in July, the lath a firm root, from which arife two or three oval flalks about two feet high, garnifhed with broadly oval leaves placed alternat, fitting clofe to the flalks, the veins of the leaves are ftrander, and ftrander like net-work. The flalks are terminated by one yellow flower, fubfied in a fough fealy empolvement, and at the two joints of the flalk immediately under the flower, come out fmall foot-flalks, with fmall flowers that clofe on the top. This plant follows ourfelves above two or three years,

The twelfth fort was difcovered by the late Dr. Houfhou, growing naturally at La Vera Cruz; this riles with a flubby flalk about two feet high, dividing into many fmall branches, which are hairy, and garnifhed with narrow fluff leaves placed oppofit, without foot-flalks; from the edges of thofe are long hairs, which are fliff, and come out by pairs, at the end of the branches with the naked foot flalks, which are four or five inches long, containing one fmall, yellow, radiated flower.

This is propagated by cuttings during the fummer feafon, which muft be planted on a bed of light earth, and fhaded till they have taken new roots, which the plants muft be treated in the ufual manner as other hardy exotics, fhading them in winter. The fourteenth fort grows naturally in Maryland, where it grows naturally; this rife with a ftrong flalk about a foot and a half high, and is very clofely fet with prickly leaves, which are fpear-shaped, and near one inch broad in the middle: toward the upper part of the flalk they are broader, and terminate by a clufter of fmall yellow flowers, difpofed in form of an umbel. This plant flowers here in Auguft, but has not as yet perfected feeds in England. The fifteenth fort was difcovered growing naturally at Carthagena, by the late Dr. Houfhou; this riles with a flubby flalk to the height of ten or twelve feet, divided into feveral large branches, which are terminated by fpear-shaped leaves five inches long, and one inch and a half broad in the middle, and ftrander on their upper fide, but on their under have three longitudinal veins. The flowers are produced at the ends of the branches, having very large fealy empolvements, they are of a large and a fmall fower, of a pale yellow colour. This plant is too tender to live in the open air in England, fo muft be continually kept in the back-ftove. It is propagated by feeds, which muft be procured from the country where it naturally grows, for it does not propagate here; these muft be fown in a bed of light earth, and when the plants are fit to remove, they fhould be each planted into a fmall pot filled with light earth, and plunged into a frefh her-bed, raising them in the fame manner as other tender plants from the fern copery.

JOHNSON. LA. Dale Callicarpa. Lin. Gen. Plant. 127. Spondylococcus. Mich. 20. This plant was difcovered by the late Dr. Dale, of South Carolina, in memory of Dr. Johnfon, who published an edition of Gerard's Herbal, corrected and much improved.

therefore your plants fhould be raifed from feeds in fauxed ilic.li. The feeds may be fown in the faine lime, and in the faine manner as is directed for the tenth fort, and the plants afterward treated in the fame way.

The fifth fort grows naturally in the fide of the hills in the north of England, which are fowed by the air, therefore is feldom attended from abroad. The roots of this are perennial, but the flalks decay in autumn; and if any one has curiofity to keep a plant or two of it in their gardens, they may conveniently fet to a fandy border from the place of its natural growth, and, by keeping it moft in dry weather, it will thrive pretty well, but the flalks will not rife high, nor will the leaves be near fo fliffy as in the fide of the hills.

The twelfth fort will not live abroad in the open air in England, during the winter feafon, fo muft be removed into fhelter in autumn, but fhould have as much free air as poffible all times, when the weather is mild, otherwife it is apt to draw up weak, and cold weather the plants muft have very little water, for their flalks and leaves being fo tender, they are very apt to rot with too much wet; in fummer they fhould be placed about wuh ailver harly garden plants in a fhaded fite, where they will add to the variety, though they are plants of no great beauty, and feldom D Sower in England, unless the fummer is very trunnt. This is eafily propagated by cuttings, any time in fummer, which, if planted in a fandy border, will take root in a fhort time.

The thirteenth fort was difcovered by the late Dr. Houfhou, growing naturally at La Vera Cruz; this riles with a flubby flalk about two feet high, dividing into many fmall branches, which are hairy, and garnifhed with narrow fluff leaves placed oppofit, without foot-flalks; from the edges of thofe are long hairs, which are fliff, and come out by pairs, at the end of the branches with the naked foot flalks, which are four or five inches long, containing one fmall, yellow, radiated flower.

This is propagated by cuttings during the fummer feafon, which muft be planted on a bed of light earth, and fhaded till they have taken new roots, which the plants muft be treated in the ufual manner as other hardy exotics, fhading them in winter. The fourteenth fort grows naturally in Maryland, where it grows naturally; this rife with a ftrong flalk about a foot and a half high, and is very clofely fet with prickly leaves, which are fpear-shaped, and near one inch broad in the middle: toward the upper part of the flalk they are broader, and terminate by a clufter of fmall yellow flowers, difpofed in form of an umbel. This plant flowers here in Auguft, but has not as yet perfected feeds in England.

The fifteenth fort was difcovered growing naturally at Carthagena, by the late Dr. Houfhou; this riles with a flubby flalk to the height of ten or twelve feet, divided into feveral large branches, which are terminated by fpear-shaped leaves five inches long, and one inch and a half broad in the middle, and ftrander on their upper fide, but on their under have three longitudinal veins. Dr. Linnaeus ranges this genus of plants in the first
section of his fourth class, entitled Pentandria Monog-
gynia, which includes the plants whose flowers have
four stamens and one pistil. As the seeds of this plant
were first discovered in Carolina by the late Dr. Dale with
this title, in the year 1744, and with them the
name of the genus, which was before it was men-
tioned by Dr. Linnaeus, I have continued it un-
der Doctor's title.

We have but one species of this genus, viz.
JONQUILLA (Americana) floribus verticillatis bulbibus,
foliis ovato lanceolatis oppositis, caule frutescente. Dale.
Astrucy Jonquilla with oval spear-shaped leaves placed op-
posite, and flowers growing in whorls from the top of the
stalk. Carolinae. Ad. Upland. 1744. Mr. Catesby,
in his History of Carolina, has figured it under the
following title, Frutes baccafer verticillata, foliis obo-
vatis lanceolatis deorsum de conjugatis, baccais purpureis deni-
catis. B. Carol. vol. II. p. 47.

This shrub grows plentifully in the woods near
Charleston, in South Carolina. It rises from four
to six feet high, sending out many branches from the
root, which are woody when young, like those of the
Waxing-tree, garnished with oval spear-shaped leaves
placed opposite, standing on short stalks; they are
about three inches long, and one inch and a quarter
broad in the middle, growing narrow at both ends,
and a little indented on their edges, their surface

anc

into four obscure lobes as the
and one of a deep purple colour;
which afterwards change
turn lUft to a bright red colour, bu:
to 3 deep purple when ripe, and inclose four lin
lung l

The Jonquilla of rhit plant wetr frm me b
from Carolina, in 1744. The plants were
then raised in several curious gardens in England;
most, if not all all of them were afterward planted in
the open air, where they flourished very well for some
years, and several of the plants produced flowers in
the Chelsea garden for four or five years, but these
were not succeeded by fruit; and in the severe frost
in 1740, they were most of them destroyed, as were
in 1740, they were most of them destroyed, as were
in 1740, they were most of them destroyed, as were

dlb ilu
young plants which were raised from Dr.
Dale's seeds the year before, which were only sheltered
under a frame; so that until the Doctor sent a fresh
supply of seeds in 1744, there were scarce any of the plants
living in the English gardens; but since then, there
has been quantities of the seeds brought to England.

This plant rises easily from seeds, if they are sown in
a moderate hot-bed, the best way is to sow the seeds
in pots, and plunge them into a raised bed of a moderate
warmth; and when the plants come up, and have ob-
tained some strength, they should be gradually raised
to the open air, from which they should be removed
in June, and placed in a fresh-red situation, where
they may remain till autumn, during which time
they must be kept clear from weeds, and gently re-
freshed with water in dry weather; but as these young
plants are tender, they should be placed under a frame
before the early frost comes on; for a frost in au-
tumn will kill the tender part of their shoots, which
often settles their stalks to decay most part of their
length before the spring. During the winter season
they should be covered from frost, but in mild weather
they should enjoy the free air, otherwise their shoots
will turn m

Jul't I. sive the plants shoot, they should be carefully
carefully

turned oilt of the pots, fo at not to break thsir ror;tg)
and pan oj ilitm my be planted in finall pota
with light i irth, and die otliera into .1 run kJ
to a warm situation, at about four or five inches above
ijwi chofc : the pots should be plunged into a moder-
derm; but bed, which will forward their taking root,
but afterwards they should be opened in the open air
as before; their piano in the pots should be flack-
tured under a frame in winter for three or four years,
ill ility havi obtained strength, then they may be
tum'd out of rie pots, and planted in a warm situa-
tion, where they will line in the open air in common
countries; but in severe frost they are in danger of be-
ing killed, if they are not sheltered; therefore the
surface of the ground about their roots should be cov-
ered with old tan to keep out the frost, and their
tops covered with Straw, Peat-moss, or Fern, which
will protect them.

These plants in the beds should also be covered with
peat, or straw, in frosty weather, and after they have
obtained strength, they may be transplanted into a
warm situation, and treated every winter in the same
manner as the other.
The leaves of this shrub were often used by Dr.
Dale in tiropfic] cases, with very good success. A
particular account of the virtues of this, and many
other plants of Carolina, was sent me with dried sam-
ples of each, by the Doctor, during the last war; but
at this time were taken in their passages, they were all
lost, and the Doctor dying soon after, I could never
recovery ilictn.

JONQUILLA VSPI. Sec-
JONQJIL, Sec-
IPO MOEA. Lin. Gen. Plant. 192. Quamoclit.

Tourn. Inst. R. H. 116. tab. 39. Quamoclit, or Jon-
quilla Americana.
The CHARACTER is,
The flower both a small permanent capsule, cut into
five parts at the top. The pistil is four-lobed, being
cylindrical tube, which rises to five parts, spread-
ing into five lobes. It hath five oval-shaped leaves, near the
base of the pistil, terminated by small filaments. In
the bottom of the tube is situated a round germ, support-
ing a slender style, crowned by a round stigma. The
tube afterward becomes a round capsule cut
into five parts, which are always full.
This genus of plants is ranged in the first section of
Linnaeus's fifth class, entitled Pentandria Monogynia,
which includes those plants whose flowers have five
stamens and one pistil.

The first grows naturally in both Indks; in the West Indies it is called Sweet-William, and is (bated Indian Pink) it rises with 2 twining stalks seven or eight feet high, ending out many Qcadet twining brinchts, which twist about any neighbouring plants for support; (the leaves are) winged, being pointed at the ends; of very fine narrow Ubc., not thicker than a ribbon; when they are about an inch long, of a deep green, and sometimes in pairs opposite, and it is then they are alternate - die flou 1 - come out singly from the side of the stalk; Hanging upon (the leaves) are about one inch long; they are funnel-shaped, and have a tube an inch long, which is narrowed at the mouth, and is divided into five or six segments; they are of a moderate size, and are of a deep purple colour, and are very beautiful. This is an annual plant in England, but in the Indies it is so in the native place; I cannot tell for as the seeds fall to the ground, (as there is a Tuccellion of young plants, which continue flowering great part of the year.

This is a tender plant, so will not thrive in the open air in England; it is propagated by seeds, which should be sown in a hot-bed in the spring, (as the plants will soon appear, they should be each transplanted into a small pot filled with light soil, where they twine about each other, for then it will be difficult to disentangle them without breaking their tops. When they are pottrf, they should be plunged into a new hot-bed, and should be covered by each plant first.

[talk] to turn about; after they have taken new root, they (should have a good share of) air in warm weather; their drawing up weak and when they are advanced (so high to remain under the frame, they should be removed into the can-bed in the stove, where they should have support, for their branches will extend to a considerable height. They will begin to flower in June, and there will be a succession of flowers till the end of September, and the seed will ripen well in this situation every autumn.

The second grows naturally in Carolina and the Bahama Islands; - this is also an annual plant in the Indies, but it is so tender as to require a hot-bed. It has a twining stalk, which rises to a considerable height; high, garnished with heart-shaped leaves ending in acute points, which are divided into three or four at their base; the flowers come out from the side of the stalk; branches, upon slender foot-stalks, which support three or four flowers of the same colour. And uze

Qowen of the same kind. This is a variety of the first with orange-coloured flowers, but they do not differ in any other respect. If the seeds of this sort are sown in a hot-bed in the spring, and when the plants come up, if they are gradually hardened, and afterwards transplanted into a warm border, it is possible to have the seed flowers and fruit in good season, but most people raise the plant on a very gentle hot-bed, and transplant them afterwards into another, by which method they are brought forward, so will permit them to be earlier.

