94 THE
GARDENERS DICTIONARY:

CONTAINING

The BEST and NEWEST METHODS
OF
CULTIVATING and IMPROVING

THE

Kitchen, Fruit, Flower Garden, and Nurseries;

Ad alfo fur Performing The

Practical Parts of AGRICULTURE:

INCLUDING

The MANAGEMENT of VINEYARDS,

WITH THE

Methods of MAKING and PRESERVING WINE,

According to the Practice of

The most skilful Vignerons in the several Wine Countries in Europe.

TOGETHER WITH

DIRECTIONS for PROPAGATING and IMPROVING,

From REAL PRACTICE and Experience

SORTS OF TIMBER

THE EIGHTH EDITION,

Revised and Altered according to the Latest SYSTEM of BOTANY; and
improved with several COPIES of PLANTS, which were first in fame by the Editor.

By PHILIP MILLER, F. R. S.

Gardener to the Worshipful Company of APOTHECARIES, at their Botanic Garden
in Chelsea, and Member of the Botanic Academy at Florence.

- . . . Digna manet divitiis gloria runs. VIRG. Georg.

MAY IT PLEASE YOUR GRACE,

OUR Grace's kind Acceptance of two former Editions of this Work, has emboldened n[^] to Si] lay this at Your Grace's Feet, as a public Acknowledgment of the many **ufeful** Obfer vat ions and Instructions, which Your Grace has at few^{ral} Times communicated to me for its Improvement. If I have been fo happy as to employ them in fuch manner, as to merit Your Grace's Approbation, I (**hall** have **lefe** Reaibn to doubt that of the Public ; fincc the moll: (kilful **Peribns in this ufeful** Branch of Science, pay the higheft Regard to Your Grace's Judgmci^{it}.

The many Improvements which Your Grace is annually making fo happily upon Your various Eftates, **fufficiently** demonftrate Your Grace's fuperior Judgment; but more particularly in a Country almoft deftitute of Timber: Where, if Your Grace contini^{es} planting, fo ardently as for **feveral** Years paft, the whole Face of the Country will be much altered for the better, and Your Grace's Eftate thereby greatly improved.

That Your Grace may long live to continue thefe Improvements, and to be an Example to others, is the fincere Wifli of

Your GRACE'S

Moil obedient humble Servant,

CHI: 118.
AUnk i, ijfcS.

Philip Miller.

P R E F A C E

THE GARDENERS DICTIONARY having already gone through several editions, it may reasonably be supposed, the public are well acquainted with the nature of it, which renders it less necessary to enlarge on that subject. The author therefore thinks himself obliged to return his thanks for the kind reception his work has met with.

But as there may be some, who may think that the reprinting it is doing them an injury, especially those who have purchased a former edition, it may not be amiss to make some apology for this.

When the first edition was published, gardening was then much less known than at present, and therefore, as the knowledge of the art increased, it became more necessary to enlarge on the subject, by adding the new improvements to the former, without which it would have been deemed imperfect: for as the author's situation in life rendered him capable of being well informed of the progress made in the art, by his great correspondence both at home and abroad, he thought it would not be unpleasing to communicate those improvements to the public: in doing which, he has been careful not to publish any thing imparted to him, until he was fully satisfied of the facts by experiments.

Others have suggested, that printing the improvements separately would give ample satisfaction in this point; but the author had made trial of former purchasers some years past, by publishing several sheets of new articles, by way of Supplement, for which there was scarce any demand; so that the few which were sold, would not defray the expence of paper and printing.

As the number of plants now cultivated in England, are more than double those which were here when the first edition of this book was published, the mentioning of them, together with their culture, could not well be avoided in a work of this nature, therefore the author hopes his care in inserting them will not be censured.

From the title of this book it may seem to be only a Dictionary on the art of gardening, but all the branches of agriculture are included in it, in a more complete manner than can be found in any other book extant, though written wholly on the same subject. Nor are the instructions here given for performing the work in every part taken up hastily, or upon flight experiment; but most of them are the result of more than twenty years practice in different parts of England, where the author has been permitted to superintend and direct the whole: therefore he can assure the public he has been very cautious in recommending any thing, which he is not thoroughly convinced to be true.

It is amazing to see, in most of the books which have been published concerning husbandry, that scarce any of the compilers have taken the least notice of the common practice of sowing eight times the quantity of Corn upon land that is necessary, to the great expence and detriment of the farmers, who are so wedded to their old customs, as not to be convinced of the error; for so obstinate are they in this matter, that unless the whole ground be covered with the blades of Corn by the spring, they judge it not worth standing, and in consequence thereof frequently plough up their Wheat and winter Corn, to sow the land with Barley, or other Lent Corn; whereas, if the former had been left standing, it would have produced a better crop than any land can do where the blades are very thick, as the author has frequently observed. I have mentioned this to several farmers, but the answer has constantly been, that on rich ground a thin crop of roots will often produce a large crop of Corn, but on poor land it will not pay cost, which is a very great absurdity; for how is it possible, that bad land can supply proper nourishment to a greater number of roots than better ground? and where this practice is observed, seldom more than three or four bushels are reaped from one fow; whereas, where the same quantity is sown upon the same, or a like soil, and has room to grow, the produce will be at least six or seven bushels. Yet I have seen growing upon land apt very good, and uncultivated, for more than twenty years, which and was sown with

P R E F A C E .

lent plants, have been most of them, at least the fine sorts, greatly improved by culture, they are fully treated of under their proper genera.

On this article a long series of observations has been made by the author, who for near fifty years has applied himself closely to this subject, for as many former botanists have enumerated a great number of varieties as so many species, the study of botany was thereby rendered greatly perplexed; some of the modern writers on this subject, by going into the contrary extreme, have abridged the species almost as much. Indeed it must be allowed, that ascertaining the real specific difference of plants, would be of great service to the science of botany; but this cannot be done otherwise, than from many years experience in their culture, especially by observing the varieties which arise from the same seeds, as also the difference produced by different soils and situations, which is frequently so great as to perplex very good judges in this matter. There are likewise many other varieties which have arisen from seeds, sowed from plants, and grown near others of a different species, by which means they have partaken of both; but these hybridine plants rarely producing any seeds afterward, the alteration goes no farther.

O F T H E

T E C H N I C A L T E R M S o f S O T A N Y

Mentioned in this

W O R K.

A ROOT, *Radix*, is that part of a plant, by which it usually receives its nourishment. There are several sorts of this, as

A fibrous Root, *Radix fibrosa*, is that which consists of many small fibres. See plate i. fig. 3.

A tuberous Root, *Radix tuberosa*, is that which consists of an enlarged part of the stem, which is cut horizontally in the middle. See plate i. fig. 4.

A bulbous Root, *Radix bulbosa*, is that which consists of several coats involving one another, as the onion. See plate i. fig. 5.

A grumous Root, *Radix grumosa*, is a kind of tuberous root, with several knobs resembling the grains of Corn. See plate i. fig. 7.

A knotted Root, *Radix nodosa*, is a kind of tuberous root, consisting of two knobby knobs resembling a knot. See plate i. fig. 8.

An alveolate Root, *Radix alveolata*, is a kind of grumous root, whose fibres are knobby knobs* toward the bottom, resembling the dug of a comb. See plate i. fig. 9.

A gnarled root, *Radix grumosa*, is one which is composed of several knobby knobs ending in fibres. See plate i. fig. 10.

A Suck, *Cevsi*, is a part of a plant, receiving the nourishment from the root, and distributing it into the other parts which it is clothed, not having any of the qualities of the root. The ill of a tree is called the trunk or stem, i. e. *Caudex*.

A branch, *Ramus*, is the stem of a stalk. In trees it is general I called a bough.

A Pedicle, *Pediculus*, is that part of a stalk, which immediately sustains a leaf, a flower, or a fruit. Dr. Linnaeus has distinguished these. Those which sustain the leaves he calls *Pedunculi*, and those which sustain the fruit, *Pediculi*.

A Spike, *Spike*, is a part of a stalk which bears flowers or fruits, in such a manner as to form an anacutecone. See plate i. fig. 11.

A Thyrse, *Thyrse*, differs from a spike in that the flowers or fruits are far more loosely set on it, so that the spaces visible between them.

A Panicle, *Panicula*, is a stalk divided into several pedicels sustaining the flowers or fruits. See plate i. fig. 12.

An Umbel, *Umbella*, is the extremity of a stalk or branch, divided into several pedicels or rays, beginning from the same point, and opening in such a manner as to form an inverted cone. See plate i. fig. 13. When the pedicels are of the same length, it is called a simple umbel; otherwise it is called a compound umbel, and is subdivided into several orders, there or the same form, upon which the following terms are applied. The

first order (a) is called rays, the second (b) Pedicels. That umbel which consists of one pedicel only is called a simple umbel. See fig. 14. That which is composed both of rays and pedicels, is called a compound umbel, as fig. 15.

A Cymose umbel, *Cymose umbella*, is that the rays or pedicels are disposed in such a manner, as to form a sphere. See plate E. 6.

A twining stalk, *caulis volubilis*, is one which twines about any proper tree without the help of tendrils.

A climbing stalk, *caulis scandens*, is that which is supported by any other or neighbouring support by the help of tendrils.

A creeping stalk, *caulis repens*, is that which lies on the ground, and produces itself by emitting roots at the joints.

A trailing or procumbent stalk, *caulis procumbens*, is that which lies on the ground unless it is supported, but does not emit roots.

A Tendril, *Caupulus* or *Glomerulus*, is a part of a stalk, as a branch from the side of a stalk, placed opposite to the main stalk, which is supported by an adjacent body, and thereby supports the stalk, as in the Vine, &c.

A Node, *Node*, is that part of a plant which contains the seed with its covering. Of this there are many different forms.

A Cone, *Conus*, is a dry seed-vessel, consisting of several distinct parts, adhering closely together, and separating when ripe. Of this there are several sorts which differ in their form and texture, as in plate 1. fig. 1. is a cone of the Pine-tree, whose lignous scales find in their joints, which open by the warmth of the sun in the spring, and easily emit the seeds. Fig. 2. shows the cone of the Cedar of Libanus: whose scales are smooth, lying close over each other, and drop off leaving a brittle column on the branches. Fig. 3. shows a cone of the Fir-tree, whose scales are firm, and are set on in such a manner, that they are not so easily separated, emitting the seeds from between them. Fig. 4. plate 1. represents the cone of the Pine-tree, whose scales terminate in blunt protuberances.

Dry Set seeds, according to the number of cells into which they are divided, are called Unilocular, Bilocular, Trilocular, &c. See plate 1. fig. 1, 2, 3.

An Apple, *Pomum*, is generally understood to be a fleshy fruit, in which several hard seeds in the center; but it is very difficult to know what the ancients meant by the title Pomum, for this title is frequently used in their writings to express things of different forms, therefore the title Pomum should be only applied to those fruits which are umbellated, and contain many seeds. See fig. 11, 12. plate 1.

P L A T E IV.

Contains the figures which explain the Syfiem of Dr. Linneus who classifies the plants by the number of flamina in their flowers.*

- F**IG. i. (shews a flower with one flamina and one fyle, which he titles *Monandria Monogynia*.
- Fig 2. (shews a flower with two flamina and one fyle, which he titles *Biandria Monogynia*.
- Fig. 3. (shews a flower with three flamina and one fyle, which he titles *Triandria Monogynia*.
- Fig. 4. shews a flower with four flamina and one fyle, which he titles *Pentandria Monogynia*.
- Fig. 5. shews a flower with five flamina and one fyle, which he titles *Pentandria Monogynia*.
- Fig. 6. shews a flower with five flamina and two fyles, which he titles *Pentandria Digynia*.
- Fig. 7. shews a flower with six flamina and one fyle, which he titles *Hexandria Monogynia*.
- Fig. 8. shews a flower with six flamina and three fyles, which he titles *Hexandria Trigynia*.
- Fig. 9. shews a flower with seven flamina and one fyle, which he titles *Heptandria Digynia*.
- Fig. 10. shews a flower with eight flamina and one fyle, which he titles *OSandria Digynia*.
- Fig. 11. shews a flower with nine flamina and one fyle, which he titles *Enneandria Monogynia*.
- Fig. 12. shews a flower with ten flamina and one fyle, which he titles *Decandria Monogynia*.
- Fig. 13. shews a flower with twelve flamina and one fyle, which he titles *Dodecandria Monogynia*.
- Fig. 14. shews a flower with more than twelve flamina, but less than twenty, and these arise either from the petals or the empalement, and with one fyle, which he titles *Icofandria Monogynia*.
- Fig. 15. shews a flower with a great number of flamina and one fyle, which he titles *Polyandria Monogynia*.
- Fig. 16. shews a flower with two long, and two shorter flamina, and one fyle, which he titles *Didynamia*.
- Fig. 17. shews a flower with four long and two shorter flamina, and one fyle, which he titles *Tetradynamia*.
- Fig. 18. shews a flower with five flamina, which are connected with the fyle in one body, which he titles *Monadelphbia Pentandria*.
- Fig. 19. shews a flower with ten flamina and one fyle, which are joined at the base into one body, which he titles *Monadelphbia Decandria*.
- Fig. 20. shews a flower with many flamina joined in one body, with a many-pointed fyle, which he titles *Monadelphbia Polyandria*.
- Fig. 21. shews a flower with six flamina joined in two bodies, which he titles *Diadelphbia Hexandria*.
- Fig. 22. shews a flower with ten flamina, nine of which are joined together at their base, and the other is separated, with one fyle. This he titles *Diadelphbia Decandria*.
- Fig. 23. shews a flower with many flamina, which are connected at their base into several clutters or bunches, which he titles *Polyadelphbia Polyandria*.
- Fig. 24. shews a single floret of a compound flower, these which are hermaphrodite have five flamina and one fyle, which are connected at their base. This class he titles *Syngeneia*.
- Fig. 25. shews a flower whose flamina are connected with, and seem to proceed from, the fyle, which is divided into two parts. This he titles? *Gynandria*.
- Fig. 26. shews a flower of the sixteenth class, which is of a different figure from those before represented. The flamina of this stand round the column formed by the fyle.
- Fig. 27. shews a floret of the compound flowers fitting upon the germen or embryo of the seed, with the two reflexed flamas on the top of the fyle.

Long

Lbfig Coned Cornith Fir. The leaves of this are whiter, and much longer than the others *, the cones are also of a greater length than those of the common sort, so that by the appearance of the trees, any person might suppose them to be a distinct species. But from the seeds which were carefully taken from this sort, both varieties of plants have risen, therefore they must be only deemed varieties.

From this tree the pitch is drawn, and hence it had the title of Picea, or Pitch-tree*.

The third sort was formerly growing in the Bishop of London's garden at Fulham; and of late years there has been a great number of the trees raised from the seeds which have been brought from America. This sort makes very little progress after eight or ten years growth; the only place in which the trees have made any figure, is at his Grace the Duke of Bedford's at Woburn-abbey in Bedfordshire.

The fourth sort is a native of North America, from whence the seeds have been brought to England, and great numbers of the plants raised. This is called by the inhabitants in America, the White Spruce Fir. It grows naturally on the mountains and higher lands, and arrives to a much greater size than most of the other sorts. Those in the gardens of the late Duke of Argyle, at Whitton near Hounslow, are by much the finest I have seen: but there must be some trees of a greater age in Devonshire, unless they have been destroyed; for in the year 1724, I received some branches of this tree full of cones, from a gentleman of that county, who had several of the trees then growing, which were of a considerable size.

The fifth sort grows naturally on moist land, in many parts of North America, but rarely arrives to the size of the fourth: however, the inhabitants of America use the branches of both indifferently in making of Spruce-beer, from whence the trees obtained the title of Spruce-trees.

From both these species of Fir, exudes a fine clear turpentine of a strong scent, which the native Indians use to cure green wounds, and also for some internal disorders; and of late years the English physicians in North America, have likewise adopted it into their practice.

The sixth sort is also a native of America, from whence the seeds have been brought into Europe. This tree does not thrive well in any part of England, nor in many places of America; though in some particular spots I have been informed there are very large high trees now growing. It is a native of many parts of North America.

These trees are all raised from seeds taken out of their polyperamous cones. The way to get out the seeds is, by exposing the cones to a gentle fire, which will cause their squamous cells to open, and readily emit the seeds: but they should not be exposed to too great a heat, for the cones of all the Firs open much easier than those of Pines, especially those of the Silver and Balm of Gilead Firs, which, if permitted to hang late in the autumn, fall to pieces and scatter their seeds. This ought not to be done until the time of sowing them, which is best performed the latter end of March.

These plants should be all raised in a nursery, where they may be protected from the birds, otherwise they will be in danger of being destroyed when they first come up. For as they bring up the husk of the seed on the top of the plant, the birds, in picking off the husk, will break off the tops of the plants, whereby a whole bed may be lost in a few hours, if not carefully guarded from them.

The best time for sowing these seeds is about the latter end of March, or the beginning of April, according as the season is more or less forward, on a bed of light earth, covering the seeds about half an inch deep with the same mould. If this bed be netted over to keep off the birds, it will be a sure method of preventing them from destroying the young plants at their first coming out of the ground; it which time they should likewise be screened from

the sun in the middle of the day, by covering the beds with mats, because too much sun frequently destroys the plants when they are young. In this bed the plants should remain until the following spring when there should be a number of beds prepared in the nursery to receive the seedlings. In the beginning of April they should be transplanted into the beds, at the distance of six inches row from row, and in the rows at three inches asunder, setting them in a quincunx order. In removing these plants, they should be very carefully raised up with a trowel, so as not to break off the fibres of their roots; nor should they be kept long out of the ground. During the time they are out, their roots should be covered, to prevent the wind from drying their fibres; and in planting, the earth should be pressed close to their roots, to prevent the air from penetrating to them. If the season proves dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather, the beds should also be covered with mats, to screen the plants from the sun, and drying winds, until they have taken good root; after which time they will require little farther care, than to keep them clean from weeds. In these beds the plants may remain two years, at the end of which they should be transplanted into an open spot of ground, for their roots will in that time meet quite over the beds. This ground, to which they are to be removed, should be well trenched and cleared from all noxious weeds, and made level. The beginning of April, just before the plants begin to shoot, will be a good time to remove them. In taking up the plants, great care should be taken not to tear off or injure their roots, nor should too many of the plants be taken up at one time, but rather plant them as fast as they are taken up, that they may be as little time out of the ground as possible. For the drying winds, which usually happen at this season, will greatly injure the roots of these plants, if much exposed thereto.

The distance at which they should be placed in the nursery, should be four feet row from row, and in the rows two feet asunder. This distance may by some be thought too great; but if it be considered how much their roots spread in the ground, as also that when they are planted nearer together, it will be very difficult to take up the plants again without cutting and tearing off their roots, especially if they are not all taken up clean at the same time: these considerations must have greater weight than that of the loss of a little ground, with all who have any regard to the future welfare of the plants. In planting them, it will be advisable to draw a line across the ground, and to dig out a trench of a foot wide, into which the plants may be placed at the distance of two feet asunder. Then fill the earth into the trench, covering the roots of the plants with the finest part of it, scattering it carefully between the roots; and when the whole trench is filled in, press the earth gently down with your feet, but by no means tread it too hard, especially if the ground be strong, or apt to bind too close.

When the plants are thus planted, if the season should prove dry, they ought to be watered, in order to settle the earth to their roots, and if this be repeated three or four times, (if the season should continue dry) it will greatly promote their taking new root, and secure them from the injuries of the drying winds. In this nursery the plants may remain two or three years, according to the progress they shall have made; and during this time, the ground between the plants should be constantly kept clean from weeds, and dug between the rows every spring, in doing of which, care must be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nursery. When they are transplanted into the places where they are to remain, the necessary care to be taken is, in taking them up, not to injure or cut off their roots, and to let them be as little time out of the ground as possible *

An Explanation of Fruits.

Plate 2.

and while they are out, to guard their roots from the drying wind. The (urn time lor removing (felt trees is about the beginning of April; for though they may be, and often are, removed with success in Midwinter, yet the spring is the most sure season, especially in moist land.

Most of the kinds of Firs may be r^movKi! at the height of six or seven feet, but those of two feet high are much better to transplant, and will in a few years gain the ascendancy of taller trees: I would not, therefore, advise the transplanting of these trees when they are much above two feet high, especially if they have stood in the nursery untransplanted. For they, their root... will have extended themselves to a distance, and when great impediments are in taking them out of the ground; and when either lotheroorv or branches of these trees, the quantity of sap which com... which com... nearly issues from these wounds, will greatly weaken the trees. There is another advantage also in planting them when small, which is that of not requiring staking to secure them from being blown down by strong winds, which in tall trees is a gprar trouble at nqsei. And whoever will give them...

...and the trouble so observe, how much trees of two feet high exceed in growth those which are removed at a much greater height, will, I am sure, be convinced of the truth of what is here said.

The common Spruce Fir is what affords the white deal. The trees grow in the deep strong hills of Norway and Denmark, but will grow likewise in almost any soil or situation in England, provided it be not within the reach of the smoke of great cities, which is very injurious to all these sorts of trees, nor do they thrive not so well in damp land, as in fresh uncultivated lands. The difference these trees have been under for some years past, has been chiefly owing to their being planted too close to each other, or in too near other trees, whereby the air has been excluded from their branches, which has occasioned most of their under branches to decay; so that when viewed from the ground under these branches, they have a greater appearance of dead than living trees. But when they have been allowed a good distance, and planted in a strong fresh soil, they have had their branches quite feathered within six or eight feet of the ground, and that too in trees upward of forty feet high; therefore should not be planted nearer than twelve feet apart, nor should they be so near, when the plantation is more than three rows deep. In this case, eighteen or twenty feet consider will be full near enough, especially when the trees are designed to have their branches feathered near the ground, in which case of the beauties of these trees consist.

The Silver Fir requires a stronger land than the Spruce, for it grows in dry ground, and makes any great progress; and many times, even after they have arrived to a considerable size, are destroyed by very ill-contrived winds, when the soil is either too wet, or too dry. But when they are planted in a proper soil, they grow to a very large size, and are extremely beautiful, having the under side of their leaves white, and the upper side of a dark green color.

The last of Fir, however, is frequently injured by frosts, when they happen late in the spring, especially while the plants are young. For when these are planted in a warm situation, they are apt to shoot pretty early, and if by sharp frosts happen after they have issued, the young shoots are killed; but when they have had a year's growth, and are rendered very indurately, that many times they bear the winter out, and are thrown away. In cold situations, however, where they do not begin to shoot so early, they are not subject to this disaster; and, in many such places, these trees grow to a large size, and have their beauty. I have sometimes seen some fine trees of this sort of Fir, which grew upon natural heath, where, by extending their roots, they had drained the ground to a considerable distance round them. There were some trees of this kind lately growing in England, upwards of sixty feet high.

The method of raising the other sorts of Firs.

Aboi: the latter end of March, or the beginning of April (according to the forwardness of the season, by which every person must be guided) prepare a very moderate bed, in length proportional to the quantity of seeds to be sown, and where there are frames which can be spared for this purpose, these may be placed upon the bed; but where these are wanting, the bed should be covered over with hoops, that they may be covered with mats or canvas, then plunge the bed full of small pots, such as are commonly sold about London for four shillings and two pence per hundred. These pots should be filled with light unenriched earth,

and slices between the pots may be filled up with any other earth which is nearest to the place; then sow the seeds in these pots, covering them about half an inch with the same light earth. In drying winds the bed should be covered, to prevent the earth from being blown away; but should the seeds have too much wet, which would be equally injurious to them; therefore the earth should be last taken watered, and it must never be given in great quantities. When there is any appearance of frost at night, the bed should also be covered. With this management the plants will appear in five or six weeks time, when they must be carefully guarded from birds, as was before directed for the common sorts, and also freed from the fire in the middle of the day; but they must now have fresh air admitted to them at all times when the weather will permit. They may also be allowed to receive any gentle showers of rain, but they should not have too great plenty of moisture, which will frequently rot the young plants, and cause them to drop. Upon the judicious care of this, depends the whole success; for I have seen great numbers of these plants destroyed in one day, by being either too much watered, or by being exposed to too much wet.

It may, perhaps, seem strange to many, that I should direct the sowing the seeds of these trees which are so very hard upon a hot bed; but from many trials I have always found they have succeeded much better this way than any other, for the gentle warmth of the bed will not only cause the seeds to vegetate much sooner than they would naturally do in the cold ground, but the plants will also rise much stronger, and, consequently, be in less danger of rotting in their infancy. And as the warmth of the bed is only to bring up the plants, so there should be but little dung employed in making it; for after the plants are up, they must be treated as the common sorts, and treated as handsly as the common sorts.

Tjxre 1 may be others, perhaps, who will object to the directions given for sowing the seeds in such small pots, because, where there is any quantity of the seeds, it is usual to sow them in boxes, or large pots; but I can from many years experience aver, that most sorts of seeds succeed better when sown in small pots, than in boxes, or larger ones, and I therefore recommend this practice.

As the seeds of the Hemlock Fir will frequently remain in the ground four or five months, the pots, in which they are sown, should not be disturbed, if the plants come not up so soon as may be expected, for whilst upon stirring the ground, the seeds are found to be decayed, there may be hopes of their growing the second spring, for I have sometimes had the seeds remain a whole year in the ground, and afterwards come up very well; but, therefore, it gives us prevent the pots from being too huddled together.

The plants of these sorts of Fir must be treated in the same way as the common sorts, with this difference only, that they ought to be transplanted into a more shady situation and richer soil. For while the plants are young, they will not thrive if they are exposed to the sun, or in a dry soil; but when

when they are grown to a considerable size, they may be exposed to the sun, and in a dry soil, but when they are young, they will not thrive if they are exposed to the sun, or in a dry soil; but when

...] they have obtained [trength, they will bear tu-
 opcl l'uj very well, and in a moill toil will BUtk
 great progrri⁸; whercis in dry ground they frequent-
 ly Itinc, and produce plenty <i' male flowers and cones,

These trees are easily propagated by fowing their seeds, which fhould be done soon after th' v are ripe, in J be of common earth, covering them about ihalf an inch thick with light mould. The fpring following they will appear above ground, and, if kept clear from weeds, fome of the forts will grow above a foot high

the first fujnme. Tin: wOOWB following (if they arc CICJE in the feedrbed) it will be proper to trim-plant them in: o a nurlery, in rows a; threeSHI ditbutce, and two fecM&mdw in the rows; In which place they fray remain ibvte or luir War?, by which time they vili be large ciough to ptaniout for good.

If the seeds of any of the forts of Mapie are kept out of the ground L21 fpring, they rardy come up die fame year. . nfiny tkiusdo r^i grow; fo thai the iu re It method erf railing them is, to low the feeds a^ibonaa .b; when they are ripci and, if the feeds are to be tranfponed to^any diltant:, it will be proper to pot them^up inland, or cauls, whereby tlicir growing i^iall;v will be preferred.

The first and fourth forts arc very proper to make plantations near the leu, or to iclcler fuch plixntatiuns of trees a, arc too neatly Glutted thereto. For both theft fora thrive, and icfilbthc ipray, which is ufually blown from the fe.i, better thui molt other trees do. Tlic variegated foix a allb riifed from feeds of the In me kind; iind moft of the plants fo raifuii will be aa finely friped as die old plant from whence the feed* were uiktn, which is not common to many other va-ritgittd plants.

The common Miple is too well known to need any particular account, it growing, very frequenly, in hedge-rows in moft paru of England. It is raikd in the fame manner with the former.

The Virginian flowering Maple was raikd from feeds, which were brought from Virginia many years fince by Mr. John Tradefcant, in his garden at South I. in-ibrth, near Vauxhall, and fince, in the gardens or^ the Bifhop of London, at Kulham, where the ores have flowered tor (veral years, and produced ripe feeds, from which (even] trws have bwn raifed. It rmay be allo propagated by laying down the young brandies early in the fpring, giving them a little flit at a joint, by which means they will hart tken fvjticitnt root in tvo years, to be tranfphtned eUeffheie. They require a fixation a lit^c defended trwn the north-eaft winds, cfpecially while young-, and delight in a inoif light foil, in which they thrive much better than in a dry ground, and will produce more flowers, and better teed]. This tree commonly Havers in the beginning of April, and ihe feeds arc ripe in live or fix weeks

it'u . at rime tin.^ Cmüid be Gwedi fm ihrr arc very apt to periff, if kept long out of Uir (round. There is another variesy of the flowering Maplr, wlicli waa fent from America to Sir Cl; . . . and flouriffed feveral yrara in hb garden at Parfons-green, near ^ulham. This is by the gardeners tided Sir Charles Wager's flowering Maple. The flowen of this kind come out in large cluters, and iirround the .outig^r branches, fa as to iappear ^v taiu . . . It is now bctoint pretty cd&nbnon in fime uf tin- niiftries near Londun, fa that the former lbrt » not (a murh eikemed, being le& btautifitil i but it is doubifitJ if dtey are Jii'- tintft fpi.'^

The Afti-leaved Maple is a very ftrong (liootii: tree, and is, in Virginia, onv of the largrl] tci-M <d this kind, it mult be planted in places not too much expoftd to vioicnt winds, being fuhjeit to fplit thereby. Thus trte ripens feeds very wdFin EngSind, by which mean* it is talily proppted, or by cuttings planted in aurutmi.

The Norway Maple has a milky Iharp juice, lb that few infects care to prey theregn,^ by which means the ICJVCJ ;irr lrlrdom enen or tkfecct; and being fmooh, and of a Drinuig grwn, they hire a much be: . . . inclLhon thole of the Svcaimore; andin the fprinjj, the HoweH arc our, have great beauty. This tr« is jfo raifrd by . . . of which it :iHrds great quantities,*^hiti . . . and grow from the > iticed lecch 3B well n the coimn- : . . . will alfo grov, . . . are plantrd in rhr aity . . .

I

The variegated kind may alfi b . . . (lailarin; a bud of the friped ki . . . at prefent jure whether it . . . Maple, not taving

made the experiment; but I bdiervt it canfcirce fail. Maft, if not all tlic other forts of M.tplcs, take very well upon each other.

The American Sugar Mapte haa fome (cfemblance so the Norway, when the plants are youngs but as thry grow up the leaves .in: more deeply divided, and their iUtraces lei's fmaoth, io that they are then eafdy dilhu- gLiffhd. From thif. tree the itdutntanrj of Noi America mnkc a very good fort of fiig.;: in large quantities, by tapping the trees rarly in the ;: . . . and boiling the juke, which drawn out till the i.-. file.tsthefu^aTibut I am of Tapinion, that the people make lugar irom mure ilian one fort of Maple in AmericaTibr l h^ive found that the Alh-leaved Maple abounds with a faciharinc juice, in full p great pinny a3 any other fort. Mi, Ray and Dr. Lifter, pr^psn a tolerable good lbrt of fugar from our greater M.ipj by i: 'piling iiume Ol the tree* in their bleeding fral'n; and I have obfcnn . . . ntlics from

the lcailet Maple in February, » ereit quantity of a very fweet juice h^rh [lowed out Tbr fevetuL days i-j- gnuet.

The eighth fort of Maple is very common in mott parts of Italy, but particularly about Rome^ vl . . . ts one of the tinwft attt ot tint country, and i . . . effected for the tize of the b . . . Ba larj afbi-diflg a great flarlc; fo thai thefe trees, arc l . . . qucmly planted by the fides of roads, and ncir ha! . . . In England this tree is very rarely to be rite . . . hough it is hirtiyenough to bear the oprn air; but as the letds have not been brought over to Eng- Utid till litL-ly, there arc no huge pLints in the Eng* lifh garden) at PK . . .

The ninth fort is common in the fouth of France and ILAD); the leave) of this it faabk thole of the cotr . . . Maple, but art of s much thicker fitbltance, and not lo large, but are nt i iKiniirg green colour. They continue in verdure very late in the autumn, « . . . renders the trees- mort vituable. At prefent, this Ion: is not common in England. l raifed fevral plants trom fredt, fome of which have forievcral y . . . duced goi>-: . . . Chelfca garden, »' . . . im the fcattered fecdi the plants conic up . . . in plenty.

I he tenth fort hath fome rcfcmbance . . . niniii. The leaves of this lbrt are of a much tujinei . . . ture, and their fooi-(talks arc corrded witi a feft hiiry down, whert-i- dbove of the other arc fmooth and filf. This lbrt grows naturally in the Lev . . . M<>^ of the forts of M.iplc which come from Ame- rica, are very imj . . . of heat while young, their feeds therefore fhould be fown in ^ QjlttTed fauation, for if the plants are expofed to the full fun but one day, when they firft . . . fj Kir, few of thm wilt fi . . . it; but elpcicfally the Sugar Maple, of whkli Ion I . . . indy lolt mult of the plants 6U I had die pre- caution lo place the poti, in which xht feeds were fawn, entirely in the ttiide(for nu Conner ait they expoiectoti . . . but they are immediately attacked In- inftfte, whkh in one day will devour their feed leaves, after which the plants fudienly drop to the ground. This precaution thei . . . -ffarytobe ubfrvrd, in mfang Eiofi of ihe foru or Maple from feeds.

The timber of Uic comrnron I Maple is fa . . . (ipierior to the Beech for alt ufo of the turner, piuii;ularlydillir?, CAips.trnchen, and bowl;- andwhrm it aboundswith knots (as it very often doth), it is highly effected by the jowen for tuberyng, &c. and alfo for the light- nefs of the wood, is often employed by thofe that make medical inftruments; and for the whitenefs of its wood, it was formerly in great requeft for tables, &c. ACETOSA (of acetum, L. ennet, fmc.) The Sorrel is by Dr. Linnæus named . . . ro the gram of Dock, undt i . . . it ii alftlie known fpt- ces of Sorrel, have m . . . c flower; growing upilc, therefore by hii mrthod fhould be ranged in his twenty-f . . . mdcUh tided Dt- cember; therefore I have called the liberty to . . . | arate thofe from the Dock, rather to preferve their old title,

as the plants have been, long ufc. I both in the kitchen and thopa.

White Maudlin.
The first sort here enumerated, is the common Yarrow or Milfoil, which grows naturally on banks and by the sides of foot-paths in most parts of England, so is rarely allowed a place in gardens, but being an officinal plant, it is here mentioned to introduce the others. Of this there is a variety with purple flowers, which is frequently found wild in England, but the plants seldom continue to produce purple flowers long, when they are transplanted into gardens. The Yarrow creeps greatly by its roots, and also multiplies by seeds, so that it becomes a troublesome weed, where it is permitted to grow.

The third sort is often planted in gardens for the sake of variety. This is of humble growth, seldom rising more than eight or nine inches high. The leaves are finely cut, and are very hoary, the flowers are of a bright yellow colour, and continue long in beauty. It grows naturally in the south of France, Spain, and Italy, but will live in the open air in England. It is increased by parting of the roots, the best time for which is in October.

The fourth, fifth, seventh, and ninth sorts, are natives in the islands of the Archipelago. These were introduced into France by Dr. Tournefort. The ninth sort hath very hoary leaves, which remain all the year, and the plants growing close and low, make a pretty appearance at all seasons. The flowers are produced in umbels on the top of the stalks, which are yellow, these appear in June, July, August, and September, and are of long duration, so that frequently some of them continue the greater part of the winter. This sort must have a dry soil and a warm situation, where it will endure the cold of our ordinary winters in the open air, but in very severe frost they are often destroyed, a few plants therefore ought to be tied under a frame in winter, to preserve the kind. It is propagated by slips, which may be taken off and planted in a shady border, any time in summer, when they will take root in about six weeks, and then may be transplanted either into pots, or the borders where they are to remain. This sort rarely perfects its seeds in England.

The fourth, fifth, and seventh sorts, are of taller growth, propagating by their roots, and ripening seeds in England, so that they may be obtained in plenty, and as they require little care to cultivate them, being hardy enough to live in the open air, they may be allowed a place in gardens, where, by their hoary leaves, they will make a pretty diversity; and their flowers continuing long, though not the most beautiful, yet make a pretty contrail when intermixed with others.

The sixth sort is a very humble plant; the foot-stalks which support the umbels of its flowers, rarely rise above six inches high. As for the flowers themselves, they are near as large as those of the common Sneezwort, white, and growing in flat umbels; these appear in June and July. The leaves of the plant have some likeness to those of the common Wormwood, and are very hoary, growing close to the ground, decaying in autumn, so that in winter they make little appearance. This species of Yarrow is propagated by parting of the roots, either in spring or autumn, and should have a dry soil, for much wet in winter will rot them. It never perfects its seeds here, and therefore can only be multiplied the other way. This sort is a native of the Alps.

The eighth sort is commonly known by the title of Sweet Maudlin in the markets, it was formerly more used in medicine than at present, so that there is scarce

any of it cultivated in the gardens for sale; and when it is asked for, the people in the markets commonly give the fourteenth sort for it, which being a very hardy plant, and easily propagated, is now generally sold for the other. For though the true Maudlin is hardy in respect to cold, yet in wet winters the roots are often killed by moisture, especially those which are in good ground, but when the plants grow out of the joints of walls, or in rubbish, they will live many years without care. There are two other varieties of this plant which are found growing naturally in Spain, one of them having longer and more compact umbels of flowers, and the other hath broader leaves and smaller flowers, but these approaching so near to the common sort in every other particular, I thought it would be needless to enumerate them as distinct species. The common Maudlin is propagated by parting of the roots, either in spring or autumn, and as it ripens seeds very well, so it may be propagated by sowing the seeds in April. It flowers in June and July, and the seeds are ripe in September.

The tenth sort is the common Sneezwort; this grows wild in the woods and other shady places, in many parts of England, so is not admitted into gardens; this creeps greatly by its roots, so as to cover a large spot of ground soon. It is sometimes used in medicine, and in the spring the young tender shoots are put into salads, to correct the coldness of other herbs; and the roots are used for the tooth-ach, whence some have given the title of Field Pellitory to this plant. There is a variety of this with double flowers, which is preferred in gardens, and is commonly known by the title of double Maudlin. When this is planted in pots, so as to confine the roots from creeping, the stalks will grow closer together, and then they make a tolerable appearance when in flower; but where the roots have full liberty to run, the stalks grow farther distant from one another, in which case they make but an indifferent appearance. It flowers in July and August.

The fourteenth sort has some resemblance to the tenth, but the leaves are longer, deeper cut on their edges, and are of a darker green colour. This propagates fast enough by its creeping root and is very hardy.

The eleventh and twelfth sorts are natives of the Alps, and consequently very hardy, they multiply by seeds, and also by parting of their roots, and will thrive in almost any soil, but love an open exposure. The eleventh produces many stalks which rise near three feet high, having loose branching umbels of white flowers on their top, resembling those of the common Sneezwort, but larger. The twelfth sort hath hoary leaves, and the umbels of its flowers are more compact, the stalks of this do not rise more than a foot high. Both these deserve a place in gardens.

The thirteenth sort approaches near the first, but the leaves are of a pale green, and not so long, or so much cut as those of the first, and these have a strong sweet scent when bruised. It is equally hardy with the first, and therefore requires little culture.

poisonous. This is by some writers titled Anthora, and by others Antithora, as the poisonous kinds have been called Thora. Whenever therefore any of the species of this genus is ordered in medicine, this is the sort intended.

Most, if not all the other sorts are "steemed poisonous", but those with blue flowers are supposed to be of a much stronger quality, than the yellow or white flowered kinds. It is confidently affirmed, that the hunters on the Alps, who hunt the wolves and other wild animals, dip their arrows into the juice of these plants, which renders the wounds made by them deadly. The first sort is the first which flowers, this grows near four feet high, and the spikes of flowers are upward of two feet long, so that when it is in flower, it makes a pretty appearance; and being very hardy, growing in any soil or situation, and multiplying greatly by the root, has induced many persons to allow it a place in their gardens, for the sake of its flowers, who being ignorant of its dangerous qualities, have permitted it to spread and propagate greatly. It flowers in May and June. The seeds are ripe in September, but as this sort multiplies so greatly by the root, it is rarely propagated the other way.

The first and second sorts are the next which flower; these come about the middle of June, and if the season is not warm, will continue in flower till August. The first grows upwards of three feet high, and the second above four, the spikes of flowers too in this being much longer than the former.

The third sort flowers a little later than either of these, but seldom grows more than two feet high, and the spikes of flowers are much shorter than either of the two last.

The wholesome Wolfsbane flowers in the middle of August, and often continues in beauty till the middle of September, the flowers are not so large as those of some other sorts, but being of a sulphur colour, make a pretty appearance in the borders of the flower-garden. This sort will not thrive so well under the shade of trees as many of the other sorts, and therefore must have an open exposure.

The ninth and tenth sorts flower the beginning of July. The ninth usually grows about four feet high, but the tenth I have seen upwards of six. This sort is at present very rare in Europe. It was found by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris, where it was first cultivated in Europe, and from that garden, others have been furnished with the seeds.

The eighth sort flowers in July. This grows about four feet high, having a long spike of yellow flowers of a middling size, wherefore they may be allowed a place among shrubs, or in such parts of the garden as are not frequented by children.

The fifth, sixth, and seventh sorts flower in August, when they make a pretty appearance; and were it not for their noxious quality, would deserve a place in every garden. There are two or three varieties of the fifth sort, one with white, another with rose coloured, and a third with variegated flowers; but these are only varieties which often change. The *Napellus minor* is also apt to change in the colour of its flower, of this sort I have had some plants with variegated flowers, but they changed in two years and became plain, nor did their seeds produce any plants with variegated flowers. The seventh sort will grow to the height of five feet in good ground, the flowers are very large, but not many upon each spike. These are of a deep blue colour.

All the sorts of Monkhood may be propagated by seeds, which should be sown in the autumn, in a shady situation: the plants often come up the first year, if the seeds are sown in autumn, otherwise it is the second spring before they appear, therefore the ground should be kept clean from weeds all the following summer, and when the plants come up, they should be watered in dry weather until they are fit to transplant, when they are to be carefully taken up, and planted in shady borders, at the distance of four

inches each way, observing to water them until they have taken good root in the ground; after which time they will require no other care but to keep them clean from weeds, till the following autumn, when they may be transplanted to the places where they are to remain.

The common Monkhood will grow under the shade of trees, in wilderness or woods, and will increase fast enough by means of its creeping roots; but the most of the other sorts delight in shade, yet few of them will thrive under trees, for which reason they should be planted in shady borders which are not overhung by trees, where they will continue much longer in flower, and thrive better than in an open exposure.

A C O N I T U M H Y E M A L E . See HELLEBORUS.
A C O R U S , the Sweet Rush.

The CHARACTERS are,
It hath a simple cylindrical stalk, which is closely covered with small flowers, so as to form a sort of catkin (or iulus). These flowers have no empalement, but are composed of six concave obtuse petals. In the center of the flower is situated a swelling germen, attended by six stamina, which are extended beyond the petals, and are crowned with thick double funnels; the germen afterward turns to a short triangular capsule, having three cells, in which are lodged oval oblong seeds.

Dr. Linnaeus ranges this genus in his sixth class of plants, entitled Hexandria monogynia, the flowers having six stamina and one style.

We have but one SPECIES of this plant,
A C O R U S (*Calamus*) Roy. Leyd. 6. *The sweet smelling Flag or Calamus.* *Acorus verus*, five *calamus aromaticus*. C. B. P. 34.

This plant grows naturally in standing waters which are shallow, and is found wild in some parts of England; particularly in Norfolk, and also near Uxbridge in Middlesex, and in several parts of the north. In Holland this plant abounds in most of their ditches and standing waters. The leaves of this plant, when broken, lend forth a strong aromatic scent; the roots are much stronger, and have been long used in medicine. This may be transplanted into a garden, where if the ground is moist it will grow very well; but never produces its spike, unless it grows in the water. It loves an open situation, and will not thrive well under the shade of trees. The spikes of flowers (which are by many writers termed (Juli) appear toward the latter end of June, and continue till August. When this plant is fixed in a proper situation, it will multiply by its creeping roots fast enough.

A C R I V I O L A . See TROP/BOLUM.
A C T J E A , Herb Christopher.

The CHARACTERS are,
The empalement of the flower is composed of four concave obtuse leaves which fall off; the flower hath four petals which are much larger than the empalement. In the center is placed the oval germen, crowned with an oblique depressed stigma, attended by numerous slender stamina, crowned with erect double roundish funnels. After the flower is past, the germen becomes an oval or globular berry having one cell, in which are lodged four seeds, which are roundish on their outside, but angular where they are joined.

Dr. Linnaeus ranges this genus under his thirteenth class of plants, entitled Polyandria monogynia, the flowers having many stamina and one germen.