The third sort is like the second, but the leaves have

no alpiK, and the flowers are of a Rose colour, and are called italk Itallainini one flower. This may be treated in the lime manner as the second fort.

The fourth fort grows naturally in the West-Indies, where it twines about any neighbouring support, and rises ten or twelve feet high; it is furnished with heart-shaped entire leaves; the flowers come out from the side of the branch, and are upon slender foot-stalks; they are of a blue colour, and they are not an inch long in the finest specimens, but entire.

This sort is propagated by seeds, which should be sown in a hot-bed in the spring, and when the plants come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

The fifth fort is cultivated in most of the West-Indies, but is supposed to have been introduced thence from the Spanish Main, the seeds of which are called in the Indies, and sent out many years ago; (as the seeds are) very tender, and are not so hard as the seeds of the first fort, from whence it has the appellation of Spanish Arbour Vine.

The sixth sort is a perennial plant, but too tender to thrive in the open air in England; the seeds of this must be sown in a hot-bed in the spring, and when they come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

This is a perennial plant, but too tender to thrive in the open air in England; the seeds of this must be sown in a hot-bed in the spring, and when they come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

The eighth fort grows naturally in most of the West-Indies; it has a twining stalk, which rises ten or twelve feet high, and is furnished with leaves divided into three or four at their base; the flowers are of a purple colour, and are upon slender foot-stalks, which support three or four flowers of the same colour. This is also an annual plant, and should be sown in a hot-bed in the spring, and when the plants come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

The ninth fort grows naturally in the West-Indies; it has a twining stalk, which rises ten or twelve feet high, and is furnished with leaves divided into three or four at their base; the flowers are of a purple colour, and are upon slender foot-stalks, which support three or four flowers of the same colour. This is also an annual plant, and should be sown in a hot-bed in the spring, and when the plants come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

The tenth fort grows naturally in the West-Indies; it has a twining stalk, which rises ten or twelve feet high, and is furnished with leaves divided into three or four at their base; the flowers are of a purple colour, and are upon slender foot-stalks, which support three or four flowers of the same colour. This is also an annual plant, and should be sown in a hot-bed in the spring, and when the plants come up, they should be gradually hardened, and afterwards transplanted into a warm border, it is possible for the first fort, for it is 100 tender 10 thrive in the open air here.

The first sort grows naturally in ditches and standing waters in most parts of England; this is called in the Plantarum, A torui rj.lui

roots of rhil ire pretty thick, fleshy, and spread every way near the surface of the ground, the leaves are sword-shaped, very long, of deep green colour, and not so stiff as those of the Garden Iris, the stalks rise from three to four

lowers one above another, which gradually succeed each other; they are shaped like the ordinary Flower-de-luce, but the three inner petals are less than the flagons, so they want the three upright petals which are termed lunilards. These appear in June, and are succeeded by large three-cornered capsules, containing three rows of flat seeds.

This sort is not cultivated in I fsnlrv but bring an official pl.mt, h is here mentioned 10 introduce tht

been : The second sort grows naturally in Germany, but has long cultivated in the English garden for ornament; the roots of this are very thick, fleshy, and divided into joints, spreading just under the surface of the ground; they are of a brownish colour on their outside, but white within, the leaves are in clusters, embracing each other at their base, but spread slender

spread in form of wings; they are a foot and a half long, and two inches broad, having sharp edges, ending in points like swords; the stalks between them, which are a half longer than the leaves, having at each joint one leaf without a root stalk, thick enough in their first upward; the stalks divide into three branches, each of which produces two or three flowers one above another at distance, each enclosed in a

Under each flower is fnu.iii-J long germen, which turns to > large tin c.iplulc with three Ltlli, hiltvl with laj-v

This flow •Ti in June, and c! seeds ipea in August.

There is a vari ••/ of thi) with blue standards and purple falls, which is called Iris ho: rnis latifolia, by Casper Bauhin, and one with pale purple standards, another with white, and a third v,uh .1 Inialler flower, but these are accidental varieties whidi liaw come from seeds.

The third sort is 1 brooder kiv « than tht l*ft, the stalks iiivcnole^, upon them, and are called ii-ngh with die Itave»; they have liircc Or tour large bright .l.tnd above each other, h

h ficaths 01 lie liircc bending petals or falls are striped with white, from the base to the end of the beard; the flowers are succeeded by large blunt triangular capsules with three cells, filled with con; jit

It flowers the latter end of May, and the seeds ripen the beginning of August.

The fourth sort grows naturally in Hungary; die leaves of this are like those of the second sort, but are of a darker green; the stalks rise as tall as the leaves, and toward the bottom are furnished with one leaf at each joint, whose base embraces the stalks. The upper part is naked, and branches into Jirre, eicli having two or three flowers above one another. tilt: three upright petals or standards are yellow, and the bending petals or falls are variegated with purple stripes. This sort is rarely succeeded by seeds in England.

The fifth sort grows naturally near Constantinople, and in other parts of the east. The leaves of this sort are not so broad as those of the second sort, and are of a grayish colour, the stalks rise two feet and a half high, supporting one very large flower; the three upright petals are almost as broad as the leaves, but very thin, of mixed black and white stripes; the three bending petals or falls are of a darker colour. IVort whence some gardeners have called it the Mourning Iris. This flowers the latter end of May, or the beginning of June, but never has any seeds in England.

The sixth sort hath broad leaves like those of the second sort, but shorter; the stalks rise six or seven inches high, branching into two or three at the top, each supporting two deep purple flowers. This flowers in May, but is not succeeded by seeds in England.

The seventh sort hath narrower and flower leaves than the former; the stalks are shorter than the leaves, and support one flower on the top, of a light purple colour. This flowers the beginning of May, but rarely produces seeds in that country. There are two or three varieties of this, which differ in the colour of their flowers.

The eighth sort hath the largest leaves of any of the Flower-de-luce; they are of a grayish colour and spread wide, embracing each other at their base, where they are purple. The stalks rise near four feet high, and divide into several branches, each supporting three or four flowers above each other at distance, colored with a thin flesh; the three bending petals or falls are of a faint purple inclining to blue, with purple veins running lengthways; the beard is yellow, and the three erect petals or standards are of a bright blue with some faint purple stripes; the flowers last in a considerable space. They appear the latter end of June but are seldom succeeded by seeds in England.

The seeds of the sixth sort were brought from Carolina, by the Right Rev. Dr. Pocock, Bishop of Orlery, who found the plants growing there naturally; these were sown in the Chelsea garden, where they flourished very well, and the plants have been since communicated to many curious gardeners in Europe.

IRI

This plant hath a thick fleshy root, divided into many
 ltnots or tubers, iviich frctj ajid multiply in the
 ground; thric lend out many II: long, thick, fleshy fi-
 brers, which (trike deep in t^l earth, putting out fev-
 venil jmall< fibres from their sides. From the roots
 arise clusters of lin broad-shaped leaves of ¹ deep
 colour, wlv- in three feet long,
 and iitile more t^l in one inch broad, ad in the broad "it
 ^..rt, eni) in points, these leaves are connected to-
 getha at their base into several heads or bundles,

wrapping over each other; and between these arise
 (he t: lower stalks, which grow four feet high and are
 jointed, having very long spines or filicals. M eitli
 of the upper joint- which include the flower, Tbdc
 stalks generally consist of two flowers, one coming out
 each fhesth o: (petals); these are permanent, and
 when the first are past, chiefly cover the seed-vell.

The flowers are divided into nine leaves, three of
 these stand erect, which are white, and fix turn down,
 which are joined together at their base, the lower
 spreading out into a broad ovate, upward fall,
 having a broad white line of a bright yellow colour; the
 upper is arched over the lower, so as to form
 a sort of semicircle; the third is arched backward; under this
 is situated an oblong three-cornered seamen, which af-
 terward becomes an oblong, swollen, three-cornered
 seed-vell, ending in a long point, which opens
 three longitudinal cells, in which the seeds are lodged;
 these are angular and compressed. This plant flowers
 the latter end of June, at the beginning of July, and
 the seeds ripen in the summer. It is very hardy, and
 thrives well in the open air without any protection.

The leaves decay to the root in the
 UEuui, and new
 ones arise in the spring. The root also propagates
 very fast, when they are in a light moist soil, so that
 it may soon be had in plenty, without waiting for
 plants from seeds.

The tenth fort grows naturally in Aurfri: this hath
 narrow, flat, Grass-like leaves, about a foot long, of
 a light green colour; between these arise the stalks
 about six inches high, having two narrow green leaves,
 which are much longer than the stalks; these stalks
 sustain two or three flowers, which are smaller than
 any of the former species; the petals have no beard,
 but have a broad yellow line adorned with purple
 stripes; the three falls are of a light purple colour
 striped with blue, and have a convex ridge running
 longitudinally; the other are of a reddish purple va-
 riegate with violet; rfun have a foot like frsh
 Plum: It flowers in July, and is succeeded by seed-
 vells which are short, having three borders or wings
 running lengthwise, opening in three cells, which are
 filled with angular seeds, which open in September.

The eleventh fort grows naturally near the sea, in the
 fields of France, and in Italy. This hath narrow
 broad-shaped leaves, three more than a foot long, of
 a deep green colour; the stalks do not rise so tall as
 the leaves, they sustain at the top two or three flowers
 which stand near together; they consist of a bright
 purple colour with very deep falls, and the three
 standards are blue; the beading teeth have no beard,
 but instead of that white broad stripes through the
 middle. This flowers in July, and the seeds ripen in
 September.

The twelfth fort hath narrower leaves than the former,
 but of the same deep green colour; the stalks do not
 rise higher than the leaves, and support two or three
 flowers, which have long permanent standards
 standing erect, which cover the seed-vell; the
 seeds are ripe; the flowers are smaller, and of a
 paler colour than those of the eleventh fort.

The thirteenth fort has very narrow long, Grass-like
 leaves, of a light green; the stalks rise two feet and
 a half high, sustaining three or four flowers above each
 other, which have blue falls, and purple standards;
 Bowers in July,
 (trip) and the seeds ripen at Michaelmas.

The fourteenth fort grows naturally in Germany; this
 hath leaves like those of the eleventh fort, which,
 when broken, have a disagreeable scent; but this is
 accidental) ind not aconxM a all the plants; the
 ftUu of tl, are taper, and rise a little above the
 leaves, and sustain three or four flowers >one above
 another, which have light blue standards; SUJ puqjlc
 variegated falls without beard; instead of which, they
 have a broad white line in the middle; Idle; thele a: s-
 eceeded by ihort thick capsules, which are filled with
 angular seeds. It to ws in July, ami tic leedj ripm
 in September.

The fifteenth fort has narrower triive* than rfioll* of
 the (econd, of a pale green colour, and not j'o tuiff,
 rfe stalks are equal in height with the leaves, and
 bwnel out on both sides wjth long foot (talks, each
 sustaining one pretty large yellow flower, iittdL-LJ in
 a long two leaved sheath, at each joint: wtere tht
 seed-stalks come out there is a single leaf which em-
 braces the stalks with their base. This flowers in June»
 but rarely produces seeds in this country.

There are two varieties of this fort, one with
 purple-coloured, and the other with a variegated flower,
 which is supposed to be only varieties which have
 been accidentally produced from seeds.

The sixteenth fort hath broad broad-shaped leaves
 about eight inches long; the stalks rise about the same
 height with the leaves, and divide into two or three
 foot-thick stalks, each sustaining two or three
 flowers, which have yellow standards, and the
 falls are variegated with dark stripes. This flowers
 in June, but does not produce seeds here.

The seventeenth fort grows naturally in North Amer-
 ica; this hath thick fleshy roots, from which arise
 many Grass-like leaves about nine inches long; from
 between these come out the stalks, which are shorter
 than the leaves, flaring out purple flowers with
 blue standards. This fort flowers in May, but seldom
 produces seeds in England.

The eighteenth fort grows also in North America; j
 this hath narrow broad-shaped leaves about a foot
 long, of a light green colour; the stalks rise a little
 above the leaves, they are taper, and support two or
 AKC flowers one above another, the flinthirds are of
 a light blue, and the falls are purple variegated, with
 a broad white line instead of a broad stripe in the
 middle. The germs, which is situated under the
 flower, is three-cornered below, but taper toward the
 top. This flowers in June, and often produces seeds
 in this country.