The SPECIES are,
1. *ACTIEA (Spicata) racemo ovato fructibusque baccatis.* Lin. Sp. Plant. 504. *Common Herb Christopher, or Bane Berries.* *Christophoriana vulgaris nostras racemosa & ramosa.* Mor. Hist. p. 2, 8.
2. *ACTIEA (Alba) racemo ovato baccis niveis, radice tuberosa.* *American Herb Christopher', with white berries.* *Christophoriana Americana baccis niveis.* Mor. Hist. p. 28.
3. *ACTIEA (Racemosa) racemis longissimis fructibus uncapularibus.* Lin. Sp. PL 504. *American black or wild Snakeroot.* *Christophoriana Americana procerior & Ion-giCs spicaria.* Hort. Elth. 79.

The first sort grows naturally in several places in the northern counties of England: I found it in pretty great

great plenty in a wood near Kirby Lonfdale, as also near Ingleborough Hill in Yorkfliire. It grows two feet and a half high, the foot-ftalks of the leaves arise from the root, these divide into three smaller foot-ftalks, each of which divide again into three, and these have each three lobes, so that each leaf is composed of twenty-seven lobes (or small leaves). The flower-stem which arises from the root, is garnished with leaves of the same form, but are smaller. On the top of the stalk appears the flowers, which grow in ramose spikes, and are of a pure white; these come out in May, and are succeeded by black shining berries about the size of Pease, which ripen in the autumn. This is propagated by seeds, which should be sown soon after they are ripe, for if they are kept out of the ground till spring, the plants will not come up till the year after, so that a whole year will be lost. They should be sown on a shady border, and kept clear from weeds. As the seeds seldom come up all at the same time, the border in which they are sown should not be disturbed till the following autumn, to see what plants may appear, when the plants should be transplanted into a shady border, where they may remain to flower. This plant hath a perennial root, which lasts many years, but the stalk is annual, and perishes in autumn, soon after which is the best time to transplant them.

The second sort grows naturally in North America, from whence I have received the seeds, the leaves of this are somewhat like those of the first sort, but are not so deeply indented on their edges. The flowers grow in a more compact spike, and the berries are very white and transparent when ripe; the roots of this is composed of thick tubers, or knobs. This is an abiding plant, and delights in a light moist soil, and a shady situation \ it may be propagated in the same manner as the former.

The third sort is a native of North America, where it is called Black Snakeroot, to distinguish it from the common Snakeroot. This plant hath large compound leaves, which rise immediately from the root, and are branched after the same manner as the first sort, which grow more than two feet high. The flower-stems frequently rise to the height of four or five feet, being terminated by a long spike of white flowers, which is reflexed at the top. This flowers in June, or beginning of July, but does not perfect seeds in England. During the time of its flowering, the plant makes a good appearance in a garden, and therefore deserves a place in the shady borders, or among shrubs; where, if it be not over-hung by them, it thrives very well, and being hardy, will require no other care than the shrubs themselves. It is generally propagated by seeds, which are annually sent from North America; it loves a moist light soil, and a shady situation.

The root of this plant is greatly used by apothecaries and physicians in America, in many disorders, and is supposed to be an antidote against poison, or the biting of the rattle-snake.

ADANSONIA, Ethiopian four Gourd, or Monkies Bread.

This plant is so named from one Mr. Adanson, a French surgeon, who resided some years at Senegal, in Africa, and during that time made several discoveries in natural history, and brought home a curious collection of seeds and plants.

The CHARACTERS are,

It hath a cup-shaped empalement, divided into five segments at the brim which turn backward, and the empalement falls off: the flower has five roundish petals, whose brims are reflexed; at the tail of these are situated many stamina joined in a tube, which spread horizontally above, and are crowned by kidney-shaped funnels. The germen, is oval, the styles are long and variously intorted, having many hairy stigmas. It hath a large ovalligenous capsul often cells filled with a farinaceous four pulp, inclosing many kidney-shaped seeds.

This genus of plants is ranged in the fifth section of Linnaeus's sixteenth class, intitled Monodelphia polyandria, the flowers having many styles which coalesce with the stamina in one house.

There is known but one SPECIES at present, ADANSONIA. This is the Baobab. Alp. Egypt. c. 27. f. 28. The young plants, and also most of the new branches, have single spear-shaped leaves towards their lower part, but at their extremities the leaves have some three, and others five lobes, of the same size and form as the lower, which are disposed like a hand; these are entire, ending in a point, and fall off in winter. The stems are large and woody, but of a soft texture, and have generally a large swelling near the root.

It is propagated by seeds, which must be procured from the country where it grows naturally (for it doth not produce any in Europe); these must be sown in pots, and plunged into a hot-bed, where, in about six weeks, the plants will come up, and in a short time after be fit to transplant, when they should be each planted into a separate pot, filled with light sandy earth, and plunged into a fresh hot-bed, observing to shade them until they have taken new root, after which time they should have free air admitted to them every day in warm weather, but must be sparingly watered, for as their stems are soft (specially when young) too much wet will cause them to rot. As the plants advance in their growth, they are to be shifted into larger pots, but must constantly be plunged into the bark-bed, being too tender to thrive in this country without this artificial heat, therefore they must constantly remain in the stove with other tender exotic plants: the plants when young make great progress in their growth, where they are properly treated; for in three years many of them have been more than six feet high, and have put out several lateral branches, their stems were also proportionable, but after four or five years growth, they are almost at a stand, their annual shoots rarely exceeding two or three inches.

The account which Monsieur Adanson gives of the trees he saw at Senegal and other parts of Africa, in regard to the size of them is amazing, several of which he measured round their stems from sixty-five to seventy feet in circumference, but their height was not extraordinary. The trunks of these trees were from eight to twelve feet high, dividing into many horizontal branches which touched the ground at their extremities, these were from forty-five to fifty-five feet long, and were so large in circumference, that each branch was equal to a monstrous tree in Europe; and where the water of a neighbouring river had washed away the earth, so as to leave the roots of one of these trees bare and open to sight, they measured one hundred and ten feet long, without including those parts of the roots which remained covered with earth or sand: for he describes the plains where the trees grow to be a barren moveable sand, so that from its being continually stirred by the winds, there are no traces discoverable, whereby persons can be guided in travelling over them.

Prosper Alpinus in his history of Egyptian plants, describes this tree, to which he gives the title of Baobab, so that it also grows in that country, but he does not mention any of them to be near the size of those described by Monsieur Adanson.

There were some plants of this sort in several gardens, which were raised from seeds obtained from Grand Cairo in the year 1724, by the late Dr. William Sherard, some of which were grown to the height of eighteen feet* but in the severe winter 1740, they were all lost, and since that time there has not been any of the seeds brought to England, till the return of Mr. Adanson to Paris in 1754, who sent some of the seeds over here, which have succeeded, and many of the plants are now upwards of eight feet high.

ADELIA, we have no Ertu title for this genus of plants.

The CHARACTERS are,

It hath male and female flowers upon different roots: the male flowers have an empalement of one leaf cut into five concave segments, but no corolla \ it hath many kidney-shaped stamens the length of the empalement, crowned by roundish funnels. The female flowers have a five leaved concave empalement which is permanent \ they have no corolla, but

A D E

et roUndifhgermenwith three Jhort divaricated flyles, and torn ftigma. The capfule bath three cells, each containing one roundijh feed.

This genus of plants, is ranged by Dr. Linnaeus, in the twelfth fection of his twenty-fecond clafs, which includes thofe which have male flowers on diftindt plants from the female, whofeftamina joinat their bafe.

The SPECIES are,

1. ADELIA (*Bernardia*) foliis- oblongis tomentofis ferratis. Lin. Sp. Plant. 1473. *Adelia with oblongs woolly* lawed leaves.*
2. ADELIA (*Ricinella*) foliis obovatis integerrimis. Lin. Sp. Plant. 1473. *Adelia, with oval entire leaves.*
3. ADELIA (*Acidotori*) ramis flexuofis, fpinis gemmaceis. Amcen. Acad. 5. 411. *Adelia with flexible branches and prickly gems.*

Thefe plants grow naturally in the ifland of Jamaica, and are near a-kin to the Ricinus, or Croton, but the male flowers growing upon different plants from the female, has occasioned their being ranged in a different clafs. Dr. Houftoun confituted a genus, of them by the title of *Bernardia*, in honour to Dr. Bernard de Juffieu, demonftrator of plants in the royal garden at Paris 5 but Dr. Linnaeus has fixed the title of *Adelia* to them. The plants are propagated by feeds, when thefe can be procured from the countries where they grow, for they do not produce good feeds in England. The feeds muft be ibwn upon a hot-bed in the foring, and when the plants are fit to remove, they fhould be each tranfplanted into a fe>arate fmall pot, filled with light earth, and plunged into a hot-bed of tan, treating them in the fame manner as is hereafter directed for Croton. In the autumn, the pots fhould be plunged into the tan-bed in the ftove, where, if they are-kept in a temperate heat in winter, and not over-watered daring that feafon, the plants may be preferred, and the fummer following will produce flowers; but as thefe have little beauty, the plants are feldom propagated except in botanic gardens.

A DENANTHERA. Prod. Leyd. 462. *Baftard Flower-fence.*

The CHARACTERS are,

The empalement of the flower is of one leaf, lightly cut into five at the top; the flower is of the bell-fhaped kind, and is compofed of five petals, which are reflexed and concave on their under fide. In the center is fitted an oblong germen, fupporting a fyle crowned with a fingle ftigma \ this is attended by ten ereff ftamina of the fame length, which are crowned with roundijh fummits; after the flower is paf, the germen becomes a long comprreffed pod, containing many convex fsmooth feeds, placed at a dijfance from each other.

Dr. Linnreus ranges this genus of plants in the firft fection of his tenth clafs, entitled *Decandria monogynia*, the flowers having ten ftamina and one germen; but he feparates it from the *Poinciana*, becaufe the petals of the flower are equal, and the empalement is of one leaf, whereas the *Poinciana* hath a five leaved empalement, and the petals are unequal.

A DENANTHERA foliis decompofitis. Prod. Leyd. 462. *Baftard Flower-fence with decompounded leaves.*

There is another fpecies, or at leaft a variety of this kind, with fcarlet feeds, which is at prefent rare in this country. I received the feeds of it from India, from which many plants have been raifed, but they are of very flow growth in England.

The fort here mentioned grows to a very large tree in its native country, but it is fo tender as to require a ftove to preferve it through the winter in England, fo that there are no large plants in the Englifh gardens at prefent *, the young plants which are not more than two feet high, have large branching leaves, compofed of many equal divifions, garnifhed with fmall oval leaves, which are placed alternately on the midrib, and are of a bright green colour. The items of the plants are woody, the bark of a brown colour, and the leaves continue all the year-, but I have not feen any flowers produced in England as yet, but by fome dried famples which were brought from India, they

A D O

feem to be/mall, and of little beauty *, the fine branching leaves of the plant, however, make a very handsome appearance in the ftove. The feeds are of a fhining black colour, and are fomewhat larger than thofe of the great Lentil, and nearly of the fame ftape. This plant muft be raifed on a hot-bed, and afterwards placed in the bark-ftove with other tender exotics.

A D H A T O D A. See JUSTICJA.

A D I A N T H U M, i. e. Maidenhair.

The CHARACTERS are,

This genus is diftinguihed from the other capillary plants by the fruification, being confufedly joined in ovalfpots, and the points of the leaves reflexed.

The SPECIES are,

1. ADIANTHUM (*Capillus Veneris*) frondibus decompofitis foliis alternis pinnis cuneiformibus lobatis pedicellatis. Lin. Sp. Plant. 1096. *The true Maidenhair. Adiantum foliis Coriandri. C. B. P. 356.*
2. ADIANTHUM (*Pedatum*) frondibus pedata foliolis pinnatis pinnis antice gibbis incifis fru&ificantibus. Lin. Sp. Plant. 1095. *American Maidenhair. Adiantum Americanum. Corn. Canad. 7. tab. 6.*
3. ADIANTHUM (*Trapeziforme*) frondibus fupradecompofitis foliolis alternis, pinnis rhombeis incifis utrinque fru&ificationibus. Lin. Sp. Plant. 1097. *The largeft black American Maidenhair with branching ftalks, and leaves Jhaped like the figure of a rhombus.*

There are many fpecies of this genus, which are natives of the Eaft and Weft-Indies, greatly differing in fize and form from each other. I have upwards of thirty diftindt fpecies in my collection of dried plants, which to enumerate in this place, would be fuperfluous, as they have not been introduced into the Englifh gardens. The three forts here mentioned, are all that I have feen growing in England.

The firft fort is the true Maidenhair, which is dire&ed to be ufed in medicine; but as it does not grow naturally in England, fo the *Trichomanes* is ufually fubftituted for it, which grows in great plenty in feveral parts of England. The other is a native of the fourth of France, Italy, and the Levant, from whence I have received the plants. It ufually grown Out of the joints of walls, and the fiffures of rocks, fo that whoever is inclinable to keep this plant in their gardens, fhould plant it in pots filled with gravel and lime rubbifh, in which it will thrive much better than in good earth -, but the pots muft be fheltered under a frame in winter, otherwife the plants are often killed by the froft.

The fecond fort is often preferred in gardens for the fake of variety; this may be preferred in pots, and treated in the fame manner as the former *, for altho* it will live through the winter in the open air in moderate feafons, yet in fevere froft it is fometimes deftroyed. This grows naturally in Canada in fuch quantities, that the French fend it from thence in package for other goods, and the apothecaries at Paris ufe it ?or the Maidenhair, in all their compofitions in which that is ordered.

The third fort grows naturally in very warm¹ countries *, I received it from Jamaica in a tub of earth among other plants. This fort will not thrive in England, unlfs it be preferred in a ftove, where its fhining black ftalks and odd fhaped leaves will afford an agreeable variety among other exotic plants.

A D N A T A, A D N E S C E N T I A, are thofe off-fets, or fmall bulbs, which are produced from the roots of bulbous plants, and are clofely connected to the parent root; of this fort is the *Narciffus*, *Amaryllis*, *Panocratium*, &c.

A D O N I D I S H O R T I, i. e. the gardens of Adonis, æ? plants, flowers, &c. in pots or cafes, fet on the outside of windows, in balconies, &c.

A D O N I S, or FLOS ADONIS, Bird's-eye, or PheafantVeye.

This genus is by Dr. Linnaeus ranged in the seventh section of his thirteenth class, entitled Polyandra Polyandria, the flowtri having many stamens and many gmrattt.

The S... 1. Adonis (Adonis) vernalis octopetala fructibus cylindricis Hort. Upsal. 16. ... mmsit A&rncjt

2. ... Adonis vernalis fructibus ovatis. Annual Adonis with pale yellow flowers. Adonis vernalis flore lutea foliis longioribus. C. B. l. 178.

3 APOV (Fernalis) flore duodecapetala, fructu ovato. Lin. S] Plant. 771. Perennial Adonis with yellow flowers, of four times four-lined black hollows. Adonis Hellebori radix Buchenbaum name. H. L.

There is a variety of the first kind, which hath been cultivated in the gardens, the flowers of this are larger, and the leaves shorter, than those of the first kind. But, from many repeated trials of sowing their seeds separately, they appear to be only accidental varieties arising from culture, and therefore may be properly esteemed as such.

The second kind is undoubtedly a distinct species. I have cultivated both these sorts above thirty years, and have never observed the second to vary either in the shape of its leaves, colour, or size of the flowers, or in any other particular. The first kind grows naturally in the woods, particularly by the side of rivers, between Manchester and Macclesfield, where it is found in great plenty in the fields which are sown with wheat; but in the neighbourhood of Macclesfield the seeds are permitted to fall on the ground, they generally succeed better than when sown by hand. The first kind grows naturally in the woods, particularly by the side of rivers, between Manchester and Macclesfield, where it is found in great plenty in the fields which are sown with wheat; but in the neighbourhood of Macclesfield the seeds are permitted to fall on the ground, they generally succeed better than when sown by hand.

Both these sorts are annual, and if die feeds SW liwn in autumn, the psna mil come up till following spring, but when die il-sda a; on luwn rill spring, they rarely come up the first year. As that which the seeds are permitted to fall on the ground, they generally succeed better than when sown by hand. The first kind grows naturally in the woods, particularly by the side of rivers, between Manchester and Macclesfield, where it is found in great plenty in the fields which are sown with wheat; but in the neighbourhood of Macclesfield the seeds are permitted to fall on the ground, they generally succeed better than when sown by hand.

The first kind grows naturally in the woods, particularly by the side of rivers, between Manchester and Macclesfield, where it is found in great plenty in the fields which are sown with wheat; but in the neighbourhood of Macclesfield the seeds are permitted to fall on the ground, they generally succeed better than when sown by hand.

of lowinp the seeds in autumn, for these fields of fine corn it is inferred to be sown in the first year. The same years past, great quantities of the flowers of this plant have been brought to London, and sold in the streets by the name of Red Monarda.

JJgiththfcinnusi ... flowers in the beginning of June, and the seeds ripen in August and September; this will be untierfood nt tKok; plants which arise from seeds sown in autumn, or such as have fallen to the ground in any place, come up from the seeds sown in the first year; if they do not flower till July or August, aot these seeds seldom ripen before October.

These plants will thrive best in a light soil, but may be fit in a very firm soil, and will grow in a warm situation, and others in the shade. The plants will continue longer in flower, if they are not removed while the plants are very young; therefore they should be sown in pits in the borders of the flower garden, and when the plants come up, they should be thinned, leaving six or four in each pit, which will make a better spttanu than where they grow single.

The third kind hath a perennial root, and an annual stalk. This grows naturally on the mountains of Bohemia, Prussia, and other parts of Germany, where the root is often used as the true Black HiHebore, thfttl from the delicia. It gives a white colour to the thuploni, tlik by no means will agree with them; this hath been used in the cure of the stone. It produces

it flowers the latter end of March, or the beginning of April, according to the severity of the season; the stalks rise about a foot and a half high, and when the seeds are large, and have good improvement for some years, they will produce a great number of stalks from each; these are furnished with five slender leaves, which are placed in circles at intervals. At the top of each stalk, is produced one large yellow flower, composed of an unequal number of petals, the center of which is occupied by a great number of stamens, surrounded by many filaments; after the flowers drop, the stamens become naked seeds, closely adhering to the base of the stalk, forming an oblong spike. These ripen in August, and should be sown soon after, or in winter they seldom succeed.

When the plants come up, they must be carefully kept clear from weeds, and, in very dry weather, if they are new and thin, watered with water, will promote their growth. They should be sown in the place where they are sown until the second year, for they make but slow progress while young. The best time to transplant them is in autumn, when they ought to be planted where they are to remain, for if often removed, they will not produce many flowers, nor their stalks be so strong as on the plants which are sown there.

ADOXA, Lin. Gen. 400. Mollifera. Tournefort. Tuberosa Mollifera, or Hollow Root. This is ranged in Linnaeus's eighth class, entitled Oligandria Tetragynia, the flowers of which are four-lined, and four-lobed.

The Character is, The capsule of the flower is light and permanent, when which opens the seeds, the flower is of one leaf, which is cut into four equal segments. The seeds are situated in the center, forming four rows from each, each are attended by eight flowers, arranged in roundish joints; after the flower is past, the seeds become a black berry, which is the capsule, which hath four cells, each containing a single winged seed.

There is but one sort of this genus. ADOXA, Hort. Cliff. 172. tuberosa Mollifera, or Hollow Root. This is ranged in Linnaeus's eighth class, entitled Oligandria Tetragynia, the flowers of which are four-lined, and four-lobed.

This plant grows naturally in the woods of Jiver; parts of England; I have frequently gathered it on the top of Hampstead among the bushes, and it is a very low plant, seldom rising more than four or five inches high, the leaves resemble those of the herbaceous Primrose, the flower-stalk arises immediately from the root, upon the top of which is placed four or five small flowers of an herbaceous white colour; these appear the beginning of April, and the berries ripen in May, soon after which the leaves decay. There is little beauty in this plant, but as some persons are fond of collecting the several kinds of plants in their gardens, which are not commonly found, it is mentioned here. The roots may be transplanted any time after the leaves are decayed, till winter; they are subterranean, and shaped somewhat like a turnip; they must be planted in the shade, under a tree; for if they are exposed to the open sun, they will not thrive. The leaves and flowers smell like a musk, from whence it has been by some called Musk-Crosswort.

EGLOPS, Wild Pheasant, a sort of grass which grows naturally in many parts of Europe, it is rarely cultivated except in botanic gardens.

EGOPodium, Small Wild Amaranth, or Gourd; this plant grows naturally in several places near London, but the roots run to fall in a garden; it is considered a troublesome weed.

ESCHYNOMENE, Lin. Gen. Plant. 769. Substantive plant. This genus of plants is ranged in the third section of Linnaeus's seventh class, entitled Diadelphia decandria; the flowers of this class have ten distinct stamens, nine of which are united, and the other is separate.

The Character is, The capsule of the flower is four-lined, and four-lobed, the seeds are situated in the center, forming four rows from each, each are attended by eight flowers, arranged in roundish joints; after the flower is past, the seeds become a black berry, which is the capsule, which hath four cells, each containing a single winged seed.

The Character is, The capsule of the flower is four-lined, and four-lobed, the seeds are situated in the center, forming four rows from each, each are attended by eight flowers, arranged in roundish joints; after the flower is past, the seeds become a black berry, which is the capsule, which hath four cells, each containing a single winged seed.

flower trifid; the flower is of the butterfly kind, the standard being large and Jheart-Jhaped *, the two wings are oval, and Jhorter than the standard; the keel is moon-Jhaped, and as long as the standard. In the bottom of the flower is situated an oblong hairy germen, supporting an arched fyle, attended by tenftamina, nine of which coalesce, and the other is separated from them; after the flower is past, the germen becomes a long, plain, jointed pod, which separates at the joints, in each of which is lodged one kidney-Jhaped feed.

The SPECIES are,

1. **IESCHYNOMENE** (*Afpera*) caule scabroleguminumarticulis medio scabris. Lin. Sp. Plant. 713. *Bastard Senfitive plant with a rough stalk, and a jointed pod. Mimofa non spinosa major Zelanica.* Breyn. Cent. 51.
2. **JESCHYKOMZKE** (*Americana*) caule herbaceo hispido, foliis acuminatis, leguminum articulis femicordatis, bradeis ciliatis. Lin. Sp. Plant. 1061. *Bastard Senfitive plant with a flinging herbaceous stalk, pointed leaves and the joints of the pods beart-Jhaped.* Hedyfarum caulihirtutumimofae foliis alatis, pinnis acutis minimis gramineis. Sloan. Cat. Jam.
3. **IESCHYNOMENE** (*Arborea*) caule lsevi arboreo leguminum articulis femicordatis glabris. Prod. Leyd. 384. *Bastard Senfitive plant with a smooth tree-like stalk, and fsmooth jointed pods.* Sefban caule simplici glabro, foliis pinnatis glabris. Monier.
4. **IESCHYNOMENE** (*Sefban*) caule herbaceo lnevi, foliolis obtufis, leguminibus cylindricis aequalibus. Lin. Sp. Plant. 1061. *Bastard Senfitive plant with a smooth stalk, obtufe leaves, and equal cylindrical pods.* Galcga Egyptiaca filiquis articulatis. C. B. P. 352.
5. **JESCHYNOMENE** (*Pumila*) caule herbaceo fcevi, foliolis acuminatis, leguminibus hinc ferratis medio scabris. Lin. Sp. Plant. 1061. *Bastard Senfitive plant, with a smooth herbaceous stalk, pointed leaves, and serrated rough pods.* Hedyfarum annum minus Zeylanicum mimofae foliis. Inft. R. H. 402.
6. **IESCHYNOMENE** (*Grandiflora*) caule arboreo, floribus maximis, leguminibus filiformibus. Lin. Sp. Plant. 1060. *Bastard Senfitive plant with a tree-like stalk, large flowers, and flender pods.* Galege affinis malabancarbofencens, filiquis majoribus umbellatis. Raii Hift. 1734.

The first fort rises to the height of four or five feet, having a fingle herbaceous stalk, which is in some parts rough. The leaves come out on every fide towards the top, forming a fort of head-, these are composed of a great number of fmall leaves (or pinnae) which are fsmooth, and of a glaucous colour. The flowers come out from between the leaves, two or three together upon long foot-ftalks; they are yellow, and fliaed like those of Peafe. After the flower is past, the germen becomes a flat jointed pod, about four inches long, which, when ripe, parts at the joints, and in each division is lodged a fingle kidney-fliaed feed.

The second fortfeldom rises more than two feet high, but fends out three or four lateral branches; these are clothed with narrow winged leaves, whose pinnae are placed alternate on the midrib. The flowers come out from the leaves upon branching foot-ftalks, five or six together *, these are much less than those of the first fort, and of a paler yellow colour. After the flowers are past, the germen becomes a jointed pod, having three or four fwelling divisions, in each of which is lodged a fingle kidney-fliaed feed.

The third fort grows to the height of fix or feven feet, with a fingle stem; the leaves are fsmooth, and come out towards the top of the stalk, as in the first fort they are composed of many pinnae, placed alternate on the midrib. The flowers come out from the wings of the leaves, two or three together, being of a copper colour, and as large as those of the first fort. After the flowers are past, the germen becomes a fsmooth jointed pod, each division being halfheart-fliaed, and inclofing a fingle kidney-flheped feed.

The fourth fort grows naturally in Egypt, and also on the coast of Guinea, from whence I received the feeds. This hath woody stems and branches, which

are garnished with fsmooth leaves, composed of many blunt pinnae, fet by oppofite pairs *, the flowers, which are fmall; and of a deep yellow colour, come out from the wings of the leaves in long fpikes, which hang downward. After the flower is past, the germen becomes a taper-pointed fsmooth pod, not jointed.

The fifth fort rises about three feet high, with a fingle herbaceous stalk, feldom putting out any fide branches. The flowers come out from the wings of the leaves, fometimes fingle, and other times two or three upon each foot-ftalk; these are fsmall, and of a pale yellow colour. After the flower is past, the germen becomes a long falcated pod, divided into eleven,* or thirteen partitions, each containing a fingle kidney-fliaed feed.

The sixth fort rises fix or eight feet high, with a woody stem, fending out branches towards the top, garnished with obtufe leaves *, the flowers are large, yellow, and fucceeded by large pods, including kidney-fliaed feeds.

The first, third, and fourth forts, will live through the winter in England, if placed in a warm ftove; but as their stalks are fucculent, they must be kept dry in winter, otherwife they are very fubject to rot. They should be plunged into the tan-bed, for when put into a dry ftove, the fibres of their roots soon grow dry, and their leaves hang and fade, which flies their want of moifture *, but when they have water given them, it caufes the tender fibres of their roots to perify and the plants soon after decay.

The fifth fort is annual, therefore the feeds should be fown early in March on a hot-bed, and the plants should be brought forward in the fpring, and afterwards placed in an airy glafs-case, or a ftove in fummer, for if they are expofed to the open air, the feeds rarely ripen in England.

The sixth fort grows to a large shrub in hot countries, but is with difficulty preferved through the winter in this country. The plants are propagated by feeds, which must be fown on a hot-bed in the fpring, and the plants, when fit to remove, should be planted in pots, and brought forward on a hot-bed, then fhould be plunged into the bark-bed in the ftove, where, if they are tenderly treated, they will live through the winter, and flower the fuimper following.

These are all propagated by feeds, which should be fown on a hot-bed early in the fpring, and when the plants have ftrength enough to be removed, they should be put each into a feparate fmall pot, filled with light earth, and plunged into a freth hot-bed, to bring them forward; and as they advance in their growth, they should be fhifted into large pots, but great care fhould be taken not to over-pot them, for if the pots are too large, the plants will not thrive. The first, fecond, and fifth forts are annual, therefore must be brought forward early in the year, otherwife they will not perfect their feeds *, but the third, fourth, and sixth forts may be preferved through the winter, and will flower early the following fummer, and their feeds will ripen in the autumn. The other forts usually flower in July, and their feeds ripen in Q&ober.

IESCULUS. Lin.Gen.420. TheHorfeCheftnut.

The CHARACTERS are,

The empalement of the flower confifts of one leaf, flighly cut into five fegments. The flower is composed of five roundijh petals, folded at their border, and waved; these are narrow at their bafe, and are inferted in the empalement. In the center is placed a roundijh germen, having a fingle fyle, crowned with a pointed stigma, attended by feven ftamina, which extend to the length of the petals, and arc declining, crowned with upright fummits When the flower is past, the empalement becomes a thick* roundijh, echinated capfuk, opening into three cells, in one or two of which are lodged globular feeds.*

This genus of plants, is, by Dr. Linnaeus, ranged in his feventh dais, entitled Heptandria Monogynia, the flower having feven ftamina and one fyle.

The SPECIES are,

1. **TESCULUS** (*Hippocastanum*) floribus heptandriis. Hort. Upfal. 92, *The common Horfe Cheftnut.* Hippocastanum

num vulgare. Tourn. -Inft. Caftanea equini. Cluf. Hift. i. p. 7.

ESCULUS (*Pavia*) floribus o&andris. Lin. Sp. 488. *Scarlet Horfe Chefnut*. Pavia. Boerh. Ind. Alt. 2. p. 260. The Horfe Chefnut was brought from the northern parts of Afia about the year 1550, and was lent to Vienna about the year 1588. It was called Caftanea from the fhape of its fruit, and the title of Equini was added to it from its being a good food for horfes when ground.

This tree was in much greater efteem formerly than at prefent, for fince it is become fo very common, few perfons regard it. What has occafioned its being fo feldom planted, is the decay of the leaves early in fummer, fo that where they are growing in gardens, their leaves frequently begin to fall in July, and occafion a litter from that time, until all the leaves are fallen; but notwithstanding this inconvenience, the tree has great merit, for it affords a noble fhade in fummer; and during the time of its flowering, there is no tree has greater beauty, for the extremity of the branches are terminated by fine fpikes of flowers, fo that every part of the tree feems covered with them; which are finely spotted with a rofe colour, and thefe being intermixed with the green leaves make a noble appearance.

The former method of planting thefe trees in avenues and ftrait lines, has allb been in fome meafure the occafion of their prefent difrepute, becaufe in fuch plantations great part of their beauty is loft; for when their branches are fo far extended as to nearly meet, moft of the flowers which are produced are hid from fight, and as the trees grow larger, their branches will interfere with each other, and produce few flowers; the leaves will alfo decay much fooner in clofe plantations, than on fingl'e trees: therefore the great beauty of them is, to ftand fingly at a diftance from nil other trees, upon lawns of grafs in parks, where their fruit will be of great fervice to deer, who are very fond of them. In fuch fituations, when the trees are grown to a good fize, there is not a finer obje&6l than they will afford during their feafon of flowering, which is in May, and when the weather is moderate, they will continue in beauty near a month.

As this tree is quick in its growth, fo in a few ye&8rs they will arrive to a fize large enough to afford a good fhade in fummer, as alfo to produce plenty of flowers. I have known trees which were raifed from nuts, in twelve or fourteen years, large enough to fhade two or three chairs under the fpread of their branches, and have been covered with flowers in the feafon, fo that few trees make greater progrefs than thefe. But as their wood is of little value, the trees fhould not be propagated in too great plenty: a few therefore of them placed at proper diftances in parks for ornament is as many as fhould be preferved, the wood not being fit even for burning, nor any other ufe that I know of. Thefe trees are propagated by fowing the nuts; the beft time for doing this is early in the fpring; but the nuts fhould be preferved in fand during the winter, otherwife they are apt to grow mouldy and rot. They may indeed be planted in autumn, but then they will be in danger of rotting if the winter fhould prove very wet, as alfo of being removed or eaten by vermin.

When the nuts fucceed, and have a proper foil, the plants will fhoot near a foot the firft fummer, fo that where they grow pretty clofe together, it will be proper to tranfplant them the following autumn, when they ought to be planted in rows at three feet diftance, and one foot afunder in the rows: in this nurfery they may remain two years, by which time they will be fit to plant where they are defigned to be continued; for the younger thefe trees are planted out, the larger they will grow. But there are many who will obje&6t to their being planted out young in parks, becaufe they will require a fence to fecure them againft the cattle-, which will alfo be neceffary, whatever fize they are when planted; and if large, they muft be well ftaked to prevent their being difplaced by ftrong winds: which is another expence, and when we con-

fidder how much f after a young tree will grow, than thofe which are removed at a greater age, there can be no excufe for planting large trees.

This tree is not very nice in its culture, for it requires little care in the management, and will thrive in moft foils and fituations, but in a fandy loam they make the greateft progrefs; and if the foil be inclining to moiiture, the leaves will continue in verdure much longer, than in very dry ground/

When thefe trees are tranfplanted, their roots fhould be preferved as entire as poffible, for they do not fucceed well, when torn or cut; nor fhould any of the branches be fhortened, for there is fcarce any tree, which will not bear amputation better than this* fo that when any branches are by accident broken, they fhould be cut off clofe to the item, that the wound may heal over.

There is fomething very fingular in the growth of thefe trees, which is the whole fhoot being performed in lefs than three weeks, after the buds are opened; in which time I have meafured fhoots a foot and a half long, with their leaves fully expanded: and no fooner are the flowers fallen, than the buds for the fucceeding year are formed, which continue fwelling till autumn; at which time the folding covers are fpread over with a thick tenacious juice, which ferves as a pigment to defend the tender buds from the froft and rain in winter; but upon the firft return of warmth in the fpring, this melts and runs off, whereby the bud is at full liberty to extend. And what is remarkable in this pigment, it is never fo far hardened as to injure the tender buds, which are always formed at the extremity of the former year's fhoot; a plain dire&6tion not to fhorten them, for by fo doing, the future fhoots are entirely cut off.

In Turkey the nuts of this tree are ground, and mixed with the provender for their horfes, efppecially thofe which are troubled with coughs, or are broken winded; in both which diforders, they are accounted very good. Deer are very fond of the fruit, and at the time of their ripening will keep much about the trees, but efppecially in ftrong winds, when the nuts are blown down, which they carefully watch, and greedily devour as they fall.

There are fome old trees now ftanding, which were planted fingly, at a great diftance from any other; thefe are grown to a very large fize, and their heads form a natural parabola, and when their flowers are in full beauty, there is not any tree yet known in Europe, which makes fo fine an appearance. I have meafured fome of thefe trees, whofe branches have extended more than thirty feet in diameter, and their heads have been fo clofe, as to afford a perfedl fhade in the hottelt feafons. Thefe were planted in 1679* as appears by fome writings which are in the poffeffion of the perfons, who have now the property of the land where they grow: fo that although they are of quick growth, yet they are not of fhort duration.

The Scarlet Horfe Chefnut grows naturally in North America, where it rifes to the height of twenty feet, but does not fpread its branches to any great extent, the flowers are wholly red, which are much fmaller than thofe of the common fort, they are tubulous, but want brims to expand, fo make but an indifferent appearance, when compared to the other: however for variety this fhould have a place in gardens.

It may be propagated by the nuts, if they are procured from the country where the trees naturally grow; for the feafons are feldom favourable enough to ripen them in England. The nuts fhould be ibwa in pots early in the fpring, and the pots plunged into a moderate hot-bed to forward their growth; toward the end of May, the pot fhould be plunged into the ground in a fourth-eaft border, and in dry weather the plants fhould be duly watered, whereby they will acquire ftrength by the autumn; when it will be very proper to fcreen the plants from early frofts which often pinch the top buds, and occafion their decay in the winter, for while the plants are young they are impatient, of frofts, but when they have obtained

Dr. [• ... has separated the plants of this genus from the Aloe, to which they had been joined by former taxonomists, because the stamens and style in their blossoms are extended much longer than the corolla, and the corolla rest upon the germen, which in the Aloe are not so. We may also mention another difference in the growth of the plants, by which they may be distinguished. In the Aloe, which is all the plants of this genus have their center leaves closely folding over each other, and embracing the flower stem which is turned in the coil; in this I fe never flower until all the I civet BIT expanded, to give the stem its liberty to advance, uu! when the flower is fallen, the plants die. Whereas the flowers of Jit Aloe, is produced in one side of [In- I east or center of the plant, so they never • annually, and the leaves are always more expanded, than those of this genus.

The first sort here mentioned, has been long preferred in the English gardens, whose of late years there have been several of the plants in flower. The stems of this which the plants are vigorous, generally rise upward of twenty feet high, and branch « • on every side, in an so form a kind of pyramid, the lowermost being furnished with greenish yellow flowers, which stand erect, and come out in thick clusters at every joint. They have six long stamens, crowned with yellow fimbriae, placed round the style. The pistil is also inserted in the same length as the stamens. After the flowers fall away, the green men, which is situated beneath the flower, becomes an oblong tritricoid, divided into three cells, the lowermost compressed seeds; but these do not come to maturity in England.

When the plants are young, they take in fine appearance, and continue a long time in beauty, if they are protected from the cold; in autumn, there will best succession of new flowers produced, for near thirty months, in the south of England. I have seen several of these plants, which were believed to be a hundred years old; but this is a great mistake, for the time of its flowering depends on the growth of the plant; so that in hot countries where it grows tall, and expands many leaves every year, it may outlast a hundred years, but in colder climates, where their growth is slow, it will be much longer before it shoots up their stem. There is a variety of this sort with striped leaves, which is now pretty common in the English gardens.

The plants of the second sort are so like those of the first, that they are distinguished from them, but by good judges. The principal difference is, the leaves of this are narrower, and grow to a pale colour; the stems of this sort do not rise so high, but the flowers are collected in a close head at the top, they are however of the limit shape and colour. There has been three or four plants of this sort, which have lately died in England, one of which was in the garden of a few years past. This is a very curious plant, which produces so many offsets as the common Aloe.

The seventh sort greatly resembles these; that many persons have supposed it to be the same; but the leaves of this are much thinner, the indentures on their edges absolutely other, and not like the former; the stamens are thicker. How this differs from the others in the south of England, having fifteen or more of their flowers produced in England. These three sorts are hardy; I have known plants of the first sort live in the north for many years in mild climates, but in colder winters they are almost killed, if not sheltered; they are propagated by offsets, which the first sort sends out in plenty, but the third seldom runs out any, so that it is increased by taking off some of the larger ones, at the time when the plants are lifted, planting them in pots filled with light sandy earth, which will root out and become good plants, as I have experienced. The second sort generally puts out suckers enough for propagation, though not in so great plenty as the first. All these should be planted in pots filled with light sandy earth, and shaded in winter with mats, myrtles, &c. and during this season, should have but little wet. In the summer they must be placed abroad in the open air, where they may remain till toward the end of October, when they should be brought again. The seventh sort being a little smaller than the other two, should be planted in pots not so large as the first, and may stay there a little longer in the spring. The third sort runs out many offsets, of a pale green colour, not indented on their edges, but frequently a little curved; the side leaves spread open, but these is the center held closely over each other, and finally narrowed toward the head. The plants of the second sort rarely produce more than three or four suckers, but the Bower brandies out much larger than the first.

that of the first, but more horizontally; the flowers are of the same shape, but smaller, and of a greener colour. After the flowers are pale, instead of feedveffels, young plants succeed to every flower, so that all the branches are closely beset with them. There was a plant of this kind which flowered in the Chelsea garden 1755, the stem of which begun to shoot the beginning of October, and by the end of that month was upwards of ten feet high, by the end of November it was near twenty, and the lower lateral branches were upward of four feet long, the others decreasing gradually, so as to form a regular pyramid. In December the stalks were closely garnished with flowers, and in the spring, when the flowers dropped off, they were succeeded by young plants, which as they fell off and dropped into the pots which stood near, put out roots and become good plants. This sort never produces offsets from the root, so that it cannot be increased but when it flowers, at which time there will be plenty enough. The old plant presently after dies.

The fourth sort hath leaves somewhat like the third in shape and colour, but they are indented on their edges, and each indenture terminates in a spine -, the root of this sort is thick, and dwells just above the surface of the ground, in other respects it agrees with the former. This sort hath not flowered in England, therefore I cannot tell how it differs in its flowers from the other. I have raised this from seeds which were sent me from America, but the plants never put out suckers from the roots, so that it can only be propagated by seeds. Dr. Linnaeus supposes it to be the same with the third species, but whoever sees the plants will not doubt of their being different.

The fifth sort never grows to a large size; the leaves of it are seldom more than a foot and a half long, and about two inches and a half broad at their base -, the end in a slender spine, being (lightly indented on their edges; they are also reflexed backward toward their extremity, and are of a dark green colour. The flower-stem rises about twelve feet high, and branches /rot toward the top in the same manner as the third sort; the flowers are nearly of the same size and colour as those of the third, and after they fall off, are succeeded by young plants in the same manner. A plant of this kind flowered in the garden at Chelsea, in December 1754. This never produces any suckers from the root, so cannot be increased until it flowers. The leaves of the sixth sort are from two feet and a half to three feet long, and about three inches broad, being of a dark green colour, ending in a black spine; the borders of the leaves are of a brownish red colour, and (lightly ferrated. These stand more erect than in the other species 5 but as this sort hath not flowered in England, so I cannot say how it differs from the other. The plants of it were sent me from St. Christopher's, by the title of Koratto, which I suppose is given indifferently to other species of this genus -, for I have frequently heard the inhabitants of America call the common great Aloe by the same name,

'the eighth sort hath long, narrow, stiff leaves, which are entire, and are terminated by a stiff black spine. These leaves are seldom more than two feet long, and little more than an inch broad, being of a glaucous colour. The side leaves stand almost horizontally, but the center leaves are folded over each other, and inclose the flexure-bud. This sort never puts out suckers from the root, nor have I seen any plants of this kind in flower, although there are many of them in the English gardens, some of which are of a considerable age.

The third, fourth, fifth, sixth, and eighth sorts, are much tenderer than the others, so cannot be preferred through the winter in England, unless they are placed in a warm stove 5 nor will they thrive if set abroad in summer, therefore they should constantly remain in the stove, observing to let them enjoy a great share of free air in warm weather. They require a light sandy earth, and (should have little wet in winter; but in warm weather, may be gently watered twice a week,

which is as often as is necessary, for if they have much water given them, it rots their roots, and then their leaves will decay and infect themselves. They (should be (lifted every summer into fresh earth, but must not be put into large pots, for unless their roots are confined, the plants will not thrive.

A GERATUM. Lin. Gen. Plant. 842. Bastard Hemp Agrimony.

The CHARACTERS are,

The flowers are included in one common oblong empalement, which is composed of many fiales. > These are uniform, tubulous, and hermaphrodite, and little longer than the empalement, each being cut at their margin into five segments, which spread open. These have five slender stamina, crowned with cylindrical juments: in the center of the flower is situated an oblong germen, supporting a slender style, crowned by two fine stigmas. The germen afterward becomes an oblong angular seed, crowned with its proper little cup, cut into five narrow segments, which spread open. The receptacle of the seed is small, naked, and convex.

This genus of plants is by Dr. Linnaeus ranged in his (eventcenth class, entitled Syngenesia polygamia aequalis, the flowers having their stamina joined together in a cylinder, and there being male, female, and hermaphrodite florets included in the same common empalement.

The SPECIES are,

1. AGERATUM (*Conyzoides*) foliis ovatis caule piloso. Lin. Sp. Plant. 839. Bastard Hemp Agrimony, with oval leaves and a hairy stalk. Eupatorium humile Africanum fenecionis facie folio lamii. Herm. Pars 161.
2. AGERATUM. (*Houstonianum*) foliis oppositis petiolatis crenatis, caule hirfuto. Bastard Hemp Agrimony, with leaves having long foot-stalks placed opposite, whose edges are bluntly indented, and a hairy stalk. Eupatorium herbaceum mellifae folio villosum flore coeruleo. Houft. MSS.
3. AGERATUM (*Altissimum*) foliis ovato cordatis rugosis floralibus alternis, caule glabro. Lin. Sp. Plant. 839. Bastard Hemp Agrimony, with rough, oval, heart-shaped leaves, flower branches growing alternate, and a smooth stalk. Eupatorium urtica: foliis Canadense flore albo. H. L.

The two first are annual plants. The seeds of these must be sown on a hot-bed in the spring, and when the plants are come up and are strong enough to remove, they (should be transplanted into another moderate hot-bed, observing to water and (shade them until they have taken root, after which time they must have a good share of air in warm weather. In June they (should be inured to bear the open air, toward the middle of which month, they may be transplanted into the full ground, where they will begin to flower in July, and continue flowering till the frosts in autumn destroy them. The seeds ripen in September and October, and when any of them scatter upon the ground, and the same earth happens to be put on a hot-bed the following spring, the plants will come up in great plenty, as they frequently do in the open air; but these plants will be too late to produce good seeds, unless the summer proves warm. The first sort grows naturally in Africa, and also in the islands of America, for in tubs of earth which I received with plants from Jamaica, Barbadoes, and Antigua, I have had plenty of the plants arise, from seeds which were scattered on the ground. The second sort was found growing naturally at La Vera Cruz, by the late Dr. William Houftoun, who sent the seeds to Europe, which have so well succeeded in many gardens, as to become a weed in the hot-beds. There is a variety of this with white flowers, which arises from the same seeds.