The nineteenth fort grows naturally in many parts
 of England, so is seldom admitted into
 gardens. This hath thick tufted fleshy roots; the
 leaves are of a Grass-green broad-shaped, and when
 broken emit a strong odour, not much unlike that of
 hart's wood beef at the first heat, but if fresh too close,
 becomes disagreeable. It is generally (a) I think
 Glasweg in England; the stalks rise about the same
 height with the leaves, supporting two small flowers,
 of a purple colour, variegated. It flowers in June,
 and the seeds ripen in autumn.

The twentieth fort grows naturally in Aulbia and
 Bohemia; this hath narrow broad-shaped leaves
 a foot and a half long, of a dark green colour; the
 flower stalks rise above the leaves, and support two
 or three flowers with light blue standards, and deep
 blue falls, with a broad stripe of white, instead of
 the middle. This flowers in July, and the seeds ripen in
 September.

There are several varieties of these flag or weed-leaved
 Irides, which chiefly differ in the colour of their flow-
 ers, so are not to be regarded as distinct species; those
 which are here enumerated are supposed to be spec-
 ially different, (some part of them) have cultivated
 by seeds, and found them constantly produce the same
 as the parent plants.

All these forts are generally propagated by sowing
 of their roots, which most of them maturely fall
 enough. The best time to remove and put the roots
 in is in summer, that they may get good roots before the
 spring, otherwise they will not flower during the fol-
 lowing summer. All these forts which spread much

ac their roots flould be mofplanted every other year, to keep them within bounds, urtherwife they will firact lo much as to become traubldome, especially il they arc planted new other flowersj indeed, the large growing kinds are matt of them too fpredltdg for the flouvrr-garden, fo are only fit CO fill up the fpacea between trees and frubrs in large plantations, whete they will have a good effect during the time of their flowering.

The fitli, fixth, feventh, tenth, eleventh, ftxcecnlh, fevritocntfi ami eighteenth forts, grow in left compafe, fo may be admitted into the large borders, or in flumps of flowers in the pteafu re-garden, where thty will add to die variety. The fifth fort ftioufd hive a wannr litumicn, being a tilde tender, but all tic other forts will grow in almeft any foil or ftuation *, thefe (Bay all be propagated by lced;, which fhould be fcwn loon after they are ripe, then the plants will come up lbe following Jpring; but it the iecds arc femm in the fpring, they will Fie a yeir in the ground before they vegetate : when the plant* come up they mult be kept dean from weeds, and the following autumn fhould be transplanted into beds at ten inches or a foot diftceuce, where they may remain till they Jlowfr, which will be the fceond fummCT after trans-planting-, but as moft of the forts nre fo eafily propagated by their roots, few penpie care to wait tor i l !

The twenty-firft forts grows naturally in die ill fide of the Archy lagO; this liftha tubenous koubbe- root, from which rife five or UK long, tiirrow, four-w need leaves, between which anfe the flalk, which fuppo ooeflower, fhaped like thole of the Irb, but fmall, and of a dirk purple eolotu- This flowers in April, but ..Ki not produce lced'. in England. It is propa ed by the root-, which fend out oBseti-, thife i p and tmnflplamed -when their leaves decay, but fceon l not be kept TOO long our of the ground. If the v are planted in a deep loofe foil, the roots will rounown, and be loll in a feu- years where they are not difhirbed, lb they fhould be annually trinlplantitt, and have a fiifllow foil; they are iiarjy in relJKCI to cold, and require no farther can; but to keep thtrn clt'an ftyom w

The twenty-fecoad lort grows naturally in ttf vrim parts ot Europe, but is hardy enough to thrive in the open air iaEDglantd the leaves of this fort are broad, of apale green colour; the flower-Halki rife caller ihan the leaves, fupporting one or two white Bowers which fit dofe to (he IUTks. The roots of this are ufrd in TH-dicine, and it ufually calle! Sut-et ! • Tiic twenty-thitd fort hath broid leave;, of JI deeper green than thofe of the latt lbrt. The (talk* rife much abow the leaves, each having four or five flower*, h have * yellow ground, variegated with dark brown Gripes, ;tnd have * frent like lilderj the two fotu flower the latter tfl of May, or beginning of June.

They are fo hardy fli w thrive *) well ax rhe fceontl fort in the open ar in this cr tinnny, and may be pm- propagated by parting of their root, or by feedf, in the luma way as is dire- ted for that fort,

The fir lirl fort is cuivired in icvent pan of England tor the pilrpofo E • during the be- g ufed as a m- dication tor numy of the dirk coloure.

Thb is a wmmody well rating in jll places where the iand it luhablt; for it, which ; will be i pccrv frongfoil, li' not too .oift.

The plant is olennial, m which it differs from the third wd fourth ion, which are annual. The lower leaves, ot thlit are of air obltt; oval figure, and pretty thick comfiance, when growing in a proper foil, they are narrow it their bale, bur broad ibe^, and endin chiufe roundilh potn's, entire t. their edges, anci of a lucid n: . The flalks rife near four feet high, dividing , into feveral branches, garnifh i wj,h MTOvr-lhaped liaves, fitting clofe to the flalks, the ends, of the bra: are ornamented by fmall yellow flowers, in >erj (Cloufters, which are compofed of four final ietai< . placed in form of a crofs; thefe are fucceti! and by roots fhaped like a bird's tongue, half an inch long, and nne eighth c: an inch broad, which

*he,i ripe <orn black, a-d open with two valves, having one cell, in which is fituated a fingle feed. It flowers in July, and the lcedz ripen the t of September.

The third fort his been (bppoftd to be the fsmr fpeciew the fir, only differing by culture, but I have propagated both forts ! • have been forty years, and have not found either of them alvay, there are alio very effential differences between the two plants, particularly in the (hape of the ur:: leaves, which n ;h* with fort are narrow and fpear-feaped, and xho't t-n the (talk; are not more than half the breadth of thofe of the cultivated Woad. The (l>ks < i> not branch f> much, and the jxiri? are narrow- than thofe of the other Coir, nor do the root, abide fo long, tor (hff generally die the : one year.

The fecond fort growj naturally it Dalmatia; this is a bit: nial plant, the lower leaves are fpear-fhaped, sndatnato: on their edges, but thofe on the flalks arc very rarroMfr. The flalks rife more than thole « the fir fort, and rife higher. The flowers are Ltrerr, and oi s a brighter yellow colour. The r:d-reficls Arc Ihorter, m: broader at their ends, which are indented. I have plants all flower in July, and their fetus ripen in September.

The fourth fort grows naturally in Egypt, and is an annualplanc, which a toou-der to thrive in the open air in rngl.iml, (hertrorf the feeds fhould be fown in a hot-beu io cbe lpnng ; it: when the plants are fo lo n.TiiiVc they mod be i;nlj>Unc bed to bri: them toward, but as foon as they have taken new : , they fhould have a large fhare of frifh air admitted to them daily, to prevent their being drfwn up weak. In that bed they may remain for a Gx we , by which time they will be fit to transplant into poti, v which fhould be carefully performed, not

to let the c.uh fail I own their ; Kits; the pott should ailb be plunged into n nift.icra;c hot-bed, giving tin plants jtnnty of Ml at .ill tunes who) the weathe will permit, and liipportirig their llnfcs, which will other wile LLiil on ilie grou;id*, with (his management the pdnii itill (lower in June, and ripen their feejd in ptember.

i he three lafl ibrts art nor cultivated for oft, fo • only prferred in botanic gwtiens tor the fitke of .I icty ; the frcond and third TOTIS arc prop>gaid by the seeds, which should be sown in aour.in ; and when

• plans Cflne up, the^ muft be thinned, leaving them i ix incbciapajX) aherwsu-J they mult be kept clear, from weeds; the summer following •>' will fewr an J produce ripe seeds, after which the forts must decay, the roots of the first fort will live another year. A second fort which is propagated for use, is sown upon fresh land which is in KO-XI heart, for * which is a cultivation of Woad pay a large rent, they generally think that their land is i,nain\ near prr: towns, where there is plenty of dreAing, I

Ions ii will no: admit of being sown with Woad more than twice, for if it is sown repeated, the crop seldom pays the charge, OS CI Cl

le wboc omtnoditf, have g*n^s of people, who have been bred to this employment, so that whole families travel about from place to place, wherever their principal busi-ness is for the purpose ; but these people go on in one track, just as their predecessors have done, and do not have their principal de- VULII twm tli i tap: I

decrfii VULII twm tli i tap: I

trial: in the culture of this plant, therefore I shall in- fect them here for the benefit of those who may invc ingenuity enough to strike on i t the old beaten track.

As the good K-6 of Woad conflt? in the fize and fatness of the leaves, the only method to obtain this, is by sowing the seed upon ground at a proper season, and allow the plants proper room to grow, to be able to keep them clean from weeds, which, if permitted to grow, will rob- the plant* vi tlieir nourishment.

The method practised by some of the most I ikilnil kitchen gardeners in the culture of Spinach, would be a great improvement to this plant, for some of them have improved the round-leaved Spinach to such by culture, as to have the leaves more than six times the size they were formerly; and their success has been in the same proportion, upon the best land, which has been obtained by sowing of the plants when young, and keeping them perfectly clean from weeds, but to /urn to the culnife of Woad.

After having made choice of a proper ipoE of land, which should be tot be too right ancf flkndy, nor m of fluf and moist, but rather a sandy soil, the whole part will earth (enime' thf JUFhtijup high ridges, just before winter, laying it in narrow ridges, so that th. ten the<lod>, then in the spring plotigh row ridge* i

it <g>J), nimrt** and the after the rain some time in this season, when the weeds begin to grow, it should be well harrowed to destroy them; this should be twice repeated while the weeds are young, and if there are any sorts of large perennial weeds, they must be harrowed out, and re- moved off the ground. In June the ground should be a third time ploughed, and the furrows should be nar- row, and the ground turned as deep as the plough will go, and the parts may be as well prepared as possible; and when the weeds appear again, the ground should be well harrowed to destroy them. Toward the end of July, or the beginning of August, it should be ploughed the last time, when the land should be laid (smooth) and when there is a D'oft)rl of lhowcj, the

ground must be harrowed to receive the lctta, which should be sown other in rows with the drill plousii or in broad rows, after the common metjujj, butjt ijj •f P^oP7 T to free the feeds ne night in wntei before 'AF" is sown, which will prevent the nforveeteion; * t f l e : i seeds are sown in drills with a Plough, thierwm

be covered by an instrument fixed to the plough for that purpose; but should be sown broad-cast in the common way, mull be wclt harrowed in. If the feeds are good and the (vitfon (t vourable, the plants will .app^ai in a fortnight, and in a month T five week.l after will be fit to hoe; for the sooner this is performed when ! the plants are distinguished, ii', the ijTut! they will thrive, and the weeds being then young, will be soon destroyed. The method with hoe- ing their plants is the best in the T crops, with this difference only, that these plants need not be thinned so much; for at the first hoeing, if they are sown to the distance of three or four inches, and at the IC Lift

of the Tljhr. if this is carefully performed, and in dry weather, most of the weeds will be destroyed; but as some of them may escape in this operation, and young weeds will arise, in the ground, a second time hoeed in October, always choosing a dry time for this work, at this second operation, the plants should be sown to the distance of six inches, they are to remain. .. say this the ground will be clean from weeds till the spring, a few young weeds will come up, there- fore about a fortnight in April will be a good time to hoe the ground again, when the weeds will be young, so may be performed in less than half the time it would require if the weeds were permitted to grow; and the sun and wind will much sooner kill them; this hoeing will also fix the surface of the ground, and greatly retard the growth of the plants, if it is performed in dry weather, the ground will be elrjn till the first crop of Woad is gathered, after which it must be again well cleared, if this is ctBcAIRI repeated, after the gathering of each the land will always be close, and the ;lmm will thrive the better. The expense of the first hoe- ing < will be about six shillings per acre, and :Ot E)C

vittt-1, things half that price will be suffi- cnr, provided they are performed when the weeds are young. (or if they ore [u' rred to grow large, it will require more labour, and can it be so well performed; therefore it is not only the best husbandry to do this work soon, but it will be found the cheapest method; for the same number of men will hoe a field of ten acres three times, when it is performed while the weeds are young, as LI re.. need to hoe it twice only, because the weeds have longer time to grow between the operations.