The third sort grows naturally in North America, but has been many years an inhabitant of the English gardens. This hath a perennial root and an annual stalk; the stalk will grow five or six feet high, and toward their tops put out side branches: the leaves are shaped like a heart. At the ends of the shoots the flowers are produced in large tufts, which are of a pure white and

lice appearing in October, at a season when there is a scarcity of other flowers, renders it more valuable. This sort is propagated by seeds, as also by parting of the roots, the latter method is commonly practised in England, because there are few autumns so favourable as to ripen the seeds: but the seeds are frequently brought from North America, where this plant is very common; for being light, they are easily wafted about to a great distance, where they come to maturity; so that where there are any plants growing, all the adjoining land is filled with the seeds of them. The best time for planting and transplanting the roots of this plant, is in autumn, soon after their stalks decay, that they may have good root before the drying winds come on, otherwise they will not flower strongly, or make a good increase. The roots should be allowed three feet room every way, for as they spread and increase very much, so when they are cramped for room, the plants starve, and in dry seasons their leaves will hang. They delight in a rich moist soil and open situation, wherethy they will produce many stalks from each root, which will grow so large as to form a considerable brush. This plant will bear the severest cold in winter.

AGERATUM, or MAUDLIN. See ACHILLEA.
 AGERATUM PURPUREUM. See ENIENUS.
 AGNUS CASTUS. See VITEX.
 AGRIFOLIUM. See ILEX.
 AGRIMONIA. Lin. Gen. Plant. 534. Agrimony.

The CHARACTERS are,

The empalement of the flower is of one leaf which is cut into five acute segments, and rifts on the germen. The flower has five petals, which are plain and indented at their extremity but are narrow at their base, where they are inserted in the empalement. In the center arises a double style, resting on the germen, which is attended by twelve slender stamina, which are crowned with double compressed summits. After the flower is past, the germen becomes two roundish seeds fastened to the empalement.

This genus of plants is ranged by Dr. Linnaeus in the second section of his eleventh class, entitled Decandria digynia, the flowers having twelve stamina and two styles.

The SPECIES are,

1. AGRIMONIA (*Eupatoria*) foliis caulinis pinnatis impari petiolato, fructibus bipidis. Hort. Cliff. The common Agrimony. *Agritaonia officinarum*. Tourn.
2. AGRIMONIA (*Minor*) foliis caulinis pinnatis, foliolis obtusis dentatis. The white Agrimony. *Agrimonia minor flore albo*. Hort. Cath.
3. AGRIMONIA (*Odorata*) altissima, foliis caulinis pinnatis foliolis oblongis acutis serratis. The sweet-scented Agrimony. *Agrimonia odorata*. Camer.
4. AGRIMONIA (*Repens*) foliis caulinis pinnatis, impari feffili, fructibus bipidis. Lin. Sp. 643. Eastern Agrimony with pinnated leaves and a thick creeping root. *Agrimonia orientalis humilis radice crassissima repente fructu in spicam brevem & densam congesto*. Tourn. Cor.
5. AGRIMONIA (*Agrimonoides*) foliis caulinis ternatis fructibus glabris. Hort. Cliff. 179. Three leaved Agrimony with smooth fruit. *Agrimonoides* Col. Echpr.

The first sort grows naturally in several parts of England, by the sides of hedges, and in woods. This is the sort which is commonly used in medicine, and is brought to the markets by those who gather herbs in the fields.

The second sort is the smallest of all the species, the leaves of this have not so many pinnae as the common sort, and the pinnae are rounder, and the indentures on their edges blunter. The spike of flowers is slender, and the flowers smaller, and of a dirty white colour. This sort grows naturally in Italy, from whence I received the seeds, and have constantly found that the seeds of this when sown never vary.

The third sort grows near four feet high, the leaves of this have more pinnae than either of the former, which are longer and narrower, ending in acute points; the serratures of the leaves are sharper than any of the other, and when handled emit an agreeable odour. The leaves of this sort make an agreeable cooling tea,

Which is a very good beverage for persons in a fever, in which disorder I have known it often prescribed by good physicians.

The fourth sort is of humble growth, seldom rising above two feet high; the pinnae of its leaves are longer and narrower than either of the former, and the spikes of flowers very short and thick. The roots of this are very thick, and spread widely under ground, by which it multiplies faster than either of the other; the seeds are also much larger and rougher than those of the common sort. This was sent by Dr. Tournefort to the royal garden at Paris, and from thence the other botanic gardens have been supplied with them. The fifth sort greatly resembles the other in the shape of its pinnae (or smaller leaves) but there are but three upon each foot-stalk; the flower of this hath a double empalement, the outer one being fringed. There are but seven or eight stamina in each flower, and the seeds are smooth, for which reason Fabius Columna, and other writers on botany, have separated it from the Agrimony, making it a distinct genus.

All these sorts are hardy perennial plants, which will thrive in almost any soil or situation, and require no other care but to keep them clear from weeds. They may be propagated by parting of their roots, which should be done in autumn, when their leaves begin to decay, that the plants may be well established before the spring. They should not be planted nearer than two feet, that their roots may have room to spread. They may also be propagated by seeds, which should be sown in autumn, for if they are kept out of the ground till spring, they seldom come up the same season.

AGROSTEMMA. Lin. Gen. Plant. 516. Wild Lychnis or Campion.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, which is tubulous, thick, and cut into five narrow segments at the edge, the flower is composed of five petals, which are the length of the tube, but spread open at the top. In the center is situated an oval germen supporting five styles, which are slender, erect, and crowned with simple stigma. These are attended by ten stamina, five of which are inserted in the base of the petals, and the others stand alternately between: after the flower is past, the germen becomes an oval oblong capsule, having one cell opening into five divisions, which is filled with angular seeds.

This genus of plants is by Dr. Linnaeus ranged in the fifth section of his tenth class, entitled Decandria pentagynia, the flowers of this division having ten stamina and five styles.

The SPECIES are,

1. ACROSTEMMA (*Githgo*) hirsuta calycibus corollam quantum petalis integris nudis. Lin. Sp. Plant. 435 J Hairy wild Lychnis, whose empalement is equal with the corolla, and the petals entire and naked, commonly called Corn Campion. *Lychnis fegetum major*. C. B. P.
2. AGROSTEMMA (*Celirofa*) glabra foliis lineari-lanceolatis petalis emarginatis coronatis; Hort. Upfal. 115. Smooth wild Campion with narrow spear-shaped leaves, and the petals of the flowers indented at their brim. *Lychnis foliis glabris calyce duriore*. Bocc. Sic. 27.
3. AGROSTEMMA (*Coronaria*) tomentosa foliis ovato-lanceolatis, petalis integris coronatis. Hort. Upfal. 115. The Jingle Rose Campion. *Lychnis coronaria Diofcoridis fativa*. C. B. P. 203.
4. AGROSTEMMA (*Flos Jovis*) tomentosa petalis emarginatis. Lin. Sp. Plant. 436. Umbelliferous Mountain Campion. *Lychnis umbellifera montana Helvetica*. Zan. Hift. 128.

The first sort grows naturally in the corn fields in most parts of England, so is seldom admitted into gardens. The second sort grows naturally in Sicily, and being a plant of little beauty, is only preserved in botanic gardens for the sake of variety.

The Jingle Rose Campion has been long an inhabitant of the English gardens, where, by its seed having scattered, it is become a kind of weed. There are three varieties of this plant, one with deep red, another with flesh-coloured and a third with white flowers,

but these are of small esteem; for the double Rose Campion being a fine flower, has turned the others out of most fine gardens. The single sorts propagate fast enough by the seeds, where they are permitted to scatter, for the plants come up better from self-sown seeds, than when they are sown by hand, especially if they are not sown in autumn.

The sort with double flowers, which is a variety of the former, never produces any seeds, so is only propagated by parting of the roots -, the best time for this is in autumn, after their flowers are past; in doing of this, every head which can be flipped off with roots should be parted. These should be planted in a border of fresh undunged earth, at the distance of six inches one from the other, observing to water them gently until they have taken root -, after which they will require no more, for much wet is very injurious to them, as is also dung. In this border they may remain till spring, when they should be planted into the borders of the flower-garden, where they will be very ornamental during the time of their flowering, which is July and August.

The fifth sort grows naturally upon the Helvetian mountains *, this is a low plant, with woolly leaves -, the flower-stem rises near a foot high -, the flowers grow in umbels on the top of the stalk, which are of a bright red colour. It flowers in July, and the seeds ripen in September. It must have a shady situation, and will thrive best in a moist soil.

AIR [*Aer**, Lat. *Aer*], of *TS del pxy*, because it always flows j or as others, of *fopi*, to breathe.] By air is meant all that fluid expanded mass of matter which surrounds our earth, in which we live and walk, and which we are continually receiving and casting out again by respiration.

The substance whereof air consists, may be reduced to two kinds, viz.

*. The matter of light or fire, which is continually flowing into it from the heavenly bodies.

2. Those numberless particles, which is in form either of vapours, or dry exhalations, are raised from the earth, water, minerals, vegetables, animals, &c. either by the solar, subterraneous, or culinary fire. Elementary air, or air properly so called, is a certain subtle, homogeneous, elastic matter, the basis or fundamental ingredient of the atmospheric air, and that which gives it the denomination.

Air therefore may be considered in two respects; either as it is an universal assemblage, or chaos, of all kinds of bodies; or as it is a body endowed with its own proper qualities.

1. That there is fire contained in all air is demonstrable, in that it is evident, that there is fire existing in all bodies, and to this fire it is that air seems to "owe all its fluidity", and were the air totally diverted of that fire, it is more than probable that it would coalesce into a solid body* for it is found by many experiments, that the air condenses and contracts itself so much the more, the less degree of warmth it has; and, on the contrary, expands itself the more, according as the heat is greater.

2. In respect of exhalations, air may be said to be a general collection of all kinds of bodies; for there are no bodies but what fire will render volatile, and diffuse into air; even salts, sulphur, and stones, nay and gold itself, though the heaviest and most fixed of all bodies, are convertible into vapours by a large burning-glass, and are carried on high.

Those floating particles, thus raised from terrestrial bodies, are moved and agitated by the fiery particles divers ways, and are diffused through the whole atmosphere.

Of the matters thus raised in the atmosphere, those which come from fluid bodies, are properly called vapours, and those from solid or dry ones, exhalations. The cause of this volatility and ascent is the fire, without which all things would fall immediately down towards the center of the earth, and remain in eternal rest.

Thus, if the air be full of vapours, and the cold suc-

ceeds, these vapours before diffused are congregated and condensed into clouds, and thus fall back again into the form of water, rain, snow, or hail.

From the time of the entrance of the spring till autumn, the evaporation is constant -, but then it begins to fail, and in the winter ceases, to lay up fresh matter for the coming season.

And thus it is that frosty winters, by congealing the waters, and by covering the earth with a crust, and thus imprisoning the exhalations, make a fruitful summer.

And this seems to be the reason why in some countries, where the winter is severer than ordinary, the spring is more than ordinary fruitful; for in such places the exhalations being pent up along time, are discharged in the greater quantity, when the sun makes them a passage; whereas, under a feebler cold, the flux would have been continual, and consequently no great stock reserved for the next occasion.

This vaporous matter then being at length received into the atmosphere, is returned again in the form of rain, a forerunner of a cheerful crop.

As the sun retires, the cold succeeds, and thus the diversity of the seasons of the year depends on a change in the face of the crust of the earth, the presence of the air, and the course of the sun.

And hence we conceive the nature of meteors, which are all either collections of such vapours and exhalations, or diffusions thereof.

The subtiler oils are always rising into the air. Now two clouds, partly formed of such oils, happening to meet and mix, by the attrition, the oil frequently takes fire, and hence proceed thunder, lightnings, and other phenomena, which may be farther promoted by the disposition of the clouds to favour the excitation.

And hence arise great and sudden alterations in the air, inasmuch that it shall be now intensely hot, and raise the spirits perhaps to eighty-eight degrees in a thermometer and yet, after a clap of thunder with a shower, it shall fall again in a few minutes no less than twenty or thirty degrees.

It is therefore impossible to pronounce what the degree of heat will be in any given place at any time, even though we know ever so well the places and position of the sun and planets with respect to us, since it depends so much upon other variable things, no ways capable of being ascertained.

The lower the place, the closer, and denser, and heavier is the air, till at length you arrive at a depth where the fire goes out -, so that miners, who go deep, to remedy this inconvenience, are forced to have recourse to an artificial wind, raised by the fall of waters, to do the office of the other air.

Now, considering the air as such a chaos, or assemblage of all kinds of bodies, and a chaos so extremely liable to change, it must needs have a great influence on vegetable bodies.

3. Air considered in itself, or that properly called air. Besides the fire and exhalations contained in the circumambient atmosphere, there is a third matter, which is what we properly mean by air.

To define the nature of it would be extremely difficult, inasmuch as its intimate affections are unknown to us; all we know is,

1. That air is naturally an homogeneous similar body.
2. That it is fluid.
3. That it is heavy.
4. That it is elastic.
5. That it rarefies by fire, and contracts by cold.
6. That it is compressible by a weight laid thereon, and rises, and restores itself upon a removal of the same: all which circumstances should incline it to coalesce into a solid, if fire were wanting.

r. Air is divided into real and permanent, and apparent transient.

Real air is not reducible by any compression or condensation, or the like, into any substance besides air. Transient air is the contrary of the former, and is cold,

A I R

cold, &c. may be consented into original water; the difference between permanent or permanent air, amounts to the same as that between vapour, and exhalation \ thtrmc, c. g. being i, and the ilic-r moiV Hence, as Sir Iſaac Newton ſays, it is, that as the particles of permanent air are gntikT, and arise from dens: r bod It', than ikefk of tranſient air or vapour, true ai is Inose jHmik'rjus Oiiin v:r, and I mout atmosphere lighter than a dry i.

Bui t] a real air no where conliiU in its purity, but that air which concerns us, and the properties and effects of which are chiefly to be considered, n that which has been extracted or refined, which Mr. Boyle acknowledges to be the most licterogencntis bod'ir the universe; and Dr. Baeduuvt ilievs it to be an unmcvra] chaos Old colhivies of all the kinds of created bodies in the univerſe, and in which may be found whatever fire can v ilatbe,

2: That the air is fluid Vom the eil; pafage it allords 10 bodies through it; is in the i opa-gatji, and other i liluvia, for these tilings flitw it a body that gives -way to any force impred, and in yielding are easily r loved among themselves, which nr the properties ofafhad} lb that force any body will call hi queftion, whether air be a fluid, and thence being always in motion, and al-W>y] moving of her bodies, for no surface of any liq-uid that is contiguous to the air, can be at rest.

3. As to the gravity or h winds of the air, that is like vile easily proved -, for that the air is heavy, follows from its being a body, weight being an cHI-nibl property of matter.

Se&K and otcpritnt i'uffitiently prove this: for, if a person lay his hand upon an open veill: placed on an air-pump, and the air be exhausted, hr will letifi-ly feel the load of the incumbent leroofbhere to in-crcife, and pfeft upon the upper part of his hand, as the air is cxaufing.

In like manner, .1 Eollo-v fphere of five or six inches diameter, divided into two (cgmems exactly fitting each other, after the air is txhauled out of them, are ptdlbi tO^jthei with a force equal to a hundred pounds weight, and require the lhnvngth of two fining perluus to pull them afunder; which, s' lioon as ever the if is let into them again, will fall alunderby the tnerc weight of tin' under In- spheres.

Mr. Boyle found that a lamb's Madder, containing about two thirds of a pint, and blown up, and well dried, loft about a grain and onr eighth, when it was pricked, and the KIT let out.

Mr. Grav; and loun; that the air in a gkfs ball of about two hundred i eighty-three inches capacity, weighed a hundred .ij; and iccoritingto Buvdict die Volder, a cubic foot of air vs in weight one ounce, and twenty-seven grains.

Mr. Boyle has computed, thit the weight of any quantity of air, near the iortace of the earth, is to water as 1 to 1000; and Mr. Halley, as 1 to 800; and Mr. Hawkhee, as 1 to 882; and the gn>ity of the same quantity of air to 1 die lanir iquantity of mercury, as 1 to 1000.

Air therefore may be considered, • jn univerſal oper-ations, or cases, which by its weight keeps all ter-restrial bodies down, and hns U>s them from trying off.

4. The air is elastic. Elasticity is 1 I qualiry whereby jk dy yields to any exten: ; inpreGiois by contract- ing into Inf coimafs, and U>an (cmoving or dimimJliii returns to its former Ipifc ur rigi. And by this quality, rlie air is distinguished from all other bodies in the JUNofpherc, nci: for fire and exhalations appear to be ebu- as lean in any sensible degree.

That in fact a quality in the air, is evident from innumerable experiments; and this property is inseparable from it. A bladder full blown being squeezed in the hand, the included air may be sensibly per-ceived to refill the watch, so that upon ceasing to com-press it, (he cavities, t' impressions, which were nude in its lirtace, we immediately ex- panded again, and filled up.

A I R

Alfo thin glifs bubbles, or bladders full of air, and exafily cloied, and put into the receiver of an air-pump, the air bciiip; < exhausted out of the receiver, the glafs bubbles fly in pieces by the force of the air included in them.

From these experiments, and many others, it appears, that the air we breathe near die lurfacc of the earth is compressed by its own weight into at least 1679 pits or the (pace it would pofels in v<CUO; and if the same air be condenld by art, the {pace it will occupy, when moll dilated, will bu j-. 505000 to 1, to that which it podcfil, when com-ncd; and Dr. Walli: suggests, dial we arc far from knowing [lie uimolt it is capable of.

Nur docs th'sspov. appear capable by any means to be ddroyed or J' annihilated; for Mr. Boyle ms-J- verj] oterimenis to ilifcover liow long air, brought to the jirtatcl: degree of expanſion. Be could reduce it to in h air-pump, would retain its temp, and could never obli-rve an; I fide alonuncing, altho' I tie air was clogged ibi' mofa with a weight that one would imirchowit fhould tuppontonc mi< hant.

It is, indeed, a wonderful property in air, that it should v capable of being J' Jniraited and extended infinitely; bui, as hath been laid, it does not appear, by ill the ntpenments ye: tucl, that there at any time 1 of itse.omprefiiriMior expanſion, buttlill I by the addition of a new weight, a U TM:ittract Fartlicri and byuktngri: e weight away, will exi:nd farther.

5. Air rarifies by (ire, and conuafo by cold.

The colder the air is, the icls spaci; it tak« up; and, on the contrary, the uarmtr the air is, it pofels the larger space; and fo co-luse and comprefion h:vc die fame ttreCts upon air; and lb cold and tomprtfiun keeps air with « in iher.

The fame holds of wanning and dinoinlling of weight, or heat and eoapanſion, which go hand ID hand.

And to the fimcebftio pner iKfore-mentbncl, and its being expanded by heat, it is owing, that air in-cloies in glass eflck, at a time when it is much con-densed, when the heat of U comes to expand by alar-ther degree of heat, frojucmly burfts the bottles.

6. Air iscr: ptefible by a weight of mercury, and ril'ci and rftorr stand upon a removal of the Came. This property III5 bern liitv.vi-july liicwn by wlut has been laid before, and et'pccially under the licit I uf elasticity;

wherefbre, having conli-ered the properties of air, 1 (ball uke noti:c of fame or" its opinrions and effects as t' die biifinels of vegetation.

Air, by being heavy and fluid, invert- the whole darth, and l' has all the bodies thereof with a great force, equal to what tin would fallen from the preflure of a column ur it' inches depth of mercury, or 1 feet of water; and conſtrains and binds them down with a force amounting, according to the computation of Mr. Pifthai, to .u^ pounds weight upon every square foot, or upward] of 10 pounds upon every f]iare iuth. Hence it prevents, e. g. the arterial vessels of plants and animals from being too much diltenJed by the impel: of the circulating juices, or by the diffie fottcof il. air is principally: sed in the blood of one, and ti, at the top of the other. For, The air pfeftls equitl; every wif, ai is confirmed in what vrc obli-rve of loft bwliei luftaining this preflure without any change of figure, and brittle bodtei without their br:iking.

Air It a principal] cause of the veget-ation of plants, an iofiance (1 which we have from Mr. R-., in the Phi-lofo; and I can laftionu of P'ettuce-iced, that was sown in the glafs-receiver of the air-pump, iviitli wa? exhausted and O: ved from all air, wlucl grew not at all in eight days time; w JL-reas fume of thit fanK Ford that was sown in die lame time in the open air, wai rifeu to the height of an inch and a half in that time, but the air being let into the empty receiver, the seed grew up to the height of two or three inches in the space of one week.

That 1) tena-n portion of air is aecllkry to preſerve die growing qua-ty of seeds is m:iifclt, from many re-pe;

From the 20 ... March to ... L- iftiti of April, 11 cu- bic inches of ... Rain, with ... re- cubic inches of a ... i and then water, generated 411 ... r three tokl

... HI 10 the ifth of May, it uenerpte! ... after which, the 9th of

F June,

June, it continued in a reforcing ftate, fo as to reforb 13 cubic inches: that there were at that feafon many hot days, with much thunder and lightning, which deftroys the elafticity of the ait: there were generated in all 489 cubic inches, of which 48 were abforbed. The liquor was at laft vapid.

On the 10th of Auguft, 26 cubic inches of Apples being mafhed, they generated 986 cubic inches of air in 13 days time, which is a quantity equal to 48 times their bulk*, after which they reformed a quantity equal to their bulk, in three or four days, notwithstanding the weather was then very hot; after which time they were ftationary for many days, neither generating nor abforbing.

From which before-mentioned experiments on Raifins and ale, the ingenious author concludes, that wine and ale do not turn vapid in warm weather by imbibing the air, but by fermenting and generating too much; by which means they are deprived of their enlivening principle the air: for which reafon, thefe liquors are beft preferved in cool cellars, whereby this adtive invigorating principle is kept within due bounds; which when they exceed, wines are upon the fret, and are in danger of being fpoiled.

Upon thefe, and many other experiments, which the learned author has given in his aforefaid treatife, he obferves, that this air which arifes in fo great quantities from fermenting and diftblving vegetables, is true permanent air, which is certain, by its continuing in the fame expanded and elaftic ftate for many weeks and months; which expanded watery vapours will not "do, but foon condense when cold.

Upon the whole, he concludes, that air abounds in vegetable fubftances, and bears a confiderable part in them: and if all the parts of matter were only endowed with a ftrongly attrafting power, all nature would then immediately become one unadtive cohering lump.

Wherefore it was abfolutely neceffary, in order to the aduating this vaft mafs of attrafting matter, that there fhould be every where mixed with it a due proportion of ftrongly-repelling elaftic particles, wjiich might enliven the whole maif by the inceffant adtion between them and the attrafting particles.

And fince thefe elaftic particles are continually in great abundance reduced by the power of the ftrong attrafters, from an elaftic to a fixed ftate, it was therefore neceffary that thefe particles fhould be endowed with a property of refuming their elaftic ftate, whenever they were difengaged from that mafs in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and diffolution of vegetables as well as animal bodies.

The air is very inftrumental in the production and growth of vegetables, both by invigorating their feveral juices, while in an elaftic adtive ftate, and alfo by greatly contributing in a fixed ftate, to the union and firm connexion of the feveral conflituent parts of thofe bodies, viz. their water, fire, fait, and earth.

To conclude, by reafon of thofe properties of the air before-mentioned, it is very ferviceable to vegetables, in that it blows up and breaks open the clouds, thofe treafures of rain, which fertilize the vegetable kind.

The air alfo helps to waft or difperfe thofe foggy humid vapours which arife from the earth, and would ©therwiie ftagnate, and poifon the whole face of the earth.

The air, by the affiftance of the fun, affumes and fublimate thofe vapours into die upper regions; and thefe foggy humid vapours are, by this fublimation; and the coercive power of the air and fun, rarefied and made of fecond ufe in vegetaticg.

And on the contrary, to the benign quality of the air, which is fo many ways fubfervient jo vegetables, it is alfo fometimes, and upon fome accounts, injurious and pernicious to them; not only to the ligneous, herbaceous, and flowery parts abc ve, but alfo to the roots and fibres below: for in th:at the air penetrates

into the earth, it is eafy to be concluded, that a dry, hufky, fcorching air, may be very prejudicial to the tender fibres of new planted trees.

It may be likewife fuppofed, that all bodies of earth are more or lefs capable of imbibing the fluid air, and of attrafting fuch falts as either the air can give, Or the earth is capable of receiving.

A I Z O O N. Sempervive.

This name Dr. Linnaeus has given to a plant near of kin to the Ficoidea, which has been called Ficoidea, by fome modern botanifts.

The CHARACTERS are,

It hath a permanent empalement of one leaf which is cut into five acute fegments at the top: there are no petals in the flower, but the five-cornered germen refts on the empakment, fupporting five ftyles^ which are crowned with fimplefigma\ thefe are attended by many hairy ftamina* which are infer ted into the empalement, and are crowned with fimple fummits.. The germen afterward becomes a /welling five-cornered capfule, having five cells, in which are lodged many roundifh feeds.*

This genus of plants is by Dr. Linnaeus ranged in the fifth divifion of his twelfth clafs, entitled Icofandria Pentagynia, the flowers of this clafs having more than nineteen ftamina, and in this divifion they have five ftyles.

The SPECIES are,

1. AIZOON (*Canarimfe*) foliis cuneiformi-ovatis floribus feffilibus. Hort. Upfal. 127. *Sempervive with oval wedge-jhaped leaves^ and flowers without foot-ftalks.* Ficoidea procumbens portulacae folio. Niffol. Adt. Par. 1711.
2. AIZOON (*Hifpanicum*) foliis lanceolatis floribus feffilibus. Lin. Sp. Plant. 488/ *Sempervive with fpear-jhaped leaves and flowers^ having no foot-ftalks.* Ficoidea Hifpanica annua folio longiore. Hort. Elth. 143.
3. AIZOON (*Paniculatum*) foliis lanceolatis floribus paniculatis. Lin. Sp. Pl. 448. *Sempervive with fpear-jhaped leaves and flowers growing in panicles.* Aizoon foliis lanceolatis fubtus hirtutis. Prod. Leyd. 221.

As we have no Englifh names for thefe plants*-fo I have adopted this of Sempervive, which hath been applied to the Aloe and Seduril, both which have been alfo titled Aizoon and Sempervivum.

The firft fort is a native of the Canary Iflands: this is an annual plant, which muft be raifed on a moderate hot-bed in the fpring *, and when the plants are fit to tranfplant, they fhould be carefully taken up, and planted each into a finall pot filled with frefh light earth, and plunged into another moderate hot-bed, obferving to fhade them from the fun until they have taken frefti root; after which they muft be hardened by degrees to bear the open air, into which they fhould be removed in June, placing them in a fheltered fituation, where they will flower, and ripen their feeds in September, foon after which the plants will periffh.

The fecond fort grows naturally in-Spain; this is alfo an annual plant, whole branches trail on the ground; the flowers have no beauty, fo thefe plants are only preferved by thofe who are curious in colledting rare plants for the fake of variety.

The third fort grows naturally at the Cape of Good Hope, from whence the feeds were brought to Europe, This is alfo of humble growth, and periffhes foon after the feeds are ripe.

Thefe may be propagated in the fame manner as the firft, and when the plants have acquired ftrength, they may be planted in the full ground *, but they require a poor fandy foil, for in rich ground they will grow very luxuriant in branches, but will not flower till late in the feafon, fo rarely perfed their feeds; but when they are planted in dry fand, or lime rubbifh, they will be more productive of flowers, and lefs vigorous in their branches.

A L A is the hollow of a ftalk, which either thctaf, or the pedicle of the leaf, makes with the ftalk or branches; or it is that hollow finus placed between the ftalk or branch and leaf, from whence a new off-fpring is wont to put forth, which the French call,

Aiffelles des Plantes. Sometimes it is used for leaves which consist of many lobes or wings.

Alae is also used to signify those petals of papilionaceous flowers placed between the Vexillum and the Carina, which the French call, *Les Ailes des Fkurselegumineuses*.

Alae is also used for those extreme (tender membranaceous parts of certain feeds; as is the Bignonia Plumeria, the fruit of the Maple, &c. which the French call *Semences ailes*. Again,

Alae is used for those foliaceous membranes which run the whole length of the stem; whence it is called, *Caulis alatus*, a winged stalk; in French, *Tige ailee*: but modern writers have styled *alae foliis decurrentibus*, or running leaves, because these alae or wings are connected with the leaves.

A L A B A S T R A, are those green herbaceous leaves that encompass flowers. Jungius explains Alabastrum to be the globe, or roundish bud, that is but just peeping out.

A L A T E R N O I D E S. See PHYUCA, CLUTIA, and CEANOTHUS.

A L A T E R N U S [called *EAαrpι], as though of iW-i, an Olive, and αrpTv&j an Ilex], or evergreen Privet.

The CHARACTERS are,

It hath male and female flowers in different plants in some species, and in others both sorts of flowers on the same. The male flowers are composed of an empalement of one leaf which is funnel-shaped and cut into five segments at their brim -, to the sides of the empalement are fixed five small petals; at the base of these petals are fastened so many stamina which are crowned with round funnels. The female flowers have a great resemblance to the male, but have no stamina. In the center is placed the germen, supporting a trifid styck crowned by a round stigma. The germen afterward becomes a soft round berry* containing three seeds.*

Dr. Linnaeus has joined this genus to the Rhamnus, to which he has also added the Frangula, Paliurus, and Zizyphus, and ranges them in his fifth class of plants, entitled Pentandria Monogynia.

THE SPECIES ARE

1. ALATERNUS (*Phylla*) foliis ovatis marginibus crenatis glabris. Common Alaternus with smooth leaves indented on their edges. Alaternus, i Clus. Hist. 56.
2. ALATERNUS (*Glabra*) foliis subcordatis ferratis glabris. Alaternus with heart-shaped smooth leaves which are fawed on their edges. Alaternus minore folio. Tourn. Inf. 595.
3. ALATERNUS (*Angujifolia*) foliis lanceolatis profunde ferratis glabris. Alaternus with smooth spear-shaped leaves which are deeply fawed. Alaternus monij>elica foliis profundius incis. H. R. Par.
4. ALATERNUS (*Latifolia*) foliis ovato-lanceolatis integerrimis glabris.* Alaternus with smooth oval spear-shaped leaves* which are entire. Alaternus Hispanica latifolia. Tourn. Inf. 566.

The varieties of these plants are, the first sort with variegated leaves, which is commonly called Bloatched Phillyrea by the nursery gardeners. And the third sort with leaves striped with white, and another with yellow; these are known by the Silver and Gold striped Alaternus: but as these are accidental Varieties, I have omitted placing them among the number of species.

The common, distinction of this genus from the Phillyrea, is in the position of their leaves, which in the plants of this are placed alternately on the branches, whereas those of Phillyrea are placed by pairs opposite, this is obvious at all seasons, but there are more essential differences in their characters, as will be explained under the article Phillyrea. *

The first sort has been long cultivated in the English gardens, but the plain sort is now uncommon here; the bloatched-leaved sort has been generally cultivated in the nurseries, and the other has been almost totally neglected.

These plants were much more in request formerly than they are at present, when they were planted

against walls in court-yards to cover them, as also to form evergreen hedges in gardens, for which purpose these were improper, for their branches illot very vigorously, and being very pliant, they are frequently displaced by the wind and in winter, when much snow falls in still weather, the weight of that which lodges on the hedges, frequently breaks them down: add to this the trouble of keeping them in order, which cannot be effected with less than three times clipping in a season, which is not only expensive, but also occasions a great litter in a garden: these inconveniences have justly brought these hedges into disesteem.

The third sort with silver-striped leaves, was also in great request some years ago, for planting against out-houses, and other buildings, to hide the brick-work, but as these required to be often clipped, and their branches frequently wanting to be fattened up to the wall, which was troublesome and expensive, and this sort of wall hedges being great harbour for vermin, there has been of late but little demand for these plants. The sort with gold-striped leaves is pretty rare in the English gardens, and is not so hardy as that with silver stripes, so that in severe winters they are often killed. But the taste for these variegated plants is almost lost in England, there being few persons now, who do not prefer the plain green leaves to those which are striped.

The second sort was formerly in the English gardens, in much greater plenty than at present. This was generally called Claftrus, or Staff-tree. The leaves of this sort are placed at greater distances than those of the first, so that their branches appear thinly covered with them, which may have occasioned their being disesteemed. The leaves of this are shorter than those of the first sort, and are rounded at their foot-stalks somewhat like a heart-shaped leaf, the edges are also fawed.

The third sort has been an old inhabitant in some gardens, but was not much propagated till of late years, the leaves of this are much longer and narrower than those of either of the other sorts, and the ferratures on their edges are much deeper; this shoots its branches more erect, and forms an handsome bush than any of the other, and is equally hardy, so may be allowed to have a place in all plantations of Evergreens. This grows naturally in the south of France, where the berries are gathered, and sold by the name of Avignon berries, for the use of painters, &c. for making a yellow pigment.

These sorts are by some supposed to be only varieties and not distinct species; but from many repeated trials, in raising them from seeds, I can affirm they do not vary, the seeds constantly producing the same species as they were taken from.

The second sort grows naturally about Turin, from whence I have been supplied with the seeds.

All these sorts are easily propagated by laying their branches down, as is practised for many other trees. The best time for this is in the autumn, and if properly performed, the layers will have made good roots by the autumn following, when they may be cut off from the old stock, and planted either into the nursery, or in the places where they are designed to remain. When they are planted in a nursery, they should not remain there longer than a year or two, for as they shoot their roots to a great distance on every side, so they cannot be removed after two or three years growth, without cutting off great part of them, which is very hurtful to the plants, and will greatly retard their growth, if they survive their removal; but they are frequently killed by transplanting, when they have stood long in a place. They may be transplanted either in the autumn or the spring, but in dry and the autumn planting is best, whereas in moist ground the spring is to be preferred.

The plain sorts may also be propagated by sowing their berries, which they produce in great plenty, but the birds are greedy devourers of them, so that unless the berries are guarded from them, they will soon be

bedevoured when they begin to ripen. The plants which arise from seeds, always grow more erect than those which are propagated by layers, for are fitter for large plantations, as they may be trained up to stems, and formed more like trees, whereas the layers are apt to extend their lower branches, which retards their upright growth, and renders them more like shrubs. They will grow to the height of eighteen or twenty feet, if their upright shoots are encouraged; but to keep their heads from being broken by wind or snow, those branches which shoot irregular should be shortened, which will cause their heads to be closer, and not in so much danger.

All the sorts thrive best in a dry, gravelly, or sandy soil, for in rich ground they are often injured by frost, when the winters are severe, but in rocky dry land they are seldom injured: and if in very hard frost their leaves are killed, yet the branches will remain unhurt, and will put out new leaves in the spring.

A L B U & A, Bastard Star of Bethlehem.

The CHARACTERS are,

The flower has no empalement, it has six oblong oval petals, which are permanent, the three outer spread open, and the three inner are connected) it hath six three-cornered stamina the length of the corolla, three of which are fertile, crowned with moveable summits, the other three, which are barren, have no summits. The nectarium is situated near the base of the three fertile stamina, it has an oblong three-cornered germen, with a broad triangular styk, crowned by a pyramidal three-cornered stigma, the capsule is three-cornered, having three cells filled with plain seeds.

This genus is ranged in the first section of Linnaeus's sixth class of plants, the flower having six stamina and one style.

The SPECIES are,

1. ALBUCA (*Major*) foliis lanceolatis. Lin. Sp. 438. *Star-flower with spear-shaped leaves.* Ornithogalum alutivirens. Indicum. Corn. Canad.

2. ALBUCA (*Minor*) foliis fubulatis. Lin. Sp. 438. *Star-flower with awl-shaped leaves.* Ornithogalum Africanum, flore viridi altero alteri innato. Herm. Parad. 209. *African Star-flower with a greenish yellow flower.* These plants have been generally ranged under the genus of Ornithogalum, but as their flowers differ in their form from the other species of that genus, Dr. Linnaeus has constituted this genus for them. The first sort grows naturally in Canada, and in some other parts of North America; the root is bulbous, from which shoot up eight or ten long narrow spear-shaped leaves. In the center of these arise a flower-stem a foot or more in height, garnished with a loose spike (or thyrse) of greenish yellow flowers, each have a long pedunculus, which turns downward, having pretty large spikes at their base, which are erect, and end in sharp points. After the flower is past, the germen swells to a three-cornered capsule* having three cells filled with flat seeds.

The second sort grows naturally at the Cape of Good Hope; this hath also a pretty large bulbous root, from which arise four or five narrow awl-shaped leaves, of a deep green colour: the flower-stem which comes from the center of the root, is naked, and rarely rises more than eight or nine inches high, having five or six greenish yellow flowers growing almost in form of an umbel at the top: these are rarely succeeded by seeds in England.

The Canada Albuca is hardy, for the roots may be planted about four inches deep in a border of light earth, where they will thrive, and produce their flowers late in the summer; but as the seeds rarely ripen in England, and the bulbs do not put out many offsets, the plants are not common in this country.

The African sort I raised from seed, a few years past; this generally flowers twice a year, the first time in March or April, and again in July or August, but has not produced any seeds. If the roots of this sort are kept in pots, filled with light earth, and sheltered under a hot-bed frame in winter, they will thrive and produce flowers, but the best method is to have

a border in the front of a green-house, or stove, where the roots of most of the bulbous flowers may be planted in the full ground, and screened in winter from frost. In such situations they thrive much better, and flower stronger, than when kept in pots.

ALCEA. Lin. Gen. 750. The Hollyhock.

The CHARACTERS are,

The flower hath a double empalement, of which one is permanent. The outer one is spread open, and cut at the top into six segments, the inner is larger, and flightly cut into five. The flower is composed of five petals, which coalesce at their base, and spread open at the top in form of a rose. In the center is placed the round germen, supporting a short cylindrical style, crowned with numerous stigma, which is attended by many stamina joined below to the pentagonal column, and spread open at top, these are crowned with kidney-shaped summits: after the flower is past, the germen becomes a round, depressed, articulated capsule, homing many cells, in each of which is lodged one compressed kidney-shaped seed.

This genus is ranged by Dr. Linnaeus in his sixteenth class of plants, entitled Monadelphica Polyandria: in this class the stamina and style coalesce and form a fore of column in the center of the flower, from whence Dr. Van Royen has given to this class the title of Columnifera, and in this division there are a great number of stamina.

The SPECIES are,

ALCEA (*Rosea*) foliis finuatis angulosis. Hort. Cliff. 348. *Hollyhock with angular finuated leaves.* Malva rosea folio fubrotundo. C. B. P. 315.

2. ALCEA (*Ficifolia*) foliis palmatis. Hort. Cliff. 348. *Hollyhock with handed leaves.* Malva rosea folio ficusj C. B. P. 315.

These are distinct species, whose difference in the form of their leaves always continues. The leaves of the first sort are roundish, and cut at their extremity into angles, whereas those of the second are deeply cut into six or seven segments, so as to resemble a hand.

The various colours of their flowers being accidental, as also the double flowers being only varieties which have risen from culture, are not by botanists deemed distinct species. I have not enumerated them here, therefore shall only mention the various colours which are commonly observed in their flowers, which are white, pale, red, deep red, blackish red, purple, yellow, and flesh colour. Besides these, I many years ago saw some plants with variegated flowers, in the garden of the late Lord Burlington, in London, raised from seeds which came from China.

Although these varieties of double Hollyhocks are not constant, yet where the seeds are carefully saved from the most double flowers, the greatest number of the plants will arise nearly the same, as the plants from which they were taken, both as to their colour and the fulness of their flowers, provided no plants with single or bad coloured flowers are permitted to grow near them. Therefore so soon as any such appear, they should be removed from the good ones, that their farina may not spread into the other flowers, which would cause them to degenerate.

The first species grows naturally in China, from whence I have often received the seeds. The second sort I have received from Itria, where it was gathered in the fields, but these seeds produced single red flowers only; whereas from some seeds of this sort, which were given me by the late Charles Du Bois, Esq; of Mitcham, in 1726, which he procured from Madras, I raised many double flowers of several colours.

These plants, although natives of warm countries, yet are hardy enough to thrive in the open air in England, and have for many years been some of the greatest ornaments in the garden, toward the latter part of summer; but since they have become very common, have not been so much regarded as they deserve, partly from their growing too large for fix garden, and their requiring tall stakes to secure them from being broken by strong winds. But in large gardens,

gardens, where they are properly disposed, they make a fine appearance; for as their spikes of flowers grow very tall, there will be a succession of them on the same stems, more than two months; the flowers on the lower part of the spike appearing in July, and as their stalks advance, new flowers are produced till near the end of September. When the plants are planted in good ground, their stalks often rise to the height of eight or nine feet, so that near six feet of each will be garnished with flowers; which when double, and of good colours, will make a fine appearance, especially if the various colours are properly intermixed.

They are propagated by seeds, which, as hath been already observed, should be carefully saved from those plants whose flowers are the most double, and of the best colours. If these are preferred in their capsules until spring, the seeds will be better, provided they are gathered very dry, and care be taken that no damp comes to them in winter, which will cause their covers to be mouldy, and thereby spoil the seeds.

The seeds should be sown on a bed of light earth, about the middle of April, which must be covered about half an inch deep, with the same light earth; some persons sow them in shallow drills, and others scatter the seeds thinly over the whole bed. When they are sown in the former method, the plants generally come up thick, so will require to be transplanted sooner than those which are sown in the latter. By the first, the seeds may be more equally covered, and kept clean with less trouble, because the ground between the drills may be hoed. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, at a foot distance from each other, observing to water them until they have taken good root; after which they will require no farther care, but to keep them clean from weeds till October, when they should be transplanted where they are to remain.

Some persons let their plants remain a year longer in the nursery-beds to see their flowers, before they remove them to the flower-garden, but when this is intended, the plants should be planted at a greater distance in the nursery-beds, otherwise they will not have room to grow. However, I have always chosen to remove my plants the first autumn, for young plants more freely grow, than those which are older, and if the seeds are carefully saved, there will not be one in ten of the plants come single or of bad colours.

ALCHEMILLA, Ladies Mantle.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is spread open at the brim and cut into eight figments. There are no petals to the flower, but the centre of the empalement is occupied by the oval germen* into which is inserted a long style, crowned with a globular stigma: this is attended by four erect stamina resting on the brim of the empalement and crowned with roundish funtits -, the germen afterwards turns to a single compressed seed.*

Dr. Linnaeus ranges this genus in the first section of his fourth class of plants, entitled Tetrandria monogynia, the flowers having four stamina and one style.

The SPECIES are,

1. *ALCHEMILLA (Vulgaris) foliis lobatis ferratis, segmentis involucri acuto. The common Ladies Mantle. G B. P. 319.*
2. *ALCHEMILLA foliis lobatis fericeis acutis ferratis, segmentis involucri subrotundis. Small silvery Ladies Mantle with lobed leaves sharply ferrated, and the figments of the involucrium cut into roundish figments. Alchemilla Alpina pubescens minor, Tourn. Inf. R. H., 508.*
3. *ALCHEMILLA (Alpina) foliis digitatis ferratis? Flor. Lapp. 61. Silvery Alpine Ladies Mantle with banded leaves. Alchemilla perennis incana argentea five ferice*, fatinum provocans. Mor. Hist. 2. p. 195.*
4. *ALCHEMILLA (Pentaphylla) foliis quinatis multifidis f. Shris. Lin. Sp. Plant. 123. Smooth five-leaved Ladies Mantle* cut into many figments. Alchemilla Alpina*

pentaplyllea minima lobis fimbriatis. Bocc. Mufc. 1. p. 18.

The first sort grows naturally in moist meadows in several parts of England, but is not very common near London: the roots are composed of many thick fibres, which spread greatly when they are in a proper soil; the leaves rise immediately from the root, sustained by long foot-stalks; they are roundish, and scalloped round the borders into seven or eight IOIKS, shaped somewhat like the Ladies scalloped Mantles, from whence it had its name. The flower-stems arise between the leaves about a foot high, which divide into many branches, and are at each joint garnished with one small leaf, shaped like those below; the flowers are composed of an herbaceous empalement, in the center of which is the style attended by four stamina, crowned with yellow funtits; so that the only beauty of this plant is in the leaves, which are used in medicine, and are esteemed to be vulnerary, drying and binding, and of great force to stop inward bleeding.

The second sort is much smaller than the first, the leaves are much whiter and appear silky; the flower-stems do not branch out so much, nor are the flowers produced in so large clusters: their empalement is broader, and the segments more obtuse than those of the first sort.