If the land in which the seed is sown, should I have been incut, it will require dressing before it is sown, in which cali rotine thier thing is preferable to any other; but this should not be lost on till the J.ilt ploughing before the seeds are sown, and not spiv: id but as the land is ploughed, that the sun may not nehale the gotxli

of it, which in summer is. soon lost, when sown on the ground. The quantity should (I not be k-ks than twenty loads to each acre, which will keep the ground in heart till the crop of Woad is sent.

The time for gathering the crop is according to the season, but it should be performed as soon as the leaves are fully grown, while they are perfectly green; for when they begin to change pale, great part of the chcir g odata is over; for the quantity will be less, and the quality greatly diminished.

If the land is good, and the crop well husbanded, it will produce three or four gatherings, but the two first are the best; these are commonly mixed together in the i

manure; for if these are mixed with the other, the whole will be of little value. The two first crops will fall from twenty-five to thirty pounds a ton i bu the latter will not bring more than feven of eight pounds, a r k. *Wie not ! i much

As

As

An acre of land will produce a ton of Woad, and is torn! Jealous near a ton and 1 half, when the pianists intend to favc the freiK they cut three crop* of the leave*, and then let the plants rtanJ till rhf notl year for feed ; but if onJy one crop is cut, and iliac only of the outer leaves, ktin" all the mid- dle leaves (land to nourilh the ftlnks, tnc puivi will grow frongcr, and produce a much greater quantity of feed.

Thefe feeds are often kept two years, but it is al- ways belt tofow new feeds when they can be obtained. The feeds riprn in Auguft; when the pod« turn to a dirk colour, the feeds lhoul be gichrrred i it a beft done by (taping the Halle* in die fatre nuntr a; Wh it, (pTCiling thi; (tdki in rows upon the ground, and in four or live Jays the fee4i will be fit to thedb out, provided the weather is dry ; for if ir lies long, rhe penis will open and Jet t>ut the feeds.

Thrrr ire Jomc of the Wosd pUnters who feed down the tram in winter with (beep, which is a very bad method ; for all plants which are to remain for a future crop, fhould never be cuen by cattle, for that greatly weakeni die plants; therefore lliofc who eat down their Wh<l rit winter with Jleep are equally blamcable.

ISOPYRUM. Lin. Gen. Pbnt. 611. Hellebore. Amman.

The CHAFACT!

The flower has an embowment. It hath five equal oval petals, which fall off, and five flcies tubularis setaria, situated within the petals, divided at their base into three lobes, the middle one being the largest. The stem is very hairy, the middle one being the largest. The stem is very hairy, the middle one being the largest. The stem is very hairy, the middle one being the largest.

ISORA. See He... ITEA. Lin. Gen. Plant. 14. Flac. Vig. 143. Di- conangia. Mitch, Gen. 5. The CiiAaActi are.

The empowment of the flower is small, permanent, and erect, rising in five acute points. The flower has five petals, which are inserted in the empowment. It hath five stamens, which are inserted in the empowment, which are as long as the petals, terminated by smooth filaments, and an oval germis supporting a tubular style, which is permanent, crowned by an oblong stigma. The stigma afterwards becomes a long oval capsule, with six style at the top, having one cell fixed with each style.

This genus of plants is ranged in the fifth section of Linnæus's fifth... which flowers have five flamina am one flye.

We have but one Species of this genus, viz. ITEA (f'rgimca.) Ftor. Vigf. 143. We have no English name for this plant.

This ihrub grow in moist hills in several parts of North America, where it rises to the height of six or seven feet, sending out many branches from the ground upwards garnished with spear-shaped leaves placed alternately, singly fixed on their edges, which are reflexed, wrinkled, and of a light green. At the extremity of the lower year's shoots, in the month of July, are produced fine spikes of white flowers, three or four inches long, erect, and when these shrubs are in viir, they will be entirely covered with these spikes of flowers, so that they make a fine appearance at their season of flowering.

This shrub is now pretty common in England; but [he gprJen where I have seen it in the greatest vigour, is that of his late Grace the Duke of Argyll, at Whitton, near Hounslow, where the fall agrees to well with this plant, that it thrives and flowers there is well as in its native country.

This shrub will live in the open air in England, the cold nor... ;vgrouj

IV A. Lin. Gen. 1099. Taraxacum. Vall. Ad. Pelt. 1710.

The Characters arc. It hath male and female flowers in the same plant, the female have a roundish permanent empowment, including several stamens, which are curved, the male flowers have one petal, which is funnel shaped, and inserted in five parts of the base; these are situated in the eye, they have five long filaments, terminated by oval filaments, oppositely

Thecflrt (on ^rows n... naturally in many parts of the
West-In... annual plant, with an her-
bacous stalk, which rises from two to three feet
high, arising out of the sides,
which are furnished with oval
leaves, having three deep longitudinal veins, and are fringed
on their lower edges; the stalks and branches are termi-
nated by small clusters of pale blue flowers, which
appear in July, and are succeeded by seeds which ripen
in the autumn.

This is propagated by seeds, which should be sown in
the spring upon a moderate heat, and when the
seedlings are fit to remove, they should be transplanted
into a nursery, where they should be kept forward, treating
them in the same manner as the preceding species, until
they are fit to be planted in the field.
The second sort has been introduced by the
English gardeners, which is less known by the
name of the French Walnut. It has slender lignous
branches which rise eight or ten feet high, furnished
with spear-shaped leaved leaves; the branches (in
warm seasons) are terminated by small clusters of
purple flowers, which appear in August, but we are
not informed by seeds in England.

This third sort has been introduced in green-
houses, being supposed too tender to live through the
winter in the open air; but late trials have made it
apparent, that the ordinary winters in England seldom
hurt it, provided it is placed in a dry soil and a sheltered
situation. It is propagated in the nursery-
ground about London for sale, and if the branches are
laid into the ground in the spring, they will in six
months or a year be fit to be planted in a
shady border in May, they will be ready.

JUGLANS LIN. GEN. PLANT. 930. NUX. TOURN.

uti...
The CHARACTER...
It hath male and female flowers at separate distances on
the same tree. The male flowers are disposed in an oblong
spike, or tail, which is cylindrical and tuberculated, with
flavescent scales, each scale has one flower, with
one pistil fixed to the same stem, towards the middle of
the scale. The pistil is divided into four parts; the
middle is furnished with four stamens, surrounded by one
ovary furnished. The female flowers grow in small clusters,
sitting close to the branches, they have a short, thick, four-
pointed involucre, fitting on the ground, and are
terminated by a large oval pistil, supporting one pistil only,
surrounded by large reflexed scales. The ground is
furnished with a large oval dry leaf, with one vein, and a
large oval nut with round corners, which grows
flat like a shield, which are commonly forward.

This species of plants is ranged in the eighth section
of Linnæus's taxonomy Scd class, called Monocotylæ
Pentandria, including those plants which have male and
female flowers on the same plant, and the male flowers
have many stamens.

JUG

The Species are.
1. JUGLANS (Nux) foliis ovatis serratis glandibus subternatis
subterminalibus. Hort. Cliff. 499. Walnut with oval
small leaves or lobs, which are serrated, female, and round.
Nux juglans. 1. See Regia vulgaris. C. B. P. 417. Com-
mon Walnut.

2. JUGLANS (Nux) foliis lanceolatis serratis, exterio-
ribus minoribus gemmulis super axillari-
bus. bui. 1. n. Sp. 1212. Walnut with oval
leaves which are strongly serrated, the middle being the
largest. Nux juglans Virginiana nigra. H. L. 452.
Black Virginia Walnut.

(Glabra) foliis cordato-lanceolatis in-
terius serratis, pediculis foliorum pubescentibus.
Walnut with heart spear-shaped lobes, bearing many veins
on their lower side, and having flat stalks to the leaves.
Juglans nigra, fructu oblongo pedunculato inflexato.
Cat. Hort. Cliff. Black Virginia Walnut, with an oblong
fruit very much forward.

4. JUGLANS (Alba) foliis lanceolatis serratis, exterio-
ribus majoribus. Lin. Sp. Plant. 907. Walnut with
spear-shaped serrated lobes, the outer being the broadest.
Nux juglans alba Virginiana. Park. Theat. 1414.
White Virginia Walnut called Hickory Nut.

5. JUGLANS (Glabra) foliis trunciformibus serratis, ex-
terioribus majoribus. Walnut with wedge-shaped lobes
which are serrated, the outer being the longest. Juglans
alba fructu ovato cordato glabro. Cliff. Flor. Virg.
White Walnut with a smaller fruit, and a smooth bark.

6. JUGLANS (Glabra) foliis lanceolatis serratis glandibus
subterminalibus. Walnut with smooth spear-shaped serrated
lobes, which are equal. Juglans alba fructu ovato
compresso, nocivo dulci, cortice spinoso. Cliff.
Flor. Virg. White Walnut with an oval compressed fruit,
a joint kernel, and a hard lark, commonly called Dog-
lark in America.

There are several varieties of the common Walnut,
which are distinguished by the following titles; the
large Walnut, the thin-shelled Walnut, the French
Walnut, the late ripe Walnut, and the double Wal-
nut; but these do all of them vary when raised by
the seed, so that the nuts from the same tree will pro-
duce plants whose fruit will differ; therefore those
who depend upon the trees which are raised
from nuts, till they have produced fruit, so that
those persons who plant the trees for their fruit,
should make choice of the best when they
may be directed, by having such as they would
not choose.

The second sort is commonly called Binck Vi-
giniana Walnut; this grows to a large size in North America.
The leaves of this sort are composed of five or six
pair of spear-shaped lobes, which end in acute points,
and are fringed on their edges; the lower pair of lobes
are the least, the other gradually increase in their size
to the top, where the pair at the top, and the single
lobe which terminates the leaf, are smaller; these
leaves, when bruised, emit a strong aromatic flavour,
as do also the outer cover of the nuts, which are
rough, and rounder than those of the common Wal-
nut. The shell of the nut is very hard and thick, and
the kernel small, but very sweet.

The third sort grows naturally in North America,
where the trees grow to a large size. The leaves of
this sort are composed of seven or eight pair of long
heart-shaped lobes, broad at their base, where they
are divided into two round ears, but terminate in acute
points; they are rougher, and of a deeper green than
those of the second sort, and have nothing of the aro-
matic taste which they have. The fruit is very long.
The shell is deeply furrowed, and is very hard. The
kernel is small, but well flavoured.

The fourth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The fifth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The sixth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The seventh sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The eighth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The ninth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

The tenth sort is very common in most parts of
North America, where it is called Hickory Nut. The
leaves of this sort are composed of two or three pair
of oblong lobes, terminated by an odd one; these are
of a light green, and fringed on their edges; the lower
pair of lobes are the smallest, and the upper the
largest. The fruit is fringed like the common Wal-
nut.

nut; but the fliell is not furrowed, and isi/a ligit colour.

The fifth fort is nor (a Urge as \K fourth. Vh= leave; are competed of two pair of lobci, terminated by sn wtd OIK S ihffe are narrow at their bife, but ... and rounded at their ends; they asr Ciwiedon (heir edges, and arc of a light green. The noti art fmsll, haw a Imooih ftdl, and art very hard ami white,

Tlit sixth fort grows iaruraHy in North America, where it riles to a middling (laiure. The fcaura of this (on are computed of ihree pair of Imooth fpear-Jhaped lobes, of a chirk green colour, fawedon their edges, and ending in scute points. The fruit isoval, the (hell white, hart!, and Imooth; the kernel limit, boi very fwert. The young (hoots of the ttte ate covered with a very Imooth brownilh bark, but the Items and older branches have a ruugli icajy bark, from whence it had the appellation or Shagbaik, in

America.

Tta common Walnuts propagated in many parttof England :^r the fruit, and formerly the trees were pr.ipagaied for their wood, which was in very great e'lecm, till the quantity of Mahogany, and other uit-ful woods which have been of tare years imported into England, have almolt banilhed the ufc of Walnut.