The third sort grows naturally on the mountains in Yorkshire, Westmoreland, and Cumberland, generally upon moist boggy places. It is also a native of Sweden and Denmark, the Alps, and other cold parts of Europe, and is admitted into gardens for the sake of variety. The leaves of this sort are very white, and deeply cut into five parts like a hand; the flower-stems seldom rise more than six inches high, nor do the flowers make a better appearance than the other sorts.

The fourth sort grows naturally in Sweden, Lapland, and other cold countries, so is only to be found in some few curious botanic gardens in this country. These are all abiding plants, which have perennial roots and annual stalks, which perish in autumn. They may be propagated by parting their roots; the best time for doing this is in the autumn, that their roots may be established before the drying winds of the spring come on. They should have a moist soil and a shady situation, otherwise they will not thrive in the southern parts of England. When they are propagated by seeds, they should be sown in the autumn, for when they are sown in the spring, they seldom grow the first year. They should be sown on a shady moist border, and when the plants come up, they will require no other care but to be kept clean from weeds.

A L D E R-TREE. See ALNUS.

ALETRIS.

The CHARACTERS are,

The flower has no empalement, but hath one oblong oval petal, cut into six figments at the brim and are permanent \ it hath six awl-shaped stamina the length of the corolla, whose base are inserted in the figments \ these are crowned by oblong erect funtits, and an oval germen supporting an awl-shaped style the length of the stamina, crowned by a trifid stigma. The germen afterward becomes an oval three-cornered capsule with three cells, filled with angular seeds.*

This genus of plants is ranged in Linnaeus's first section of his sixth class, the flowers having six stamina and one style.

The SPECIES are,

1. *ALETRIS (Farinosa) acaulis, foliis lanceolatis membranaceis, floribus alternis. Lin. Sp. 456. Aletris without stalks, spear-shaped membranaceous leaves, and flowers placed alternate. Hyacinthus caule nodo, foliis linguiformibus acuminatis dentatis. Flor. Virg. 38.*
2. *ALETRIS (Capers) acaulis, foliis lanceolatis undulatis, spica ovata floribus nutantibus. Lin. Sp. 456. Aletris without stalks, waved spear-shaped leaves, and an oval spike of alternate flowers.*

3. ALETRIS (*Hyacinthoides*) acaulis, foliis lanceolatis carnofis, floribus geminatis. Lin. Sp. 456. *Aletris without stalks, fiejhy fpear-Jhaped leaves* and flowers fet by pairs.*
4. ALETRIS (*Zeylanica*) acaulis, foliis lanceolatis planis ereftis radicalibus. *Aletris without stalks, and plain, fpear-Jhaped, ere fit leaves rifing from the root.*
5. ALETRIS (*Fragrans*) caulefcens, foliis lanceolatis amplexicaulibus. *Stalky Aletris, with fpear-Jhaped leaves embracing it.* Aloe Africana arborefcens, floribus albis fragrantiffimis. Hort. Amft. 2. tab. 4.

The firft fort grows naturally in North America *, it hath a tuberoie root, from which arife feveral fpear-Jhaped leaves, and a naked ftalk fupporting a fpike of flowers placed alternate, of a greenilh white colour 5 thefe appear in June, but are rarely fucceeded by feeds in England.

This plant is tolerably hardy, fo may be preferred thro' the winter, if flickered under a hot-bed frame -, but as the feeds do not ripen here, and the roots increafe but (lowly, the plants are at prefent rare in England.

The fecond fort grows naturally at the Cape of Good Hope. This is a low plant, feldom rifing more than a foot high -, the leaves are fpear-Jhaped and undulated *, the foot-ftalks of the flower arife from the root, which fuftain feveral white nodding flowers, in fhape fomewhat like thofe of the Hyacinth,

The roots of this fort muft be planted in pots filled with light earth, that they may be (heltered in a dry airy glafs-cafe in winter, being too tender to thrive in the open air in England *, therefore the pots fhould be removed into fhelter in Oftober, and during the winter fealbn, they fhould be fparingly watered. In May they fhould be placed abroad in a Ihehered fituation, and in warm weather muft be frequently refrefhed with water; with this management the plants will flower; but as they do not perfect their feeds here, nor do they increafe faft by roots, the plants are fcarce in England.

The third fort has been long preferred in the Englifh gardens, and has been known by the title of Guinea Aloe *, this hath thick flefhy roots like thofe of the Flag Iris, which creep far where they have room. The leaves arife fingly from the root, and are near one foot and a half long, ftiff, waved, and have no foot-ftalks, arifing immediately from the root, as do alfo the foot-ftalks of the flowers, which when the rdots are ftrong, are often a foot and a half high, garnifhed great part of their height with clear white flowers, fhaped like thofe of the Hyacinth, whofe brims are cut into fix fegments, which are reflexed; thefe feldom continue in beauty more than two or three days, and are never fucceeded by feeds here.

The fourth fort is alfo pretty common, in gardens where there are conveniences for preferring exotic plants. This hath flefhy creeping roots, which multiply greatly. The whole plant feldom rifes more than fix inches high: the leaves are plain and upright, arifing without foot-ftalks *, but as I have never feen any flowers produced on the plants, I can give no defcription of them, but have followed Dr. Linnaeus in ranging it, though I have great reafon to believe he has not feen the flower * for he fuppofes this to be a variety of the third fort, which no perfon who is acquainted with the two plants can ever admit. This has been always known by the title of Ceylon Aloe. The fifth fort rifes with an herbaceous ftalk to the height of eight or ten feet high, having many joints, and is adorned toward the top with a head of fpear-ftiaped thin leaves, which are of a deep green colour and reflexed at* their ends, embracing the ftalkr with their bafe. The foot-ftalks of the flower arife from the center of the heads, which are generally two feet high, branching out on each fide, and fully garnifhed with white flowers, in fhape fomewhat like thofe of the third fort; but thefe open only in the evening, when they emit a moft fragrant ododr, but clofe again in the morning, and are not of long duration; but thefe are fomecimes fucceeded by feeds, which, al-

though fair to appearance, yet I could never raife any plants from them *, but they are eaflly propagated from the fide heads, which they put out after flowering.

The laft three forts are too tender to live through the winter in England, unlefs they are placed in a warm ftove *, nor will the third and fifth forts produce their flowers, if the plants are not plunged into a tan-bed; for although the plants may be preferred in a dry ftove, yet thofe make but little progrefs there; whereas when they are in a tan-bed, they will advance as much in one year as the other will in three or four; the leaves will alfo be much larger, and the whole plant much ftronger. The third fort will fometimes flower in a dry ftove, but the flower-ftems will be weak, and do not produce half fo many flowers as when in tan; but the fifth has not yet flowered here when kept in the dry ftove.

The third and fourth forts propagate very faft by their creeping roots, which fend up many heads; thefe may be cut off in June, and laid in the ftove for a fortnight, that the part wounded may be healed over; then they fhould be planted in fmall pots, filled with light fandy earth, and plunged into a moderate hot-bed of tanners bark, giving them but little water till they have put out good roots; then they muft be treated like other tender fucculent plants, never fetting them abroad in fummer.

The heads of the fifth fort when taken from theftems fhould be laid in the ftove a week, for their wounds to heal, then fhould be planted in pots and treated as the other.

science of botany, may not ... r<iii[y] turn ro (60C: articles, therefore we thail itii'en their culture unJcr their fuchscritles.

The r • • • • • species are easily propagated by plaining ilic da • • • • • or small bulbs, in the fpring. 1. bctit about • • • • • or five inches distance from each other, keeping them clear from weeds. About the beginning of June, the leaves of the first fort should be tied in knots, to prevent their fpanning, or running to feed, which will greatly enrage the bulb. In the middle of July, the leaves will begin to wither and decay, at whidinms the; should be taken out of the ground, and ha • • • • • up in a dry room, to prevent their rotting, ami mai • • • • • be thus preserved for winter use.

The roots of the second fort may remain in the ground till the leaves are decayed, when their bulbs may be taken up and dried, to be preserved for use during the winter season; but some of the roots may be at the same time planted again for the succeeding year; for this fort requires w • • • • • be planted in autumn, especially on dry ground, otherwise the bulbs will not be large.

The third fort was formerly in greater esteem than at present, it being rarely cultivated in gardens. It is found wild in much shady places in many parts of England; and may be cultivated by planting the roots in a moist shady border, at almost any time of the year; but the best season is in July, just as the green leaves are decaying.

The fourth fort grows naturally in the Hebrides, from whence it has been transplanted into several gardens, where it is preserved more for the sake of variety than for use.

The eleventh and thirteenth forts are very hardy, and may be removed in July or August, when their leaves begin to decay, and be rooted out of the ground.

The fifth fort was formerly preferred in gardens for the sake of its yellow flowers, but having a very strong garlic smell, it is now almost entirely rooted out of the garden.

The sixth fort is preferred by many persons in their gardens for the sake of variety, but as this is a very strong garlic, it is not so much preferred as the flower-ivort.

The ninth and twelfth forts are sometimes preferred to have a place in gardens for the sake of variety.

The seventh, eighth, and ninth forts grow naturally in Tartary and Siberia, from whence their seeds were first brought, and from thence some of the best gardens have been supplied with seeds; these are only preferred for the sake of variety.

The fourth, fifth, sixth, and seventh forts, have been planted in gardens for the sake of their flowers, but of late years most people have turned them out, to make room for better sorts. But the fourth multiplies so fast by itself, as to render it difficult to destroy them, when they have remained any time in a garden.

This produces large umbels of white flowers, sown in the month of April and May.

The nineteenth fort was brought from Virginia, and is preferred in some gardens for the sake of its flowers, but has no great beauty; it is very hardy, and will thrive in the open air very well, and is propagated by setting the bulbs, which are produced in plenty on the top of the stalk.

They are all of them very hardy, and will thrive in almost any situation, and are easily propagated either by their roots, or their seeds: if from the roots, the best time is in autumn, that they may take good root in the ground before the spring, which is necessary, in order to have them flower during the following summer. If they are propagated by seeds, they may be sown in any part of common earth, either in autumn, or after the seeds are ripe, or in the spring following, and will require no farther care, but to keep

keep them clear from weeds, in the following autumn, the plants may be transplanted into the borders where they are to remain for good.

The greatest part of these plants produce their flowers in May, June, and July.

The yellow Moly will grow about a foot high, and having some beauty in the flowers, is worthy of a place in such borders of the flower-garden, where few better things will thrive. These increase plentifully both by roots and feeds.

The sixth and seventeenth sorts grow upwards of two feet high, and when they are in flower, make a pretty appearance, and as they are not troublesome to keep, may be allowed a place in the borders of the flower-garden.

All the other sorts are equally hardy, and will grow in any soil or situation, but as they have little beauty, they are rarely preferred, except in botanic gardens for the sake of variety.

ALOE [Gr. ἄλκο].

The CHARACTERS are,

The flower is naked, having no empalement; // is of one leaf, having a long smooth tube, which is divided at the top into six parts, spreading open \ it hath six awl-shaped lamina, which are inserted at their base to the germen, and are extended the length of the tube, these are crowned with oblong summits \ in the center is situated the oval germen, supporting a five-angled style, which is of the same length with the flaming crown with a trifid stigma. The germen afterward becomes an oblong capsule, having three furrows, which is divided into three cells opening in three parts, and filled with angular seeds.

This genus of plants is by Dr. Linnaeus ranged in the first section of his sixth class, titled Hexandria monogynia, from the flowers having six lamina and one style.

The SPECIES are,

1. ALOE (*Mitriiformis*) floribus pedunculatis cernuis corymbosis sub-cylindricis. Lin. Sp. Plant. 319. i. e. *Aloe with dependent flowers, bowing foot-stalks which are ranged in a cylindrical corymbus.* Aloe Africana mitriiformis spinosa. Hort. Elth. 1. p. 21. Mitre-shaped Aloe.
2. ALOE (*Barbatenjis*) foliis dentatis erectis succulentibus fubulatis, floribus luteis in thyrso dependentibus. *Aloe with creft, succulent, awl-shaped leaves, and yellow flowers growing in a loofepike, hanging downward.* Aloe vulgaris. C. B. P. 386.
3. ALOE (*Arborefcens*) foliis amplexicaulis reflexis, margine dentatis, floribus cylindricis caule fruticosa. *Aloe with leaves embracing the stalks, which are reflexed and indented on their edges, flowers growing cylindrical, end affirubby stalk.* Aloe Africana caulefcens foliis glaucis caulem amplectantibus. H. Amft. Commonly called Sword Aloe.
4. ALOE (*Africana*) foliis latioribus amplexicaulis, margine & dorso spinosis, floribus spicatis, caule fruticosa. *Aloe with broader leaves embracing the stalks, whose edges and back are set with spines, flowers growing in spikes, and * Jhrubby stalk.* Aloe Africana caulefcens foliis minus glaucis dorfi parte supremâ spinosa, Com. Pnel. 68.
5. ALOE (*Difticba*) foliis latiflimis amplexicaulis maculatis, margine spinosis floribus umbellatis. *Aloe with very broad spotted leaves embracing the stalk, whose edges are set with spines and flowers, growing in an umbel.* Aloe Africana caulefcens foliis spinosis maculis ab utraque parte albicantibus notatis. Hort. Amftel. 2. p. 9. by some called the Sope Aloe, and by others Carolina Aloe.
6. ALOE (*Obfcura*) foliis latioribus amplexicaulis maculatis margine spinosis floribus spicatis. *Aloe with broad spotted leaves embracing the stalks, whose edge* have spines, and flowers growing in a pike.* Aloe Africana caulefcens foliis spinosis maculis ab utraque parte albicantibus obfcurioribus magis glaucis quam praecedens. Boerh. Ind.
7. ALOE (*Plicatilis*) foliis eniformibus inermis ancipitibus floribus laxè spicatis caule fruticosa. *Aloe with sword-shaped smooth leaves, standing two ways, the flowers growing in loofe spikes^ and a Jhrubby stalk.* Aloe Africana arborefcens montana non spinosa folio longiflimo plicatili flore rubro. Com. Hort. Amft. 2. p. 5.
8. ALOE (*Brevioribus*) foliis amplexicaulis utriusque spinosis, floribus spicatis. *Aloe with leaves embracing the stalks, which are prickly on every side, and flowers growing in spikes.* Aloe Africana caulefcens foliis glaucis breviflimis foliorum parte internâ & externâ nonnihil spinosa. Com. Prael. 71.
9. ALOE (*Variegata*) floribus pedunculatis cernuis racemosis prismaticis ore patulo aequali. Lin. Sp. Plant. 321. *Aloe with hanging floaters, having foot-stalks, and spreading equally at the brim.* Aloe Africana humilis foliis ex albo & viridi variegatis. Com. Prael. 79: commonly called Partridge-breast Aloe.
10. ALOE foliis erectis fubulatis radicatis undique inermis spinosis. Hort. Cliff. 131. *Aloe with erect awl-shaped leaves, set with soft spines on every part.* Aloe Africana humilis spinis inermibus & verrucosis obfita. Com. Prael. 77. commonly called Hedge-hog Aloe.
11. ALOE (*Vifcoja*) floribus feffilibus infundibuli formibus bilabiatis laciniis quinque revolutis fumma eredita. Lin. Sp. Plant. 322. *Aloe with funnel-shaped flowers, without foot-stalks, opening in two lips, and cut into five segments, which turn backward, and are erect at the top.* Aloe Africana eredita triangularis & triangulari folio vifcofo. Com. Prael. 82.
12. ALOE (*Spiralis*) floribus feffilibus ovatis crenatis segmentis interioribus conniventibus. Lin. Sp. Plant. 322. *Aloe with oval crenated flowers, without foot-stalks, and the interior segments closing together.* Aloe Africana eredita rotunda folio parvo & in acumen acutiffimum exeunte. Com. Prsel. 83.
13. ALOE (*Linguiforme*) feffilibus foliis lingui formibus maculatis floribus pedunculatis cernuis. *Aloe with dwarf tongue-shaped, spotted leaves, and hanging flowers, which have foot-stalks.* Aloe Africana flore rubro folio maculis albicantibus ab utraque parte notato. H. Amft. 2. p. 15. commonly called Tongue Aloe.
14. ALOE (*Margaritifera*) floribus feffilibus bilabiatis labio superiore erecto & inferiore patente. Lin. Sp. Plant. 322. *Aloe with Jewel flowers, gaping with two lips, the upper being erect, and the under spreading.* Aloe Africana folio in fummitate triangulari margaritifera flore subviridi. Com. Hort. Amft. 2. p. 19. commonly called large Pearl Aloe.
15. ALOE (*Vera*) foliis longiflimis & angustiffimis marginibus spinosis, floribus spicatis. *Aloe with very long narrow leaves, having spines on their hedges, and flowers growing in spikes.* Aloe Indise Orientalis, ferrata succotrina vera flore Phcenicio. Hort. Beaumont. The Succotrine Aloe.
16. ALOE (*Glauca*) caule brevis, foliis amplexicaulis bifariam versus spinis marginibus erectis floribus capitatis. *Aloe with ajhortstalk, leaves standing two ways, which embrace the stalk; the spines on the edges erect, and flowers growing in a head.* Aloe Africana caulefcens foliis glaucis brevioribus foliorum parte internâ & externâ nonnihil spinosa. Com. Prael. 71.
17. ALOE (*Arachnoidea*) feffilibus foliis brevioribus planis carnofis apice triquetris marginibus inermis spinosis. *Low Aloe with jhort, plain, fleshy leaves, triangular at their ends, and borders^ set with soft spines.* Aloe Africana humilis arachnoidea. Com. Prael. 72. commonly called Cobweb Aloe.
18. ALOE (*Herbacea*) foliis ovato-lanceolatis carnofis apice triquetris angulis inermis dentatis. Hort. Cliff. 131. *Aloe with oval, spear-shaped, fleshy leaves, having three angles at their extremities, which are indented and set with soft spines.* Aloe Africana minima atro-viridis spinis herbaceis numerosis ornata. Boerh. Ind. Alt. 2. p. 31.
19. ALOE (*Retufa*) floribus feffilibus triquetris bilabiatis labio inferiore revoluta. Lin. Sp. Plant. 322. *Aloe with flowers divided into three parts, the under lip being turned*

The 5ft fort of Aloe grows with an upright fl: to the height of five or six feet, the leaves closely embrace the stalks; they are thick, succulent, broad at the base, growing narrower, and tend to a point, of a dark green colour, and imbricate on the edges, as alfo few on their upper furfices; the leaves (land creel, and draw together towards the tap, where they form the remembrance of a mitre, from whence it is called the Mitre Aloe. The flower-stem rises about three feet high, on the top of which the lowers come out in a fan of globular spikes, but afterwards is funned into a cylindrical spike: these have long foot-stalks, which come out horizontally, and the Bowers hang downward; they are tubulous, and cur into six unequal (segments to the bottom, these bring alternately broader than the others. There are six stamens, none of which are as long as the tube of the flower, the other three are shorter. The crown of the fruit is oblong funnel-shaped of a gold colour, the chalice-crowned germen is seated in the bottom of the Bower, surrounded by a single style, which is thicker than the stamens, having no stigma on the top. The tube of the Rower is of a reddish colour, and the brim is of a pale green, so that it makes a pretty appearance when the spike is shown at large.

This fort will live in a warm dry green-house in winter, and may be kept in the open air in summer, in a flickered duanpni but the plain should not have much water, lest it should rot their stems. "With this management the plants will not grow so fast, as when they are placed in a box (but they will be stronger) and their stems will support their heads much better.

The second fort is very common in the islands of America, where the plant is propagated from the poorest land, to obtain the Hepatic Alois which are brought to England, and used chiefly for medicines, being too coarse for medicine.

The leaves of it are about four inches long at their base, where they are near two inches thick, and gradually taper to a point, having a few incisions on the edges; the flowers are of a wa-green colour, and when young are spotted with white. The flower-stem rises near the chalice high, and the flowers stand in a slender loose spike, with very tubulous, hanging downward. They are tubulous, and cut into six parts, of a bright yellow colour, and the Aamina Hand but beyond the tube. This never produces seed in England, and is too tender to live through the winter of our climate, in a common green-house, therefore it should be planted in a moderate degree of warmth in the open air. I have known plants of this kind, which have had an unaltered kind about

their roots) and hang up in a warm room for two years, and afterwards plant in a pot, which will grow very well, from whence the plant is called Sempervivum by the inhabitant of Anierica. The third fort will grow to the height of ten or twelve feet, with a naked stem, the leaves stand at the top, which are closely embraced together; they are about two inches broad at their base, growing narrower to a point, and are reflexed, and stand on the edges, each being armed with a strong crooked spine. The leaves are of a green colour, and very succulent. The flowers are of a yellowish (pike, or turbid), and of a bright red colour. These are in beauty in November and December.

This fort will live through the winter in a good green-house, but they will not flower unless they have a moderate (share of warmth, therefore they should lie covered up in October, which should be kept above a moderate heat, in which they will not fail to flower.

The fourth fort is somewhat like the third, but the leaves are broader, and have several small tubulous flowers on the sides of the stem towards their extremities. The flowers of this grow in a loose spike, and the plant never put out any suckers, so that it is very difficult to increase.

The fifth fort is somewhat like the second fort high, the leaves are very broad at the base, where they closely embrace the stem, and gradually decrease to a point. The edges are fetid (spines, and the under surface is covered horizontally every way; these are of a dark green colour spotted with white, somewhat resembling the colour of soft soap, from whence some have given it the title of Soap Aloe. The flowers grow in umbels on the tops of the stalks, which are of a beautiful red colour, and appear in August and September. This fort is hardy, so may be kept in a common green-house in winter, and in the summer placed in the open air.

The sixth fort is somewhat like the fifth in its manner of growth, but the leaves are broader, of a lighter green colour, the edges and also the spines are of a Clippier colour, and the flowers are of a light green. This is as hardy as the former, it may be treated in the same manner. It flowers in September.

The seventh fort grows to the height of six or seven feet, with a strong stem, the upper part of which is produced two, three, or four heads, composed of loose, round, jointed leaves, of a feagreen colour, entire, and ending in obtuse points; these are placed two ways, lying over each other with their edges die same way. The flowers are produced in loose spikes, which are of a red colour, and appear at different times of the year.

The eighth (on an annual plant, seldom rising more than a foot high) the leaves are produced near the ground, which are broad at the base, where they embrace the stem, and gradually diminish to a point; they are of a feagreen colour, wide imbricate spots; their edges, and also their upper parts below and above, are hairy with pretty (spines, the flowers grow in loose spikes, the tubulous part being red, and the brim of a light green colour.

The ninth is a low plant, (scarcely rising above eight inches high). The leaves of this are triangular, and stand back at their extremities; the leaves are entire, their edges being very tightly fan-shaped. They are curiously variegated (potted, the leaves are like the feathers of a partridge's breast, from whence it has the name. The flowers grow in very loose spikes, upon stalks about one foot high; they are of a line red colour tipped with green. This will live in a good green-house through the winter.

I have raised a raney of this from the seeds which I received from the Cape of Good Hope, with broader triangular leaves, which spread much more than those of the former, and are not so beautifully (pictive the lower part of the leaves is of a low much taller.

The tenth is also a very low plant, never rising to have stalks, the leaves are broad at their base, but are tapering (to a point where they are triangular; they

they are Wet on their edges, and both surfaces* with soft spines, very closely, from whence this plant had the name of Hedgehog Aloe. The flowers grow in a loose head, on the top of the stalk which is very thick, but seldom a foot high: they are of a fine red colour below, but of a pale green above. This fort may be preserved through the winter in a good greenhouse, and placed in the open air in summer.

The eleventh fort grows near a foot high* and is furnished with triangular leaves, from the ground upward; these are of a dark green colour, and are placed in form of a triangle, the flowers grow thinly upon very slender stalks, and are of an herbaceous colour, and their upper part turns backward. This fort requires a moderate warmth in winter, so should be placed in a cool part of the stove.

The twelfth fort grows somewhat like the former* being beset with leaves from the bottom, but these are rounder, and end in sharp points, the flowers grow upon taller stalks, which branch out and grow in long close spikes. There is a variety of this fort which has been raised from seeds, which is much larger, the leaves thicker, and the flowers grow upon taller stalks, but this is only a female variety.

This fort may be preserved through the winter in a good greenhouse, but must have very little water given it during the cold weather.

The thirteenth fort grows with its leaves near the ground, which are about six inches in length, and shaped like a tongue, from whence it had the title of Tongue Aloe. The flowers grow in slender loose spikes, each hanging downward, of a red colour below, and green at the top. This is pretty hardy, so may be kept in a common greenhouse in winter, and set abroad in summer. There is a variety of this fort, with leaves much more potted.

The fourteenth fort is of humble growth, the leaves come out on every side without order near the ground, they are thick, triangular at their ends, and closely studded with white protuberances, from whence it was called Pearl Aloe. There is a smaller fort of this which hath been long preserved in the English gardens, but the manner of its flowering being the same, I suspect it to be only a variety. This may be preserved through the winter in a common greenhouse. It flowers at different seasons of the year.

The fifteenth fort is the true Succotrine Aloe, from whence the best fort of Aloe for use in medicine is produced. This hath long, narrow, succulent leaves, which come out without any order, and form large heads. The stalks grow three or four feet high, and have two, three, and sometimes four of these heads, branching out from it: the lower leaves spread out on every side, but the upper leaves turn inward toward the center; the flowers grow in long spikes, upon stalks about two feet high, each standing on a pretty long foot-stalk; they are of a bright red colour tipped with green: these generally appear in the winter season. This fort may be preserved through the winter in a warm greenhouse, but the plants so managed will not flower so frequently, as those which have a moderate degree of warmth in winter.

The sixteenth fort resembles the eighth in some particulars, but the leaves are much broader, and spread wide on every side, whereas those of the eighth are ranged only two ways, and are narrow. This flowers but seldom, whereas the sixteenth flowers annually in the spring, and may be kept through the winter in a common greenhouse.

The seventeenth fort never rises from the ground, but the leaves spread flat on the surface, these are plain, succulent, and triangular toward their end. The borders of the leaves, and also the ridge of the angle on their under side, are closely beset with soft white spines. The flower-stalk rises about a foot high, is very slender, and hath three or four small herbaceous flowers standing at a distance from each other. These are tubulous, and cut into six parts at the brim, which turn backward. This fort is tender, so should be placed in winter in a moderate degree of heat, and

thrust have little water. It seldom puts out offsets, but is generally increased by planting the leaves.

The eighteenth fort is also a small plant growing near the ground; the leaves of this fort are almost cylindrical toward their base, but angular near their ends, and are set with short soft spines at the angles: these leaves are shorter and of a darker green colour than those of the former fort, and the plants produce many suckers on every side. I have raised a variety of this from seeds, which hath shorter, whiter, and smoother leaves, but this hath not yet flowered. This will live in a common greenhouse in winter.

The nineteenth fort hath very short, thick, succulent leaves, which are compressed on their upper side like a cushion, from whence it had the name. This grows very close to the ground, and puts out suckers on every side: the flowers grow on slender stalks, and are of an herbaceous colour. This may be preserved through the winter in a good greenhouse, but should have very little water during that season, especially when it hath no artificial heat.

The twentieth fort hath long narrow tongue-shaped leaves, which are hollowed on their upper side, but kept whorled below: these are closely studded on every side, with small white protuberances, from whence the plant hath had the title of Pearl Tongue Aloe. The flowers of this kind grow on pretty tall stalks, and form loose spikes, each hanging downward: they are of a beautiful red colour, tipped with green. This fort produces offsets in plenty, and is so hardy as to live in a common greenhouse through the winter. It flowers at different seasons of the year.

The twenty-first fort hath some resemblance to the last, but the leaves are much broader and thicker, these spread out every way, and are not so concave on their upper surface, nor are the protuberances so large as those of the former; the flowers are of a paler colour, and the spikes are shorter. I have raised plants from the seeds of this fort, which have varied from the original, but none of them approached near the twentieth fort. This is as hardy as the former fort.

The twenty-second fort rises to the height of eight or ten feet, with a strong stem; the leaves grow on the top, which closely embrace the stalk; these come out irregularly, and spread every way, they are near four inches broad at their base, and diminish gradually to the top, where they end in a spine. They are of a dark green colour, and closely beset with short thick spines on every side. This fort hath not as yet flowered in England, nor does it put out suckers, so that it is difficult to increase. It must have a warm greenhouse in winter, and very little water.

The twenty-third fort hath very long, narrow, triangular leaves, shaped like those of the Bull-rub; the flowers are produced in close thick spikes, upon stalks near three feet high. They are of an Orange colour, having six yellow stamina, which come out beyond the tube of the flower, so that when the plants are strong, and produce large spikes, they make a fine appearance. It flowers in August and September. There is a variety of this with narrower leaves, and longer spikes of flowers.

The soil in which these plants thrive best, is one half fresh light earth from a common (and if the turf is taken with it and rotted, it is much better), the rest should be white sea sand and sifted lime rubbish, of each of these two, a fourth part; mix these together six or eight months at least before it is used, observing to turn it over often in the time.

The middle of July is a very proper season to shift these plants; at which time you may take them out of the pots, and with your fingers open the roots, and shake out as much of the earth as possible, taking off all dead or mouldy roots, but do not wound or break the young fresh ones: then fill the pot about three parts full of the above-mentioned earth, putting a few stones in the bottom of the pot, to drain off the moisture, and after placing the roots of the plant in such a manner as to prevent their interfering too much with each other, put in as much of the same earth, as

A L O

to fill the pot almost to the rim, and observe to shake the plant, so as to let the earth in between the roots; and then with your hand fettle it close to the roots of the plant, to keep it steady in the pot; then water them gently, and set them abroad in a shady place, where they may remain for three weeks* giving them gentle waterings, if the weather should prove hot and dry.

Toward the latter end of September, in a dry day, remove them into the house again, observing to give them as much free open air as possible, while the weather is warm; but, if the nights are cool, you must shut up the glasses, and give them air only in the day; and, as the cold increases, you must not open the glasses, but observe to give them gentle waterings often, till the middle of October, when you must abate watering according to the heat of the house in which they are kept. For those plants which are placed in a stove, will require to be watered at least once a week, most part of the winter; whereas those which are kept in a green-house without artificial heat, should not be watered oftener in winter than once a month.

When these hardier sorts of Aloes are placed abroad in summer, they should have but little water given them; and if much rain should fall during the time they are abroad, they should be screened from it: for when they imbibe much wet in summer, they frequently rot the following winter, especially if they are not kept in a moderate warm air. Therefore, those who choose to treat these plants hardily, should be cautious of their receiving too much moisture.

The tender sorts should constantly remain in the stove, or be removed in summer to an airy glass-case, where they may have free air in warm weather, but be protected from rain and cold. With this management the plants will thrive and increase, and such of them as usually flower, may be expected to produce them in beauty at their seasons.

The hardier sorts thrive much better when they are exposed in summer, and secured from the cold and rain in winter, than if they are treated more tenderly. For when they are placed in a stove, they are kept growing all the winter, whereby they are drawn up weak; and although they will flower oftener when they have a moderate share of heat, yet in two or three years, the plants will not appear so fitly as those which are more hardily treated.

The twenty-third sort is hardy enough to live abroad in mild winters, if they are planted in a warm border and a dry soil, but as they are often destroyed in severe winters, it is proper to keep some plants in pots, which may be sheltered in winter under a frame, to preserve the sort. This is propagated by seeds, which the plants generally produce in plenty: (The seeds must be sown in pots soon after they are ripe, and in winter should be sheltered under a common hot-bed frame: in the spring the plants will come up, when they should be inured to bear the open air by degrees; and when they are large enough to remove, some of them should be planted in pots, and the other in a warm border, where they will require to be sheltered the following winter, as they will not have obtained sufficient strength to resist the cold.)

Most of these Aloes are increased by offsets, which should be taken from the mother plant, at the time when they are shifted, and must be planted in very small pots, filled with the same earth as was directed for the old plants; but if, in taking the suckers off, you observe that part which joined to the mother root to be moist, you must let them lie out of the ground in a shady dry place six or eight days to dry before they are planted, otherwise they are very subject to rot. After planting, let them remain in a shady place (as was before directed in shifting the old plants) for a fortnight, when you should remove the tender kinds to a very moderate hot-bed, plunging the pots therein, which will greatly facilitate their taking new root; but observe to shade the glasses in the middle of the day, and to give them a great share of air.

A L S

Toward the middle of August, begin to harden the young plants, by taking off the glasses in good weather, and by railing them at other times with props* that the air may freely enter the bed, which is absolutely necessary for their growth, and to prepare them to be removed into the house, which must be done toward the end of September, and managed as before directed for the old plants.

The African Aloes, for the most part, afford plenty of suckers, by which they are increased; but those few that do not, may be most of them propagated, by taking off some of the under leaves, laying them to dry for ten days or a fortnight, as was directed for the offsets; then plant them in the same soil as was directed for them, putting that part of the leaf which adhered to the old plant, about an inch, or an inch and a half (according to the size of the leaf) into the earth, giving them a little water to settle the earth about them; then plunge the pots into a moderate hot-bed, observing to screen them from the violence of the sun, and give them gentle refreshings with water once a week: the best season for this is in June, that they may push out heads before winter.

The second sort produces the Aloes commonly sold in the shops for horses, and is called Aloe Hepatica* But it is from the fifteenth sort, the Succotrine, or best sort of Aloes, is produced; which is done by cutting their leaves transversely, and placing earthen vessels under them to receive the juice which drops from these cut leaves; which juice, when inspissated, becomes the Aloe which is used in medicine. But I believe in making the coarser sort of Aloes, they press the leaves, whereby a greater quantity of juice is obtained: but this is not near so fine as the other.

ALOPECUROS [C[^]/AAwito[^]], Fox-tail, a kind of grass.

ALPINIA,

This plant is so called after Prosper Alpinus, who was a famous botanist in his time, and travelled into Greece and Egypt, and has written two books in quarto of the plants of those countries.

The CHARACTERS are,
// hath a trifid empalement, upon which rests the germen.
The flower is of one leaf, which is unequally divided at the top into four parts, and resembles a perforated flower; the upper segment which resembles the helmet, and also the two side segments, are indented in the middle, and the lower one is divided into three parts at the brim; in the center is placed the round germen supporting a single style crowned with a three cornered stigma: this is attended by a single stamina fixed to the tube of the flower, which is crowned with a very narrow summit. After the flower is past, the germen becomes an oval fleshy fruit, divided into three parts, including several oval seeds, which have tails.

This genus of plants, is by Dr. Linnaeus ranged in his first class, which is entitled Monandria Monogynia, the flowers of which have but one stamina and one style.

We know but one SPECIES of this genus, viz* ALPINIA. Royen. Prod. 12. This is by father Plumier titled, Alpha racemosa alba Cannacori foliis. Nov. Gen. 26. i. e. *White branching Alpina, with leaves like the flowering Reed.*

This plant is a native of the West-Indies, from whence it has been brought into some of the curious gardens of Europe, where it must be preserved in a good green-house, and the pots plunged into a tub of water, otherwise it will not thrive in this country. The leaves decay every winter, and are pushed out from the roots every spring, like the Maranta; so may be propagated by parting of the roots when the leaves decay.

ALSINE [Gr. 'Aarfa], Chick-weed.

These plants are so well known to most persons, it will be needless to mention them in this place, unless it be to caution persons from permitting them to grow either in their gardens, or on dunghills, where they will soon shed their seeds, and become troublesome weeds;

w ^{eddi} but as they are annual, they may 'with little trouble be destroyed, if they do not Hand to produce feed.

AL TH / EA. [^{AX}0ai⁸] fo called from *ti&cuwe*, Gr. to heal], Marfmallow.

The CHARACTERS are,

*The flower hath a double empalement \ the outer is of one leaf, and is unequally divided into nine narrow segments at the brim *, the inner one is also of one leaf, cut into five broad acute segments at the top *, these are both permanent. The flower hath five petals which coalesce at their base, but spread open above and are Jhaped like a heart. There are many stamina joined below, and form a kind of cylinder \. but are loose above, and inserted in the column. In the center is placed the orbicular germen, supporting a short cylindrical style, crowned with numerous stigmata which are of equal length with the stamina. The empalement afterward becomes an orbicular depressed capsule, divided into several cells, each containing one compressed kidney-Jhaped seed.*

This genus of plants is ranged by Dr. Linnaeus in the third section of his sixteenth class, which is titled Monodelphia Polyandria, the stamina being joined together to form a fort of column.

The SPECIES are,

1. ALTH/EA foliis simplicibus acuminatis acute dentatis tomentosis. *Marfmallow with Jingle woolly leaves which are indented in sharp segments.* Althaea Diofcoridis & Plinii. C. B. P. 315. *Common Marfmallow.*
1. ALTH/EA (*Officinalis*) foliis simplicibus angulato-rotundioribus tomentosis. *Marfmallow with angular, woolly, round-pointed leaves.* Althaea folio rotundiori aut minus acuminato. Sutherl. Edinb.
3. ALTHJBA (*Hirfuta*) foliis trifidis piloso-hispidis supra glabris. Hort. Cliff. 349. *Marfmallow with trifid, hairy, pungent leaves.* Alcea villosa. Dalechamp. Hist. 594.
4. ALTH/EA (*Cannabina*) foliis inferioribus palmatis superioribus digitatis. Hort. Cliff. 205. *Marfmallow with the under leaves Jhaped like a hand, and the upper leaves more divided.* Alcea fruticoso cannabino folio. Cluf. Hist. p. 2. pag. 25.

The first fort is the common Marfmallow, which grows naturally in moist places in divers parts of England, and is frequently used in medicine. It hath a perennial root and an annual stalk. The plant grows erect, to the height of four or five feet, and puts out a few lateral branches on the side of the stalks, garnished with leaves which are hoary and soft to the touch, they are angular, and placed alternately on the branches; the flowers come out from the wings of the leaves, which are shaped like those of the Mallow, but are smaller and of a pale colour. These appear in June or July, and the seeds ripen in September. It may be propagated fast enough, either by seeds or parting their roots. When it is propagated by seeds they should be sown in the spring, but if by parting their roots, the best time is in autumn, when the stalks decay. It will thrive in any soil or situation, but in moist places will grow larger than in dry land. The plants should not be nearer together than two feet, for their roots spread wide on every side.

The second fort is somewhat like the first, but the leaves are not so long, nor do they end in a sharp point, but are angular, and rounder than those of the first. I have cultivated this in the Chelsea garden many years, and find it retains its difference.

The third fort grows naturally in Spain and Portugal *, from both these countries I have received the seeds. This is a low plant, whose branches trail on the ground, unless they are supported by stakes. The leaves and stalks are beset with strong hairs *, the flowers come out at the wings of the stalks, and are smaller than those of the common fort, having purple bottoms. The leaves are deeply cut into three parts, and have long foot-stalks; the stalks are woody, but seldom last more than two years.

If the seeds of this fort are sown in April, the plants will flower in July, and the seeds ripen in September.

ber. They should be sown in the places where they are to remain, for as the roots shoot deep into the ground, unless the plants are removed very young, they seldom survive transplanting.

The fourth fort has a woody stem, which rises to the height of four or five feet, and puts out many side branches. These are garnished with leaves of different shapes; those which are on the lower part of the stalks are like a hand, very (lightly cut toward their outside, but those which are placed on the upper part of the branches, are deeply cut into several parts; these are hairy, and grow alternately on the branches; the flowers come out from the wings of the stalks in the same manner as the other forts, but are not so large as those of the common Marfmallow \ they are of a deeper red colour, and the empalement is much larger. This fort seldom flowers the first year, unless the summer proves warm *, but when the plants live through the winter, they will flower early the following summer, and produce good seeds. This grows naturally in Hungary and Iliria, from both which places I have received the seeds.

It is propagated by seeds, which should be sown in the spring in the place where the plants are to remain; or if otherwise, the plants must be transplanted young, else they will not succeed. They should have a sheltered situation and a dry soil, otherwise they will not live through the winter in England. When these plants grow in a stony soil, or in lime rubbish, they will be stunted in their growth, but they will have less sap in their branches, so will better endure the cold of this climate. This fort seldom continues longer than two years in England, but as the seeds ripen here, the plants may be had in plenty.

ALYSSUM, [^{Atomy}, of ^{αλυσσω}, Gr. to be mad; fo called, because it was believed to have the virtue of curing madnefs.] Madwort.

The CHARACTERS are,

The flower hath an oblong four-leaved empalement, which falls away. It hath four petals in form of a cross, which spread open above the empalement. It hath six stamina, two of which are shorter than the other four, crowned with broad summits; in the center of the flower is situated the oval germen, supporting a single style, crowned with an obtuse stigma. After the flower is past, the germen becomes a globular or compressed seed-vesicle, in which are lodged several compressed seeds.

This genus is ranged in the fifteenth class of Linnaeus, entitled Tetradynamia Siliculosa, the flowers of this class have six stamina, four of which are longer than the other two, and the seed-vesicles are short, in some globular, and in others they are compressed.

The SPECIES are,

1. ALYSSUM (*Saxatile*) caulibus frutescentibus paniculatis foliis lanceolatis molliflimis undulatis integris. Prod. Leyd. 331. *Madwort with jhrubby stalks, flowers growing in panicles, and whole, soft, spear-Jhaped waved leaves.* Alyffon Creticum saxatile foliis undulatis incanis. Tourn. Cor. 15.
2. ALYSSUM (*Halimifolium*) foliis lanceolato-linearibus acutis integerrimis caulibus procumbentibus perennantibus. Hort. Cliff. 333. *Madwort with whole, spear-Jhaped, pointed leaves, and trailing perennial stalks.* Alyffon halimi folio fempervirens. Tourn. Inf.

5. ALYSSUM (*Incanum*) caule erecto foliis lanceolatis incanis integerrimis floribus corymbosis. Hort. Cliff. 332. *Madwort with an ereff stalk, hoary spear-shaped leaves which are entire, and flowers collected into round heads.* Alyfbn fruticofum incanum. Tourn. Inf. R. H.
6. ALYSSUM (*Clypeatum*) caule erecto herbaceo filiculis feffilibus ovalibus compreffib-planis petalis acuminatis. Lin. Sp. Plant. 651. *Madwort with an ereS herbaceous stalk, pods growing chfe to the stalks, which are oval and compreffed, and the flower leaves pointed.* Lunaria leucoii folio filiquâ oblongâ majori. Tourn. Inf. 218.
7. ALYSSUM^V (*Sinuatum*) caule herbaceo foliis lanceolatis dentatis filiculis inflatis. Lin. Sp. Plant. 651. *Madwort with an herbaceous stalk, Jpear-Jhaped indented leaves, and fwollen feed-veffels.* Alyffoides incanum foliis finuatis. Tourn. Inf. 213.
8. ALYSSUM (*Creticum*) caule herbaceo ere&o foliis incanis lanceolatis integerrimis filiculis inflatis. Lin. Sp. Plant. 651. *Madwort with an ereff herbaceous stalk, hoary, Jpear-Jhaped, entire leaves, and a fwelling feed-veffel.* Alyffoides fruticofum Creticum leucoii folio incano. Tourn. Cor. 15.
9. ALYSSUM (*Feficaria*) foliis linearibus dentatis, filiculis inflatis angulatis acutis. Lin. Sp. 910. *Madwort with linear indented leaves and fwollen pods, which are angular and acute pointed.* Veficaria Orientalis, foliis dentatis. Tourn. Cor. 49.
10. ALYSSUM (*Deltoideum*) caulibus fuffrutefcentibus profratis, foliis lanceolato-deltoidibus, filiculis hirtis. Lin. Sp. 908. *Madwort with trailing Jhrubby stalks, deltoide Jpear-Jhaped leaves, and hairy pods.* Alyfbn Creticum foliis angulatis, flore violaceo. Tourn. Cor. 15.
11. ALYSSUM (*Calycinum*) caulibus herbaceis, ftaminibus omnibus dentatis, calycibus perfittentibus. Jacq. Vind. 114. *Madwort with herbaceous stalks, all the ftamina indented, and a permanent flower-cup.* Thlafpi < Alyfbn didtum campeftre majus. C. B. P. 107.
12. ALYSSUM (*Campeftre*) caule herbaceo, ftaminibus ftipatis pari fetarum, calycibus deciduis. Lin. Sp. 909. *Madwort with an herbaceous stalk, and the flower-cup deciduous.* Alyfbn incanum, fcrpylli folio, frudlu nudo. Tourn. Inf. 217.

The firft fort is a low perennial plant, with a fleffy ftalk, which feldom riles more than one foot high, but divides into many lefs branches which grow near the ground, fo that a fingle plant will fpread to a confiderable diftance. The branches are garnifhed with long Jpear-shaped leaves, which are hoary and waved on their edges, placed on without any order. The flowers are produced in loofe panicles, at the extremity of every branch, and are of a bright yellow colour, confifting of four petals, placed in form of a crofs: thefe being numerous, make a fine appearance during their continuance. They appear the latter end of April, or the beginning of May, and if the feafon is moderate, will continue three weeks in beauty. The feeds ripen in July, but it is only from young plants that feeds can be expedted; for the old plants, or thofe which are raifed from flips or cuttings, rarely produce feeds in England.