Thefe trees are propagated by pUning their nuts, wlich, as wai before obferved, fldom produce the lame (bit of fruit as are Town ; (a thac the only way to h*v'e the defired fort, n to few the nuts ci* the beft kindii and if thii is dewe in a nurcry, ilic trees Qiculd be tmfpntated out vrhen they have liati three or four years growth, to the place where they arc ddigndc to remain i tor ihic teen tia not bear tranfplimng when they mrt of a larat fat, therefore there may be a good number of (tre trew plmtcti, which need not be put at more than fix feet ap^rt, which will be diftance enough for them to grow till they produce fruit; when wofc whofc truii ate of the defired kind may remain, and the otlicrs cut up, to ailow them room to grow; by this method a fufficient number of die trees may be generally found among them to remain, which will thrive and flourth greatly when they hive room *. Uuc K; many people do rut care to wait (6 long for the fruit, fo the next beft method it to make choice of fume young trees in the nuicries, when they have their fruit upon them; but though theft trees will grow and bear fruit, yet they will never be lb large or fo long lived, u thole which are planted young.

All the forti of Walnut* which are propagated for timber, (hould be town in the placo where they are to remain -, for the roots of thefc treej always incline downward, which being flopped or broken, prevent their afpiring upward, fo that they afterwards divaricate into branches, and become low ipreading trees ^ but iich as are propagated for fruit, are greatly mendtd by iranfpantung j for hereby they are rendered more fruitful, and their fruit arc f ually large i and fairer; it being i common obfervatijti, that downrigit roots greatly encour>gc the l^ nutz grow [h of timber in all fortj of tri , but h^h neti 3i have their rood fpreadr... near the fort'ace «f the pound, are alwayi the owl fruitful ind bdt B>vouted.

The nun mouW be preferred in (heir outer ewer* in 'ry land until February, *hen they fhould be planted in fines, at the diftance you intend them to remain; but in the ro* they may be placed pretty tlofe. For feir the nuu Oio ... millerry, and the young trees, where they are too thick, may be removed, after they kave grown two or three years. Itaring the reuinde; at the diftance they are to ftand.

In rratifplanting thrfe trees, you fhould ob- ferve never to prune either their roots or large branches, both which are very neceffary to them ; nor fhould you be too bold in hipping or pning the branches of thofe trees when grown to a large

file, for it often caufesthjttn 10 decay; but when tile re ... a neceffary for cutting any of their branches off. it:: ... could be done early in September (before the

fralbn; ... be from an eye to fubject to blight) that the wounci ... may heal over before the cold inclofes ... the branches (i.e. ... fhould be cut off quite ... at the trunk, ... fhould be the ftump which is left and decay, ... the body of the tree.

The beft ieafon r ... transplanting thofe trees is as foon as the leaves begin to decay, at which time if they ire rarctuliv ... ferved entire, di ... will be little danger of their fucceeding, although thej ... are eight or ten years old, as I have feveral times experienced ; tl ... though, at weather before oblerred, thofe trees will not grow to large, or continue to long, as thofe which are removed young.

THIB tree di ... grows in a firm, rich, moift foil, or fuch as is inclinable to chalk or gravel; and will thrive very well in fhady ground, and on fhady hills, as may be icci. ... their large plantations near Earthenhead, Godftone, ... and Carthage in Surrey, where are great numbr: ... of thofe trees planted upon the downs, which annually produce iarp quantities of fruit, to the great advjni; ... of thofe owners, one of which I have been told, hrm- ... the fruit of his trees, to thofe who fupply the markets, hr wl ; or annum.

The diltii; ... thofe trees fhould be placed, ought not to be lds t! ... in forty feet, especially if they be had to their fruit j ilmugh vrher. they are only d ... ed for timber, if they ftand much nearer, it prevents their ujright growth. The black Virginis Walnut it much more inclinable to « low upright than the conjni ... on foot, and the wood being, generally of a n.uil. i ... careful again, renders it peculiarly fit for, antt be ... for worth cultivating. I have feen fome of [K19 WQO1 wKlch luib berfi beat ... only wound with black, and wi ... which, when pointed, has appeared at a diftao ... like virginis marble. This wood is generally cftemed by die cabinet-makers for inlaying, as alfb for bedfhw ... beds, tables, and cabinets; and is one of tht ... of Englilh growth, being lefs liable to be injured with moft other kinds (which may proceed from its extraordinary brittlenefs); but it is not proper for Lvailings of ftrenngth, it being of a brittle n.lurc, and exceeding fubject to break very fhort, though it commonly grows under thofe, by its cracking (bmi: time before it breaks.

The general opinion is, that the befting of this fruit impro' ... the trees, which I do not believe, ftand in the doing • f that, the younger branches are generally broken and dtroyed; but as it would be exceeding troublefome to gather it by hand, fo in burning it off, great care On ... be taken that it be not done with violence, for the reafon before affigned. In order to preliirvc A ... fruit, it fhould remain upon the trees till it is thoi ... hough ripe, when it fhould be beaten down, and laid in heaps for two or three days, after which they fhould be ftrawed abroad, when, in a little time, their fhells will eafily part from the fhells; then you muft dry them well in the fun, and lay them up in a dry place, where mice or other vermin cannot come to them, in which place they will remain good for four or five months; but thofe are ion* y perfons who put thofe Walnuts into an oven p ... heated, where they let them remain four or five hours to dry, and then put them up in oil jars, or any other clofe velfel, mixing them with dry fand, by which method they will keep good fix months. The putting of them in the oven to dry the germ, and prevent their fprouting, but if the oven is too hot it will caufe them to fhew, therefore • it OUT: limit be i

All the other forts are propagated in the fame way, but as few of the forts produce fruit in England, fo their nuts muft be procured from North America; which fhould be gathered when fully ripe, and put up in dry fand, to preserve them in their juftnefs to England; when they arrive here, the fooner they are planted the greater chance there will be of their fucceeding.

 The iirt lbrt grows naturally upon chaiky lands
 many pna of England. This is a low fnrub, fel-
 tn ritng more than three feet high, fending out
 ny frwdtng branches, which incline on ev
 ivered with a brown bark, and garni;
 iW awl-lhaped leaves ending in acute points, which
 placed by threes round the branches, pointing
 rond* thtfc arc of a grayifh colour, and conti-
 ihroujtfc the year; the male Eawcre lbmttaies
 t fituaicil on the lame plant with the female, but at
 ce, at other tiaiM they are upon diftinf
 plints: ihe frmatc Bowen are fucc<TLd by round-
 berries, which are firft green, but when ripe, <re
 a dark purple colour. The berries ripen in the
 mn.

The wood, the btries, and the gum, arc ufcd in
 tcinc •, tlic gum is titled Saadcuracui.
 The lechil fort it known in tlc garden; by the ti-
 ot Swcdifh Jumpei this is many iuppofed to
 be only a variety of the firft,- but is ,
 diHincL fpecies, for t liave many year raised both
 forts : on the top di, and have nev
 lei. Thb Un n to the height of ten or twelve
 the branches grow more erect, the leaves are
 rurto^rer, and end in more ocute points: they are
 placed further ftander on the br*i>, and t< ber-
 ries are longer. It grows untunly in Sweden, Den-
 mark, and Norway.

The third fort grows nalvrelly in mod : :
 North America, where it is called red Cedar, to diffi-
 guifh it from u i^ri ol Cyprefi, which is called white
 Cedar Lhere. Of this there are two, if not tin
 rietiei, belides the ipccies here enumerated •, one of
 which has leai-cs in everv Jiart, like thofe of the Sa-
 vin, and upon bring rubl^cd, emir, a very ftron" un-
 grateful odour; this is commonly ilibnguilicil in
 America, by the title of Suvin-tree. There is ano-
 ther with leaves very like thofe of Cyprefi, but as
 ibefc generally arile from the fame feeds wicth tity
 arc fnt from America, ib they may be fur
 to be only lcminal virtaions.

The lower leaves of the fourth fort are like thofe
 of the Swcdifh Juniper, but the tiprrr kaves a;
 tliofo of the Cyprefi; and thu difference is tonftant,
 if the fteds arc carefully gathered from itic linne tree ;
 but xi molt tif thtpe people who fend over thefc feciis,
 arc not very careful to diftinguifh the differen-
 it ofwn liippens that the f«Ji of two or thrt.
 are mixed together, which has given occafion to peo-
 ple to imagine them hut one fpecies; but all the Itaves
 of the third arc Uk: vhoie of ihc Juniper, fo the gar-
 deners call ih» red Virginia Cedar; and the fourth
 they c •-J] Caroli.Ti Cedar, ihough kti JIB lbr> grow
 naturally in Virginia.

The fifth fort is the Bermudas Cedar, whole wood
 has a very Strong odour, ami was formerly in great
 dteem for wainkoting of rooms, and atfb for l'ur-
 niture; but the odour tie in^ too powerful for l
 rxrfbns, has rendered it let vilLabii-, and at prt-
 bnt there is nst much of l: imported Lira Eng-
 bn^ . Tlitfc phnts, »hi young, have acute-pointed
 leaves, which ftead open, and are placed by three
 round the branches, but as the trees advance, fo
 the leaves are very •, and placed by fours round
 the branth
 of filh; the berries ue prtnuccd I toward the end of
 the branches -, the
 are of a dark red colour, inclining
 to purple. J there are few of thefc trees of any
 great hzc in !
 I have not had an oppor-
 tunity of examining itw
 flowers, thefc
 re du not
 know if tity ha
 male and female flowers on the
 fame plane, or ii they are on different planes; for
 although I have received very fine fpecimens from
 Bermudas, yet they ate all wi-
 fully grown, and nntonrwith male (lwvers,
 and entire
 treesartcommonlydeltrojcdinEngljndwhe::! it r
 there happens a fever winter, where they are not Ihcl-
 cd, ib we h:ive little hopei of feeing them in (lower here.
 The fixth fort grows naturally in I rta, from vrlenci
 I receivcttthe berriesj which i, *er hccou, -d»*
 in the Chdlt-a garikn. This hath fceding branches,
 grow
 g thinly, which are gatml
 with acute-pointed le-
 c>, placed by fours round the branches
 they
 are of a deep green, and no;
 other, but grow horizontally, pointing out
 the berries arc much larger than thole of the cc
 Juniper, and are blue when ripe.

The fevetvth fort grows naturally i Porto"
 whence I have fr.
 I have lately received the berries. This
 fort
 has branches in a pyramidal form;
 the lower ones are covered with fhort, acute-pointed,
 grayifh leaves, placed by threes round the branches;
 the upper branches
 are of a dark green, lying Ol
 for each other like the
 ftuiks of tuiit iit en>!
 in acute points. The male
 iluven arc produced at ilL
 extremity of the branches;
 they are fi:>lin) in a luali
 foaly, conical habit;
 ftanding upon a fhort foot-ftalk erect, the foot it
 produced fometimes upon the fmg tree, at diftance
 from the flowers, and at other times they are upon
 feparate trees; the berries of this are of a pale yellow
 when ripe, and about the fize of thofe of the common
 juniper.

The cigl-,h fort growl naturally iñ Spa. Q arft ft
 from both which countries I have received it. The
 branches of this fort grow erect, and are covered with
 a reddifh-brown bark, the leaves are fmall, obov-

and like over each other like the folks of fffhj the jialc ilowrrs grow at the exu-emicy of the branches in a conica • • iikin, ami die fruit gro

The ninth fair grows naturally in Jamaica, anil idfo w the other iAji... ihtre it rites to be one of die largest timber trees in thofe countries : (L-L woexi is frequently fetched from the tree by tilt inhabitMite oi North America, for bull I \A of (hips. *H^a a i ... i thLm t for the branch ... of the f'rr, i ... leaves are shorter ... acute points which ... upward, ... rise to the height of ... feet, and produce great quantities of berries. I have propagated them from seeds, but have never found it vary. It has been distinguished by most of the old b - inifts, by the title of berry-bearing Savin. It grows wt naturally on the Alps, from whence I have received the berries.

The twelfth fort grow* naturally in Spjin, Pen ... and the south of France, where it rises to a twelve feet high, ... IJng out brsn, ... i fifb, the branches are small and taper, having no angles or corners, as most of the others have; the male flowers are situated at the end of the branches in conical heads, and the berries grow below from the side of the same branches. These are larger than those of the common Juniper, and when ripe are brown. The thirteenth fort grows naturally in Spain Mid Portugal, where it rises from twenty-five to thirty feet high, sending out many branches which form a sort of pyramid; the branches are furnished with acute-pointed leaves, which lie over each other four ways, so as to make the branches four-cornered; the berries of this fort are very large, and black when ripe.