This plant is hardy, and although brought from a more lbutherly climate, yet, if planted in a dry, lean, or rubbifhy foil, will endure our fevereft winters abroad. It is increafed by fowing the feeds in March in a light fandy foil, or by planting cuttings in April or May; which are very apt to take root, if kept lhaded in the heat of the day, and gently refrefhed with water.

The fecond fort feldom continues above two or three years with us, and muft therefore be often fown to preferve it; or if the feeds are fuffered to fall, and remain upon the ground, the plants will rife without any trouble. This plant fpreads itfeff upon the ground, and never rifes to any height. It produces, at the extremity of its branches, very pretty tufts of fmall white flowers; of which the plant is feldom detitute for fix or feven months fuceffively, for which reafon it deferves a place in the ffaivens of the curi-

ous. This will grow from feeds, and alfo from editings, if planted and managed as the former.

The third fort hath ligneous branches which rife about two feet high; thefe are armed with fmall fpines; the leaves are hoary, Jpear-flaped, and thinly placed on the ftalks without any order. The flowers are white, crofs-shaped, and grow in fmall clufters at the extremity of the branches. After the flowers are paff, the germen turns to an oblong feed-veffel, containing feveral round feeds.

This may be propagated in the fame manner as the firft fort, either by feeds or flips; and when the plants grow in rubbifh, or on old walls, they will laft much longer, and endure the cold of our winters better than thofe which are in a good foil. It grows naturally in Spain, Italy, and the fourth of France.

The fourth fort hath trailing branches, which lie on the ground; thefe are garnifhed with oblong hoary leaves, which are rough to the touch, and are placed alternately on every fide of the branches. The flowers are produced in fmall clufters at the extremity of the branches, which are of a dark yellow colour, and are fucceeded by feed-veffels flaped like thofe of the third fort. This grows naturally upon rocks and ruins, in Burgundy, and fome other parts of France, as alfo about Bafil. It may be propagated in the fame manner as the former forts, and when it grows in rubbifh, the plants will continue fome years; but in rich ground, they feldom live through the winter in England.

The fifth fort grows to the height of two feet, having ligneous ftalks, which divide into feveral branches toward the top. Thefe are garnifhed with hoary Jpear-shaped leaves, which are placed alternately on the branches: at the extremity of every fhoote, the flowers are produced in round bunches, which are fmall, white, and crofs-shaped; thefe are fucceeded by oval feed-veffels, which are full of brown feeds. It grows naturally in the lbuth of France, Spain, and Italy, chiefly on rocky or gravelly foils. When this is fown in a rich foil, it feldom furvives the winter; but in lime rubbifh, or upon old walls, it will continue feveral years. It flowers in June, July, Auguft, and September, and the feeds ripen foon after; which if permitted to fcatter, the plants will come up, and require little care.

The fixth fort is a biennial plant with an herbaceous ftalk, which is garnifhed with oblong hoary leaves, placed alternately, the flowers come out from the wings of the ftalks fingle, and are fucceeded by oval compreffed feed-veffels, shaped like thofe of the Lunaria, which contain many flat feeds. It grows naturally in Spain and Portugal, from whence I have received the feeds. It is propagated by feeds, which muft be fown upon dry ground, or lime rubbifh; for in rich land the plants will grow too vigorous in fummer, fo that in autumn they generally rot off and decay.

The feventh fort is a low fpreading plant, which divides into fmall branches; thefe fpread near the ground, and are garnifhed with oblong hoary leaves which continue through the year: the flowers are produced in fmall clufters at the extremity of the branches; they are of a bright yellow colour, confifting of four petals placed in form of a crofs. After the flower is paff, the germen becomes an oval fwelling feed-veffel, which is filled with roundifh feeds. This grows naturally in the iflands of the Archipelago, but is hardy enough to live in the open air in England, in a dry foil and a warm fituation. It is propagated by feeds, and feldom lafts longer than two or three years.

The eighth fort grows more erect, having an herbaceous ftalk, which fends out a few lateral branches toward the top, garnifhed with oblong hoary leaves. The flowers grow in fmall clufters at the extremity of the branches, which are fucceeded by oval fwelling feed-veffels like the former. This feldom continues longer than two years in England, it muft have a warm dry fituation, otherwife it will not live in the open air, and is propagated by feeds, which fhould

be fowri in Auguft, foon after they are ripe •, and if a few of them are potted in Oftober, and fheltered under a frame in winter, they will flower the follow-
 1 Ing June, fo good feeds may be obtained the lame year-, for thofe plants which arife early in the year, grow luxuriantly in fummer, fo do not often live through the winter, or ripen feeds.

The ninth and tenth forts have trailing ftalks, which fpread on the furface of the ground •, the plants produce their flowers toward the extremity of the ftalks in loofe fpikes, which are formed like thofe of the other forts, having four petals in each in form of a crofs ; thofe of the ninth fort are fucceeded by fwollen feed-veffels, but the tenth, which flowers early in the fpring, are rarely fucceeded by feed-veffels in this country. This is an abiding plant, which may be propagated from its trailing branches, which, if planted in April, will take root and become good plants by the following autumn, when two or three plants may be placed in a common frame for ihelter in winter, to preferve the fpecies •, for in hard winters, thofe which are expofed are fometimes deftroyed. The eleventh and twelfth are both annual plants, fo are propagated by feeds, which fhould be fown in a border of light earth in April, in fuch places where the plants are to remain; if thefe are thinned and kept clean from weeds, they will flower in July, and perfect their feeds in autumn.

AMARANTHOIDES. See GOMPHRENA.

AMARANTHUS [A^a^p*^ol *privative, and /^ani^w, Gr. to wither •, fo called, becaufe the flower of this plant being cropped, does not foon wither; but being dried, keeps the beauty of its colour a great while.] Flower-gentle.

The CHARACTERS are,

It hath male and female flowers in the fame plant. The flower hath no petals, but the empalement confifts of three or five pointed fpear-fhaped leaves which are coloured and permanent •, this is common to both fexes. The male flowers have in fome fpecies three, and in others five slender ftamina, which are of the fame length with the empalement, crowned with oblong fummits. The female flowers have an ovalgermen, fupporting three fhort awl-fhaped ftyles, which are crowned with Jimple ftigma. The empalement afterward becomes an oval coloured feed-veffel having one cell, in which is lodged a Jingle globular Jecd. This genus of plants is by Dr. Linnseus ranged in the fifth divifion of his twenty-firft clafs, entitled Monoeia Pentandria, from their having male and female flowers on the fame plant, and the male flowers having five ftamina.

The SPECIES are,

1. AMARANTHUS (*Tricolor*) glomerulis triandris axillaribus fubrotundis amplexicaulibus foliis lanceolato-ovatis. Lin. Sp. Plant. 1403. *Flower-gentle with roundih heads, placed at the wings of the ftalks embracing them, whofe flowers have three ftamina, and the leaves are oval and fpear-fhaped.* Amaranthus tricolor. Lob. Icon. 252. i. e. *Three coloured Amaranthus.*
2. AMARANTHUS (*Melancholicus*) glomerulis triandris axillaribus fubrotundis feffilibus foliis lanceolatis acuminatis. Lin. Sp. Plant. 1403. *Flower-gentle with three ftamina, roundih beads growing clofe to the ftalk, and acute-pointed fpear-fhaped leaves.* Amaranthus colore obfcuriori five mas. Tourn. Inf. 236. Amaranthus bicolor.
3. AMARANTHUS (*Triftis*) glomerulis triandris rotundatis fubpaticatis, foliis bvato-cordatis emarginatis petiolo brevioribus. Lin. Sp. 1404. *Flower-gentle with three ftamina, roundih heads growing from the wings of the ftalks in fpikes, and oval heart-fhaped leaves with fhort foot-ftalks.*
4. AMARANTHUS (*Caudatus*) racemis pentandris decompoftitis cylindricis pendulus longiaimis. Hort. Cliff. 443. *Flower-gentle with five ftamina, and very long, hanging, cylindrical fpikes.* Amaranthus maximus paniculii longa pendula femine rubello. Raii Hift.

7. AMARANTHUS (*Flavus*) racemis pentandris compoftitis, fummo infimique nutantibus, foliis ovatis mucronatis. Lin. Sp. 1406. *Flower-gentle with a compound fpike of flowers having five ftamina, and oval pointed leaves.*
8. AMARANTHUS (*Blitum*) glomeratis lateralibus trifidis foliis ovatis retufis, caule diffufo. Lia. Sp. Plant. 990. *Flower-gentle with roundih heads at the joints of the ftalks, oval blunt leaves, and diffufed ftalks.* Blitum album minus. C. B. P. 118. *The fmaller white Elite.*
9. AMARANTHUS (*Gradzans*) glomerulis triandris axillaribus foliis lanceolatis obtufis. Lin. Sp. Plant. 1405. *Flower-gentle with flowers having three ftamina, which grow in clufters from the wings of the ftalks, and blunt fpear-fhaped leaves.* Amaranthus floribus lateralibus congeftis foliis lanceolatis obtufis. Flor. Virg. 116. *Commonly called Pellitory-leaved Blite.*
10. AMARANTHUS (*Ilybridus*) racemis pentandris decompoftitis congeftis nudis, fpiculis conjugatis. Flor. Virg. 148. *Flower-gentle with five ftamina, decomposed fpikes having double fpicuhe.* Amaranthus fylveftris maximus Novae Angliae fpicis viridibus. Raii Hift. 201. *Or Wild New England Blite with green fpikes.*
11. AMARANTHUS (*Hypocondriacus*) racemis pentandris compoftitis confertis ere&is, foliis ovatis mucronatis. Hort. Cliff. 444. *Flower-gentle with five ftamina, ereft cluftred fpikes, and oval-pointed leaves.* This is the Amaranthus fylveftris maximus Novae Angliae fpicis purpureis. Tourn. Inf. R. H. 235. *Commonly called Purple Flower-gentle.*
12. AMARANTHUS (*Spinofus*) racemis pentandris cylindricis ereftis axillis fpinofis. Hort. Cliff. 444. *Flower-gentle with five ftamina, upright cylindrical fpikes, and fpines at the joints of the ftalks.* Amaranthus Indicus fpinofus fpica herbacea. H. L. 31.
13. AMARANTHUS (*Sanguineus*) racemis pentandris compoftitis erectis, lateralibus patentiffimis, foliis ovato-oblongis. Lin. Sp. 1407. *Flower-gentle with compound fpikes, whofe lateral fpikes fpread out, the upper are ereit, and oblong oval leaves.* Amaranthus racemis cylindricis lateralibus terminalibufque cruciatim poftitis. Fig. Plant. 22.
14. AMARANTHUS (*Retroflexus*) racemis pentandris lateralibus terminalibufque paule flexufo villoib ramis retrocurvatis. Lin. Sp. Plant. 991. *Flower-gentle with five ftamina, fpikes proceeding from the wings of the ftalks, and alfo at their extremities, and flexible, hairy, re-curved branches.*
15. AMARANTHUS (*Oleraceus*) glomeribus triandris pentandrifque, foliis ovatis obtuffimis emarginatis rugofis. Lin. Sp. 1403. *Flower-gentle whofe globes have flowers with three and five ftamina, and rough, obtufe, indented leaves.* Blitum album majus. C. B. P. 118.
16. AMARANTHUS (*Viridis*) glomerulis triandris, floribus mafculis trifidis, foliis ovatis emarginatis, caule erefto. Lin. Sp. 1405. *Flower-gentle with globular heads whofe flowers have three ftamina; the male are trifid, oval, indented leaves, and an upright ftalk.*
17. AMARANTHUS (*Cruentus*) racemis pentandris decompoftitis remotis patulo nutantibus, foliis lanceolato-ovatis. Lin. Sp. PL 1406. *Flower-gentle with decomposed fpikes of flowers with five ftamina, the outer fpreading afunder, and oval fpear-fhaped leaves.* Amaranthus finenfis foliis variis, panicula fpiciofa patula. Cent. tab. 6.

The firft fort has been long cultivated in gardens for the beauty of its variegated leaves, which are of three colours, viz. green, yellow, and red •, thefe are very elegantly mixed: and when the plants are in full vigour, the Wives are large, and clofely fet from the bottom to ti e top of the ftalks, and the branches form a fort c^e pyramid 5 fo that there is not a more

beautiful plant than this, when it is in full lustre. From the leaves of this plant being principally coloured like the fathers of parrots, I should have separated this species from the others, and constituted a genus of K by the title of : *Parrotia*.

The second sort hath been introduced into the English gardens much later than the former. This grows to the lame height, and in the manner of its crowd greatly resembles it [but the leaves have only two colours, which are an obscure purple, and a bright crimson; these are blended as to let till each other, and when the joints are vigorous, they make a fine appearance.

The third sort hath no grown becometh it grows about three feet high with an upright stem, which is furnished with several branches toward the top, these are garnished with several lance-shaped leaves. The flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The fourth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The fifth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The sixth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The seventh sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The eighth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The ninth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The tenth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

And these feeds will remain in the ground several years, and as often as they are turned up to the surface, they will produce plants; so that when plants are suffered to stand till their feeds fall, there will be a summer crop of the plants for several years.

The twelfth sort grows about two feet high, putting out many side branches, so as to form a bushy plant, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The thirteenth sort grows about two feet high, putting out many side branches, so as to form a bushy plant, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The fourteenth sort is a native of North America, from whence the seeds were first brought to Europe, and is now become a common weed in many gardens near London, so is seldom allowed a place in the garden.

The fifteenth sort has many becometh it grows about three feet high with an upright stem, which is furnished with several branches toward the top, these are garnished with several lance-shaped leaves. The flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The sixteenth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The seventeenth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The eighteenth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

The nineteenth sort grows naturally in America, this is a plant of a moderate height, three feet high, the leaves are of a green colour, and the flowers are of a purple colour, and the wings of the petals in round spikes, but have very little beauty, but are not difficult to be raised in the garden. The young plants of this sort are not difficult to be raised in the garden, and are not difficult to be raised in the garden.

AMANTHUS CRISTATUS. See COLONIA.

KYLLIS, Lily Daff

AM (...) Characters are, bdit

It bears an oblong compressed spathe, (or sheath) which includes the flower-buds, and upon file rays, becomes dry, ... persistent; the lower teeth are spear-shaped points. In the centre is placed the reniform perianth-germen, supporting a slender style, crowned with a three-angled stigma; this is attended by six anal-floret flowers, which are crowned with numerous bristles. After the flower is past, the perianth ... dm f ... appears in three parts, leaving three cells, which contain seeds. mud

This genus is ranged by Dr. Jiriniecti in the lrfst ic-r-tion of his fifth class of plants. Moutanica, from the flower ... liavmg fix ftsmnn ir:tl

The Species are,

- 1. AMANTHUS (Linn.) spathe ... cocolla equali, filamentis declinatis. Hort. Sto. 420. Lily Daffail with a single flower in each spathe, which is equal, and the filament declinat. Lilio Narcissus luteus acrommally-nunc. Tourm. Inst. 186. Commonly called amantus Narcissus.
2. AMANTHUS (Linn.) spathe ... unil, corolla ... b, petals declinatis. Hort. Cliff. 135. Lily Daffail with a single flower in each spathe, which has equal petals, and the petals declinate. Lilio Narcissus Indicus parvulus micranthus albus. Mar. Hist. 3. 266. Commonly called amantus Lili.
3. AMANTHUS (Linn.) spathe ... unil, corolla ... b, petals tribus generalibus declinatis. Hort. Cliff. 135. Lily Daffail with one flower in each spathe, which has unequal petals, and the filament declinat. Lilio Narcissus luteus acrommally-nunc. Hort. Blik. 195. Commonly called Jactatus Lili.
4. AMANTHUS (Linn.) spathe ... multiflora, corolla ... pediculis albis. Hort. Ur. 1. 75. Lily Daffail with

- with many flowers in one cover \ the petals equal, spread open, and turned backward, with broken stamina, commonly called *Guernsey Lily*.
5. AMARYLLIS (*Regina*) fpatha multiflora, corollis campanulatis aequalibus, genitalibus declinatis. Hort. Cliff. 135. *Lily Daffodil with many flowers in one cover, the petals equal and bell-shaped, and the stamina declined.* Lilio Narcissus polyanthos flore incarnato, fundo ex luteo albefcente. Sloan. Cat. Jam. 115. commonly called *Belladonna Lily*.
 6. AMARYLLIS (*Belladonna*) fpatha multifloracorollis campanulatis marginibus reflexis genitalibus declinatis. *Lily Daffodil with many flowers in one cover, the petals equal and bell-shaped, their borders turning backward, and declining stamina.* Liliim Americanum puniceo flore, Belladonna di&um. Par. Bat. 194. commonly called *Mexican Lily*.
 7. AMARYLLIS (*Longifolia*) fpatha multiflora, corollis campanulatis aequalibus, fcapo compresso longitudini umbellae. Flor. Leyd. 36. *Lily Daffodil with many flowers in one cover, the petals equal, and the cover compressed the length of the umbel* Liliium Africanum humile longifolium foliis polyanthos iaturato colore purpurascens. Par. Bat. 195.
 8. AMARYLLIS (*Zeylanica*) fpatha multiflora corollis campanulatis aequalibus, genitalibus declinatis fcapo tereti ancipiti. Flor. Leyd. 36. *Lily Daffodil with many flowers in one cover, the petals equal, and the cover opening two ways.* Lilio Narcissus Zeylanicus latifolius flore niveo externe linea purpurea striato. Hort. Amft. 1. 73. commonly called *the Ceylon Lily*.
 9. AMARYLLIS (*Ciliaris*) fpatha multiflora, foliis ciliatis. Flor. Leyd. 37. *Lily Daffodil with many flowers in one cover, and the edges of the leaves hairy.* Lilio Narcissus fphaericus iEthiopicus foliis guttatis & ciliis instar pilosis. Pluk. Aim. 220. commonly called *the African Scarlet Lily*.
 10. AMARYLLIS (*Fernalis*) fpatha uniflora, corolla asquali, ftaminibus ereftis. *Lily Daffodil with one flower in a cover, with equal petals, and ereSi stamina.* Lilio Narcissus luteus vernus. Tourn. Inf. 386. commonly called *Spring yellow Lily Narcissus*.
 11. AMARYLLIS (*Orientalis*) fpatha multiflora corollis inaequalibus foliis linguiformibus. Butt. *Lily Daffodil with many flowers in a cover, whose petals are unequal, and leaves shaped like a tongue.* Lilio Narcissus Indicus maximus fphaericus floribus plurimis rubris liliaceis. Mor. Hist. 2. 268. *Brunfwigia of Dr. Heister*.
 12. AMARYLLIS (*Capensis*) fpatha triflora corollis campanulatis aequalibus genitalibus declinatis. *Lily Daffodil with three flowers in each cover, whose petals are equal and bell-shaped, with declining stamina.*
The first fort is very hardy, and increases very fitly by offsets. The season for transplanting these roots is any time from May to the end of July, when their leaves are decayed, after which it will be too late to remove them -, for they will begin to push out new fibres by the middle of August, or sooner if the season be moist, and many times they flower the beginning of September *, so that if they are transplanted, it will spoil their flowering. This plant will grow in any soil or situation; but it will thrive best in a fresh, light, dry soil, and in an open situation, i. e. not under the dripping of trees, nor too near walR It is commonly called by the gardeners, the Yellow Autumnal Narcissus, &c. and is usually sold by them with Colchicums, for autumnal ornaments to gardens; for which purpose this is a pretty plant, as it will frequently keep flowering from the beginning of September to the middle of November, provided the frost is not so severe as to destroy the flowers *, for although there is but one flower in each cover, yet there is a succession of flowers from the same root, especially when they are suffered to remain three or four years unremoved. The flowers seldom rise above three or four inches high; they are shaped somewhat like the flowers of the large yellow Crocus -, the green leaves come up at the same time, like th^Saffron, and after the flowers are past, the leaves increase all the winter ^TJ^ roots are bulbous, and shaped like those

of the Narcissus, so are proper ornaments for the borders as are planted with Cyclamens, Saffron, Autumnal Crocus, Colchicums, and such low autumnal flowers.

The tenth fort is more rare in England than any of the other, at present. It was formerly in several curious gardens, but as it flowers at a season when there are many finer forts in beauty, it was neglected and cast out of the gardens, whereby it is almost lost in England: it grows naturally in Spain and Portugal, where it flowers early in January. This is as hardy as the first fort, and may be planted in the open borders, and treated in the same manner, excepting that this will not lose its leaves so soon, so should not be taken out of the ground to transplant, till the end of July, or beginning of August. It flowers in April or the beginning of May, but is not of long duration.

The second fort is a native of Virginia and Carolina, in which countries it grows very plentifully in the fields and woods, where it makes a beautiful appearance when it is in flower. The flowers of this fort are produced single, and at their first appearance have a fine Carnation colour on their outside \ but fades away to a pale, or almost white, before the flowers decay. This plant is so hardy, as to thrive in the open air in England, provided the roots are planted in a warm situation, and on a dry soil; it may be propagated by offsets from the roots. The flowers of this fort are almost as large as those of the small Orange Lily, but do not grow above six or eight inches high *, they appear the latter end of May, or beginning of June, and sometimes it flowers in August in this country.

The third fort, which is commonly called Jacobseal Lily, is now become pretty common in the curious gardens in England, the roots sending forth plenty of offsets, especially when they are kept in a moderate warmth in winter: for the roots of this kind will live in a good green-house, or may be preserved through the winter under a common hot-bed frame; but then they will not flower so often, nor send out so many offsets, as when they are placed in a moderate stove in winter. This will produce its flowers two or three times in a year, and is not regular to any season; but from March to the beginning of September, the flowers will be produced when the roots are in vigour. The stems of these flowers are produced from the sides of the bulbs, so that after the flowers produced on one side are decayed, there is another stalk arising from the other side of the bulb *, but there is no more than one flower produced on the same stalk. The flowers are large, and of a very deep red -, the under petals, or flower-leaves, are very large, and the whole flower stands nodding on one side of the stalk, making a beautiful appearance.

It is propagated by offsets, which may be taken off every year; the best time to shift and part these roots is in August, that they may take good root before winter; in doing of this, there should be care taken not to break off the fibres from their roots. They should be planted in pots of a middling size, filled with light kitchen-garden earth; and if they are kept in a moderate degree of warmth, they will produce their flowers in plenty, and the roots will make great increase.

The sixth fort, which is commonly called the Mexican Lily, is not so hardy as the former fort, so must be placed in a warm stove; and if the pots are plunged into a hot-bed of tanners bark, the roots will thrive better, and the flowers will be stronger. This is increased by offsets, as the others of this tribe *, and flowers usually the beginning of spring, when it makes a fine appearance in the stove: the flower-stems of this fort, seldom rise more than one foot high, each stem supports two, three, or four flowers, rarely more than that number. The flowers are large, and of a bright copper colour, inclining to red; the fpatha, or sheath, which covers the buds before they open* divides into two parts to the bottom, (landing on each side the umbel of flowers, joined to the small foot-stalks.

than those which are kept in pots, and will multiply faster.

The fourth sort is supposed to come originally from Japan, but has been many years cultivated in the gardens of Guernsey and Jersey, in both which places, they seem to thrive as well as if it was their native country; and from those islands their roots are sent annually to the curious in most parts of Europe, and are commonly called Guernsey Lilies. The roots of this plant, are generally brought over in June and July-, but the sooner they are taken out of the ground after their leaves decay, they are the better: for although the roots which are taken up when their flower-stems begin to appear, will flower, yet their flowers will not be so large, nor will their roots be near so good after, as those which were removed before they had sent out fresh fibres.

When these roots come over, they should be planted in pots filled with fresh, light, sandy earth, mixed with a little very rotten dung, and placed in a warm situation, observing now and then to refresh the earth with water: but by no means let them have too much wet, which would rot their roots, especially before they come up. About the middle of September, such of the roots as are strong enough to flower, will begin to show the bud of their flower-stem (which is commonly of a red colour); therefore you should remove these pots into a situation where they may have the full benefit of the sun, and may be sheltered from strong winds: but by no means place them too near a wall, nor under glasses, which would draw them up weak, and render them less beautiful. At this season they should be gently refreshed with water, if the weather be warm and dry, but if it should prove very wet, they should be screened from it.

When the flowers begin to open, the pots should be removed under shelter, to prevent the flowers from being injured by too much wet: but they must not be kept too close, nor placed in a situation too warm, which would occasion their colour to be less lively, and hasten their decay. The flowers of this plant will continue in beauty (if rightly managed) a full month; and though they have no scent, yet, for the richness of their colour, they are justly esteemed in the first rank of the flowery tribe.

After the flowers are decayed, the green leaves will begin to shoot forth in length, and if sheltered from severe cold, will continue growing all the winter; but they must have as much free air as possible in mild weather, and covered only in great rains or frosts; for which purpose, a common hot-bed frame is the properest shelter for them, under which if they are placed, the glasses may be taken off constantly every day in dry open weather, which will encourage the leaves to grow strong and broad; whereas when they are placed in a green-house, or not exposed to the open air, they will grow long and slender, and have a pale weak aspect, whereby the roots will become weak, so that it seldom happens that they produce flowers under such management.

These roots should be transplanted every fourth or fifth year toward the latter end of June, or beginning of July, and planted into fresh earth (but they should not be oftener removed, for that would retard their flowering.) The offsets should also be taken off, and planted into several pots, which, in three years time, will produce flowers; so that after a person is once stocked with these roots, they may increase them, so as to have a supply of blowing roots, without being at the trouble or expence of sending to Guernsey every year for fresh roots, and the roots preserved here will flower stronger than those which are usually brought from thence, for the inhabitants of those islands are not very curious in cultivating them. Their usual method is to plant them at a great distance in a bed of common earth, where they let them remain for many years: in which time they produce such a number of offsets, that many times one single cluster has contained above a hundred roots; by which means, those which grow on the inside are much compressed

by the outer roots, that they are perfectly flattened; and from the number of roots growing in each cluster; they are all rendered weak, and unfit to produce such large stems of flowers, as those which have grown single, and are of a spherical figure.

But when a person is possessed of a large number of these roots, it will be troublesome to preserve them in pots, therefore there should be a bed prepared of the following earth, in some well sheltered part of the garden, viz. Take a third part of fresh virgin earth from a pasture ground, which is light, then put near an equal part of sea sand, to which you should add rotten dung, and sifted lime rubbish, of each an equal quantity. With this earth (when well mixed and incorporated) you should make your bed about two feet thick, raising it about four or five inches above the surface of the ground, if the situation be dry; but if the ground be wet, it should be raised eight or nine inches higher. In this bed, about the beginning of July (as was before directed), you should plant the roots about six or eight inches asunder each way; and in the winter, when the frost begins, you should either cover the bed with a frame, or arch it over, and cover it with mats and straw, to prevent their leaves from being pinched with cold; but in the spring the covering may be entirely removed, and the bed kept constantly clear from weeds, during the summer, observing to stir the surface of the earth now and then; and every year, when the leaves are decayed, you should shift a little fresh earth over the beds, to encourage the roots. In this bed the roots may remain until they are strong enough to produce flowers, when they may be taken up and planted in pots, as was before directed, or suffered to remain in the same bed to flower.

The roots of these plants do not flower again the succeeding year (as in many other sorts of bulbs;) but if their bulbs contain two buds in their center, as is often the case, they very often flower twice within the compass of three years; after which, the same individual root does not flower again in several years, but only the offsets from it.

AMBROSIA [so called from *d* privative and *MOIS* mortal,] because feigned by the poets* to be the food of the gods*

The CHARACTERS are,

It hath male and female flowers on the same plant. The male flowers are composed of many florets, which are included in one common empalement of one leaf, which is plain, and extended the length of the florets: each floret is of one leaf funnel-shaped, and cut into five parts at the brim; in the center is situated the five small stamens, which are crowned with pointed ereb summits. The female florets are placed under the male in the same spike-, these have an empalement of one leaf, which is pointed and permanent: they have no-petals, but an oval germen placed in the bottom of the empalement, supporting a slender style, crowned with two long hairy stigma. The germen afterward becomes an oval hard capsule with one cell, crowned with the acute segments of the empalement, and inclining one roundish feed.

This genus of plants, is by Dr. Linnaeus ranged in the fifth division of his twenty-first class, entitled Monocia Pentandria, from their having male and female flowers in the same plant, and the male flowers having five stamens.

The SPECIES are,

This genus of plants: 1 by Dr. Linnæus ranked in the 11th section 1 histentii dat, entitled Dttuitirii Monogj'nia; the flower) ut ttua having ten D... Ha and a single style.

We taavebut one SPICEL of this genus, . h.

ANACARDIUM (Orientalis) Hort. Cliff. 16 1, /& tecUcit-1111 Aacardisaii,er Ltjehew. Acajou. Pif. Hilt. Ural! 58, This tree grows to the feet... ur more, in i... ;;ry_n which ii bodi Indies, but in Engiam! die plunu arv with g... ferved... i though by I... it from the seeds, they appear in... and vigour, as to produce a much greater progrt!': th... they are ever seen to... naked,

They are easily raised from the nuts, which are annually brought from America in great plenty; cch of th'de (ould be plnsi... in a small pot filled with light sandy earth, and plunged into J food hoi-bed of wners!... being t^retul tu prevent tlici h;^inf» wet, till the plants come up, for the 1115 frequently rot with moisture. The reason of myadsiffig die nuts to be... is, because the young seedling are when they are 1 ir;:irplanted. If the nuts are fresh, the plants will come up in about a month after planting, and I in two months they will be four iuir or five ii'rites high, with large leaves; from this quick growth, many p... have been destroyed by supposing them hardy, and that they would continue the like progress... icreis they seldom advance much farther the same year.

The plants must be constantly kept in the shade, for they are too tender to live abroad in England, in the warmest season of the year, nor will they thrive in a common green-house in winter. As these plants alwund wrth ;i lilly aerial juice, they should have but little water, even in summer; and in winter, if they are sparingly watered once in a fortnight, it will be sufficient, for their roots are inn^c? and li>oj) perill with moisture.

When these plants are transplanted, it will be the best method to break the pots, for the roots do not put out many fibres to hold the earth about them, so that when they are taken out of the pots, earth will fall from the earth.

The two hrft forts grow naturally in the [Hands of
the ArchipclaRo, from whence Dr. Tuurnefort fed
their feeds to the royal garden at Paris. I have alfo
received the feed) of both thefe plants from Portugal,
fo that it may alfo grow naturally [here, as do many
of thofe plants which were difcoveml by Tournefort
in [he Levant. Thefc are low plants, whole br...
croil on die ground. The firft ibrt has fine cut leaves
thole of ChancHnBe) the flowerfarefmall, white,
and grow fngle, with their heads declining. thefc
art like thofe of the common Mayweed. The fecond
hadi winged leaves like thofe of the Ox-cyc-, the flow-
ers arc white, and like thole of Chamomile.

The third lbrt crows naturally in Spain, from whence
I h.tve received the feeds. This grows a foot and
half high, fending out many fide branches; the leaves
are finely divided like thole of Chamomile, an...
hairy: the (lowers grow fngle at the extremity of die
brandits, and are of a bright yellow colour, with vi
filvery fealy empahment. Thefe are as large as thofe
of the Ox-eye.

AH thefc plants arc annual: the feeds fhould be fown
early in ilie ijiring in a border of light cartli, where
they arc defignrtl to Rinain, and rvijuire no oilier
care but to keep them dean from WCL; ... and thin
ill- plants when l • y are too thick. As thefe have
no great bf.iurj', a tew plgnp cilty may be i-
for the ukeof vxnetp. They flower in July and ;uguft,
and thdr Kad' ripen in September.

Dr. LinniEus has joined this to the Bromelia of father Plumier, to which he has also added the Karatas of tlw fame author, fuppoing them to be of the fame genus; which mi Sake he may have been led into by Plum fert figures, for he has joined the fruit of the Caraguata to the flowers of the Kimtas, and ra< vcrfa. The other differences will be exhibited under the article Karate.

The VAUIETIES of this are,

- 1. ANANAS (K/virus) nuculeatus, frufru ovato, earne atbida. Plum. Ovaf-fbaped Pine-appU, with a vibiiifb

- 2. ANANAS (Pymmidoiis) aculcatuj, frufru pyramidalis, came aurea. Plum. Pyramidal Pint-apple, -Jiitb a wijbfjib, called the Sugar-leaf Pine.

- 3. ANANAS (Glabra) folio vix ierrato. Boerh. Ind. Alt. 5- 83, Pim-apph with fmoftb leaves.

- 4. AMANAS (Lucid:is) lucide virens, folio vix ferrnto. Hort. Elth. Pitte-apple with fbining great leaves, and fcarce atfpinneton tbtir.

- 5. AKANAS iSerotix*) frufru pyramidaroliv* color*. intus aureo. Pyramidal Oli'-i-n.tixed Pine-apple, with

- 6. ANASAs^WMiu) aculearos, fruhi) pyramiitw ex viriLLi (lavJiente. The green Pine-n.

The ... arc fveral whet Mrieti ... of rait. Tome of h may %avi' b<n obtained from^'-i.-, and L

doubt not but if the feeds were fown frequently, in the countries where they are in plenty, there may be as great variety of these fruit, as there are of Apples or Pears in Europe. And this I have found true by some trials which I have made by fowing the feeds, which have always produced a variety of sorts from those of the same fruit.

This fruit (which is justly esteemed for the richness of its flavour, as it surpasses all the known fruits in the world), is produced from an herbaceous plant, which hath leaves somewhat resembling those of Aloe, and are, for the most part, fawed on their edges, but are much thinner, and not so juicy as the Aloe: the fruit resembles the cones of the Pine-tree, from whence it is supposed to have its name.

Where this plant is a native, I believe is hard to determine; but it is probably an indigenous plant in Africa, where, I have been informed, they grow in uncultivated places in great plenty. They have been long cultivated in the hottest islands of the West-Indies, where they are in great plenty, and extraordinary goodness; but they have not been many years in the European gardens, so as to produce fruit: the first person who succeeded in this affair, was Monsieur Le Cour of Leyden in Holland, who, after a great many trials, with little or no success, did at length hit upon a proper degree of heat and management, so as to produce fruit equally good (though not so large) as those which are produced in the West-Indies, as hath been often affirmed by persons who have lived many years there: and it is to this worthy cultivator of gardening, who did not spare any pains or expence to accomplish it, that all the lovers thereof are obliged, for introducing this king of fruits amongst them-, and it was from him that our gardens in England were first supplied, though we have since had large quantities brought from America. I cannot here avoid taking notice of a common error which prevails amongst many people, which is, that the plants brought from America are not so good as those which came from M. Le Cour; which is a great mistake, for were the people who send over these plants from America careful to send the best kinds, there would be found many better than those cultivated by M. Le Cour, who had his from thence at first, as his gardener assured me; and I have seen as good fruit produced from American plants, as any I have yet seen, and some three times larger than any I saw in M. Le Cour's garden.

The first sort is the most common in Europe; but the second sort is much preferable to it, the fruit of this being larger, and much better flavoured: the juice of this sort is not so astringent as that of the first, so that this fruit may be eaten in greater quantity with less danger. This frequently produces suckers immediately under the fruit, whereby it may be increased much faster than the common sort; so that in a few years, it may be the most common sort in England.

The third sort is preserved by some curious persons for the sake of variety, but the fruit is not worth any tiling. The sixth sort is at present the most rare in Europe, there being very few of the plants at present. This has been esteemed the best sort known, by some of the most curious persons in America, many of whom have thrown out all the other sorts from their gardens, and cultivate only this kind. The plants of this sort may be procured from Barbadoes and Montserrat, in both which places it is cultivated.

The sort with very smooth grass-green leaves, was raised from feeds taken out of a rotten fruit, which came from the West-Indies to the late Henry Heathcote, Esq., from whom I received one plant, which hath produced large fruit: this, I am told, is what the people of America call the King Pine. I have since raised some plants of this kind from feeds, which were brought me from Jamaica.

These plants are propagated by planting the crowns which grow on the fruit, or the suckers which are produced either from the sides of the plants, or under

the fruit, both which I have found to be equally good-, although by some persons the crown is thought preferable to the suckers, as supposing it will produce fruit sooner than the suckers, which is certainly a mistake. For by constant experience I find the suckers (if equally strong) will fruit as soon, and produce as large fruit as the crowns.

The suckers and crowns must be laid to dry in a warm place for four or five days, or more (according to the moisture of the part which adhered to the old fruit;) for if they are immediately planted, they will rot, especially the crowns*. The certain rule of judging when they are fit to plant, is by observing if the bottom is healed over and become hard; for if the suckers are drawn off carefully from the old plants, they will have a hard skin over the lower part, so need not lie so long as the crowns, or those whose bottoms are moist. But whenever a crown is taken from the fruit, or the suckers from old plants, they should be immediately divested of their bottom leaves, so high as to allow depth for their planting; so that they may be thoroughly dry and healed in every part, left when they receive heat and moisture, they should perish, which often happens when this method is not observed. If these suckers or crowns are taken off late in the autumn, or during the winter, or early in the spring, they should be laid in a dry place in the stove, for a fortnight or three weeks before they are planted, but in the summer season they will be fit for planting in a few days.

As to the earth in which these should be planted, if you have a rich good kitchen-garden mould, not too heavy, so as to detain the moisture too long, nor over light and sandy, it will be very proper for them without any mixture: but where this is wanting, you should procure some fresh earth from a good pasture; which should be mixed with about a third part of rotten neat's dung, or the dung of an old Melon or Cucumber-bed, which is well consumed. These should be mixed six or eight months at least before they are used, but if it be a year, it will be the better; and should be often turned, that their parts may be the better united, as also the clods well broken. This earth should not be screened very fine, for if you only clear it of the great stones, it will be better for the plants than when it is made too fine. You should always avoid mixing any sand with the earth, unless it be extremely stiff, and then it will be necessary to have it mixed at least six months or a year before it is used. And it must be frequently turned, that the sand may be incorporated in the earth, so as to divide its parts: but you should not put more than a sixth part of sand, for too much sand is very injurious to these plants.

In the summer season, when the weather is warm, these plants must be frequently watered, but you should not give them large quantities at a time: you must also be very careful, that the moisture is not detained in the pots, by the holes being stopped, for that will soon destroy the plants. In very warm weather they should be watered twice or three times a week; but in a cool season, once a week will be often enough: and during the summer season, you should once a week water them gently all over their leaves, which will wash the filth from off them, and thereby greatly promote the growth of the plants.

There are some persons who frequently shift these plants from pot to pot, but this is by no means to be practised by those who propose to have large well-flavoured fruit; for unless the pots be filled with the roots, by the time the plants begin to show their fruit, they commonly produce small fruit, which have generally large crowns on them, therefore the plants will not require to be potted oftener than twice in a season: the first time should be about the end of April, when the suckers and crowns of the former year's fruit (which remained all the winter in those pots in which they were first planted) should be shifted into larger pots, i. e. those which were in halfpenny, or three-farthing pots, should be put into penny, or

tt nwl three-hilfrnj- pots, according to th? fci of the plants, for you must • very oar/lul nw in over-
 pot them, nothing being more prejudicial to their
 plants. The second time for lifting is in the
 beginning of August, when you must take out
 the plants which are of a proper size for i u tin; the fill-
 ing being, into two penny pots, which are full

 great nun (ccl), iftr tl they are fully grown, ap-
 pear like bees, and adhere so clofly to the leaves, as
 not to be cailly washed off, and form as if they had
 ins lift in them. They were originally brocgi from
 America upon the pi which were imported from
 thence, a I believe they art ik same insects which
 have deft; oved the figs cases of late years in some
 of the Jjwiif.ird iflands. E ncc they have been in
 England, they have spread greatly, as fack (Qef)
 where ih- • has not been more than ordinar y care
 taken to destroy them. They have also attacked the
 Orange-tree in many gardens near London, and have
 (toil them terrible damage, but I do not find they
 will endure the cold of our climate in winter, so that
 they are never found on fack plants as low in the open
 air. The only method I have been yet able to dis-
 cover for destroying these insects, is by washing the
 leaves, branches, and stems, of these plants as they
 attack, frequently with water, in which there has
 been a strong infusion of Tobacco-tobacco, which I find
 will destroy the insects, and also preserve the plants.
 But this method cannot be practis'd on the Orange
 plant, because the insects will take them.

Thinking, to remedy this ^convenience, it is now
 the practice of thofc persons who are desirous to pro-
 duce the fruit, to erect low frames, with pits therein
 for the bark-bed, in the manner here-fore described and
 figured-, Aicfeai- built in different ways, according
 to the fancy of the contriver. Some persons build
 them with upright glass in front, about four feet
 high,

high, so that there is just height enough for persons to walk upright on the back-side of the bark-bed. Others make but one dope of glasses, from the top of the stove down to the plate, which lies about six or eight inches above the bark-pit, so that in the front of this stove, there is no walk made between the bark-pit and the glasses, but the inconvenience of watering the plants, as also of coming near those plants which are placed in the front of the stove to clean them, has, in some measure, brought them into disesteem, so that few persons now build them, though the expence is much less than of the other kind of stoves, but of both these stoves the figures and descriptions which are hereafter exhibited under the article of stove, will be sufficient for any person to build either of the sorts. One of these stoves about thirty-five feet long in the clear, with the pit or the tan reaching from end to end, and six feet and a half wide, will contain about four score fruiting plants, so that whoever is desirous to have this fruit, may easily proportion their stove to the quantity of fruit which they are willing to have.

But it will be also necessary to have a bark-pit under a deep frame, in order to raise the young plants; in which you should plunge the suckers, when they are taken from the old plants, as also the crowns which come from the fruit, so that this frame will be as a nursery to raise the young plants to supply the stove: but these plants should not remain in these frames longer than till the beginning of November, unless the frame is built with brick-work with flues in it to warm the air (in the manner hereafter described and figured), which are very useful, as nurseries, to keep the young plants till they are of a proper size to produce fruit; so that you may keep these either warmer or cooler than the stove, according as the plants may require, so that the stove may be every autumn filled only with bearing plants, whereby a much greater quantity of fruit may be annually produced, than can be where young and old plants must be crowded into the same stove. But where there are no conveniences of this kind, the young plants, about the middle or latter end of October, must be removed into the stove, and being finally may be crowded in among the larger plants, for as they will not grow much during the winter season, they may be placed very close together. The beginning of March, where there is no nursery for the young plants, they must be removed out into the hot-bed again, which should be prepared a fortnight before, that the tan may have acquired a proper heat: but you should be careful that the tan be not too hot, for that might scald the fibres of the plants, if they are suddenly plunged therein. Therefore if you find the bark too hot, you should not plunge the pots above two or three inches into the tan, letting them remain so until the heat of the tan is a little abated, when you should plunge the pots down to their rims in the bed. If the nights should continue cold after these plants are removed into the bed, you must carefully cover the glasses with mats, otherwise by coming out of a warm stove, they may receive a sudden check, which will greatly retard their growth, therefore must be carefully avoided; because the sooner the plants are set growing in the spring, the more time they will have to gain strength, in order to produce large fruit the following season.

You should not plunge the pots too close together in this frame, but allow them a proper distance, that the lower part of the plants may increase in bulk, for it is on this that the magnitude of the fruit depends; because when the plants are placed too close, they draw up very tall, but do not obtain strength, so that when they are taken out of the bed, the leaves are not able to support themselves, but all the outward long leaves will fall down, leaving the fiddler middle leaves naked, and this sometimes will cause them to rot in the center. You must also observe, when the sun is very warm, to raise the glasses of the hot-bed, in order to let out the steam of the bed, and to admit fresh air. It is also neglected of this kind, in a very, hot

day, may destroy all the plants, or at least so fast, that they will not get over it in several months. It will be also very proper, in extreme hot weather, to shade the glasses in the middle of the day with mats; for the glasses, lying so near to the leaves of the plants, will occasion a prodigious heat at such times. During the summer season these plants must be frequently watered, giving them but little each time; and in hot weather, they must have free air admitted to them every day, from ten o'clock till four; for if they are kept too close, or have too much wet, they will receive a check in their growth, when the insects will immediately spread over them; for there are generally some of these insects on all these plants, which do not much injury to them while they are in a growing state, but whenever they are unhealthy, the insects multiply greatly, and contribute to their decay. There are some persons who regulate the heat of their stoves by thermometers in summer, but at that season this is unnecessary, for the outward air in hot weather is frequently greater than the Ananas heat marked on the thermometers, so that the heat of the stoves at that season will be much greater. The use of the thermometer is only in the winter, during the time the fires are continued, by which it is easy to judge when to increase or diminish the fires; for at that season, the stoves should not be kept to a greater warmth than five or six divisions above Ananas, nor suffered to be more than as many divisions below it. In winter the plants must have less water, but they will require to have it repeated once a week, giving them but little each time: when the plants are placed into the tan for the winter season (which should be done about the beginning of October) the tan-bed should be renewed, adding two thirds of new tan, to one third of the old. If this be well mixed, and the new tan is good, the bed will maintain a proper degree of warmth till February, at which time it will be proper to stir up the bed, and add a load or two of new tan, so as to raise the bed as much as it sunk since the autumn; this will give a fresh heat to the bed, and keep the plants growing, and as the fruit will now begin to appear, it will be absolutely necessary to keep the plants in a growing state, otherwise the fruit will not be large.

In April it will be proper to stir up the tan again, and if the bed has sunk since the last stirring, it will be proper to add some fresh tan to it; this will renew the warmth of the bed, and forward the fruit. At this time it will be proper to shift the young plants, which are designed to produce fruit the following year, the tan-bed into which these are plunged must be renewed, in order to forward their growth, that they may have strength enough in autumn to produce good fruit, for in this is the principal care required.

Those plants which flower their fruit early in February, will ripen about June, some sorts are at least a month or five weeks longer in ripening their fruit than others, from the time of the appearance of the fruit: but the season in which the fruit is in greatest perfection, is from the beginning of July, to the end of September, though in March, April, and October, I have frequently eaten this fruit in pretty good perfection; but then the plants have been in perfect health, otherwise they seldom are well flavoured.

The method of judging when the fruit is ripe, is by the smell, and from observation, for as the several sorts differ from each other in the colour of their fruit, that will not be any direction when to cut them; nor should they remain so long as to become soft to the touch before they are cut, for then they become flat and dead, as they do also when they are cut long before they are eaten, therefore the best way to have this fruit in perfection, is to cut it the same day it is eaten; but it must be cut early in the morning, before the sun has heated the fruit, otherwise it will be hot, observing to cut the stalk as long as the fruit is possible, and lay it in a cool, but dry place, preferring the stalk and crown unto it, until it is eaten.

That fort with green fruit, if fuffered to ripen well, is of an Olive colour *, but there are feme perlbn who cut them before they are rife, when they are not fit to be eaten, for no other reafon but to have them green: and although many perfons have much recommended this fort for its excellent flavour, yet I think the Sugar-loaf fort is much to be preferred to it. This Sugar-loaf fort is eafily diftinguifhed from all the other, by its leaves having purple ftripes on their infide the whple length. The fruit is of a paler colour than the others when ripe, inclining to a fraw colour. This fort was brought from Brafil to Jamaica, where it is efteemed far beyond the other kinds.

The next in goodnefs to this, is what the inhabitants of the iflands in America call the Montferrat Pine*, the leaves of this are of a dark brown, inclining to purple on their infide; the protuberances of the fruit are longer and flatter than thofe of the common fort. I raifed feveral plants of this fort from feeds which I received from the ifland of St. Thomas, where this fruit is in greater perfedtion than in any of the Britiifh iflands.

As fome of the fruit produce feeds in England, when the greater number have no appearance of any, I doubt not whether there are not fome with male, and others with hermaphrodite flowers-, becaufe thofe fruit which have feeds, are remarkably different from the others, when cut through the-cells in which the feeds are lodged, lying nearer to the center of the fruit than the abortive cells, which are chiefly clofe to the rind *, but not having diftinguifhed this difference till the fruit was cut, I had no opportunity of examining their flwers.

I have continued this title of Ananas to the genus, being the moft generally known and ufed, left by altering it, the pradtical gardeners fhould be rather confufed than inftrued: and I was the rather inclined to this, as Dr. Linnaeus has miftaken the chara&ers of the three genera, which he has joined in one. The different varieties are alfo enumerated, for the lake of thofe who cultivate the fruit, though they We not diftinf species, but vary in their fhape, colour, and flavour, the fame as other fruits. Therefore, as this work is intended to inftrudt the pradtical gardener, the mentioning thefe varieties is more excufable here, than in thofe books which are only intended for the improvement of botany.

ANAPODOPHYLLON. See PODOPHYLLUM.
ANASTATICA, Rofe of Jericho.

The CHARACTERS are,

// hath a four leaved empatementy which falls off the flower has four petals placed croffivife, which fpread open, whofe tails are the length of the tube of the empatementy and fix awl-jhaped ftamina > two of which are fhorter than the other four, crowned with roundijh fummitSy and a fmatt bifid germ fupporting an awl-jhaped fyk the length of the ftamina^ and is permanent\ crowned by a headed fummiu Thegermen afterward becomes a fhort bilocular pod* having an awl-jhaped partition placed obliquely to the pody and is longer.*

We have but one SPECIES of this genus in the Englifh gardens, viz.

ANASTATICA (*Hierocunticayfolns obtufis, fpicis axillari-bus breviflimis, filiculis unguatis fpinofis.* Lin. Sp. 895. *Rofe of Jericho with obtufe leaves, fhortfpikes of flowers at the wings of theftalksy and prickly pods.*

This plant grows naturally in Paleftine and Cairo, in fandy places near the fea. The ftalks are ligneous though the plant is annual 5 it rifes five or fix inches high, dividing into many irregular branches; the flowers which are fmall and white, are difpofed in fhort fpikes at the wings of the ftalks, and have little beauty; thefe are fucceeded by fhort prickly pods, having two cells, in each of which are two feeds.

It is preferred in botanic gardens for the variety, and in fome curious gardens for the oddnefs of the plant, which, if taken up before it is withered, and preferved entire in a dry room, may be long preferved *, and after being many years kept in this fituation, if the

root is placed in a glafs of water a few hours, the buds of flowers will fwell, open, and appear, as if newly taken out of the ground, to the great furprife of moft people.

The plant is annual, fo can only be propagated by feeds, which rarely ripen in England, unlefs the feeds are fown upon a hot-bed in the fpring, and the plants afterward put into pots, which fhould be plunged into another hot-bed to bring them forward, for although the feeds will come up in the full ground where the foil is dry, yet the plants rarely rife to any fize, nor do they perfed feeds unlefs the fummer is very hot and dry: but if the plants are kept in a frame, giving them free air in warm weather, they will flower in June, and the feeds will ripen in September.

ANATOMY pAriipcs ofAmity*** Gr. to difleft], a diffe&ion.

Anatomy of plants is a cutting, dividing, or feparating the parts or members of plants, in order to difcover the fize, form, ftru&ure, and ufes of their feveral veffels, for the better promoting their culture.

Anatomifts have obferved a great fimilitude betwixt the mechanic frame of plants and animals: the parts of plants feeming to bear a conftant analogy to thofe of animals; and the ceconomy, both vegetable and animal, feem to be formed on the fame model.

The parts of a plant are die root, the wood, the bark, and the pith.

1. The roots of the plants are fpongeous bodies, whofe parts are difpofed for the eafy admittance of certain* humid particles, which are prepared in the ground. The quality of the root is found much to depend upon the fize of its veffels and pores.

Monfieur Renaume fuppofes the root of a plant to do the office of all the parts in the abdomen of animals, which ferve to nutrition, as the ftomach, inteftines, &c.

Dr. Boerhaave confiders the roots of plants to be compofed of a number of abforbent veffels, which are analogous to thela&eals in animals.

The root, according to Dr. Van Royen, is that part of the plajit by which the nutriment is taken in, or that by which the aliment is attra&ed, as Theophrastus has defined it: but ix is not all that part, which is committed to the earth, to be nourifhed by the matter which is about it, which is properly to be called the trunk of the root *, this is to be referred rather to the ftalk or ftem, than to the root, in that it confifts of the fame implicated kincks of veffels *, but that part which is by its furface contiguous to the exterior matrix, which, being perforated with infinite little mouths, promotes the received moiftures, that they may be afterwards carried, by veffels not unlike to laftel ones, into the very body of the plant; this is properly to be called the root.

Which definition, although it may feem too ftri&, is the moft general, and applicable to all plants, for it agrees as well with them which have no root, as the vulgar opinion is, as to thofe which have a manifeft root, of the former kind there are but very few plants, but of the latter a great many.

As to thofe that want a manifeftroot, the fuperficies of them is found to be perforated on all fides with very fmall holes, by which they take in their nutriment, as in the Porno Aurantio, called Neptuni, or Pila Marina by fifhermen, and many other fubmarine plants; and in thefe the whole fuperficies ferves for roots, as is plainly feen in fome ftony plants that grow under the fea, and may be in fome fort proved to be deduced from the analogy of animals *, for thefe being become *fid generis** take in aliment, not only by the iBOUth, but alfo the whole furface, expofed to the moiffoir, feems to ferve to the fame defign. But although thefe fubmarine bodies have, by moft naturalifts, be^n ranged with vegetables, yet, by later difcoveries^ many of them have been found to confift of beds of infe&s, inclofed in fmall cavities of thefe incrufted bodies, therefore fhould rather be ranged with minerals.

But

But those plants that are endued with a conspicuous root, and more obvious to the senses, differ among themselves very much in this part: for some are bulbous, some are squamous, or tuberous, others grumous, others fibrous, and lastly, others nodous; which, as it will be sufficient to have taken notice of the primary differences of roots, I shall omit their particular definition in this place, and refer them to their several heads, where each of them shall be particularly described.

The first part of the root, which is called the Epidermis, or cuticle, is, for the most part, of a brown or dusky colour, very thin, and easily peeled off from the under skin (if it be first soaked in warm water); which being viewed by a microscope, shews its most tender structure much like a net pierced through with many small holes. And these little orifices of the epidermis being dilated, and filled with the received moisture, resembling vesicles, which, being exhausted yearly by the mutation of the air, become consolidated, and perish; to wit, this being driven out by a new cuticle growing under it, after the same manner as squamous animals annually cast the old epidermis, a new cuticle coming under it; so that these little vessels, fibrils, or by what name soever they are called, may not unfitly be compared to the veins of animals.

But the other part, which on the outside constitutes the cortex, or outer bark, and on the inside the liber, or inner bark, is called cutis; in which there are parts to be considered of a four-fold kind.

1. Certain strong fibres, cohering and elastic, stretched out vertically with the lateral fibres communicating among themselves, and compacting, or thrusting in the former, they form a hollow cylinder, or zone, under the epidermis; and this hath another under it, which also includes a third; and so of the rest, to the inmost inward of all, which luxuriates near the wood, and is by a peculiar name called liber, or inward bark. And these zones, or girdles, although they are most innumerable, may all be peeled off as the lamellae of bulbs, when the sap flows through them; and inasmuch as those fibres in the harder roots of trees are almost of a bony nature, they procure a firmness to the cortex or outward bark; and these fibres are in all plants, and appear as well in gnaws as in the Cedar tree, although they are more compact in trees, than in plants of a tenderer structure, which are more easily sustained.

2. In the areas, or spaces, which are between the fibres and their anatomies, there are every where membranaceous vessels full of moisture, or little utricles, which, in the areas, or intercepted spaces that are of a different figure, are found to be various, and accommodated to all the spaces; but all these utricles communicate among themselves, as is best seen in the greatercelandine, when we squeeze out that golden coloured liquor with which it is filled; and the middle spaces betwixt these zones have like utricles, and all the fibres constitute hollow canals; but the utricles have receptacles communicating among themselves.

3. Aerial vessels, or tracheae, are open from the lower to the upper part of the plant, and are twisted or curled after an admirable manner, and disposed round about with fibres and utricles in form almost of a spiral line, which in their cavities contain an elastic air; which being affected by the external air, first expanded, and afterwards condensed, will be changed after a like manner, and feel the same vicissitudes of cold and heat, and will undergo a reciprocal motion of cold and heat. This action is exerted in the vessels filled with moisture, which when they cannot be condensed, give place, and are driven up those that are higher, and are moved forward.

4. Lastly, besides fibres, utricles, and tracheae, a peculiar kind of vessels appear, containing the moisture, as it seems secreted by the organical disposition of the plant itself, which water, or moisture not only the cortex, but the wood, and the rest of the

part* of vegetables, and are turgid with a concocted juice, which seems far more elaborate than is the moisture contained in the fibres or utricles; and the mouths of these vessels being of a different figure, pour forth sometimes a various liquor, according to its peculiar nature, chiefly near the outward region of the cortex; so the Tithymalus and Cichory commonly distill a milky humour, and the Cypress, Fir, and Pine, a certain species of turpentine.

And by how much these circles are more outward, by so much the middle spaces between the two zones are greater; and are lessened always towards the more inward in a certain proportion, which seems to depend on this, viz. the outward air acting on all sides with an equal pressure, and by a certain power presses the second; and this also by this means, is pressed by its own condensed air, and presses together those which are more inward, because it cannot exert its force upon the external air; therefore the second circle is necessarily more compressed than the first, and the third more than the second, and so of the rest. And the utricles placed between the circles are pressed by the same proportion; which, by degrees, are more and more exhausted; thence the inner circle loses most of all the compressed and condensed utricles, and by degrees grows solid.

And this is properly called Liber (the inward bark), and is that circle, which, being middlemost by place and nature, between the cortex, or outward bark, and the wood, comes nearest to the nature of the wood, and in time passes into it, for the cortex loses every year one such circle, and becomes wood, which may be distinguished from the former circles of the root, stock, or trunk; and if they are cut horizontally, will shew the number of such circles, and how many years the tree is old.

And this successive mutation of the cortex into liber, and of liber into wood, is like to that we observe in the human body in the beginning of a callus; for a callus consists of (skin, but so compressed, that all the vessels are lost; and that skin, being become solid, is increased, and grows to a greater bulk. But besides these hitherto described, there occur certain peculiar vessels (of which mention has been made in describing the cortex), which are found full of turpentine, gum, or a certain concreted juice proper to them; the constant progress of which is not very conspicuous in all of them, by reason of the transparency of the moisture.

5. The fifth and last part is the most inward, the medulla or pith, disposed in the middle center of the root; and as it seems different from the former, seeing this is sometimes wasted, and that never, this appears more fungous, that more durable.

As to the manner of the root's performing its function, it may be observed, that the root having imbibed the saline and aqueous juices of the earth, and saturated itself with them, for the nourishment of the tree, those juices are put into motion by heat; which having entered the mouths of the arterial vessels from the root, they mount to the top with a force answerable to what lets them in motion; and, by this means, they gradually open the minute vessels rolled up, and expand them into leaves.

2. The wood; this is considered as consisting of capillary tubes, running parallel from the root throughout the stalk. Some call the capillary tubes arterial vessels, because the sap rises from the root through these. The aperture of these tubes are, for the most part, too minute to be perceived by the bare eye, unless in a piece of charcoal, cane, or the like.

Wood, says Dr. Grew, by microscopical observations, appears to be only an assemblage of infinitely minute canals, or hollow fibres, some of which arise from the root upwards, and are disposed in form of a circle; and the others, which are called inferdons, tend horizontally from the surface to the center, so that they cross each other, and are interwoven like the threads of a weaver's web.

fecides the capillary tubes, &c. before-mentioned, there are other larger vessels, which some call venal vessels, which are disposed on the outside of the arterial vessels, between the wood and the inner bark, and lead down to the covering of the inward root. These vessels are supposed to contain the liquid sap found in plants in the spring, &c.

The Rev. Dr. Hales tells us in his excellent treatise on Vegetable Statics, that, in order to find whether there was any lateral communication of the sap and sap-vessels, as there is of the blood in animals, by means of the ramifications and lateral communications of their vessels; he took a young oak-branch, seven or eight inches diameter, at its transverse cut, six feet high, and full of leaves; and having cut a large gap to the pith, seven inches from the bottom, and of an equal depth the whole length, and also cut another gap four inches above that on the opposite side, he set the end of the stem in water, and in two nights and two days time it imbibed and perspired thirteen ounces; while another like oak-branch, somewhat bigger than that, but with no notches cut in its stem, imbibed twenty-five ounces.

From this and many other experiments he there mentions, he says, we see a most free lateral communication of the sap and sap-vessels, those great quantities of liquor having passed laterally by the gaps; in that, by several experiments on cylinders of wood, little evaporated by the gaps.

The bark is the exterior part of trees, serving them for a skin or covering: it is generally of a spongy texture, and communicates with the pith by a multiplicity of small fibres passing through the capillary tubes, of which the wood consists: so that the roots having imbibed the proper nutriment of the tree, it is carried up by the warmth of the sun, through the fine arterial vessel of the tree, to the top of it, and being there condensed by the cold, it does, by its own gravity, return down by the vessels which lie between the wood and the inner bark, which perform the office of veins, and as it passes by, leaves such parts of its juice as the texture of the bark will receive, and requires for its support.

Some are of opinion, that that soft whitish rind, or substance, which lies between the inner bark and the wood, does the office of veins: and some call this a third bark, and suppose it to differ from the other in nothing but having closer fibres, and that it contains the liquid sap, gums, &c. which are found in the plants in the spring and summer months, which hardens by degrees, by means of the sap it transmits, and is imperceptibly conveyed into the woody part of the tree.

The bark serves for divers purposes, for it not only transmits the nutritious juices of the plants, but also contains divers fat oily humours, to defend the inner parts from the injuries of the weather. As animals are furnished with a panniculus adiposus, usually replete with fat, which invests and covers all the fleshy parts, and screens them from external cold; so are plants encompassed with a bark, replete with fat juices, ~~by means whereof the cold is kept out, and, in winter-time, the spiculae of ice prevented from sinking~~ and freezing the juices in their vessels; whence it is, that some sorts of trees remain ever-green throughout the year, by reason their barks are more compact, and contain a larger quantity of oil than can be spent and exhaled by the sun.

The pith is the inward central part of a tree or plant, answering to the medulla, or marrow of an animal. As for its substance, it consists of little transparent globules, chained or linked together, somewhat like the bubbles that compose the froth of liquor.

Some suppose, that the circulation of the sap is effected by means of the pith, others by the bark, and others by the wood.

Borelli, in his book De Motu Animalium, supposes the tender growing shoot to be distended like soft wax, by the expansion of the moisture in the spongy pith, which dilating moisture he concludes, is hindered

from returning back, while it expands by the springiness of the pith without the help of valves.

And the Rev. Dr. Hales is of opinion, that it is very probable, that the particles of water that immediately adhere to, and are strongly imbibed into, and attracted by, every fibre of the spongy pith, will suffer some degree of expansion before they can be detached by the warmth of the sun from each attracting fibre; and, consequently, the mass of spongy fibres, of which the pith consists, must therefore be extended.

And that the pith may be the more serviceable for this purpose, nature has provided in most shoots a strong partition at every knot, which partitions serve not only as plinths or abutments for the dilating pith to exert its force on, but also to prevent the too free retreat of the rarefied sap from the pith.

But a dilating spongy substance, by equally expanding itself every way, would not produce an oblong shoot, but rather a globous one, like an apple to prevent which inconvenience it is observable, that nature has provided several diaphragms, besides those at each knot, which are placed at small distances across the pith, thereby preventing its too great lateral dilatation.

These are very plain to be seen in the shoots of the Walnut-tree, and the same may be observed in the pith of the branches of the Sun-flower, and several other plants, where those diaphragms are not to be distinguished while the pith is full and replete with moisture; yet when it dries up, they are often plain to be seen. And it is farther to be observed, that where the pith consists of distinct vessels, the fibres of those vessels are often found to run horizontally, whereby they can the better resist the too great lateral relaxation of the root.

The trunk and branches of a tree, bear a resemblance to the exterior members and limbs of an animal, which it may subsist without, though the rotting and mortification of them oftentimes occasion a total destruction of it. Accordingly the like effects are found from the wounding or lopping of a tree, as from the wounding or cutting off a limb, an extravasation, callosus, or the like.

A leaf is part of a plant extended into length and breadth in such a manner, as to have one side distinguishable from the other. The leaves, according to Malpighius, consist of so many interwoven utricles, as to be not much unlike a pulmonary net, and serve instead of lungs to the plant. As the perspiration and respiration are chiefly performed thereby, those vessels are very conspicuous when the leaves are dried. In the day-time, when the heat hath rarefied the mounting juices, so as to become specifically lighter than the air, they flow out through the pores of the leaves, and evaporate, which is the occasion of the leaves becoming so flaccid in very hot weather; but in the night, when by the cold the juices are more condensed, then the leaves are erected again, and draw in a great share of nourishment from the air. These leaves we may observe to be of different textures on each side, the upper surface being for the most part smooth, the better to shoot off the redundant moisture, while the under surface is many times of a rough and cottony texture, by which it is capable of retaining the moisture; for which reason we find, if by bad management, &c. the shoots of trees are nailed to a wall, &c. so as to turn the surfaces of the leaves the wrong side upwards, the shoots will be at a stand, until the leaves have obtained their proper disposition. These leaves, as the learned Dr. Hales observes, are carefully distributed at small distances throughout the whole length of the shoots, and serve as so many jointly-acting powers, placed at different stations, thereby with more ease to draw plenty of sap to the extending root.

A flower is the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the rudiment of the fruit, and contains the organs of generation, some of these flowers contain the male organs, as the stamens and apices, which are loaded

with the farina fecundants, which, when ripe, is scattered into those flowers which are female, and consist only of the ovarium, with the style and stigma, which are surrounded with the petals*. Other flowers there are, which have both sexes contained in the same flower; these are called hermaphrodite flowers. A fruit, *Kypwbs*, is not that part of a plant which is eatable, but rather the seeds, with their covering, should be called the fruit. This covering cherishes the seeds until they come to maturity, and defends them from the injuries of the weather, as that they are not hurt thereby; and also prepares the juices designed for their nourishment, that it may with ease enter their small bodies in a just proportion.

The motion of the nutritious juices of plants is produced much like that of the blood in animals, by the action of the air; and, in effect, there seems to be something equivalent to respiration throughout the whole plant.

Malpighius was the first who observed, that vegetables consisted of two series, or orders, of vessels.

1. Those which have been treated of before, which receive and convey the alimental juices, and which answer to the arteries, lacteal vessels, veins, &c. of animals; and,

2. The tracheae, or air-vessels, which are long hollow pipes, in which the air is continually received and expelled, i. e. inspired and expired, within which tracheae all the former vessels are contained.

Hence it follows, that the heat of the year, nay, of a single day, hour, or minute, must have an effect on the air included in these tracheae, i. e. it must rarefy it, and, of consequence, dilate the tracheae; and hence also a perpetual spring or source of action must arise, to promote the motion of the sap in plants.

For when the tracheae are expanded, the vessels which contain the juices, are, by that expansion, pressed; and, by that means, the juice contained is continually propelled and accelerated; and, by this propulsion, the juice is continually comminuted, and rendered more and more subtil, and adapted to enter into vessels still finer and finer y the thickest part of it being at the same time secreted, and deposited into the lateral cells, or loculi of the bark, to defend the plant from cold, and other external injuries.

The vessels, or containing parts of plants, consist of mere earth, bound or connected together by oil, as a gluten, or glue; which being exhausted by fire, air, age, or the like, the plant moulders, or returns again into its earth or dust.

Thus vegetables being burnt by the most intense fire, the matter of the vessels is left entire and indissoluble, notwithstanding its utmost force; and, of consequence, is neither water, nor air, nor fait, nor sulphur, but earth alone.

Juice is a liquid substance, which makes part of the composition of plants, and communicates itself to all the other parts, and serves to feed and increase them; and is that to plants that blood is to animals. These juices are of divers sorts; aqueous, grumous, bituminous, oleaginous, resinous, vinous, of all tastes and colours.

This juice or sap of plants, is a humour furnished by the earth, and changed in the plant; it consists of some fossil, or other parts, which are derived from the air or rain; and others, from putrefied animals, plants, &c. so that, consequently, in vegetables are contained all kinds of salts, oil, water, earth, and, probably, all kinds of metals too, inasmuch as the allies of vegetables always yield somewhat which is attracted by the loadstone.

The juice enters plants in the form of a fine subtil water, which by how much the nearer it is to the root, so much the more it retains of its proper nature; and the farther it is from the root, the more action it has undergone, and approaches the nearer to the nature of the vegetable; and, of consequence, when the juice enters the root, the bark of which is furnished with excretory vessels, fitted to discharge the excre-

mentitious part, it is earthy, watry, poor, acid, and scarce oily at all.

It is further prepared in the trunk and branches* though it continue acid still; as is perceived by the tapping or perforating of a tree in the month of February, when it distils a watry juice that is fenibly acid.

The juice being carried hence to the germs, or buds, is more connected; and when it has here unfolded the leaves, these come to serve as lungs for the circulation and further preparation of the juice; for when those tender leaves are exposed to the alternate action of heat and cold, moist nights, and hot forcing days, they are expanded and contracted alternately 5 and the more, by reason of their net-like texture.

By such means, the juice is farther altered and digested, as it is farther yet in the petals, or leaves of the flowers, which transmit the juice now brought to a further subtilty to the stamina; the stamina communicate it to the farina, or that dust which appears on the apices, where it undergoes a further maturation, and leads into the pistil; and there acquiring its last perfection, it becomes the original of a new fruit or plant.

ANCHUSA. Lin. Gen. 167. Buglossim. Tourn. Inft. R. H. 133. tab. 53.

The CHARACTERS are,

The empalement is oblong taper, and permanent, cut into five acute segments which are enff. The flower is of one leaf having a cylindrical tube the length of the empalement; at the brim it is cut into five upright segments, which spread open, but the chaps are ctofed, and have five prominent little fides. There are five port stamina in the chaps of the flower which are crowned with oblong summits. In the bottom of the flower are situated four germen, having a slender style, crowned with an obtuse stigma. The germen afterward becomes four oblong blunt seeds shut up in the empalement.

Dr. Linnseus ranges this genus of plants in the first section of his fifth class of plants, entitled Pentandria Monogynia, the flowers having five stamina and a single style.

The SPECIES are,

1. ANCHUSA (*Officinalis*) foliis lanceolatis spicis imbricatis fecundis. Hort. Cliff. 46. *Alkanet with spear-shaped leaves, and fruitful imbricated spikes, or greater Garden Bugloss.* Buglossum angustifolium majus. C. B. P. 256.
2. ANCHUSA (*Angustifolia*) racemis subnudis conjugatis. Prod. Leyd. 408. *Alkanet with conjugated half naked spikes.* Borago fylvetris perennis flare rufo kermefino. Zan. Hift. 49.
3. ANCHUSA (*Undulata*) fruticosa foliis linearibus dentatis pedicellis brevibus minoribus calycibus fructiferis inflatis. Laefl. Lin. Sp. Plant. 133. *Alkanet with narrow indented leaves, small foot-stalks to the branches* and a swelling empalement over the seeds.* Buglossum Lufitanicum echii folio undulato. Tourn. Inft. 134.
4. ANCHUSA (*Orientalis*) villosa-tomentosa, ramis floribusque alternis axillaribus, bracteis ovatis. Lin. Sp. 191. *Alkanet with branches and flowers growing alternately from the wings of the stalks, and oval bractea or floral leaves.* Buglossum Orientale flore luteo. Tourn. Cor. 6.
5. ANCHUSA (*Firginiana*) floribus sparsis caule glabro. Lin. Sp. Plant. 133. *Alkanet with flowers growing thinly, and a smooth stalk.* Anchusa minor lutea Virgiana Puccoon indigena dicta qua fe pingunt Americani. Pluk. Aim. 30. *Called by the inhabitants of Virginia, Puccoon.*
6. ANCHUSA (*Sempervirens*) pedunculis diphyllis capitatis. Lin. Sp. Plant. 134. *Alkanet with foot-stalks having two leaves.* Buglossum latifolium sempervirens. C. B. P.
7. ANCHUSA (*Cretica*) foliis lanceolatis verrucosis femi-plexicaulibus, floribus capitatis, calice procumbente. *Alkanet with warted and spear-shaped leaves embracing the stalk half rounds flowers growing in a head, and a trailing stalk.* Buglossum Creticum verrucosum perlatum quibudarn. H. R. Par,

J. ANCHUSA (*finfioria*) tomentosa, foliis lanceolatis obtusis, ftaminibus corolla brevioribus. Lin. Sp. 192. *Anchusa* with woolly, spear-shaped, blunt leaves, and the stamina of the flower shorter than the corolla, or true *Alkanet* of the *Jhops*.

9. ANCHUSA (*Azurea*) foliis longis hirsutis, floribus capitatis reflexis, pedunculis longissimis. *Alkanet* with long hairy leaves, and flowers collected into heads which are reflexed, and very long foot-stalks. Borago sylvestre Cretica flore azureo. Zan. Hift. 51.

The first sort is the Buglofs, whose flowers are ordered to be used in medicine. This sends up stalks about two feet high, having oblong rough leaves, placed alternately, at the extremity of the shoots. The flowers are produced in clusters; which are of a fine blue colour, these come out with foot-stalks from the wings of the leaves, and are collected into small heads. The flowers are of one leaf, having a long tube, spread open at the top in the shape of a funnel. After the flower is past, it is succeeded by four naked seeds, situated at the bottom of the empalement, which drop out as they ripen.

The roots of this sort seldom continue longer than two years, especially in good ground, for they are subject to rot in winter, unless when they happen to grow in rubbish, or out of an old wall, where they will live several years; for in such places the plants are stunted in their growth, so their branches are firmer and not so full of juice as those which grow in better soil. The plants may be easily propagated by seeds, which may be sown in the autumn, upon a bed of light sandy earth; and in the spring, when the plants are strong enough to remove, they should be planted in beds at two feet distance, observing, if the leafon proves dry, to water them till they have taken root, after which they will require no farther care but to keep them clean from weeds. If the seeds of this plant are permitted to scatter, the plants will rise in plenty, which may be managed in the same manner before directed. There is a variety of this with white flowers, but this will not retain its difference from seeds.

The second sort grows to the height of two feet when cultivated in gardens, but in the places where it grows wild, is rarely more than a foot. The leaves of this are narrow, and less hairy than those of the first, the spikes of flowers come out double, and have no leaves about them; the flowers are small, and of a red colour. The roots will continue three or four years in poor land.

The third sort is a biennial plant, which perishes soon after the seeds are ripe. This grows two feet high, and sends out many lateral branches, which are garnished with long, narrow, rough leaves, which are waved on their edges: the flowers are of a bright blue colour, and grow in an imbricated spike; and after these fall, the empalement turns to a swollen vessel inclosing the seeds.

The fourth sort is a perennial plant, with long trailing branches which lie on the ground, the under leaves are long, broad, and hairy, but these diminish as they are nearer the top, and those which come out on the spikes between the flowers are short and roundish. The flowers are yellow, and about the size of those of the common Buglofs; there is a succession of these on the same plants great part of the year, which renders them more valuable. This, though a native of the Levant, is hardy enough to live in the open air in England, if it hath a dry sandy soil. It may be propagated by seeds in the same manner as the first sort, and if the seeds are permitted to scatter, the plants will rise without care.

The fifth sort is a native of North America, where it grows naturally in the woods, and being an early plant, generally flowers before the new leaves come out on the trees; so that in some of the woods, where this plant abounds, the surface of the ground seems covered with bright yellow flowers. It is known in that country by the title *Puccoon*. It is a perennial plant which seldom rises a foot high in good ground, but not above half that height where the soil is poor, the

flowers grow in loose spikes, upon a smooth stalk. This is propagated by seeds, which, if sown in the spring, seldom grow the first year.

The sixth sort is a very hardy perennial plant, with weak trailing branches, garnished with broad, rough, deep green leaves; the flowers are blue, and come out between the leaves on the spike, like the fourth sort, the plants frequently grow out of the joints of old walls, in those places where any of the plants have been near, for when the seeds are permitted to scatter, there will be an abundant supply of the plants. The flower great part of the year.

The seventh sort is a low, trailing, annual plant, whose branches seldom extend more than six inches; these lie on the surface of the ground, and are thin set with spear-shaped, small, warty leaves, which half surround the stalk at their base. The flowers are small, of a bright blue colour, and are collected into small bunches at the extremity of the branches. The plants perish soon after their seeds are ripe, which if permitted to scatter, the plants will come up better than when they are sown. These do not bear transplanting, so should remain in the places where they come up.

The eighth sort rises near as high as the first, to which it bears great resemblance in its leaves and branches; but the leaves and branches are more woolly, and the stamina of the flowers are shorter than the corolla; the root also is red. This plant grows naturally in the south of France and Spain, but is equally hardy with the first species, and may be cultivated in the same manner.

The ninth sort is a perennial plant, with broad rough leaves, like those of the sixth; the branches grow more erect, and the flowers which are of a bright azure colour, are collected into spikes, coming out singly from between the leaves. This is a hardy plant, and may be propagated in the same manner as the former.

A N D R A C H N E , Bastard Orpine.

The CHARACTERS are,

It hath male and female flowers on the same plant. The male flower hath a five-leaved empalement, which is equal and withers. The flower is composed of five slender leaves indented at the top, which are shorter than the empalement. At the bottom of each petal is situated an herbaceous nectarium, to which the five slender stamina are joined; these are crowned with single summits. The female flowers come out from the wings of the stalk near the male. These have a permanent five-leaved empalement, but no petals; there are five nectariums as in the male, and a globular germen supporting three slender styles which are bifid, crowned with a round stigma. The germen afterward turns to a three cornered globular capsule, having three cells, in each of which are lodged two triangular obtuse seeds.

The SPECIES are,

1. ANDRACHNE (*Telephioides*) procumbens herbacea. Lin. Sp. Plant. 1014. *Herbaceous trailing Andrachne. Telephioides* Graecum humifusum flore albo. Tourn. Cor. 50.

2. ANDRACHNE (*Fruticosa*) erecta arborea. Ofb. It. 228. *Shrubby tree-like Bastard Orpine.*

3. ANDRACHNE (*Arborea*) foliis ovatis obtusis, subtus incanis, caule arboreo. *Bastard Orpine with oval blunt leaves, hoary on their under side, and a tree-like stalk.*

The first sort is a low plant, whose branches trail upon the ground. The leaves are small, of an oval shape, smooth, and of a sea-green colour. It is found wild in some parts of Italy, and in the Archipelago, from whence Dr. Tournefort sent the seeds to the royal garden at Paris: but being a plant of no great beauty, it is seldom cultivated, except in botanic gardens for variety. If the seeds of this plant are sown on a moderate hotbed in March, the plants will arise in about a month after, when they may be transplanted each into a small pot, and plunged into another very moderate hot-bed to bring the plants forward, but in mild weather they should have plenty of air admitted to them, and often refreshed with water: in June they will produce flowers, and the seeds will ripen in August

August and September, soon after which the plants will decay.

The second fort grows naturally in China, and also at La Vera Cruz in New Spain, where it rises twelve or fourteen feet high; the branches are garnished with spear-shaped, pointed, smooth leaves, under which the foot-stalk of the flowers are produced; these are pretty long and hang downward: the flowers are finally, of an herbaceous white colour, some of which are male, and others female, but when the latter are situated at too great a distance from the former, there is rarely any seeds within their covers; though they seem very fair to fight, yet upon being opened there will no seeds be found in them; whereby several persons have been deceived, who have sown them, without raising a single plant.

The third fort was discovered by the late Dr. William Houffton, growing naturally at Campeachy; this has a strong woody stem, which rises more than twenty feet high, sending out branches on every side, which are garnished with oval blunt leaves, hoary on their under-side, and having pretty deep furrows on their upper, placed alternately on the branches: the flowers I have not seen, for the plant which rose from the seeds in the physic garden did not produce any, though it grew upward of fourteen feet high, nor were there any flowers upon the trees at Campeachy, at the time Dr. Houffton was there, the seeds being then ripe; of these the doctor sent many to Europe which appeared very fair, but on being opened, no kernels were found within them, so that but one plant was raised from all the seeds.

These two forts are very tender plants, so that when good seeds can be obtained, they should be planted in pots, plunging them into a hot-bed of tanners bark, observing to water them as the earth becomes dry in the pots; and when the plants come up, and are fit to remove, they should be each planted in a small pot, plunged into a tan-bed, shading them until they have taken fresh root, after which they should have free air admitted to them in warm weather, but must be constantly kept in the bark-stove.

There is also another fort which I have raised from seeds, sent me from Jamaica; the whole form of the seeds agree with those of the third fort, as do also the plants, but the leaves are somewhat like those of the Laurel, but are much larger; this hath not as yet flowered in Europe.

ANDROMEDA. Lin. Gen. Plant. 485. We have no English name for this plant.

The CHARACTERS are,

**the empalement is cut into five small acute segments \ this is coloured and permanent. The flower is of an oval leafy oval bell-shaped, and divided into five parts at the brim; which are reflexed. It hath ten awl-shaped stamens, which are shorter than the petals to which they are fixed \ these are crowned with nodding summits having two horns. In the center of the flower is situated a round germen* supporting a cylindrical style, which is longer than the stamens, and crowned with a blunt stigma. The germen afterward turns to a round pentagonal vessel having five cells > which are filled with small round seeds.*

This genus of plants is ranged by Dr. Linnaeus in the first division of his tenth class, entitled Decandria Monogynia, the flowers having ten stamens and one germen.

The SPECIES are,

1. ANDROMEDA (*Polifolia*) pedunculis aggregatis, corollis ovatis, foliis alternis lanceolatis revolutis. Lin. Sp. Plant. 393. *Andromeda with aggregate foot-stalks, oval petals, and spear-shaped leaves growing alternately.* Polifolia. Buxb. Aft. 2. p. 345.
2. ANDROMEDA (*Mariana*) pedunculis aggregatis corollis cylindricis foliis alternis ovatis integerrimis. Lin. Sp. Plant. 393. *Andromeda with aggregate foot-stalks, cylindrical flowers, and oval entire leaves placed alternately.*
3. ANDROMEDA (*Paniculata*) racemis fecundis nudis paniculatis, corollis subcylindricis foliis alternis oblongis crenulatis. Lin. Sp. Plant. 394. *Andromeda with naked,*

fruitful, Uffe spikes, cylindrical flowers, and oblong crenated leaves placed alternately. Vitis idsea Americana, longiori mucronato & crenato folio, floribus urceolatis racemosis. Pluk. Aim. 391.

4. ANDROMEDA (*Arborea*) racemis fecundis nudis, corollis rotundo-ovatis. Lin. Sp. Plant. 394. *Andromeda with naked fruitful spikes, and oval roundish flowers.* Frutex foliis oblongis acuminatis floribus spicatis uno versus diffusis. Catech. Carolin. 1. p. 71. *commonly called Sorrel-tree in Carolina.*

5. ANDROMEDA (*Caesulata*) racemis fecundis foliaceis corollis subcylindricis, foliis alternis lanceolatis obtusis punctatis. Lin. Sp. Plant. 394. *Andromeda with leafy fruitful spikes, cylindrical flowers, and oval roundish leaves, with punctures placed alternately.* Chamaedaphne. Buxb. Aft. 1. p. 241.

The first fort is a low plant which grows naturally on bogs in the northern countries, but is with difficulty preserved in gardens, and having little beauty, is seldom cultivated except in botanic gardens. I received the seeds from Peterburgh, which came up in the Chelsea garden, but did not continue more than one year.

The second fort grows naturally in North America: this is a low shrub, which sends out many wood-stalks from the root, garnished with oval leaves placed alternately; the flowers are collected in small bunches: these are shaped like those of the Strawberry-tree, and are of an herbaceous colour. They appear in June and July, and sometimes are succeeded by fruit, which seldom ripen in England.

The third fort is also a native of North America. This shrub grows about four feet high, sending out several branches, which are clothed with oblong leaves placed alternately; the flowers grow in loose spikes from the ends of the branches; they are of the pitcher shape, like those of the Arbutus, but are a little longer, and appear in July, but do not produce seeds in this country.

The fourth fort grows naturally in Virginia and Carolina; in the latter it is much larger than in the former, the climate being warmer, so many of the trees and shrubs grow to a much greater height there. In Virginia, it is a shrub growing ten or twelve feet high, but in Carolina it rises twenty feet. The branches are very slender, bending downward; these are garnished with leaves placed alternately, which are oblong and pointed: the flowers grow in long naked spikes, coming out from the sides of the branches, which are of an herbaceous colour, and are ranged on one side of the stalk; they are oval, and shaped like a pitcher.

The fifth fort grows naturally in Siberia, and also in North America; it is a low shrub which grows on mossy land, so is very difficult to keep in gardens. The leaves are shaped like those of the Box-tree, and are of the like consistence, having several small punctures on them; the flowers grow in short spikes from the extremity of the branches: these are produced single between two leaves, they are white and of a cylindrical pitcher shape.

All the forts, except the fourth, are very hardy plants, which delight in moist ground, they increase by their creeping roots, which put up suckers at a distance, and may be taken off with roots, and transplanted where they are designed to remain, for they do not bear to be often removed.

The fourth fort requires to be sheltered from hard frosts in winter, but in the summer should be frequently watered. It is a difficult plant to keep in gardens, as it grows naturally on boggy places, and requires a greater heat than that of this climate. It may be propagated by seeds, which should be procured from America, where it is known by the name of Sorrel-tree.

ANDROSACE. We have no English name for this plant.

8. ANEMONE (*Tbalifroides*) foliis caulinis simplicibus verticillatis, radicalibus duplicato ternatis. Lin. Sp. 763. *Anemone with simple leaves on the stalk, growing in whorles, and those at the root double ternate.*

The first fort grows naturally in many parts of Germany *, this approaches near to our Wood Anemone, but the feeds of it are round and hairy; the flower is large and white, but having little beauty, is seldom planted in gardens.

The second fort grows wild in the woods in many parts of England, where it flowers in April and May, making a pretty appearance in those places where they are in plenty. The roots of this may be taken up when their leaves decay, and transplanted in wildernesses, where they will thrive and increase greatly, if they are not disturbed; and in the spring, before the trees are covered with leaves, they will have a very good effect, in covering of the ground and making a pleasing variety at that season.

The third fort is found growing naturally in some parts of England, but particularly at Wimbledon in Surry, in a wood near the mansion-house, in great plenty; but it is not certain that they were not originally planted there, as they are not found in any other place in that neighbourhood. This fort flowers at the same time with the former, and when intermixed with them, make a fine variety. This may be transplanted from the woods as the former.

There are of these two forts, some with double flowers, which have been obtained from feeds. These make a finer appearance, and continue longer in flower than the single, but are only to be procured from the gardens, where they are cultivated. As these are only seminal varieties, I have not enumerated them with the others.

The fourth fort grows naturally in North America, from whence the feeds are frequently sent to England. This is a very hardy plant, and produces plenty of feeds in England, but having little beauty, scarce deserves a place in gardens, unless for the sake of variety.

The fifth and sixth forts are natives of the east, from whence their roots were brought, original *, but have been so greatly improved by culture, as to render them some of the chief ornaments to our gardens in the spring. The principal colours of these flowers are red, white, purple, and blue, and some are finely variegated with red, white, and purple. There are many intermediate (shades of these colours -, the flowers

are large and very double, and, when properly managed, are extremely beautiful. I shall therefore proceed to give ample directions for their culture, which, if duly observed, every person may have these flowers in perfection.

Take a quantity of fresh untried earth (from a common, or some other pasture land) that is of a light sandy loam, or hazel mould, observing not to take it above ten inches deep below the surface; and if the turf be taken with it the better, provided it hath time to rot thoroughly before it is used; mix this with a third part of rotten cow dung, and lay it in a heap, keeping it turned over at least once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of the free air: in doing this be careful to rake out all great stones, and break the clods (but by no means sift or screen the earth, which is found very hurtful to many sorts of roots); for when this earth is made very fine, upon the first great rains of winter or spring, the small particles thereof join closely together, and form one solid mat, so that the roots often perish for want of some small stones to keep the particles asunder, and make way for the tender fibres to draw nourishment for the support of the root.

This earth should be mixed twelve months before it is used, if possible; but if you are constrained to use it sooner, you must turn it over the oftener to mellow and break the clods; and observe to rake out all the parts of the green sward, that are not quite rotten, before you use it, which would be prejudicial to your roots, if suffered to remain. The beginning of September is a proper season to prepare the beds for planting (which, if in a wet soil, should be raised with this sort of earth six or eight inches above the surface of the ground, laying at the bottom some of the rakings of your heap to drain off the moisture; but in a dry soil, three inches above the surface will be sufficient): this compost should be laid at least two feet and a half thick, and in the bottom there should be about four or five inches of rotten neat's dung, or the rotten dung of an old Melon or Cucumber-bed, so that you must take out the former soil of the beds to make room for it.