These plants are all propagated by sowing their seeds, the best season for which is as soon as they are ripe, if

they ran then ha [irucured i for when il ... they are kept until :pring before they are sown, they will not come up until the second year. The ground in which the seeds of the hardy sorts are k • vn, "ihilLk be freli light, bui i should not be dug too deep: it floiitil! In well dug and levelled fury even ; iin:n fijw your diem) pretty thick, Rodfi/t ftune earth over... about half an inch thick ; this bed will require no farther core than only to keep it dt . . . words, and toward the middle or latter end of April, you will find some of your plants appear above ground,

though, perhaps, the greater I part of durra n may be till iric Ipi ... following before they come up; therefore you should carefully clear the ixve from weeds, and in very dry weather water them with some water, which will greatly promote the growth of those plants which are up, and also cause the other iixdi to vegetate; but if (lit bed in which these feed) ure fown is much expted to the Tun, it ; should be fhate'd with mats in \K Jay; for wti'n die plants come first dp, ttry v:ijj n&t bear ion much heat. In this bed they should em3in til! ihv [econd autumn, when you must prepare some beds to transplant them into, which should be i \x or' light, ... and having well dug and cleared the ground from all noxious weeds and roots, you should make it kvd |iiii then in the beginning of October • bcr, which is the proper season for removing these plants. you should raise up the young plants with a trowl, preferving as much earth as possible to their roots, and plant them into beds about five or six inches asunder each wsy, giving them some water if k-ttk the earth to their ; roots; and if it should prove very dry weather, you may lay a lit ;c muldi upon ihp lurtaz:e of the ground round their roots, which will be of ffin frvice to the plants. But as many of the beds will be yet left in the ground where they are sown, to i he beds should not be disturbed too much in taking up the plants; for I have known a bed sown with the berries, which has supplied plants for three years drawing, some of the berries i in so long in the ground before they sprouted; therefore the surface of the beds should be kept level, and continually dtnn : rain weat.

The plants may remain two yeas in these beds, observing to keep them clear from weeds v • on the first year; ymi lliailJ liir the ground yearly between them, that their roots may not grow greater eaf: rtrick into it; after which time they should be transplanted, cidicr into ariurftry, at the drfh ... of the feet row from raw, and eighteen inthes jtunder in the rows, or into the places where they are to remain for good. The best season to transplant them (as I before observed) is in the beginning of October, when you should take them up carefully, so preserve a ball of earth to their roots; and when planted, their roots should be i ... all which, if carefully attended in, as also ... rvmg W rcviffa th-m with water in vt iy dry weather until the • h«w taken new rlor, will preserve ic them from the danger of not growing; and they being ... in respect to cold, will defy the severest of our winters to injure them, provided they VK not pbnu••! in a moist or rich (oil).

In order to have these trees alike in height, I ltrir under ; inches ... JM be tik ... t)w/ arr inclined to grow • mt be ktT: their ... s do more ... i liot

weather is very wet to draw out from such places, if wounded; so that it will not be advisable to take off too many branches at once, which would make many wounds, from which ... i Htp in liot »i other would flow in such plenty, ... to render thuircci lwick and unhealthy.

The two sorts of Virginian Cedars grow to a much greater height than the former, and in their native country afford excellent timber for many uses, but with u there are very few whidl sve ii'ore twenty-

five or thirty feet high, though there is no doubt to their growing larger for they thrive very fast after the three first years, and refill the (harpest frost of on climatic exceeding well, and are very apt to grow fruit and regular, provided they are not furlered 6 (hoot out too much at bottom.

These plants are *Mo* propagated by seeds, which must be procured from Virginia or Carolina (for they rarely produce seeds in England) and sown as was directed for the other Junipers; but as this seed cannot be procured in England till spring, so when sown at that season, it remains in the ground until the succeeding spring before the plants appear; therefore you must observe to keep the bed clear from weeds, and not suffer seeds to be disturbed, which is often the fault of some impatient people, who think, because the plants do not rise the first year, that they will never come up, and to dig up the ground again, whereby their seeds are buried; but if they are let remain they seldom fail to grow, though for times it is two years after (owing before they come up. When the plants come up they must be carefully weeded, and in dry weather (should be refreshed with water, which will greatly forward their growth; and the autumn following they (should have a little rotten tan laid between them, to keep out the frost. In his bed the plants may remain till they have had two years growth, then they (should be transplanted into other beds, as was directed before for the other sorts, observing to preserve a ball of earth to their roots; and after they are planted, if the season prove dry, they must be carefully watered, and the surface of the ground covered with mulch, to prevent the sun and wind from entering the earth to dry their fibres; but they should not be too much watered, which often proves injurious to these trees, by rotting their tender fibres soon after they are emitted, whereby the plants have been often destroyed.

In these beds they may remain two years, observing to keep them clear from weeds; and in winter you should lay a little fresh mulch upon (the surface of the ground round their roots, which will prevent the frost from penetrating to them, and effectually preserve them, for while the plants are young, they are liable to be injured by hard frosts, when too much laid thereon; but when they have attained a certain strength, they will resist the severity of our

After two years, they (should either be removed into a nursery (as was directed for the common Juniper) or transplanted where they are designed to remain, observing always to take them up carefully, otherwise they are subject to rot when transplanted; and it is best to mulch the ground round them as was before directed, until they have taken their roots; after which they will require no farther care, than only to keep the ground even about their roots, and to prune up their side branches to make them aspire in height. The soil in which you plant these trees (should be fresh and light, but must not be dunged, especially in the time when they are planted, for dung is very hurtful to them, if it be not quite rotted to mould; therefore the mulch which is laid upon the surface of the ground should not be dunged, but rather some old tanners bark or sea-coal ashes, which will prevent the frost from penetrating deep in the ground.

These trees being thus managed, will in a few years rise to a considerable stature, and by the variety of their evergreen leaves and manner of growth, will greatly add to the beauty of all plantations, and are highly esteemed, which indeed is what we seldom observe in any of the English gardens or plantations; for there are few people who consider that the different growth of these few trees with which they are so much pleased to plant their plantations, as to place the tallest growing first, and the smallest next, and so gradually diminishing till we come to the common Juniper, and others of the same kind; whereby all the trees will be seen, and the gradual de-

clivity of their tops will appear like a verdant Hope, and be much more agreeable to the sight, as it is more advantageous to the growth of the trees, than to place (the tops of humble growth near such plants as will grow to the first magnitude, whereby the shrub is hid from sight, and will be over-shadowed and destroyed; nor can the distance which each tree requires, be so justly proportioned any other way; for in this distribution, the largest trees being separated by themselves, may be placed at a due distance, and then the middle growth succeeding, may be according to the allowed sufficient room; and the smallest, which are next to the first, being placed much closer, will hide the naked stems of (the larger tree), and have an agreeable effect to the sight.

The timber of these trees is of excellent use in America, for building of vessels, wainscoting floors, and for making many sorts of utensils, it also yields a bitter resin, which prevents its being destroyed by vermin, but is very brittle, therefore not so proper for tubborn uses, but however, by increasing the number of our timber trees, we (shall find many more (ago, besides the pleasure their variety affords; for we may hereby have trees of very different kinds, which are adapted to grow in various soils and situations, whereby we (shall never want proper trees for all the different sorts of soils in England, if proper care be taken in their choice; which will be a great improvement to many parts of this kingdom, which now lie unplanted, because the owner, perhaps, find that neither Oaks nor Pines will thrive there, and consequently concludes, that no other sort of tree will, which is a great mistake, for if we consider how different the sorts of trees are (being designed by the wife Author and contriver of all things, to grow on different soils and situations) and only observe what is adapted for growing on dry barren mountains, and what are designed for the lower and richer valleys, we need never be at a loss for proper trees for all sorts of ground.

The Bermudas Cedar being a native of that island, and also of the Bahama Islands, is much tenderer than either of the former sorts, except that of Jamaica, is not likely to thrive well in this country, for although many of these plants have lived several years in the open air in England, yet whenever a severe winter happens, it either kills them, or (so much defees* them, due, they do not recover their verdure in the next year. These plants are propagated by seed in this manner as the former, with this difference, that these (should be sown in pots or tubs of earth, that they may be removed into the shelter in the winter time, otherwise they will be hurt by the winter frosts; but they will require no other care than only to be placed under a common hot-bed frame, where the glass may be constantly kept in a moderate weather, when they cannot have too much (KT air, and only covered in the winter froth. The plants continually remain in the ground until the second year before they come up, therefore the earth (should not be disturbed; and in the summer time they should be placed in the Shade, to prevent the earth from drying too much, by the west wind, which they should be often watered, but do not give them much water to them (once, which would hurt them.

The spring following, when the young plants come up, they must be carefully cleared from weeds, and in dry weather refreshed with water; but should be kept in a place defended from strong winds; and in winter they should be covered under frimts, where they may be covered in hard frosts with mats, but must have open air when the weather is mild. In April following you should plant them each in a tin; the half penny pot filled with fresh earth, being careful to raise them up with a ball of earth to their roots; and when they are planted, you should water them, to settle the earth to their roots; then place the pots in a warm situation, where they may be defended from sun and wind; but if you will before * modestly hatted to plunge the pu-

will greatly promote their taking new root; however, you must carefully defend them from the great heat of the sun, which is injurious to them when fresh removed; but when they have taken root, you may expose them by degrees to the open air. If you suffer the pots to remain plunged all the summer, it will preserve the earth therein from drying so fast as it would do, if they were set upon the ground.

In October you should again remove these plants into shelter, or else plunge their pots into the ground under a warm hedge, where they may be protected from the cold north and east winds; and in the spring following you must shift the plants into pots a size larger, taking away some of the earth from the outside of the ball, and adding some fresh, which will promote their growth; and so continue to manage them as was before directed, until you plant them out in the places where they are designed to remain; which should not be done till they are four or five years old, by which time they will be strong enough to bear the cold of our common winters.

The reason for my directing these plants to be preserved in pots until they are planted out for good is, because they are difficult to transplant, and being tender will require some shelter while young; and whoever observes the method here laid down, will find the plants so managed to gain two years growth in six, from those raised in the open air, and be in less danger of being destroyed, and as the trouble and expence in raising them this way is not great, so it is worth practising, since in a few years the trees will recompense the trouble.

The timber of this tree is of a reddish colour, and very sweet, and is commonly known in England by the name of Cedar Wood; though there are divers sorts of wood called by that name, which come from different parts of the world, especially in the West-Indies, where there are several trees of vastly different appearances and genera, which have that appellation: it is this wood which is used for pencils, as also to waincot rooms, and make stair-cases, it enduring longer found than most other sorts of timber, which, perhaps, may be owing to some extreme bitter taste in the resin, with which the tree abounds; for it is very remarkable, that the worms do not eat the bottoms of the vessels built with this wood, as they do those built with Oak; so that the vessels built with Cedar are much preferable to those built with any other sort of timber, for the use of the West-India seas, but they are not fit for ships of war, the wood being so brittle as to split to pieces with a cannon ball.

The Jamaica Juniper is more impatient of cold than the Beronides, so will not flourish through the winter in the open air in England, and the plants must be preserved in pots and covered in the winter; this is propagated by seeds, in the same way as the Beronides Cedar; but if the pots are plunged into a moderate hot-bed the second spring after the seeds are sown, it will bring up the plants sooner, and they will have more time to get strength before winter.

All the other sorts are hardy enough to live in the open air, so are very well worth propagating, as they will add to the variety of Evergreen plantations; some of the sorts will rise to a very considerable height, so may prove to be useful amber, and may be adapted

in autumn in a shady border. Those plants which are raised in autumn in a shady border, will grow upright, nor to so large a size as the plants

in autumn in a shady border. Those plants which are raised in autumn in a shady border, will grow upright, nor to so large a size as the plants

which are raised from seeds; so that when these can be procured, it is much the better method, but the other is frequently practised on those sorts which do not perfect their seeds in England.

As several of these sorts grow to the height of eighteen or twenty feet, the procuring as many of the sorts as can be gotten from the countries of their growth, will be adding to the variety of our Evergreen plantations which cannot be too much propagated in England where, in general, our winters are temperate enough for them to thrive to advantage; and as the sorts which are a little more tender than the others obtain strength, they will be in less danger of suffering by severe winters, as we find by many other plants, which were so tender as not to live in the open air at first, but now defy the severest cold of our climate.

JUSSIAEA. Lin. Gen. Plant. 47S.

The CHARACTERS are,

•// bath a small permanent empalement, divided into five figments at the top, fitting upon the germen. The flower has five roundish spreading petals, and ten short flendef stamina, terminated by roundish summits. The oblong germen supports a slender style, crowned by a flat stigma, marked with five stripes. The germen afterward becomes a thick oblong capsule, crowned by the empalement, which opens lengthways, and is filled with small seeds.

This genus of plants is ranged in the first section of Linneus's tenth class, intitled Decandria Monogynia, which includes the plants whose flowers have ten stamina and one style.

The SPECIES are,

1. Jussiea (Suffruticosa) erectavillofa, floribus tetrapetalis, decandriis feffilibus. Lin. Sp. Plant. 55\$. Upright hairy Jussiea, with flowers fitting close to the stalks, having four petals and ten stamens. Lyfimachia Indica non pappofii, flore luteo minimo, filiquis caryophyllum aromaticum aemulantibus. H. L. 396. Indian Primrose with a very small yellow flower, and pods resembling Cloves.

2. Jussiea (Pubescens) villofa, caule erecto ramofa, floribus pentapetalis, decandriis feffilibus. Hairy Jussiea with an erect branching stalk, flowers having five petals and ten stamina which fit close to the stalk. Lyfimachia lutea erecta, non pappofa major, foliis hirsutis, fructu caryophylloide. Sloan. Gat. Jam. 85. Tellow upright largwTrce-Primrose with hairy leaves, and a fruit like Cloves.

3. Jussiea (Erecta) erecta glabra, floribus tetrapetalis, o&andris feffilibus. Flor. Zeyl. 170. Smooth upright Jussiea with four petals, and eight stamina to the bewers, which fit close to the stalk. Lyfimachia lutea non pappofa, erecta, foliis glabris, fructu caryophylloide. Sloan. Cat. Jam. 85. Tellow upright Tree-Primrose with smooth leaves, and a fruit like Cloves.

4. JUSSIAEA (Onagra) caule erecta ramofa glabro, floribus tetrapetalis o&andris feffilibus, foliis lanceolatis. Jussiea with an upright, branching, smooth stalk, flowers having four petals, and eight stamina fitting close to the stalk, and spear-shaped leaves. Onagra foliis pericariis amplioribus, parvo flore luteo. Plum. Cat. 7. Tree-Primrose with a large Arjijmart leaf, and a small yellow

5. JUSSIAEA (Hiritta) caule erecto simplici hirsuto, foliis lanceolatis, floribus pentapetalis decandris feffilibus. Jusfoa with a single, upright, hairy stalk, spear-shaped leaves, and flowers which have five petals, and ten stamina fitting close to the stalk. Onagra erecta, caule ruTro hirsuto, foliis oblongis, flore magno luteo. Houft. MSS. Umbel Primrose with a hairy leaf of a reddish colour, oblong leaves, and a large yellow flower.

The first sort grows naturally in the mountains whence the seeds were sent me by the late Mr. Robert Millar; this rises with a slender stalk near three feet

which come from the seed of the stalk singly, having four small yellow petals, which are crowned by the four-leaved empalement, and has a great number of small seeds.

femblance to Cloves. This plant flowets in July and Augull, and the feeds ripen in Oiflobcr.

The lecond fon grows naturally in J.unsica. The feeds of this were fent me by the late Dr. Houftwin v this rife with a hairy branching ftalk two feet high, ;nj is garrHbed with narrow fpcar-ih.ipcd I

alternatc. The flowers come our toward the end of the branches (wigly from the wings of the leaves, fitting ciofe to the (talk; they arc comi>ofcd of five prcry large yellow petals, and ten (lamina; thefe lit upon a long germen, which afterward be-comts the leed-veffel, crowned by the empale- thtfe arc Biled with fmiil feeds. It flowers and feeds al-oui the fame lime with the loft.

The third fort grows naturally in Jamaica, from whence the feeds were lent me with thole of the former fort-, ihis riles with a Smooth creel iULk three feel Ivgh, <iarnifhed with long, narrow, fmooth, fpcar- Itupnl leaves. The [lowers arc large axi yellow, firting clofe to the iULk j thet arc fucceeded by long feed-vedels, fitaped like thofe of the other forts. It Mowers and feeds at the lame time with the former.

The fourth fort was tent me from Canhagena by the late Dr. Houftoun "• this hath a branching fmooth flalk near three feet high, gamutied with fpcar-hiped leaves, (landing upon lhort tbot-ftalks. The flowers are fmall, yellow, and arc compofed of four petals nmf eight (lamina-, the[e fit very dale to the ftalk, and arc fucceeded by feed-vefliris, fiaped like thofe of i he former forts.

The fifth fort was fenn me from La Vcra Cruz, by the law Ur. Houftoun; this rifts with Tingle upright red ftalks three lest high, which arc hairy and chan-nelled. The leaves are fpcar-fiaped, and placed al-ternate on the Itslks, Handing nemr mgttlter Uiao in any of the other ions. The flowers conic our from the wings of the ICJVCS, toward the top of the Stalk, tliry arc compofed of live large yellow petals, and ten [lamina fitting dole to the rtslki, and arc fitcceeded by feed-vedcls which are one inch long, andflwped like thiofc of the former fores.

The firft, lecond, ajid founh forts arc annual plants, at leaf they are fo in England; tor if the plinu arc raifed early in the fpring, (hey wiiil flower in July, and ripen their feed the beginning of October i and thofe plants which are raifeiflater m the fpring, cannot be preferred through the winter, though they are placed in a warm ftove; nor do their iVaiks ever grow jgnous, or (hew any (igns of their being perennial ~i their native country.

he third and fifth ions have continued through the winter in the bark-ftove, but thole have bei plin in as did not Bower and Iced the fir (I ; < "tr they lud perfected feeds, the following fummcr the pbnts decayed.

Alt thefe fore are nroitagatcd by feeds, which (ioiild be fown early in the fpring, in pou filled with n foft loamy loil, ami pluntd into a moderate hot-bed; but k feeds often lie a whole year in the ground before they vegettte, the canji mufl be kept moift, and (lie gkflti of [he hot-bed lhaded in the heat of the day, by this method the feeds may be brought foon to v^Aruie; when the plants come up, and arc

to r... they Ihould be each planted into a fmall feparate pot, filled with light lojmy earth, and placed in 10 « hot-bed of uiincrs bark, where they fould be (haded from the fun till they h:ve i a w root; after which dicy (liould have free air ad-mitted to them every dayi in propoion w thic warmth of the fceion; they mufl allu be frequently refreshed with water, but it muft no(be given to them in too [plenty: when the roots" the plants have filled thic fmall jiot4, the plants fhould be removcii into others a "• c largrr j and if the pi are too tall to ftand under the : jineJ of the hot-bed, they film be removed into the bark-ftove, •

i-nts I rly in the fpring, and arc brought forward in ^heds, all the forti will flower and perfca their

feeds the fume year, which is better tlun to h.r. e them to keep through the winter.

JUSTICIA. Houll. Nov. Gen. Lin. Gen. riant*. 27. Atiliattxi*. l'ourn. lull. R..H. 175. t. 79. This plant was fo named by the late Dr. I Inultoun, in lit-tour of James Juitite, Efiji a p on laves uJ (n-couracr of gartlening and botany.

ir.ured (o beir the open air, into v> which they should be removed, placing them in a thelicred litiuuon, where they may iljy till autumn; but if they get root pretty cirly in the touner, it will U* prqptr to leparltt them ea>h into a (ingle liiall pot, fetting them in the fhjeir till they have uCn new toot, after which iliey iniy be placed as before directed; but when it is late in the feason before they take root, it will be better tolc: them remain in the fame pots till the following fprinj;. Ir: winter thefe plants muil be placed in a warm green-huule, or in a moderately warm (love, for they ue impatient of coU and damp, nor will >ly thrive in too much wsrnmbi thiy will often re^uire wawr in winter, but during thieir feafon it muil >c En^rn than nicxkrtjctly; in fuimmer they muil be moved into the open air, but fhould have a warm sheltered ftuation, and in warm weather they muil have plenty of water. This plant flowers at different feafons; but never produce* fruit Ir.

The fixth iLn giwes naturally in Jamaica, from wheri. the late Dr. Houfloun fruit in j lingUnd; ihi* i: with many thrubby flemier flalks about five fcc high, fending up branches on every fide from the r upward, which grow erect, and are covered with I whitifh b; , garnifhed with li Imjll, oblong, o:l Ifiyft, to ruing on; on each ride the ftal oppofite, and under the leaves are placed at every joint two (harp horns like thofe of the berber i • lie How- er: come out fingly from the wings of the leaves, they are tn-ill, and of a pale red colour, fhaped like thofe of the other fort.

The ninth firt was found by the late Dr. Houfloun, gT>winy [iituniJ at Cambrack; : his rife with a llrong vooi'y ft-i i twenty feet high, dividing into many i ooked irregular branches, covered with a figh brwn bat-. : with fpear-shaped oval leaves, rtenr four i>che> Wnj and two broad, which are covered with a foil (iawn on their under fiJe. The flowers; erow in Di<u; from the end of ih-i btanch, three, rom', or five of diete fuik; I arm: from the point, the middle fpike being near three inches long, *nd the othen abuuE hill' ; hat knuth. 'Jhe flower arc fmall and white, but fluped like thofcof the other fpecies.

The eighth lort grows nainrally at Malabar and in Ceylon •, this rik> in ns native fui) with a Krong woody dstr. itn or twelve fert high, dividing into many brandies, which are girnttht! with fpcf-(biped oval leaves five in •, m long, and two and a half braid, of a lucid green, place I oppolue. The flowers grow in very loiv spikes from : the end of the bndii. they arr or a E" ends color" with x lbjde of blue; the helince d thir Flower a reflexu.

Thefe three kinj are p-ogated j fecj^ in tic fame manner as the three & , and the p • i« m^l fac trcir-i in the fame WJV, t; ; ally w "le thry arc young; but after xami the eightli I'jit may be more hardi I trejU'd, when they have gotten ftrcngthi. This lorr may alii be uropigJted by curtingf, in the fame minnr u die fifth fort -, aud when the plan:>;; two or three years old, thry will thrive in a moderate degree of warmth in winter, ami in the fctnmrr they may be placed abroad for two month* in the wirnill feafon of the year; but they !••iuUt have a warm (heltered ftuation, and when the n- begin to grow cold, they muil be removed into the flou r, but "they muil have free ay admitted to them n at all timn when the v: other is warm. The other two lhorttd constantly remain in the bark-flou r, and reqi are the fame u • annct i, o;hir tL-nderplanti from the warmcil countries.

IXIA Lin. Gen. Fhr;. 54. 20jrio, iitum. Com, Hort. And.

THE CHARACTERS ARE,
It hath a long perennating falk (or flalk) which rifeth up from the ground; the flouers are in a long fpear-shaped patch which is equal, and there are fpear-shaped flowers which are placed about the patch, fometimes at equal diftances, fometimes by fingle joints. It hath an oval three-cornered green flalk above the flowers, fupporting a fingle flk

which is tin Irngth of tU Jiantina, crammed by a fat i:ftii JJJ^na; thi gennen aftercard iscsnui an aatbrc- caran .I capfull vitib thru cd's, fiiUd 'Jnlb rt&tJJji jeds.

This •jenos of plints is ranged in the firft kQxx of Linn*ta*a third dais, intitlctj Triandria Monogynia, which includes thofe plants whole flouen lave three ftoniitia ami one liyle,

ribu • *hyrioiden Armen. A. d. 5. p. 333. Ixa* - *est*
oval jpcar-jhapui leasts platti by tbrta, and jkviert in a
lecfjfpilu. Pavrrta ibliis oblongo-ovatis oppofiris, flj-
pau. ieiaceis. Brown, Jam. tab. 6. f. 2.

The firft fort grows naturally in India, where it rifes
with a woody' folk five or fix feet high, fending out
many fender branches covered with a brown bark, ear-
nished with oval leaves, pl. i Led fbmetimes oppoTi te,
and ar oibrts there arc three < r four at each joint.
The fioweti terminate the brandies in chillers -, they
have very long (lender tubes, ire cut into four oval
Icgmcms at the cop, at the end of i deep red colour.

The fecond ion grows idfo in India ; tins haili a woody
ftalk i i g fr* i high, fending out weat
brarx'ies, garnished with oval fpcar-Hiapel leaves
yhic ; tlole to tie brant It; ihe flw-
en terminate the branches in fnull cluftertj they have
long Render mbrjs, divided into four fegments at ilie
top, wid arc white, without f<nt.