And observe in preparing your beds, to lay them (if in a wet soil) a little round, to shoot off the water; but in a dry one, let it be nearer to a level; in wet land, where the beds are raised above the surface, it will be proper to fill up the paths between them in winter, either with rotten tan or dung, to prevent the frost from penetrating into the sides of the beds, which often destroy their roots. The earth should be laid in the beds at least a fortnight or three weeks before you plant the roots, that it may settle *, and when you plant them, stir the upper part of the soil about six inches deep, with a spade *, then rake it even and smooth, and with a stick draw lines each way of the bed at six inches distance, so that the whole may be in squares, that the roots may be planted regularly: then with your three fingers make a hole in the center of each square, about three inches deep, laying therein a root with the eye uppermost *, and when you have finished your bed, with the head of a rake draw the earth smooth, so as to cover the crown of the roots about two inches.

The best season for planting these roots, if for forward flowers, is about the latter end of September 5 and for those of a middle season, any time in October; but observe to perform this work, if possible, at or near the time of some gentle showers *, for if the roots are planted when the ground is perfectly dry, and there should no rain fall for three weeks or a month after, they will be very apt to grow mouldy upon the crown, and if they once get this distemper, they seldom come to good after.

You may also reserve some of your Anemone roots till after Christmas, before you plant them, left by the severity of the winter your early planted roots should be destroyed, which sometimes happens in very hard winters, especially in those places where

they are not covered & them from froft: thefe late planted roots will flower a fortnight or three weeks after thofe which were planted in autumn, and many times blow equally as fair, efpecially if it prove a moift fpring, or that care be taken to refrefh them gently with water.

But then the increafe of thefe roots will not be near fo great as thofe of your firft planting, provided they were not hurt in winter; and it is for this reafon all thofe who make fale of thefe roots, are forward in planting; for although it may happen, by fharp pinching frofts in the fpring, that their flowers are not fo double and fair as thofe planted a little later, yet if they can preferve the green leaves of the plants from being injured, the roots will greatly increafe in bulk; but in fuch gardens where thefe flowers are preferred with care, there is always provifion made to cover them from the injuries of the weather, by arching the beds over with hoops, or frames of wood, and covering them with garden-mats or cloths, in frofty nights, and bad weather, efpecially in the fprings of the year, when their buds begin to appear; for otherwife, if you plant the beft and moft double flowers, the black frofts and cutting winds in March will caufe them to blow fingle, by deftroying the thrum that is in the middle of the flower; and this many times hath occafioned many people who have bought the roots, to think they were cheated in the purchafe of them, when it was wholly owing to their neglect of covering them, that their flowers were fingle.

In the beginning of April your firft planted roots will begin to flower, which will continue for three weeks or more, according to the heat of the weather, or the care taken in covering them, during the heat of the day, with mats or cloths: after thefe are jufly flowering, the fecond planted forts will come to fucceed them, and thefe will be followed by thofe planted in the fpring; fo that you may have thefe beauties continued for near two months together, or fometimes longer, if the feafon prove favourable, or proper care is taken to (hade them in the heat of the day.

The beginning of June, the leaves of your firft blown roots will begin to decay; foon after which time you muft take them out of the ground, clearing them from decayed (talks, and wafhing them, to take the earth clean from the root; then fpread them on a mat in a dry fhady place till they are perfectly dried, when you may put them up in bags, and hang them out of the reach of mice, or other vermin, which will deftroy many of the roots if they can come at them. Obferve alfo to take up the latter planted roots as foon as their leaves decay; for if they are fuffered to remain long after in the ground, and there fhould fall fome flowers of rain, they wuld foon put forth frefh fibres, and make new fhoots, when it would be too late to remove them: at the time when you take up the roots, is the proper feafon for breaking or parting them, which may be done by feparating thofe that you would choofe to make all poffible increafe from, into as many parts as you can conveniently, provided each one of them have a good eye or bud, but thofe, you intend to blow ftrong, fhould by no means be parted too fmall, which greatly weakens their flowering.

The principal colours in Anemonies are, white, red, blue, and purple; and thefe in fome of them, are curioufly intermixed; but the moft prevailing colour amongft our Englifh raifed Anemonies, are white and red; though of late we have received from France, great varieties of blues and purples, which are exceeding fine flowers, and being intermixed with the Englifh flowers, make a fine variety: we fhould therefore obferve, in planting the roots, to diftribute the different colours, ib as to make an agreeable mixture of each in every bed, which will greatly add to their beauty.

But fince all the fine varieties of thefe flowers were firft obtained from feeds, no good florift, that hath garden room, fhould neglect to fow them: in order to which, we fhould provide ourfelves with a quantity

of good fingle (or what the gardeners call Peppir Anemonies) of the beft colours, and fuch as have more leaves than common, and have other good properties; thefe fhould be planted early, that they may have ftrength to produce good feeds, which will be ripe in three weeks or a month's time, after the flowers are paff, when you muft carefully gather it, otherwife it will be blown away in a fhort time, it being inclofed in a downy fubftance. You muft preferve this feed till the beginning of Auguft, when you may either fow it in pots, tubs, or a well prepared bed or light earth: in the doing of it you muft be careful not to let your feeds be in heaps, to avoid which is a thing little underftood, and is what I have been informed of by the late Mr. Obadiah Lowe, gardener at Batterfea, who for feveral years raifed large quantities of thefe flowers from feeds. His manner was thus:

After having levelled his bed of earth, in which he intended to fow his feeds, he rubbed the feeds well between his hands, with a little dry fand, in order to make them feparate the better, then he fowed them as regularly as poffible over the bed; but as thefe feeds will ftill adhere clofely together by their down, he took a ftrong hair brufh, with which he gently fwept over the whole bed, obferving not to brufh off the feeds; this brufh will fo feparate the feeds, if carefully managed, as not to leave any entire lumps; then gently fife fome light earth, about a quarter of an inch thick over the feeds; and, if it fhould prove hot dry weather, it will be advifable to lay fome mats hollow upon the bed in the heat of the day, and now and then give them a little water; but this muft be given gently, left by haftily watering you wafh the feeds out of the ground; but be fure to uncover the bed at all times when there are gentle flowers, and every night, that the feeds may have the benefit of the dews; and as the heat of the weather decreafes, you may begin to uncover your bed in the day till alfo.

In about ten weeks after fowing the plants will begin to appear, if the feafon has proved favourable, or your care in management hath not been wanting, otherwife they many times remain a whole year in the ground. The firft winter after their appearing above ground, they are fubje& to injuries from hard frofts, or too much wet, againft both of which you muft equally defend them; for the froft is very apt to loofen the earth, fo that the young plants are often turned out of the ground, after which a fmall froft will deftroy them; and too much wet often rots their tender roots, fo that all your former trouble may be loft in a fhort time for want of care in this particular; nor do I know of any thing more deftructive to thefe tender plants, than the cold black frofts and winds of February and March, from which you muft be careful to defend them, by placing a low reed fence on the north and eaft fides of the bed, which may be moveable, and only fattened to a few ftakes to fupport it for the prefent, and may be taken quite away as the feafon advances, or removed to the fouth and weft fides of the bed, to fcreen it from the violence of the fun, which often impairs thefe plants when young.

As the fpring advances, if the weather fhould prove dry, you muft gently refrefh them with water, which will greatly ftrengthen your roots; and when the green leaves are decayed, if your roots are not too thick to remain in the fame bed another year; you muft clear off all the weeds and decayed leaves from the bed, and fife a little more of the fame prepared good earth, about a quarter of an inch thick over the furface, and obferve to keep them clear from weeds during the fummer feafon, and at Michaelmas repeat the fame earthing; but as thefe roots fo left in the ground, will comfup early in the autumn, the beds fhould be carefully covered in frofty weather, otherwife their leaves wuld be injured, whereby the roots will be weakened, if not deftroyed. If your roots fucceed well, many of them will flower the fecond year, when you may feed all fuch as you like, by marking them with a ftick * but you fhould not deftroy any of them

The firft fort is the tommon Chamomile, which grows in plenty upon commons and other walVe land. It is a trailing perennial plantj which puts out roots from the branches as they lie on the ground. Whereby it fpreads and multiplies greatly I fo that whoever I willing to Cultivate this plant, need only procure a sfunder, that they may lifvfroom to fprcad, and they wiK soon cover the ground. Formerly this plant was used for planting of walks, Vrllich, when mow'd and rolktl, looked wdl.for fome time, but as it was very fubjct: to decay in large patches, the walks became infinitely, f) which rtafon this was d'fuU-d. The flower! of this fort air ordered for nu'dicinal ufe, but the market people generally fell the ilouble Bowers, which arc much larger, but not fo lirong a< the fingle. The double fort is equally hsnly, and may be propagated in the fame manner.

The fecondfort is a common annual weed, which grows among corn -, it flowers in May, fo m called May Weed, though ibme have .ijpliitJ tint title improperly to tile Cotula ttcikla, which ririly ilowers lit! Lie in June.

The fourth, fifth, and eighth fort? are snnuit plants, whkfl prow namrally in Spain, Portugal, "uily, and the fourth of France, from whence their feed; have been brought to England, where the plants are preferred in botanic garlens for the fake of vancity. They !ilt fillily from foils lbwn in the fpr'ng, mid rrequir ni) Other culture but to thin the plants where they are to • doff, allowing them a foot and a half room L'idiw;iy.nncUleanthemfromthe weeds. They flower ill July, and their feeds ripen in September.

The fixth and feventh lbrts are perennial plants, which jro« n.uurilk* in Spain, Purtugal, and Greece, whence their fectis have been brought to Eng- b.rid, and the plants are preferred in fome curious gardens for the ; ikeof variety. They are hnrdy and may be propagated by fewls, which (ould be in the faring upon poor land, -where the plants will tue niueh longer than in good gruuul, and will t're but to keep dttni cl'im from »xtdi. Thefe)!;ii5 do not grow tall, bin .re bn fiuy, fo floukl fee nlloweti room to erow. Th.ir fiuwers arc white, and continue from July to October, and the fecsls ripen in autumn.

The ninth lore is the Pellitory of Spain, the toon of

which are used to: **tho** [: 'Ailil bellir WM) when they are applied (Pi the part aHL-; and, they show out the **uld ru-um,** and **arc otei** i; Uii* particular. This is 2 ptennial plsini.uidialonk r too like *Alai* a Carrot, which grows natuallym Spam atitPoriur.il, from whence die roots are brought ro Fnelsnd. The branches or this [nil upon the

The firft fort grows naturally at the Cape of Good Hope *, the roots of this are flefhy, and compofed of tubers joined at the crown like thole of the Afpodel -, the ftalk rifes near two feet high, and branches out on each fide, each branch being terminated by aloofe fpike of flowers, which are white, and the petals are turned backward to their foot-ftalk. The leaves of this fort are flat, and the root is perennial, but the fpikes decay in autumn.

The fecond fort hath a perennial root; the ftalks of this rife about the fame height as the former, fend- ing out many lateral branches in like manner, which are terminated by loofe fpikes of flowers, which are white, but the petals are plain, and do not turn back as in the other fort.

The third fort hath plain leaves and an unbranching ftalk, in which it chiefly differs from the former. The root of this is perennial.

The two next forts grow naturally in Spain, Portugal, and other warm countries, and were more common fome years ago in the Englifh gardens than at prefent; for the fevere winter in 1740, killed moft of their roots. Thefe flower in June and July, and their feeds are ripe in September. They are propagated by feeds, which fhould be fown in autumn *, for thofe which are fown in the fpring, never come up unt fame year, but remain in the ground till the following fpring, or often mifcarry. Thefe fhould be fown in a bed of light fandy earth, in a warm fituation, and when the plants come up, they muft be kept clean from weeds during the fummer *, and in autumn, when their leaves decay, they fhould be carefully taken up, and tranfplanted into a bed of light earth, at a foot diftance from each other. If the winter fhould prove fevere, the bed fhould be covered with ftraw, Peafe-haulm, or fuch light covering, to keep out the froft *, or if fome old tan from a hot-bed is fpread over the ground, it will prevent the froft from penetrating the ground, and will preferve the roots. In this bed they may remain one year, by wiich time they will be ftrong enough to flower *, therefore the following autumn they fhould be carefully taken up, fo as not to break their roots, and planted in the borders of the flower-garden, where they will laft feveral years, if they are not killed by froft *, to prevent which, fome rotten tan fhould be laid over the roots in winter, which will always fecure them.

The fourth fort has been long preferred in many gar-

dens near London, and was formerly known among the gardeners by the title of Onion-leaved Aloe. This plant produces many ligneous branches from the root, each fupporting a plant with long taper leaves, in fhape of thofe of the Onion, which are full of a yellow pulp very juicy. Thefe plants fend out roots, which run down and fallen themfelves into the earth, by which they multiply greatly. The flowers are produced on long loofe fpikes, are yellow, and appear at different times, fo that the plants are not long deftitute of flowers. Thefe are fucceeded by round fmoth feed-veffels, which have three cells, filled with triangular feeds j but as the plant multiplies fo faft by offsets, the feeds are little regarded. It grows naturally at the Cape of Good Hope, and requires a little fhelter in winter; but in fome mild feafons I have had plants live without any cover, which were planted clofe to a warm wall.

The fifth and fixth forts grow clofe to the ground, never rifing with any ftalk. The fifth hath broad, flat, pulpy leaves, refembling thofe of fome forts of Aloe, fo was formerly by gardeners called Aloe with flowers of Spiderwort. The leaves fpread open * the flowers are produced on loofe fpikes, like the former, but are fhorter: the flowers are yellow, and appear at different feafons. This is produced by offsets, which are put out in plenty, and muft be planted in pots filled with light fandy earth, and in winter placed in the green-houfe, and treated as other hardy fucculent plants, which come from the Cape of Good Hope, where this plant grows naturally. It muft be kept pretty dry in winter, and if it is fcreened from froft, it will require no artificial warmth.

The fixth fort hath long, narrow, pulpy leaves, which are almoft taper, but flatted on their upper fide; this fends out many offsets, by which it may be increafed plentifully. The flowers are yellow, and grow on long loofe fpikes, as the former-, thefe appear at different feafons *, thofe of the fpring and fummw are fucceeded by feeds in great plenty, fo may be eafily propagated thereby, which ripen very well. It muft be treated in the fame manner as the former.

The feventh fort is annual: this is a low plant growing clofe to the ground, having pretty long fucculent leaves which are taper, but flatted on their upper fide *, the flowers grow in loofe fpikes, which are fhorter than either of the other forts. They are yellow, and fucceeded by round feed-veffels, like thofe of the former forts *, the plants perifh foon after their feeds ripen. The feeds of this fort fhould be fown on a warm border of light earth in April, where they are to remain; and when the plants come up, they will require no other care but to keep them clean from weeds, and to thin them where they are too clofe. This fort flowers in July, and the feeds ripen in October.

The eighth fort never rifes to a ftalk, but the leaves come out clofe to the ground. Thefe are long, taper, fucculent, and of a fea-green colour, growing ereft; the flower-ftems rife between the leaves, and are near three feet long; the upper half being thinly garnifhed with yellow flowers, ihaped like thofe of the other fpecies. Thefe appear at different feafons, fo that the plants are feldom long deftitute of flowers. This fort doth not fend out offsets fo freely as fome of the others *, but as it produces feeds annually, it may be had in plenty. It muft be treated in the fame manner as the fourth, fifth, and fixth forts.

The ninth and tenth forts grow naturally on bogs in jnoft of the northern countries j the tenth is common in many parts of England, but particularly in Lancalhire, from whence it had the title of Lancashire Afpodel; it alfo grows on a bog upon Putney-heath. The other grows naturally in Denmark, Sweden, and Lapt^nd. Thefe are both low plants, having narrow leaves^ which grow clofe to the ground *, the flower-ftems life about fix inches high, being terminated by a loofe fpike of fmall yellow flowers. Thefe differ from each other, the ftamina of the tenth being woolly, whereas thofe of the other are fmoth. Thefe

plants, growing naturally upon bogs, are with difficulty preferred in gardens.

ANTHERS [from *ἄνθος* flowery,] are the fummits or little tops in the middle of a flower, supported by the stamina.

ANTHOLOGY [of *ἄνθος*, a flower, and *λόγος*, Gr. a word,] a discourse or treatise of flowers.

ANTHOLYZA. We have no English name for this plant.

The CHARACTERS are,

It hath an imbricated sheath growing alternate, which is permanent, the flower is of one leaf tubulous, and opens above with compressed jaws. The upper lip is slender long, erect, and waved the two jaws are short, and joined at their base, the under lip is trifid, short, and the middle segment turns downward, it hath three long slender stamina, two of which are under the upper lip, and the other lies in the under lip these are crowned by pointed fummits. Under the flower is situated the germen, supporting a slender style the length of the stamina, which is crowned by a slender, trifid, reflexed stigma. The germen afterward becomes a roundish three-cornered vessel having three cells, in which are lodged many triangular feeds.

This genus of plants is ranged in the first section of Linnaeus's third class, entitled Triandria Monogynia, the flowers having three stamina and one style.

The SPECIES are,

1. **ANTHOLYZA** (*Ringens*) corolla labiis divaricatis fauce compressa. Lin. Sp. Plant. 54. *Antholyza whose flower-lips spread asunder. Gladiolus floribus rictum referens coccineus suprema lacinia erecta & fistulosa.* Breyn. 21.
2. **ANTHOLYZA** (*Spicata*) foliis linearibus fulcatis floribus albis uno versus diffusis. Fig. Plant, pi. 40. *Antholyza with narrow furrowed leaves, and white flowers ranged on one side of the stalk.*

The first sort hath round, red, bulbous roots, from which arise several rough furrowed leaves, near a foot long, and half an inch broad; between these comes out the flower-stem immediately from the root, which rises two feet high, is hairy, and hath several flowers coming out on each side. These are of one leaf, cut into six unequal parts at the top: one of these segments is stretched out much beyond the other, standing erect; the margins are waved and closed together, wrapping up the three stamina. The flowers are red, and appear in June, and the feeds ripen in September.

The roots of the second sort are in shape and size like those of the Vernal Crocus, but the outer skin is thin and white; from this arise five or six long narrow leaves, which are deeply furrowed. Between these arise the flower-stem, which is a foot and a half high, bending on one side toward the top, where the flowers come out, ranged on one side, standing erect. These have each a sheath or sheath, of one leaf, divided into two, ending in points, which are permanent. The flower is of one leaf, having a long tube, but is divided into six unequal segments at the top, which spread open, their margins being waved and turned inward. The three stamina rise under the upper segment, which is larger than the others, and below is situated the trifid style, crowned with purple stigma. After the flower is past, the germen becomes a three-cornered feed-vessel, opening in three cells, which are filled with triangular feeds. The flowers of this sort are white, appear in May, and the feeds ripen in August.

These plants are natives of Africa, from whence their feeds have been obtained, and were first raised in the Dutch gardens, where one of the sorts has long been an ornament in the curious gardens of that country.

They are propagated by offsets, which the bulbous roots send forth in pretty great plenty; or by feeds, which are sometimes perfected in Europe. These feeds should be sown soon after they are ripe; for if they are kept out of the ground till the following spring, they often miscarry, or at least remain a year in the ground before they grow. If the feeds are sown in pots of light earth, and plunged into an old bed of

tan which has lost its heat, shaded in the middle of the day in hot weather, the feeds will come up the following winter) therefore they must be kept covered with glasses to screen them from cold, otherwise the young plants will be destroyed. These may remain in the pots two years, if the plants are not too close, by which time they will have strength enough to be planted each into a separate small pot filled with light earth: The time for transplanting of these roots is in July or August, when their leaves are decayed. In summer the pots may be placed in the open air, but in winter they must be removed, and placed under a hot-bed frame, for they are not very tender; but where any damp arises, it is very apt to occasion a mouldiness upon their leaves. The roots shoot up in autumn, and the flowers begin to appear in May; the feeds ripen in August, and soon after their leaves and stalks decay; when the roots may be taken up and kept six weeks or two months out of the ground, so may be easily transported from one country to another at that time. These flowers are ornamental when they appear, and they are plants which require but little culture, so deserve a place in every good garden.

ANTHOSPERMUM, Amber-tree, vulg6.

The CHARACTERS are,

It is male and female in different plants; the male flowers have no petals, but a coloured-empakment of one leaf, which is cut into four parts almost to the bottom. Out of the bottom arise four slender stamina, crowned with oblong fattare fummits, having a deep furrow through their middle. The female flowers have the same structure as the male but have no stamina; instead of which, there is an oval germen, situated in the bottom, supporting two recurved styles crowned with a slender stigma. The germen afterward becomes a roundish capsule having four cells, which contain several angular feeds.*

Dr. Linnæus has ranged this genus in his twentieth class of plants, but it properly belongs to his twenty-second, because the plants are male and female in different plants; whereas those of his twenty-third, have male, female, and hermaphrodite flowers on the same plant.

ANTHOSPEXMUM (*Mthiopicum*) foliis kevis. Hort. Cliff. 455. *Amber-tree with smooth leaves.*

This plant has been long known in the curious gardens, under the title of *Frutex Africanus*, *ambram spirans*, or *Amber-tree*.

It is preferred in most curious gardens which have collections of tender plants, and is easily propagated by planting cuttings during any of the summer months, in a border of light earth; which will take root in six weeks time, provided they are watered and shaded as the season may require: or if these cuttings are planted in pots, and plunged into a very moderate hot-bed, they will take root sooner, and there will be a greater certainty of their growing. Afterward they should be taken up, with a ball of earth to their roots, and planted into pots filled with light sandy earth, and may be exposed to the open air until October; at which time they should be removed into the conservatory, where they should be placed as free as possible from being over-hung with other plants; and, during the winter season, they must be refreshed with water, but should not have too much given them each time; and should have as much air admitted to them as the weather will permit, for if they are kept too close, they will be subject to grow mouldy, and generally decay soon after; so that if the green-house is damp, it will be difficult to preserve these plants through the winter.

The beauty of this shrub is in its small ever-green leaves, which grow as close as heath; which being bruised between the fingers, emit a very fragrant odour. These plants must be frequently renewed by cuttings, for the old plants are very subject to decay, seldom continuing above three or four years.

It is but of late years there have been any of the female plants in the gardens, for all those which were formerly in the gardens, were the male, which being

propagated by cuttings, had been continued, so that no feeds were ever perceived in England till within a few years past, when I received some feeds from the Cape of Good Hope, from which I raised many plants of both sexes, and a few among them with hermaphrodite flowers, which have produced feeds, from which many plants have been raised.

ANTHYLLIS. Lin. Gen. Plant. 773. Vulneraria. Tourn. Barba Jovis. Tourn. Ladies Finger, or Kidney Vetch.

The CHARACTERS are,

// bath a swelling, hairy permanent empalement of one leaf, which is divided at the top into five equal parts. The flower is of the butterfly kind, having a long standard reflexed on both sides beyond the empalement, the two wings are short, the keel is of the same length, and compressed. There are ten stamina which rise together, and are crowned by single summits. In the center is situated an oblong germen, supporting a single style, crowned by a blunt stigma: the germen afterward becomes a small roundish pod inclined by the empalement, having one or two feeds.

This genus is ranged in Linnaeus's seventeenth class of plants, entitled Diadelphia Decandria, the flowers having ten (lamina joined in two bodies).

The SPECIES are,

1. ANTHYLLIS (*Tetraphylla*) herbacea foliis quaternopinnatis floribus lateralibus. Hort. Upfal. 221. *Herbaceous Kidney Vetch with winged leaves, having four lobes, and flowers growing from the side of the stalks.* Vulneraria pentaphylos. Tourn. Inf.

 4. ANTHYLLIS (*Montana*) herbacea foliis pinnatis aequalibus capitulo terminali fecundo, floribus obliquatis. Lip. Sp. Plant. 719. *Herbaceous Woundwort with equal winged leaves, terminated by the head of flowers, which are oblique.* Astragalus purpureus. Dalechampii 1347. *Purple Milk Vetch.*
 5. ANTHYLLIS (*Cornicina*) herbacea foliis pinnatis inaequalibus capitulis foliatis. Lin. Sp. Plant. 719. *Herbaceous Woundwort, with unequal winged leaves, and a single head of flowers.*
 6. ANTHYLLIS (*Barba Jovis*) fruticosa foliis pinnatis xqualibus floribus capitatis. Hort. Cliff. 371. *Shrubby Woundwort, with leaves equally winged, and flowers collected in a head.* Barba Jovis pulchre lucens. J. B. 1. p. 385. *Jupiter's Beard, or Silver Bush.*
 7. ANTHYLLIS (*Cytifoides*) fruticosa foliis ternatis inaequalibus calycibus lanatis lateralibus. Lin. Sp. Plant. 720. *Shrubby Woundwort, with three unequal leaves, and a downy flower-cup growing from the sides.* Cytifus incanus folio medio longiore. C. B. P. 390.
 8. ANTHYLLIS (*Erinacea*) fruticosa spinosa foliis simplicibus. Lin. Sp. Plant. 720. *Shrubby prickly Woundwort, with single leaves.* Genista Spartium spinosum foliis lenticulae floribus ex caeruleo purpurascens. C. B. P. 394.
 9. ANTHYLLIS (*Hermamiix*) fruticosa, foliis ternatis fupennuculatis, calycibus nudis. Lin. Sp. Plant. 1014. *Shrubby Woundwort of Crete, with ternate leaves, and naked flower-cups.* Barba Jovis Cretica, linariae folio, flore luteo parvo. Tourn. Cor. 44.
 10. ANTHYLLIS (*Heterophylla*) fruticosa, foliis pinnatis, floralibus ternatis. Lin. Sp. Plant. 1013. *Shrubby Woundwort of Portugal, with winged leaves, but false near the flowers ternate.* Barba Jovis minor Lusitanica, flore minimo variegato. Tourn. Inf. 651.
- The first sort grows naturally in Spain, Italy, and Sicily. This is an annual plant, with trailing branches, which spread flat on the ground; the leaves grow by fours at each joint, and the flowers come out in du-

ters on the sides of the stalks, having large swelling empalements, out of which the extreme parts of the petals do but just appear, these are of a yellow colour, and are succeeded by short pods enclosed in the empalement. It flowers in June and July, and the feeds ripen in September. The feeds of this sort should be sown on a bed of light earth in April, where the plants are to remain, and will require no other care, but to thin them to the distance of two feet, and keep them clean from weeds.

The second sort grows naturally in Spain and Portugal, from both which countries I have received the feeds, it also grows wild in Wales, and the isle of Man. This is a biennial plant, having single leaves at bottom, which are oval and hairy* but those which grow out of the stalks are winged, each being composed of two or three pair of lobes terminated by an odd one: the flowers grow collected into heads at the top of the stalks, these are of a bright scarlet colour, to make a pretty appearance: it flowers in June and July, and the feeds ripen in October. When the plants of this sort grow on poor land, they will sometimes continue three years, but in gardens they seldom last longer than two.

The third sort grows naturally upon chalky grounds in many parts of England, so is rarely admitted into gardens. Dr. Linnaeus supposes this and the former to be the same, but from having cultivated these for many years, I can affirm they are different species, never altering from feed. The leaves of this sort are much narrower than those of the former, and have generally one or two pair of lobes more in each. The heads of flowers in this species are single, whereas the other has generally double heads; add to these, the root being perennial, which makes an essential difference between them.

The fourth sort is a perennial plant with trailing branches, garnished with winged leaves, which have an equal number of hairy lobes at the extremity of the branches; the flowers are produced in heads, these are of a purple colour, and globular form. This sort grows naturally on mountains in the south of France and Italy, from whence I have received the feeds. It is propagated by feeds, which may be sown either in the autumn or spring: those which are sown in the autumn, will rise the following spring, and more certainly grow, than those which are sown in the spring, which seldom grow; the same year. When the plants come up, they must be kept clean from weeds; and where they are too close together, they must be thinned. The following autumn, they should be transplanted to the places where they are to remain, and will require no particular management afterward. This sort flowers in June and July, and the feeds ripen in October.

The fifth sort approaches near to the third, but the leaves are hoary, and the flowers are produced on the side of the branches; these are yellow, and collected into small heads. It is an annual, or at most a biennial plant; for when it flowers early in the summer, it commonly decays soon after the feeds are ripe; whereas those plants which flower later in the season, and do not perfect feeds, will abide another year. This may be propagated by feeds, in the same manner as the former.

The sixth sort is the Barba Jovis, or Jupiter's Beard, by many called Silver Bush, from the whiteness of its leaves. This is a shrub which often grows ten or twelve feet high, and divides into many lateral branches, garnished with winged leaves, composed of an equal number of narrow lobes, which are very white and hairy; the flowers are produced at the extremity of the branches, collected into small heads; these are of a bright yellow colour, and appear in June, sometimes they are succeeded by short woolly pods, containing two or three kidney-shaped feeds; but unless the season proves warm, they do not ripen in this country. It is propagated either by feeds or cuttings; if by feeds, they should be sown in the autumn, in pots filled with light earth, and placed under

a frame in winter to protect them from frost. The following spring the plants will rise, and when they are strong enough to remove, they should be each planted in a small pot filled with light earth, and placed in the shade till they have taken new root; after which, they may be placed with other hardy exotic plants, in a sheltered situation, where they may remain till October, when they must be removed into shelter. These plants are always housed in winter, yet I have had some of them live abroad three or four years, which were planted against a fourth-wall. It may also be propagated by cuttings, which may be planted during any of the summer months, observing to water and shade them until they have taken root. When the cuttings have taken good root, they should be planted in pots, and treated in the same manner as the former.

The seventh sort is a low shrub, seldom rising above two feet high, but sends out many slender branches, garnished with hoary leaves, which are sometimes single, but generally have three oval lobes, the middle being longer than the other two; the flowers are yellow, and come out from the side of the branches, three or four joined together, having woolly empalements, but these are rarely succeeded by seeds in England. It may be propagated by cuttings or seeds, in the same manner as the former sort, and treated as hath been directed for that. This has been an old inhabitant in the English gardens.

The eighth sort grows naturally in Spain and Portugal, from whence I have received the seeds. This is a shrub which grows nine or ten feet high, having the appearance of one sort of Gorse or Whin, but it hath round leaves growing single. It will live in the open air in mild winters, but hard frost will destroy it. It is propagated by seeds only.

The ninth sort grows naturally in Crete, and also in Palestine; this was formerly in some of the English gardens, but the severe winter of 17th destroyed most (if not all the plants) in this country, since which time I have not seen it. This shrub grows five or six feet high, the branches are garnished with oblong ternate leaves; the flowers, which are yellow, are produced in small clusters on the side of the branches; these appear in July and August, but are not succeeded by seeds in this country.

This is propagated by cuttings, which should be planted the beginning of June, and if they are closely covered with a bell-glass, and properly shaded, they will put out roots by the end of August, when they should be carefully taken up, and each planted in a small pot, filled with light earth, and placed in the shade until they have taken new root; when they may be placed in the open air till October, and then should be removed into shelter, and treated in the same way as other hardy green-house plants.

The tenth sort grows naturally in Portugal and Spain: this is a very low shrubby plant, whose branches spread near the ground, garnished with silvery winged leaves, which are acute-pointed; the flowers are produced toward the extremity of the branches; these are not succeeded by seeds in England, but the plant is propagated by cuttings in the same manner as the former, and the plants require the same treatment.

ANTIRRHINUM [which in composition sometimes indicates a likeness, Antirrhinum, of *ant* and *rhin*, the nostrils, because it represents a nose:] Snap-dragon, or Calves-foot.

The CHARACTERS are,

The empalements of one leaf, cut into five parts the two upper segments being longer than the lower. The flower is ringent, having an oblong tube, divided at the top into two tips, which are closed at the jaw. The upper lip is cut into two, and reflexed on each side; the under lip is divided into three obtuse parts: in the bottom situated an obtuse nectarium, which is not prominent. There are four stamens which are included in the upper tube, two being longer, and two shorter, crowned by short summits. In the center is placed a roundish germen, supporting a single style, crowned with an obtuse stigma. The germen after-*

ward becomes a round obtuse style, having two cells which are full of small angular seeds.*

This genus is ranged in Linnæus's fourteenth class of plants, entitled *Didynamia Angiosperma*, the flower having two long and two short stamens, and many seeds included in a capsule. To this genus Linnæus has joined the *Linaria* and *Afarina*; but as the flowers of the *Linaria* have spurs to their petals, and the nectarium being very prominent, which are not so in this genus, it should be separated from it.

The SPECIES are,

1. **ANTIRRHINUM** (*Minus*) foliis lanceolatis obtusis alternis caule ramosissimo diffuso. Hort. Cliff. 324. *Snap-dragon with obtuse spear-shaped leaves growing alternate, and a diffused branching stalk. Antirrhinum arvense minus.* C. B. P. 212.
2. **ANTIRRHINUM** (*Orontium*) floribus subpicatis, calycibus digitatis corolla longioribus. Hort. Upfal. 176. *Snap-dragon with spiked flowers, and fingered empalement longer than the flower. Antirrhinum arvense majus.* C. B. P. 212.
3. **ANTIRRHINUM** (*Majus*) foliis lanceolatis petiolatis calycibus brevissimis racemo terminali. Vir. Cliff. 61. *Snap-dragon with spear-shaped leaves having foot-stalks, and very short flower-cups, terminated by a spike of flowers. Antirrhinum majus alterum folio longiore.* C. B. P. 211.
4. **ANTIRRHINUM** (*Latifolium*) foliis lanceolatis glabris, calycibus hirsutis racemo longissimo. *Snap-dragon with smooth spear-shaped leaves, hairy flower-cups, and a very long spike of flowers. Antirrhinum latifolium amplum pallidum flore.* Bocc. Muf. 2. 49.
5. **ANTIRRHINUM** (*Italicum*) foliis linearilanceolatis hirsutis racemo brevioribus. *Snap-dragon with narrow hairy, spear-shaped leaves, and a shorter spike of flowers. Antirrhinum longifolium majus Italicum flore amplo niveo laefcente.* H. R. Par.
6. **ANTIRRHINUM** (*Siculum*) foliis linearibus floribus petiolatis axillaribus. *Snap-dragon with narrow leaves and flowers, with foot-stalks proceeding from the wings of the leaves. Antirrhinum ficulum linariae folio niveo flore.* Bocc. Muf.

The two first sorts grow naturally on arable land in many parts of England, so are seldom admitted into gardens, these are both annual plants, which come up from scattered seeds. They flower in June and July, and their seeds are ripe in September.

The third sort is not a native of England, but having been first brought into gardens, the seeds have scattered about in so great plenty, that it is become very common upon walls and old buildings in many parts of England. Of this sort there are several varieties, which differ in the colour of their flowers, some having red lowers with white mouths, some with yellow mouths, others have white flowers, with yellow and white mouths. There is also one with striped leaves. The last is propagated by slips and cuttings, which readily take root any time in the spring or summer. The different colours of the flowers are variable from seeds.

The fourth sort grows naturally in the islands of the Archipelago, from whence I received the seeds. The leaves of this are much broader, the flowers greatly larger, and the spikes longer, than in any of the other sorts. The colours of the flowers are as changeable in this sort as the former, when raised from seeds; but as this is the most precious kind, so it better deserves propagating than the common, especially as it is equally hardy.

The fifth sort has long narrow leaves, which are hairy; the flowers are large, and the spike is shorter than the former; there are some varieties in the colour of the flowers of this sort, but it is equally hardy with the common sort. *

The sixth sort is an annual plant, which seldom grows more than a foot high; the leaves of this are very narrow and smooth, the flowers come out from the wings of the leaves single, hanging on long foot-stalks; these are very white, with a dark bottom. If the seeds of this sort are permitted to scatter, the plants

plants will come up, require no other care but to thin them and keep them clean from weeds.

The third, fourth, and fifth sorts are raised from feeds, which should be sown in a dry soil, which is not too rich, either in April or May, and in July the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, for flowering the same autumn, but then they are not so likely to endure the winter; and if the autumn prove bad, they will not perfect their feeds.

These plants grow extremely well upon old walls or buildings, in which places they will endure for several years; whereas those planted in gardens seldom last longer than two years, unless they are planted in a very poor soil, and the flowers often cropped, and not fullered to feed, but any of these sorts may be continued, by planting cuttings in any of the summer months, which will easily take root.

All the sorts of Snap-dragons are pretty ornaments in a garden, and requiring very little culture, are rendered more acceptable. They are all hardy plants, and will resist the cold of our winters extremely well, especially if they are planted on a dry, gravelly, or sandy soil, for when they are planted in a rich moist soil, they will grow very luxuriant for a time, but are very subject to rot in autumn or winter; and are much more susceptible of cold, than when they are in a dry, hungry, rocky soil; so that these plants may be placed amongst stones, or they will grow in the joints of old walls, where they may be placed so as to render some adjacent part of a garden very agreeable, for they will continue in flower several months, and if the feeds are permitted to stand, there will be a continual supply of young plants, without any trouble.

Wherever these plants are designed to grow on walls, or on a rocky barren soil, the feeds should be sown the beginning of March, where they are designed to remain, (for if the plants are first raised in a better soil, and afterward transplanted into those places, they seldom succeed well.) When the plants are come up, they will require no other culture but to keep them clear from weeds, and where they come up too thick, to pull some of them out, so as to give them room to grow. In July these sorts will begin to flower, and will continue flowering till the frost prevents them. Those plants which grow on walls, will have strong woody stems, which will continue two or three years or more, and are rarely hurt by frost.

A P A R I N E [this plant is so called, because it is very rough; it is called Philanthron, of $\phi\alpha\epsilon\kappa$, to love, and $M\gamma\alpha\sigma$, man; because if a person walks in uncultivated places, the plant not only applies itself to his garments, but it holds them, as if it had a mind to bind man with an amicable band:] Goose-grass or Clivers.

The common sort grows wild almost every where, the feeds sticking to the cloaths of people that pass by where they grow: it is sometimes used in medicine, but it is too common a weed to be admitted into a garden.

There are some other sorts of this plant which are kept in botanic gardens for the sake of variety, which I shall beg leave to enumerate here.

1. **APARINE** femine laevi. Tourn. *Goose-grass with a smooth feed.* [This is under Gallium in Linnaeus.]
2. **APARINE** femine coriandri faccharati. Park. *Theat. Goose-grass with sweet feeds like Coriander.*
3. **APARINK** pumila pupina, flore caeruleo. Tourn. *Low trailing Goose-grass, with a blue flower.* The two last are included in Linnaeus's genus of *Vailantia*.

All these plants, if they are permitted to scatter their feeds, will maintain themselves in a garden without any other culture, than that of preventing other weeds from over-growing them, these being all very low plants.

The first sort grows wild in Cambridgeshire, as doth the third about Liphoeck in Hampshire, where I have gathered it.

A P E T A L O U S plants, [of $\pi\alpha\tau\epsilon\iota\sigma$ privative, and $\alpha\pi\epsilon\tau\alpha\lambda\omicron\upsilon\sigma$ a flower-leaf, *Gr.*-] are such as have no petals or flower-leaves.

A P H A C A. See **LATHVRUS**.

A P I C E S [of *Apex*, *Lat.* atop or point] these are called fummits by Vaillant, and are those little knobs that grow on the top of the stamina in the middle of the flower: which are generally supposed to be a kind of male sperm, which when ripe, diffuses itself to every part of the flower, and fecundates the ovarium and renders it fruitful.

A P I O S. See **GLYCINE**.

A P I U M [*Apium* is so called, as some say, of *Apes*, bees, because bees are said to be delighted very much with it,] Parsley.

The **CHARACTERS** are,

It is a plant with an umbelliferous flower; the rays of the great umbel are few, but those of the smaller are many; the involucrum is in some species of one leaf, and in others of many, the petals of the greater umbel are uniform, these are round, equal, and turn inward. Each flower has five stamina, crowned by roundish fummits. Under the flower is situated the germen, supporting two reflexed styles, crowned by blunt stigma; the germen afterward becomes an oval channelled fruit, dividing into two parts, having two oval feeds channelled on one side, and plain on the other.

This genus of plants is ranged in the second section of Linnaeus's fifth class, entitled *Pentandria Digynia*, the flowers having five stamina and two styles.

The **SPECIES** are,

1. **APIUM** (*Petroelinum*) foliis caulinis linearibus involucrellis minutis. Hort. Cliff. 108. *Parsley with very narrow leaves on the flower-stalks. Apium hortense vel petroelinum vulg.* C. B. P. *Common Parsley.*
2. **APIUM** (*Crippum*) foliis radicalibus amplioribus crispis caulinis ovato-multifidis. *Parsley with the lower leaves very broad and curled, the upper oval, and cut into many segments. Apium vel petroelinum crispum.* C. B. P. 153. *Curled Parsley.*
3. **APIUM** (*Latifolium*) foliis radicalibus trifidis, ferratis, petiolis longissimis. *Parsley with under leaves divided into three parts, which are sawed, and have very long foot-stalks. Apium hortense latifolium maxima craiffima fuavi & eduli radice. Bferh. Ind. alt. "The large rooted Parsley.*
4. **APIUM** (*Graveolens*) foliis caulinis cuneiformibus. Hort. Cliff. 107. *Parsley with the lower leaves fashioned like a wedge. Apium palustre five apium officinarum.* C. B. P. 154. *Smallage.*
5. **APIUM** (*Dulce*) foliis erectis, petiolis longissimis foliis quinque lobatis ferratis. *Parsley with upright leaves, having very long foot-stalks, and the smaller leaves composed of five sawed lobes. Apium dulce ceteri Italorum. Inf. R. H. 305. Upright Celery.*
6. **APIUM** (*Rapaceum*) foliis patulis, petiolis brevibus, foliolis quinque ferratis, radice rotundo. *Parsley with spreading leaves, having short foot-stalks, the smaller leaves having five lobes, and a refund root. Apium dulce degener, radice rapacea. Just. Celeriack, or Turnep-rooted Celery.*
7. **APIUM** (*Lufitanicum*) foliis radicalibus tribolatis, caulinis quinque-lobatis crenatis. *Parsley with under leaves having three lobes, and those on the stalks five, which are indented. Apium Lusitanicum maximum, folio trilobato flore luteolo. Boerh. Ind. alt.*

The first sort is the common Parsley, which is generally cultivated for culinary use, and is what the College of Physicians have directed to be used in medicine, under the title of *Petroelinum*; for when *Apium* is prescribed, the *Smallage* is always intended.

The second sort has generally been supposed to be only a variety of the first, but from many years trial I have always found, that if the feeds are carefully sowed from plants of the curled-leaved Parsley, it will constantly produce the faggie; but there are few persons who will be at the trouble to save the feeds so carefully, as not to have some of the common sort mixed with it for when feeds are bought at the

(hops,

{hops, there is generally a mixture of both: therefore the only method to have it good, is to separate all those plants which have plain leaves from the curled, as soon as they are distinguishable, leaving only such as are of the right kind; if this is duly observed, the feeds will constantly produce the same.

The third sort is chiefly cultivated for their roots, which are now pretty commonly sold in the London markets; the leaves of this sort have much longer foot-stalks, and their subdivisions are not so numerous as in the common Parsley; the lobes of the leaves are much larger, and of a darker green, so that it is easily distinguished from the common sort by its leaves, but the roots are six times as large as the common Parsley can be brought to with the utmost culture. I have sown the feeds of both sorts for several years on the same (pot of ground, and have thinned the plants when young, to an equal distance, and given the same culture to both; but when their roots were taken up, those of the common sort were not larger than a man's little finger, but the other were as large as full grown Carrots, which were very tender and sweet, whereas the other were stringy and strong, and this difference constantly holds, so it may be allowed to be specifically different. This sort was many years cultivated in Holland, before the English gardeners could be prevailed on to sow it. I brought the feeds of it from thence in 1727, and would then have persuaded some of the kitchen-gardeners to make trial of it, but they refused to accept of it, so that I cultivated it several years before it was known in the markets.

The fourth sort is commonly known by the title of Smallage. This is what the physicians intend when they prescribe Apium* Dr. Linnaeus has joined to this the Celery, supposing them to be the same, and the only difference to arise from culture, but herein he is greatly mistaken; for I have cultivated the Smallage in gardens forty years, to try if by art it could possibly be brought to the same goodness as Celery, but have not been able to alter it from its original; all that can be done by culture, is to bring it to a larger size than it naturally grows wild, and by earthing it, to give it a whiteness; but it will not grow tall as Celery, nor will it rise with a straight stem, but sends out many suckers near the root, and when it is blanched, retains its strong rank taste, which no culture can alter, therefore I make no doubt of its being a distinct species.

The fifth sort is the Celery before-mentioned, and the sixth sort was supposed to be a degenerate species from it, but I cannot agree to this opinion, for from many years trial I have never found it vary. The leaves of this sort are short, when compared with those of the other, and spread open horizontally; the roots grow as large as the common Turneps. The difference which I have observed to arise from the culture, has been only in the size of the roots, those on rich ground, which were properly cultivated were much larger than those on poorer land, but the leaves and outward appearance of the plants were never altered, so that I make no doubt of its being a different species.