The third ibrt grows naturally in Jimaiai, and fome
other ifljiiidi in the Weft-Indies, wiere it is called
Wild Jafmine. This rifez with a Ihmby (talk four
or fr ka high, fen: ing out lender brandies oppo-
pofite, which arc garnished with oval lpcar-ftiafK-d
leaves placed oppouic, whkh arc Ax inches long, and

two inches and a half broad, having iliorr foot-fbll.s,
the flowers ate produced at the end of" LIC branches
in a kuli: fpik; they uc white, and have a jetne like
Jafmine.

Thefe plants are propagated by feed*, when tlicy can
be pnxurcti from the countries where they grow natu-
rally, for they do not pcrctft any ft-tds in Knglind.
They fiould be fown in fmall pot? as (bon as tl: y ar-
rive, and plunged into a hoi-bed-, if they arrive in
autumn or winter, the poti may be piongetl in the
tan-bed in the ftove, between the other pots of planet,
fo will tike up little room ; but when they strive in
die (pring, it will be beft to plunge them in a tan-
bed undtr t'r.ncncs; the feedj wiU fometimj come up
in about fix weeks, it they arc quite frtlli; otherwile
they will lie in the ground four or five monrhs, ud
fometimes a whole year; therefore the earth *thooUi*
not be thrown ou' of the pots till there is no
of their growing ; when the plints come up, and arc
fit to remove, they fliould be eith pljncd in a fit pa-
rate fmall por, iilled with Jitrth earth, and afrerw-ij
treated in the manner directed for tic Coffcc-tree.

They may alfo be increaied by cutting; during the
fmmTncr months, and planted in t'mall poti plunged
into a moderate hotbetl, covering ihem doft¹ either
with bci! or iiland-gtafi-s to cvclgile the external air,
ihding them carefully
of the day, mitil they iiave put 'ut gix> ;
theylhould be patted,

pot, treating them at tin teedlmg plant).

of ihrubs, which inclofr them, f/>uy il
 ders where the fruit-trees stand, the least width of
 which flps fhould be twenty-five or thirty feet, but if
 they are double that, it will be yet better, and the flps
 will be more useful, and the fruit-trees will have a
 larger fpace of good ground for their roots to run.
 These walls fhould be built about twelve feet high,
 which will be a fufficient height for any fort of fruit.

liihi foil where you intend to place your kitchen-gar-
 den be very strong, then you fhould plough or dig it
 three or four times before you plant any thing therein,
 and if you throw ; ujn ridges to receive the froft in
 winter, it will br of gn... fervice to meliorate and
 loofen the foil.

Thi manure which is mod proper for futli toll, is
 fca-coal afhes, and the deanfin of flreets or ditches,
 which will render it liglii nuirh IIMIH 71 iirui any atti-
 dung or manure, and khc j^rcaitr the oi>^ntiv of
 afhes the better, efpecially if the ground be cold,
 and when: d... afhes are not to be obtained in p... y,
 fca-fand is a very proper Jrt(Ting, whtte ii tin be
 eafily procured, or rotten wood, or the parts of ve-
 getables rotted are very good; all which will greatly
 fooled the 1... and chaic it to be i... only eafier to
 work, but alfo u...

But, on the contrary, if your foil be light and warm,
 you fhould mix with rot... which
 is much preferable to any other dung for hot foils;
 but if you use horse dung, it must be well roned,
 otherwise it will burn up the crops. Lipon diti tird hot
 dry weather.

The foil of this garden fhould be at least two feet
 deep, but if deeper it will be still better, otherwise
 there will not bed... enough of foil for many forts
 of... fi knnt wots, ai Carrots, Pars;
 which ntn down i... every deep in the ground, and most
 other forts of excellent plants delight in a deep foil;
 and many plants, whose roots appear short, yet if

 growth.

You fhould alfb tntkavow to have a fupply o: wa-
 ter in the different parts of the garden, w... if pof-
 fible, fhould be ran wined into... baions or refervoirs,
 where it may be expofed to the open air and fun, that
 it may be heated thereby; for high water as it taken
 out of wells, &c. juft as it is ufed, is by no means
 prone for any fort of plants.

In the diftribution of this garden, after having built
 tile walls, you fhould lay out banks or borders under
 them, which fhould be at least eight or ten feet broad,
 whereby the roots of the fruit-trees will have ground
 liberty ih... in fucii places where the borders are not
 above three or four feet wide s ami upon these banks
 you may fow many forts of early crops, if expo... ET
 chtfouihi and upon thofe expofed to the north, you
 may have fome late crops; but I would by no means
 advife the planting any fort of deep rooting plants up-
 neM the fruit-tms, efpecaU; Peas and Beans; tho'
 for the advantage of the walls, to preferve them in
 winter, and to keep them foil... and in the fpring, the
 mnlei... are too apt to make ufe of thofe
 bon!... which are near the bcf... affected walls, to the
 eteai... of their fruit-trci... but for their pro-
 p... s... Red-bedges fixed
 in fome of the warmed q... quarters, under which you
 fhould fow... nd plant cai I... Peas, Beans, &c. where
 they will thrive as well as if planted under a wall, and
 hereby your fruit-trees will be enu... ly freed from fuch
 troublesome plants.

Then you fhould proceed to dividing the ground out
 into quarters, which must be proportioned to the lar-
 gencs of the garden; but I would advife never to make
 them too small, whereby your ground will be full in
 walks, and the quarters being inclofed by espaliers
 of fruit-trees ths i! ints therein will draw up fender,
 and

I Kver irrvtve ijj hall" the fize as diey would do in i more open rpx*/ure. The walks of this jja^rilen shoud be allb pro; ...

The brwdth of theft middle walks whkh I have here affige: I them, nw by many perfons be thought too great; but myrraJon for this is to allow proper room between i die efpaliers, that they may not fhsid each other, or thrir roots ioterftt tnd rob each other of their nourimment: but where the walks are not requied of this breadth, it a only enlarging of the borders on each fide, and lo mjucing tin- walks to the breadth of fired.

But the wnk5 of thefe gardens shouM not be gravelled, for as ihic will confUmly be ofcaftion to wheel manure, water, &c. upon them, theywouldJboa be defaced, and rcmleretl unfightly -, nor fhould they be bid with turf* for in grefli walks, when they ate wheeled upon or much troddrn, the turf is foon de-ftroyed, and whole piaces where they are much ufed, become very unfightly atlo; therefore the bert walks for 3 Kitchen-garden are uSofc which are laid with a binding fand; but where the foil's frong and apt to detain the wet, there (Wild be foine narrow under ground drains made by iht Ode of the wal- tiffthe wet, othrwile thtr will b too.

walks, in i^Ml wejther; ami where the ground i very wet, and the water is detainni by the li(fuel's ff the soil if icinc limc-ruliulii, ffinB, chik, oranyfuch aietial as can be procured with theaftexpente, and i laid at the bottom of thefe waiki; or if neither of ihrte can lie had, a rwii of Heath or Furze fhould be and tlic coat of farul laid over it; the fand will be kept drier, and the walks will be found and good *n alheafons. Thefe land-walks when thfy are well Jad, are by much the eafidt kept of atn-; for wfen either weeds or Mtifs begin to grow, it is'but fcuffling icvti ui:lifl!)!ii:iiriocin dry weather, and

making them over a day-cr two after, and they will be as clear [is when firil brid. The beft figure for ihe quarters to be difpolid into, I a fquare or an oblong, where the ground is adapted to lich a figure •, odicrwife they may be triangular, or of any other IKipe, which will be mult advantageous to the garden.

When the garden is laid out in the ^i;pe inren - : d, if the foil is ftrong, and fubject to detain the moillure, icreftliould always be undtr-(rmi:: drains made, to tarty off the wet from every cjuir-ter of the garden, for 'ithenwife motl (bro of kttech- plants will fuffer great • by mou I rein winter; and if' ihe mats of the fruit-trees go: into tlic wet, they will never produce good fruit, fo that the e cannot be too r-uch care taken to let off all fuperfluous moifture from the Kitchen-garden.

These quarters fhould be conflantly kept clear from weeds, and when any part of the ground is unoccupied, it [iiouja u I may be trench'd up into ridges, that it may be ufed to imbibe the mairous particles of the air, which is ut ; great advantage to all forts of land, and the ground will the i b; indy to lay down when ever L i m d.

The ground I in thefe quarter* fto^ld not be fawn or planted with the fame crop two years together, but the crops fhould be annually changed, whereby they will prove much better than when they conflantly grow upon the fame fpot. Indeed the kitchen-gardens near London, where the land is clay, are often obliged to put the fame crop upon the ground for two or [luce yens t'-.g;-iir i 1 but then they dig and manure

their land Ib well every ytar, as to rend it abed new, though necwUhiullngAU tliii, U i: ohii'rvcit, il'.ii irelli bntl always pi duces the best crops.

In one of thrc quarters, whii h is fanned search to the flabls, and tn it detented from the cold winds, or if either oJ the flms without the garden wall, which is well expold to tie fun, li is convenient, and is of a proper wltthi that II could be preferred for a place to make hw beds for early Cucumbers, Melons, &c. The rrafimi TV i. giving the preference to uod of these flps, is, firft, there will be no dirt or later

carried over the walks of the K itchen-garden in winter and fpring, when ;lic weather i generally wet; fecond, the w^lki will be rndnted unlightly; tertially, the vkw<; the hot be !s will bt* excluded from flps; and billj, the tonvenienceof can; ii the dung into these flps, ior by making of a gate in the J edge, or rail, wide enough for i final cart to enter, it may be done with much Ids trouble iliam!.. ar of harrowing a thir' ilir garden; and whrn-i i can be a flp long enough to contain a fiiffitait nun ber of beds for brood three years, it will bc o) great ufe; becaufe by the fiftroy of the beds anruuliy. they will succeed much better than when cl y are continued for a number of years on the fame jpot . of ground; and as it will be abfolutely neceffary to fence ih. Melon-ground round with i Rred-hedge, it may K: I be contrived as to move away in pannrls-, and thru ths hedge which was on tlr uppr Cde the lirt year, being carried down to a proper did.iice below that which was the lower hedge, and which may remain, there will be no occasion to remove more than one of the profe hcilgef in a year; iherrfort- I am perfuad'd, whoever will make i: al of this mrtlitwl, will find it the mod el-ible.

The most important points of general cymre confiffr in well digging and mowing the foil, and giving a proper distance to each plant, according to their different growth* (which i conflantly exhibited in these feveral wtkki in this 1 ok) as alfo in keeping them clear from weeds; ftr if freedj aac permitted to grow until their ferdi are rife, tlicy will fhid vjkon the ground, and fill it lb as not to be gotten out t% in a kver.il year. You (liould ally obieve to keep your dunghill] always clear from weedj, for it will be to lira purpule to keep the garden clean, if this is not obferved; for the ferfa falling am,; the dung, will be brought into the garJen, whereby ihrir K, 'I be a confl: at fupply of weeds yearly introduced, to the small ctamage of your pi mts, and ;i perpetual labour occafioned to extirpate them again. Another thing which is abfolutely neceffary to beobfervci is, to carry off all the refuse teavet of Cabbages, the (talks of Brans and haulm of IViiV, as foori as they are done with, for the ill fcent which rrrnl people cunipl. in of in the Kitchen-gardens, is wholly n-ccafioned by th*fe things being i'')Herd to rot upon die ground; therefore when the Cabbages are cut, all leaves fhould be carried out of the gi! en while they are fresh, as alk time they may h very useful for feeding of hogs, cm; her animals, and this will always keep the garden neat, and free from ill fcent. As for all other neceffary tin-itions, they will be found in the articlei of th. feveral forts of kitchen plants, which renders it need! to be repeated in this p-ee.

KLEINIA. See CACALIA. KNAUTIA. L. n.Gtn.1'ant. 109. L; chni-Seabiofa. Soerli. tnd. 1. Ijt, This time wai jpplicJ toillii! plant by Ilr. Lini in liunnurcifih nemy at Or. Christian Knaut, who publill-ed a method of claffing plants.

The CHARACTERS are, It hath a single oblong capsule, containing several fpecular flowers, which are ranged fo as to appear regular, but each irregular, having twice the length of the capsule, tui are ml at the ends into four irregular segments, ttt euirr Waf ti* Irnpb tshh tute, and is in the receptacle, terminated by short peduncles, and a perianth under the petals supporting a slender style, crowned by a thick soft stigma.