The feeds of the seventh sort I received from the royal garden at Paris, many years since, where it had been long preserved, and maintained its difference, and from more than twenty years cultivating it in the garden at Chelsea, I have found the same, so that I cannot doubt of its being different from all the other species.

The broad-leaved Garden Parsley, mentioned by Casper Bauhin, and the round-leaved Portugal Parsley, mentioned by Tournefort, I believe are only varieties of the common Parsley; for if they are distinct species, all the feeds which I have received from different parts of Europe, under those titles, have been wrong, for the plants which have risen from those feeds, have always proved to be the common sort. As Tournefort, and many other botanists, have enumerated all the varieties of plants which were found

in the gardens, and did not distinguish which of them were specifically different, so Dr. Linnaeus has gone into the other extreme, and supposed many plants, which are permanently different, to be only accidental varieties, arising from culture. But as he is now cultivating as many plants as the inclemency of the climate where he is situated, will permit, there is no doubt of his reforming his error, in this particular, when he finds what plants retain their specific difference.

The common Parsley must be sown early in the spring, for the feeds remain a long time in the earth, the plants seldom appearing in less than six weeks after the feeds are sown. This sort is generally sown in drills by the edges of borders in the kitchen-gardens near London, because it is much easier to keep it clear from weeds, than if the feeds are sown promiscuously on a border, and the Parsley is much sooner cut for use: but when the roots are desired for medicinal use, then the feeds must be sown thin, and when the plants are come up, they should be hoed out single, as is practised for Carrots, Onions, &c. observing also to cut up the weeds: if this be observed, the roots will become fit for use by July or August, and continue so till spring.

There are some persons who are afraid to use Parsley in their kitchens, lest they should suffer by having the lesser Hemlock mixed with it, whose leaves are so like Parsley, that persons who are not (killed in botany, may be easily deceived, which being a noxious plant, several persons have been injured by eating it: but to prevent this, I have for many years cultivated the sort with curled leaves, which is so unlike the Hemlock, that no person, however ignorant, can mistake one for the other, and have constantly advised those of my acquaintance to do the same. The curled sort is equally good as the common Parsley, and I have constantly found the feeds, sown from the curled sort, to produce the same.

The common Parsley is, by some skilful persons, cultivated in fields for the use of sheep, it being a sovereign remedy to preserve them from the rot, provided they are fed twice a week for two or three hours each time with this herb, but hares and rabbits are so fond of it, that they will come from a great distance to feed upon it; and in countries where these animals abound, they will destroy it, if it is not very securely fenced against them, so that whoever has a mind to have plenty of hares in their fields, by cultivating Parsley, will draw all the hares of the country to them, and this will preserve them found.

The best time for sowing it in the fields is about the middle or latter end of February; the ground should be made fine, and the feeds sown pretty thick, in drills drawn at about a foot asunder, that the ground may be kept hoed between the drills, to destroy the weeds, which, if permitted to grow, will soon overrun the Parsley. One bushel of feed will sow an acre of land.

The great Garden Parsley is now more known to us in England than it was some years past. In Holland it has been long common in all their markets: they bring these roots in bunches, as we do young Carrots to market in summer; and the roots are much of the same size: it is called Petrofeline Wortle by the Dutch, who are very fond of it for water souce.

It may be cultivated by sowing the feeds in good ground early in the spring; and in April, when the plants are up, cut them out with a hoe (as is practised for young Carrots) to about five or six inches square, and keep them constantly clean from weeds; and in July the roots will be fit to draw for use, and may be boiled and eaten as young Carrots, and are very palatable and wholesome, especially for those who are troubled with the gravel.

But if these plants are cut out, to allow them more room, if the soil is good, the roots will grow to the size of a middling Parsnep, by September.

Smallage is a common weed by the side of ditches and brooks of water, in many parts of England, so

fo that it is feldon Mptivated in gardens; but if any perfon is willing to propagate it, the feeds fhould be fown foon after they are ripe, on a moift fpot of ground *, and when the plants come up, they may be either tranfplanted in a moift foil, or hoed out, and left fix or eight inches afunder, where they may remain for good. The feed of this plant is one of the leffer warm feeds *, both the herb, and feeds are ufed in medicine.

The feeds of the two forts of Celery fhould be fown at two or three different times, the better to continue it for ufe through the whole feafon, without running up to feed. The firft fowing fhould be in the beginning of March, upon a gentle hot-bed; the fecond may be a fortnight or three weeks after, which ought to be in an open fpot of light earth, where it may enjoy the benefit of the fun *, the third time of fowing fhould be the end of April, or beginning of May, which ought to be in a moift foil; and if expofed to the morning fun only, it will be fo much the better, but it fhould not be under the drip of trees.

The feeds which are fown in the hot-bed will come up in about three weeks or a month after-fowing, when the plants fhould be carefully cleared from weeds; and if the feafon prove dry, they muft be frequently watered; and in about a month or five weeks after it is up, the plants will be fit to tranfplant: you muft therefore prepare fome beds of moift rich earth, in a warm fituation, in which you fhould prick thefe young plants, at about three inches fquare, that they may grow ftrong; and if the feafon fhould prove cold, the beds muft be covered with mats, to fcreen the plants from morning frofts, which would retard their growth: you muft alfo obferve, in drawing thefe plants out of the feed-beds, to thin them where they grow too thick, leaving the fmall plants to get more ftrength before they are tranfplanted *, by which means one and the fame feed-bed will afford three different plantings, which will accordingly fucceed each other for ufe.

You muft obferve, if the feafon proves dry, to keep it diligently watered after it is tranfplanted, as alfo to clear the feed-beds from weeds j and after every drawing, keep them duly watered, to encourage the fmall plants left therein.

The middle of May fome of the plants of the firft fowing will be fit to tranfplant for blanching, which fhould be planted in a moift, rich, light foil, upon which the firft planted Celery will often grow to be twenty inches long in the clean blanched parts, which upon a poor or dry foil feldom rifes to be ten inches.

The manner of tranfplanting it is as follows: after having cleared the ground of weeds, you muft dig a trench by a line about ten inches wide, and fix or feven inches deep, loofening the earth in the bottom, and laying it level; the earth that comes out of the trench fhould be equally laid on each fide the trench, to be ready to draw in again to earth the Celery as it advances in height. Thefe trenches fhould be made at three feet diftance from each other; then plant the plants in the middle of the trench, at about four or five inches diftance, in one ftrait row, having before trimmed the plants, and cut off the tops of the long leaves; when they are planted you muft obferve to clofe the earth well to their roots, and to water them plentifully until they have taken frefh root; after which time it will be needlcfs, except in dry foils, or very dry feafons: as thefe plants advance in height, you muft obferve to draw the earth on each fide clofe to them, being careful not to bury their hearts, nor ever to do it but in dry weather, otherwife the plants will rot.

When the plants have advanced a confiderable height above the trenches, and all the earth, which was laid on the fides thereof, hath been employed in earthing them up; you muft then make ufe of a fpade to dig up the earth between the trenches, which muft alfo be made ufe of for the fame purpofe, continuing from time to time to earth it up, until it is fit for ufe.

The firft trf your planting out will, perhaps, be fit for ufe by the beginning of July, and will be fucceed- ed by the after plantations *, and if the latter fowings

are rightly managed, there will be a fucceffion of Celery for ufe till April 5 but you fhould obferve to plant the laft crop in a drier foil, to prevent its being rotted with too much wet in winter; and alfo if the weather fhould prove extreme fharp, you will do well to cover your ridges of Celery with fome Peafe-haulm, or fome fuch light covering, which will admit the air to the plants; for if they are covered too clofe, they will be very fubjeft to rot 5 by this means you may preferve your Celery in feafon a long time, but you muft remember to take off the covering whenever the weather will permit, otherwife it will be apt to caufe the Celery to rot; By this method of covering the Celery, the froft will be kept out of the ground *, fo it may be always taken up for ufe when it is wanted, which, if neglected, it cannot be taken up in hard froft. The Celery, when fulljr blanched, will not continue good above three weeks or a month before it will rot or pipe: therefore, in ordfr to continue it good, you fhould have at leaft fix or feven different feafons of planting-> fo that if it be only intended to fupply a family, there need not be much planted at each time, but this muft be proportioned according to the quantity required.

The other fort of Celery, which is commonly called Celeriac, is to be managed in the fame manner as is dire&ed for the Italian Celery, excepting that this fhould be planted upon the level ground, or in very fhallow drills, for this plant feldom grows above eight or ten inches high, fo requires but little earthing up; the great excellency of this being in the fize of the root, which is often as large as ordinary Turneps. I fhould be fown about the middle of March, upon a rich border of earth, and, in diy weather, conftantly watered, otherwife the feeds will not grow: when the plants are large enough to tranfplant out, they fhould be placed eighteen inches afunder, row from row, and the plants fix or eight inches diftant in the rows *, the ground muft be carefully kept clean from weeds, but this fort will require but one earthing up, which fhould not be performed until the roots are nearly groF/i. both thefe forts of Celery delight in a rich, iight, moift foil, where they will grow to a much larger fize, and will be fweeter and tenderer than on a poor or dry ground.

The beft method to fave this feed, is to make choice of fome long good roots of the upright Celery, which have not been too much blanched, and plant them out at about a foot afunder in a moift foil, early in the fpring *, and when they run up to feed, keep them fupported with ftakes, to prevent their being broken down by the winds: and in July, when the feed begins to be formed, if the feafon fhould prove very dry, it will be proper to give fome water to the plants, which will greatly help their producing good feeds. In Auguft thefe feeds will be ripe, at which time it fhould be cut up, in a dry time, and fpread upon cloths in the fun to dry; then beat out the feeds, and preferve them diy in bags for ufe.

This fort will live in < • **can air,** pnvidoJ it is phuited in a warm litiuation inti 1 dry soil : for although the soil in which it grows vs with near Voice, B DUMt, yec in thi5 country ttw **ma** will rot in **vuxm**, when they are in a wet ground. The befrirrie to remove sul pLin: the roots is in j*prtiig, just before they begin to push out new stalks.

The iurth luct grows namriily in Jamaica, in the Savanna inaj, from whnce it hnd the title of Savanna Flower, by which it is chiefly known in diat island. This sort rises three or four not high, **having** < woody ltilks, which fend out 1 t'w IIUT.II briches, garnished with oval smooth leaves, placed by pairs opposite, of a shining ; **green col** or on 1 her upper side, but [alk and veart underneath; the flowers are produced* d titim iht A- of the branches, upon long root-stalks 1 ticru arc commonly i>u0r 01 five buds at the end - 1 cacia, but therc ii LL-1 Jotn more than o.ie of them which eonici to Boicyr, the orhi-r withering soon. The flower is very larjiti hiving a loiff; (ubc, which ii fpreaJs open wide at the top, 01 a brigi; w-l-low, fo make a fine appearance, especially inWif places irtiere tit- pknu trow natura%, being most part of thi- year in flower. I'hi plain is tou tender to thrive in EnjajanH without rhe affluence of aftovf- It is prop j; used by the da, which must be procured from |tm;uca, fur the plants do not perfect them in England, nor ire many of the seeds which are brought from thence good, either for their being unskillfully gathered before they are ripe, or being put up **mam,** for few of them have succeeded. Whn tfci^ediare obtained, they ihoukl be sown in poti fillcJ with light Janly earth, and plunged into a bog-bed of r • **mers** l>rk. If the feeds are g(nxl, the plants will appear in a month or five weeks after, when they ihou d be traiced in the ijmcnuniicr as other tenda plant from the fame country, with this difieti see only, to be (paring in e. use use them, for these plants, which abound with a milky juice, keep lite wry little wet. They must be constantly kirji in ilic tin-bed in the ftovc, and as they ailvai: in height, they will require torger yots, but tiiL-re must be great care not K>OVCT-pM them; for unless their roots are constant, the plants will not tiirve. The second year the plants

plants Will flower, if they have been skilfully managed, when they will make a fine appearance in die ltove ; the usual time of their flowering in England, is in July and August, but the plants retain their leaves through the year* which, being of a beautiful green, look very well at all seasons.

The fifth fort was discovered by father Plumier, in fote of the French. i(lands in America, who made a drawing of the plant. It was afterwards found by the late Mr. Robert Millar, furgeon, growing plentifully near Carthagena, in New Spain, from whence he fent the feeds, which fucceeded in feveral gardens. This plant hath twining ftalks, by which it mounts to the tops of very tall trees, garniſhed with ftiff, oblong, heart-fhaped leaves, which are fmoother, and of a (hining green colour, being of the fame thicknefs with thofe of the Citron-tree. The flowers are produced in fmall cluſters from the fides of the branches, and are of an herbaceous colour, fo do not make any great appearance. Theſe appear in Auguſt and September, but are not fucceeded by pods in this country.

The fixth fort grows naturally in India, Ceylon, and upon the coaſts of Guinea, from whence I have received the feeds. This plant rife with a woody ſtem to the height of five or fix feet, dividing into feveral branches, garniſhed with oblong, pointed, fmoother leaves, of a fhining green above, but pale underneath, placed by pairs oppofite. From the wings of the leaves the flowers are produced in looſe bunches. Theſe are fmall, tubulous, and of a purple colour, but are never fucceeded by pods in this country. It is a very tender plant, fo muſt be conſtantly kept in a hot-houſe, and plunged in the tan-bed, otherwife it will not thrive in England *, it may be propagated by cuttings during the fummer months, but they ſhould be laid to dry in the ftove, three or four days before they are planted; for as the plants abound with a milky juice, fo unleſs the ends of the cuttings where the wounds are made, are well dried and healed over before they are put into the ground, they are very fubjeſt to rot. This plant muſt be fparingly watered, eſpecially in winter, and ſhould be planted in light fandy earth.

The feventh fort grows naturally in India; I received feeds of this from Dr. Van Royen, profefſor of botany at Leyden. This plant hath a twining ftalk, by which it rife to a confiderable height, garniſhed with oblong leaves, which are much veined, and abound with a milky juice, which flows out whenever they are broken. This plant hath not yet produced flowers in England. It is tender, fo requires to be conſtantly preferred in the ftove, otherwife it will not thrive in this country.

The eighth fort grows naturally in Jamaica, from whence the feeds were ſent me by the late Dr. William Houfton. It hath a climbing ftalk, which fattens to the neighbouring trees, and rife ten or twelve feet high. The leaves are oval, ftiff, and oblique to the nbot-ftalk; the flowers are produced from the wings of the leaves, of a purplifh colour, and have very long tubes, but fpread open wide at the top. This doth not produce feeds in England, nor have I been able to propagate it, either by layers or cuttings. It is tender, 16 muſt conſtantly remain in the ftove, and ſhould have little water.

The ninth fort hath a climbing woody ftalk, and rife to a confiderable height, by the fupport of neighbouring trees. The leaves grow by pairs oppofite; they are oval, ending in a iharp point, and have many tranſverſe nerves from the midrib. The flowers come out from the wings of the leaves, each (landing upon a feperate long foot-ftalk; they are large, of a bright yellow colour, with very long tubes, fpreading open wide at the top -, theſe are fucceeded by long compressed pods, which have borders on one fide filled with long channelled feeds, which are crowned with long plumes of foft down. This fort grows naturally at Carthagena, in New Spain, from whence I received the feeds. It is tender, fo will not thrive in England, unleſs it is conſtantly preferred in the ftove. This is

propagated by feeds, which muſt be procured from the country where it grows naturally, for the feeds* do not ripen in this country. When the feeds *re procured, they muſt be fown in pots, and plunged into a hot-bed *, and when the plants come up, they ihould be treated in the fame manner as hath been before directed for the fourth fort. It flowers in Auguſt and September in England, but in its natural country it flowers great part of the year.

The tenth and eleventh forts were difcovered at La Vera Cruz, in New Spain, by the late Dr. William Houfton, who ſent their feeds to England. Theſe plants have both climbing ftalks, by which they mount to the tops of the tailed trees. In England they have climbed over the plants in the ftoves, and rife to upward of twenty feet high. The tenth fort has produced flowers, in England feveral times, but the eleventh, which grows more luxuriantly than the other, never had any appearance of flowers. Theſe are both propagated by feeds, which ſhould be fown as the fourth fort, and the plants muſt be treated in the fame manner afterward. All theſe ſpecies of Dogbane abound with a milky juice, which floors out from any part of their ftalks or leaves when they are broken *, and this is generally fupposed to be hurtful, if taken inwardly, for it doth not raife blifters on the ſkin, as the juice of Spurge, and other acrid plants, fo is not injurious unleſs inwardly taken. The pods of all the forts are filled with feeds, which are, for the moſt part, compressed, and lie over each other (*imbricatim*) like tiles on a houſe: theſe have each a long plume, of a cottony down fattened to their crowns, by which, when the pods are ripe and open, the feeds are waſted by the wind to a confiderable diftance; fo that in the countries where theſe plants naturally grow, they are fome of the moſt troubleſome weeds.

The down of theſe plants is in great eſteem in France, for fluffing of eaſy chairs, making very light quilks, which are warm, and extremely light, fo are very proper covering for perfons afflicted with the gout, frthe down is fo extreme light and elaſtic that it occasions no weight. This the French call Delawad, and in the fouthern parts of France, where fome of the forts will thrive in the open air, and perfect their feeds, there are many plantations made of theſe plants for the fake of the down.

As many of theſe forts grow plentifully in the uncultivated lands in Jamaica, this cottony down might be eaſily procured from thence in plenty, and might probably become a vendible commodity in England, which may turn to advantage, if once it becomes a faſhionable fort of furniture, eſpecially as the plants require no cultivation, the only trouble being to collect the down, which, in fome of the forts which have large pods, is produced in great quantity, fo may be colle&ed with little trouble.

The other forts which have been ranged under this genus, are now referred to the following genera, to which the reader is defired to turn, for fuch of them as are not here enumerated, viz. *Aclepias*, *Cynanchum*, and *Periploca*.

The firft Jon h found growing wild in the woods in fome parts of England j I have frequently gathered it in the woods, near Bexley, in Kent; and a lib lie-tween Mniditone and RochcJtr. The flowers of this are blue, the pctais are flort, and the nectarii ate very prominent, in which it differs from the fecond, whofe petals arc longer, and tile nectarii do not rife high. This I found growing naturally near Ingle-brough Hill, in Yorkihire. The flowers of this arc much larger than tiiofc of the Garden Columbine, and the feeds which I fowed of this in the garden at Chellea, produced the fame fpecies without the leat variation.

The third is the Garden Columbine, of which there arc great varieties, not only in the colour and funcls of their flowers, but aifo in their form. In fome there arc no vilible nedarii, but in place of them a multiplicity of petals, fo that the flowers are as double as limit ouIn.- Jnrkfpur. Thefe are commonly called **Rofe** Columbines; the colours of thefe are chefnut, blue, red, and white, and fojwe arc finely variegated with two colours.

There are others with [harp pointed petals, which expand in form of a (tar; of thcie there ire finale ami double Bowers, of the leveral colours as the former. JYom the different Iliape of theje flowers, any purlbn not Well (killed in the culture of plants, won't fup-poft they were diftinf from the others; bm having fecyal years fown their feeds, which were collected with great care, ! have found them always varying from one to the other: therefore I have not enumerated their varieties here, knowing they can never be preferved the fame from feeds, however carefully they arc fitted: however, as the forts with variegated flowers are efteemed the greateit beauties, k. I'm : cer- fon.S who are defirous to have them in perfection, ftould root out all thofc plants whofe flowers ire noi well marked* 01 N leftl tut on7 their (lemsfo 6 on as their flowers appear, leaving only the moil lx-wiiful to feed, that the fatina of the plain Mowers; may not impregnate the others, wlicreby thr plants raifed from their feeds may not be degenerated, of which 100 much can: cannot be taken.

These plants nre all raifed by lowing the feeds, or parting like old roots, but the former method is chic fly prattucdv for the old roots are very apt to degenerate after they have blown two or three years, Jo as to become quite plain.

The feeds Jhould fx (own in a nurfery-bed in Auguft ; tember, fo fch feeds which arc kept till fpring fcldm grow wel, or at lead remain in the ground a y.ii. "Of Spring following the plants will appear above (011 ml, therefore (hould be kept clear tivm vci-iy'i &nd if the faftun fhould be dry, they

(hould be refrefhed with water, that they may gatntf ftrength.

In die middle or latter end of May, thefc plants will be ftiong enough to tranipbnt; therefore fome beds of good frelh undungL-d earth fliond be prepared, planting them therein at eight or nine inches diltance every way, keeping them clear from weeds, and rc-ftitfhing them with a little water, as they may require it.

In the following autumn, by which time the plans will have acquired ftrength enough to flower the liiminer following, the roots fhould vx carefully taken up, and planted in the borders of the flower-garden; but ivliere their roots arc defigned to be preferved in perfection, all their fldwer-flems (lionld be cut off, as foon as the flowers are pair, to prevent their degenerating by the commixture of the farina from other flowers.

But in order to be fure of having no Jingle or bad flowers in the borders, you may tuffe the plants to remain in the nurfery-beds until they have blown 5 at which time you may put a Hick by each root you fancy 10 prclervc, or pull out all the Jingle or bad coloured ones, and rhrav them away, cutting off all the flowers from your beft roots as foon as they have Jliesn themfelvej, which will greatly atiti to the pre- lcrving them fair in their colours.

In order to keep up a fucccfion of good flowers, in Hi fecit fliond be fown cvty year; and if you enn meetwidia friend, at fome diftance, who is furniied with good flowers of diis kind, it will be very advantageous to both panics, to exchange feeds once in two years, by which they will not be fo apt to degenerate into phtn colours.

In laving the feed* of the variegated columbines, great care (hould be taken nor to funer any plain flowers to remain for lied, there being generally feme plain flowers intermixed with thr ftripeJ ones on the lame plant, and often in the lame branches; thefe Jhould be cut off, fir if they are permitted to feed, or if their farina mix and m the ftriped flowers, they will degenerate into plain cokunj fo thai there cannot be too much care laken in faving the kids, where the beauty of their Howers are-regarded.

The Canada Coiumbinc flowers a)molt a month before the other Jbrts; for which reafon it is preferved in the gardens of the curious, though there is no great beauty in the flowers. There is another variety of tjiij wet, mtk taller Bower S>ms, which flowers a little after the other, but do not diner, either in the fliape of its flowers or leaves from dm, fo I conclude they arc but one diitititf /iccies. The Canada Columbines flower Ill April, and their feeds ripen the beginning of Auguft. The en her firts flower toward (he end of May, and in cool frafons will continue to produce flowers till the middle of July, and their feeds ripen toward the middle or end of Srptcnijr, according as the fealbn proves more or left favourable.

The firft fort is that which is dircted for medicinal ule in the dupenlarics, but at prcfent is very rarely orderfil.

A RABIS. Lin. Gen. Plant 732. Balbid Tower Mallard,

The CHAKACTCKI are.

The fiercer belb a feur-lar-jed impalement, two of tbt op* pipe leir. -is being large, and lite ether fc# narrow; thefe full iff. jhe fiuvter bath fear petals is form of a crofti, vibich fspread open; at the bottom offtaib is finuated a re-flcxed ne(lsrjiumfi>tdt) the emptetnct, and btjfeen thefi arifejs upright jhmma, rain ofvibubettmo longer than the flowtr-tyv, the other four ore much bnger • thefmrt [Tutened with bcarf-Jb-ipedfummits. The firft feit is a low Jilsiit, feldom rifingmore than tour or five inches high, fending out many fhort hr.inches on every fide, terminatt by I ma If white flowers growing alternately the moit pan of their lenph, each having four petals in term of a crofs, Which arc fucedditi by long (lender pods fil<dwth fmall round feeds. It grows naturally on fandy dry ground, in many p.irts of England.

The fecond fort grows nacurally in Efrta. from whence I received the feedj it a alb a native of the Alps, and many other mounrainous toum cries. This is a perennial plant, which increafes by its creeping roots, which run obliquely near the iirlatc α* the ground, and fend down roots at every joint. The leave; ire collected into heads, fprmding circularly tike thofe of the London Pride. Thde are oblong, whitifh, and indrteilon their edges t out of thefe heads arife ihc Rower-llaltU) which grow near a foot high, g^{ar}-nilht-J witi leaves placed altfrnaiely, which arc broatler at their bait: thin ttiofe which grow bebw, and clofely embee the (talks); the Rowers grow in loofe bunches on the top (theft are white, and have leaves inform of a crofs, which are fuceddcil by lung flat podj, opening lengthwiys, having two celts, whitn are C-paratctj by an intehndicx partition, each •liavino one row of Ait reddilh feeds.

This BJ very hardy plant, fo will thrive in any ij-niiiiin. It produces leedsin plenty, hut as it rtiuil-plici fo fad ay its creeping routi, few perfbm arc at the trouble to lbw the ferds. It flowers early in the jbring, and having mtmy ftalks rifing from one root, they make a pretty variety in cold filiations, where many finer plants will not thrive, fo may have place in rural plantations among lhrubs, where they will thrive with very little care.

The third fort grows nsturally in Siberia, from wlence the feed* were brought to Pctcriburgh. Tliii is a perennial plant, which grows near a toot high | the k-tyes are braid, hairy, and indented on their edges; tlieli clojely embrace the Itallw. Ttie flowers grow alternately in loofe (pike?, and are of a dirty white colour. There arc fucedded by long narrow pods, which are filled with [lit brown ieeda like the former, but the pods of tliii hang downwards two n. Rowera early in fpring, and petfecb feedi very neHi, byVhichtt may be propagated in pleniv.

i'bc fourth Ion grows naturally in Hungary, Sicily,

A R A

and France. I have allb found it growing wild uimH font-old walk at Cambridge and Ely, but the 6 might probably come out of the gardens wheri were firir. planted. The plants of this kind, • grow on walls or ruins, continue much longer thait thole whiff are (own in gardens, where they k-ldorit live longer than two years. The leaves of this fort are long, broad, hairy, and a little waved on their edges; of a pile colour, and l'pccad near the ground: from thiu center oi thde come out the ftalks, which rife about a foot and a hul' high, having livcral leaves growing alternately, which clofely embrace them. Toward the top of the [talks, thiry divide into feveral fmal branches, which arc terminated by long loofe fpikea of flower?, of a dirty white colour, each having four petals placed in form of 3 crofs. After the flowers are pall, the eermen becomes long Hat pods, which turn backward tt their extremity and open length-ways, having two rows of fUt-biirdced leeds, dt a dark brown colour, fep.trated by a thin intermediate partition.

This fort Ueafily propagated by feeds, which fould be fown in the autumn; for thofc which an: town in the fpring frequently mil carry, or lie in the ground a whole year before they grow. When the plants are flrong enough to remove, they may be tranfitant into a Hutty border, or in rural plantations, where no other care will be neceflary, but 10 prevent their bving overgrown by weeds. "It is plants flower in Mvty, and (heir feeds ripen in July. There is little Ix.iury in this plant, yet many perfons preferve it in their gnrdeni to make a variety.

Tlie fifth fort is annual, it grows naturally in North America; die leaves new the root are lycr-fhapM), but thofe on the Bower-ftalks are linear, placed alternately; both arc fitiooih; ihc flower-fbUkE rife near a foot high, and are terminated by white flowers, which are fucedded by (lender pods.

The fixth fort wii brought from Virginia •, this is, a biennial plant, whole lower leaves fpread on the ground, theft aredecply indented on their fidet tlower-ftulksrife afoot high, fufbuoingfevtzai Qowen placed fcatteringly at the top, which a Clced by pretty long flat pods, filled with ibtos.

The two lail fmentioned forLs hue little beauty to recommend them, nor are their virtues known, therefore they are rarely admitted into any gardens except for variety. They are eafily propagated by feeds, which if permitted CO (tatter on the ground, will produce plants in plenty on any foil, or in any fiiuation.

A R A C H I S, Earth, or Ground Nut.

The CHAKAKTBKS arc.

The tmpalemmt of the \$m;tr tfms in l<ms parts, the upptr bring tut into tirtc at tit extrmity, tht tmdtfeitt (i ending in apuim, m:dhigr thsn tbtather. This genuj of plants is ranged in Linmus'a feventeenh clafs, entitled Diarlelphia Decandria, from the Bowers having ten ttarojna, which are in two bodies.

We have but one SPECIH of this plant, vH. AUACHIS (*Hypog-rt.*) Lin. Hon. Cliff. 353. *Earth er Ground Nut*. Arachidna quadratibla villoU fiore luteo. Plum. Nov. Gen. 40.

The iitivc country of tills plant I believe is Africa, though at prefent, all the fettlements in America abound with it 5 but many peiftns who have refided in that country affirm, they we c oripnally brought by tht-lavc from Africa there, o'hetc they have been fpcrad all over the fetitlment.i \

It tmijjplie.i very fad in 11 wirm L,^!tr), but bniiij^ impatient of cold, \i cannot be propagated in die open

• in England; therefore whoever his an inclination
 > cultivate thw plant, mud plant the feeds in a hot
 'i the ipring of the year, keeping the glalfe over
 jians till the middk or end of Junc-j after which
 il-, if the weather prove warm, they may be ex-
 poled to the open air by degrees. The branches of
 this plant trail upon the ground, and the Rowers
 (which arc yellow) are produced Jingle upon long
 fbot-falks j and as loon as the (lower begins to decay,
 the germen b thruft under ground, where the pod is
 formed and ripened-, fo that unJef the ground is
 opened, they never appear: the negroes kept this a
 fecret among themfelves, therefore could lupply Jicm-
 tAgtt with chefc nuts unknown to their mailers. The
 routs of tlidē plants art; annual, but the nuts or Teed;
 iiffidi-ntiy flock the ground in a warm country, where
 they are not very carefully taken up. In South Ca-
 rolina there is great plenty of theic nuts, which the
 inhabitants roaft, and make ufc of as chcolate.

The firft fort is lirecty common in many gardens near
 London, but the fecond is at prefent more rarely met
 with. Both theic plants grow naturally in North
 Aint-rlca, from whence their feeds were brought to
 Kuropc. They are perennial plants, whofctal a decay
 in autumn, ana new ones arife from their routs
 in the Ipiing. The (irft grows thretor tour feet high,
 and divides into many irregular branches, garniJhed
 with ramofe leaves, placed alternately-, at the wings
 of theft fee Bawep-ftaUcsait produced, which are ter-
 minaied by rouidumbd³ on¹ d^ fbw-^{cauc} d ftWci*,
 ot' whitifli colour; thefe are fucceded by round
 channelled berries, which when ripe, are black. This
 flowers in July, and the feds ripen in O> •

The fecond lbit rifes to near the lunc htiglit as the
 former j rhe k;ives of this have two trifoliate large
 lobes, which are fawed on their edges. The Howcr-
 Italks arife between thefe immediately from to
 being naked, and are terminated by round umbels
 of flowers, in flatx; and colour like the firli; thefe
 arefucceded byDerric; ivhkf i areimaller than thofe
 ci'the oshtr. This flowers toward the end of July,
 and the feeds ripen laic in the autumn. The routs
 of this fort were formerly brought over and fold for
 Sirfaparilla, and at this time leveralof the inhabitants
 of Canada make ufc of it as l'uch, but it ii fetj dif-
 fercent from the true fort.

Botli theic iorti are eafily propagated by feeds, which
 are generally produced in plenty. Thefe (hould be
 fown in the autumn &on after they are ripe, for thole
 which arc fown in t1* (prtg, never prow the fame
 year, ib that i: wfoak leafon is gained by the lowing
 he plants appear, they muft be
 I clean froni-Weeds during thi- fummer-, and in
 the autun: a following when their leaves decay, the

foouI may be taken up, and tranfplanted where drey
 are to remain. They are very hardy plums, fo may
 be planted in any fituation; and as they grow natu-
 rally in woods, Ib they may be planted in wildcrnrls
 quarters, under treeSj where, although they have no
 great beaury, yet they will add to die variety.

Thefe two forts may alfo be propagated by parting gf
 their roots; the beil time for doing thii \a in the
 autumn, foon after their leaves decay. Thefe fhouIJ
 be planted pretty far alunder, for their roots I
 w a confiderable difence, where they are left un-
 (ilturbed for lbme years.

The third fort rifes with a woody ftem to the i
 of eight or ten feet, dividL -a] brar

gainilhed with branching Iraves, which arc CO
 pounded of many divaricated wings; the lobes
 which arc oblong, and the ribs of the leaves, as I
 the branches and ftem of tie plants, are ained I
 flrong crooked fpinci, which renders the places w
 difficult to pais through vvhcre they grow in plcn.
 The flowew of this fort arc produced in large ioc
 umbels, at the extremity of tue branches, and arc u
 an herbaceous colour, lo make \w> great fji;i'-i-, but
 the planes ai-e prefervtd in molt of tile turious gardens
 in tngland. It flowcR in Auguil, but the Leeds do
 not ripen in this cotimry.

This is prop:gt.itcd by feeds, which are eafily pro-
 cured from North America-, but as they fddom ar-
 rive Acre till toward the fpring, fo the nlanrs never
 come up the firft year: therclbn: when the feeds ar-
 rive, llicy mould be fown in pots, filled with light
 earth, and placed in a lhady fituation, where they
 may remain until the next autumn,- being careful to
 wend the pots confantly •, othenvife if weeds are per-
 mitted to grow till they are large, they cannot be
 taken out, without drawing up the feeds with their
 roots. In die antunui, the pots fhouLI be \>I

icidcI into an old bed of tan, or in a warm
 under the fhelter of a hedge or wall; and if die wimer
 proves fevt-re, it will be proper ro cover the pots with
 fbuv or t'eaie-luulm, to [irevent the fro(t from pe-
 netrating deep into the ground. In \Ur di the pots
 fhould be plungcti into a moderate hot-bed, which
 will bring up the plants early, fo that they will hai-
 more D< length before the foDowing winter.

When the rjlwm conic up, they fhould be frequently
 refnJhed with waLcr, and conitunily kept clean from
 weeds; In May they (hould be inured to the open air,
 and when they are removed out of the bed, they
 fhould have n (hady fituation. Thicfe plants (houLI
 not be difturbed the Eiril li-afon, but as they arc often
 injured by froft when young, Ib in Odtncr tie poj
 fhould be placed under a frame, where they may be
 lcreendfrom hard frofts, but in mild weather mould
 be confantly opened to enjoy the free air.

Thicfe plants fall away in the autumn, fo that fame
 perfons have fupposed them dead, and hncv thron
 them • mi of the pots, which every one fhould be
 ed ag.iinf. In the fpring, before the pis
 bfcgin to pulh, they (hould be carefully lhaken out of
 the pots, and feparated; pirt of them fhould be
 I lamed llngly into fmall pots, and the other may be
 planted in 3 bed of light c.irth in a want) fituation.
 Ililiufc which arc planted in ilie finall pots are plunged
 in a moderate hot-bed, it will greatly forward their
 growth; but they muft be early inured to bear tie
 open air, otherwife they ml] dttw op weak. In the
 following Tummer ihry muft ktvc s (hatly firm
 and the next winter fhould be fliehertd aiain; the
 fprinc following they may be lhakfn out of the pots,
 and planted where they are ddigned to remain. Thofe
 plants which were planted in the bed, will require
 protection from the froft the lift winter-, therefore
 if tin: fuffice of the gruitid k covered with oid tan-
 ners bark, ir will prevent the froft from jjenctrating
 io dicir tiHitsi and if in hard frails, (ome draw,
 Pcafc-haulm, or any light covering is laid ow;
 twd, it will fecure their ftem from being injured.
 The plsmts in the bed may remain there two years, by
 whitth time they will be (trong enough to lil

to the phccs where they are designed to grow. As thefc plants do not **come** out very **truly** in the fpring. To they often continue growing pretty late in the **viu**umn, which caufo the extreme parts of their [hoo**ts** to be very tender, whereby they otter f«Fer from vht early fruits in autumn, which frequently kill the upper parts of the hoo**ts**; but a* their woody fcms are fcclom injured, fo I **bej pot** **OT** new **branches** below: **and** it* in very feveru winters the Items are dcroyed, yet the roou will remain, ami put our. new On< the following dimmer, therefore they ihould not be defreyed.

This plant may **glib** be propagated by its roots, for as thry lspread fir in the ground, fo if they arc bid open, and feme of the frongelt arc fepaiated from the plant and left in the ground, they will put out new items and make new plants. Or if part of the roots arc taken off and planted on a moderate hot-bed, they will puib out (terns in plenty, lu may be increafed with cafe,

A RBOR, a trie, is defined to be a gemirtiparous plant, with a Tingle trunk or flem, abounding with frees. Tliis is the only definition which conveys an idei whereby to diftinguilh a tree from a lhrub, which 13 a gemmipurous plant, -with many Items or trunk,.

The firft fon grows naturally in Italy, Spain, and alfo in Ireland, and is now very common in the Englilh gardens. Of this fort there are the following varieties, viz. one with an oblong flower and oval fruivr another with a double flower, and a third with red flowers; but theft bring nlyfeminal varieties, I have not mentioned them as fpecies •, though, for the fake of the curious, J JhaJl **give** & farther account of them.

The fecond fort grows natundly in the Caft, particularly about Magnesia, where it is fo plenty, as co IK the principal fuel ufed by the inhabitants of the country. This grows to a middle fiird tree; the branches are irregular, and are garnifhed with large oval leaves, fomewhat like thole ol" the **Buy-tree**, but not quite fo long-, **theft** sic Imooih **and enure**, having no ferratures on their edges; the flowers are ihaptJ **like** thilili. of the common **Arbutus**, but grow thiny on dm branches. The fruit is ova), and of the liine colour and confidence with the common fort, but the feeds of **thiis** arc Hat, wliercas thofc of the common fort are pointed and angular. Tournefort emimeimcs thire other varieties of this tree, which he obfcrwed in thic Levant, one with fawed leaves, which **h** mnw in many Engiilh gmtem, and paffes for the **Ax** another with a large oblong fruit, and a rt large compreffed fruit: bui it is doubtful if tney arc not accidental varieties, which have been produced from feeds of the firft.

The common Strawberry-tree is too well known to require any ddcipfion of it here, being at prefent in **moftof tKEnHiQi** gujens, and a one of the **greateft** ornaments to them in the months of OAober and November, thiat being the feafon when the trees are in flower, and the fruit of the former year is ripe, for the fruit is a whole year growing to perfection; *fa* thiat the fruit whkh is produced from die flowers oP one year, do not ripen till ilie bloffoms of the fuccedding year arc fully hlown; (*a* thiu **#tei** iherr it plenty at fruit and flowers upon thr trees, they make a goodly appearance, and at a feafon when moftother trees are palt their beamy.

Thofc trees which liavc large oval fruk, make the **greateft** figure, the flowers **m** this being larger, and ohlning. The ion with **double** (lowers is a curiofity, but as the flowers have only two orders of leaves, fo they make no great appearance, nor do the trees praducV thiiit in any plenty, **therefore** the other is more preferable. The fort with red flowers makes a pretty variety, when **intermixed with the otho**; *fat* thieoucdc of them are of a fine red colour at their firft nppcarance, and afterward they change to purple before they fall off. The fruit of this is the Jame with the common fort. All thde **varieties** **axe** prderved, by inarching or grafting then) upon die common **Arburus**. fortheleeds of either do not **produce** the **fiime** kind-, though from the feeds nfiln-oval fruit, thicrr is generally many more *oi* the lame produced, than from the feeds of the common fon.

The bed method to propagate the **Arbutus** is from ieedsi therefore when the wuit is **perfected**, **jpe**, it iliould be gathered and mint with dry **faf4**..ro preserve them till the time for fowuig **them**, the **bed** method of raiing the plants, Uuo fow **d** feeds in

pots,

pots, which should be plunged into in old bed of aimers bark, which has bit its hr:il. i overring the bed with pluffs, &c. to keep out froft; this should be done in December, if the fit-ii are weak, and if the bring advances, the pots are rcr'rehrtr will inter, the plant will cjttr.e up the beginning of April, when the ihoul be foqucnily but (pinugly watered, and confbntly kept clean from weeds.

As tilt- fummtr idvara, &c. ; bnr* ire (hid in II:L- heat of the day, it will ga-atly primate llicir growth; but in wirm weather they mud be open all night to receive thir dew, fo Ihonld only fac covered in ihi- middle oi the i'y.i with this n management, the plnts will rife ui the ticjeUt of five or fix inches the lirl fummcr. The beginning of Odaber, these plants m?y IK fhaken out of thit* poti, and their roots carefully separa- < J, planting them fingly in fin all pots filk-IJ with lip lit earth; then plunge the pots into an old bed of tanners bark, under a common frame, obferving to fnside than from the lun in the middk of i:c day, and to give ihtrm water as thtj¹ may require: in this bed [lit: pots fhoiM retrain during the winter, ob&mng to expofe the pbuu to [l. open air, at nil times when the (feather is favourable i W in Frofty weather they mull br coveted, otherwife they will be in d.niger if the fcafan prove- ; cover. The fpring following the pluti may be itmo ad to i very gentle hur-bni, which will requirt no other covering but matt. This will enable them to mike Arong (houts early in the fummcr, whereby thiy will be in a better condition to bear the cold of the fucceeding winter: in chit bed the plants may continue moil part of the fummcr, for ir the pots a- taken out an it let upon the ground, the finaJJnds of their fize will occafion the earth in them to dry fo fall, thai watering will I ai i dly preferv- the plnts alive; but if thw^{ty} are kept growing all die Jumiut, they will be more than a loot high by the nrxt autumn: I jut it will be adi'ifuk to lereen them from ;le froft during their continuance in pots, bj" plungrng them into the ground in s wdrn pi-ice, ind covering them with mats in be : weather.

When die plants are grown to be two or three feet hi"th, you may fhake them our of the pots ami plant them in the open ermdw in the places where they are to remain, in R thifhould be done in April, that they may have iken good root bctbre the winter, »!)*(?) would IM apt to damage them if newly planted, and as all the earth about their roots niLy bt; thu) preferved, there will be no L of the feeding at this It.i;

These plants are tolerably ha• dy, witl <re fcidam hurt, rcept ip exocme hinl win ten, which many times killthe young mi tender branches, boirarclydctroy die roots, if• afore, hom over deA they mii' appear after a haid winter, yet I wmld advif- the fctring them remain till 'lic (ucceeding fummcr has diffidently demonftrat ed what are livbtg and wlmtare de-; for the winters sinno (/^S-o, an d 1739-40, 1741, us great rva'un IU believe niot of LIC n ocs of this kind were destroye;:; and many peoj he were fo hally, A; : : dig up or eUTdOWb, many of ihtir trees; whereas all these people who had paine• • to let them remain, fuwid il:jt Icarte om- in fUt hundred failerl to come oi' again the next liimmer, and many of theiil made ban'dfcrac plants that reafott This tree delights in a moist soil, for when they art planted in dry ground, they fel! >m predua much fruit - : the flowers of this tree being produceil in autumn, if the winter proves severe, are generally destroyed, which has occasioned their producing very little fruit in England for sever• l years; therefore, in order to obtain faiii • trees, thoulk W. plant in a warm Bra; non; and where tht ground is not naturally moist, there fhould be a good quantity of loam anJ rotten man's dung laid iboul dicir • ocs; and if the spring should prove dry, they must be plaitifulty watered, in order to have plenty of fruit.

The wry best season for transplanting of the Arbutus is in Scprn»-jet, at which time the woUbins art be-

growing to appear, and it thai nfon, if it should prove very dry and they are kept moist, they will take root very soon; but toward the beginning of November, their roots should be well covered with sand, to keep out the frost.

The third sort grows naturally in Acaha, and other parts of America, upon swampy land, which is frequently overflowed with water; this is a low bushy fferub, with tender trailing branches, which are garnished with oval leaves, a little fringed on their edges, the flowers come out from the joints of the leaves, growing in thin loose bunches. The fruit of this sort is never produced in England, and it is called Jiliiailty II: e I: ocs are kept alive here.

The fourth sort grows naturally on the Alps, and the Helvetic mountains. This never rises high, but sends out from the root many slender branches, which lie close to the ground, garnished with oblong rough it&vi, of a pale green colour, which are produced from the wings of the leaves, upon long slender foot-stalks, and are succeeded by berries about the size of the common black Cherry, which are first green, iftrn-ard mil, and when ripe they are black.

These are of a pleasant taste, so are frequently eaten by the inhabitants of these countries where they grow naturally. This is also a very difficult plant to keep alive in gardens, for it is an inhabitant of bogs, growing among moss, where the ground is never dry.

The fifth sort grows naturally upon the mountains in Spain, and in most of the northern parts of Europe. The branches of this trail an die around, which are closely garnished with li IIII! u thick leaves of a oval form, placed nllt-mately; the flowers are produced in iiiiiiilLiinctiri toward the extremity of the branches, which are shaped like thofeof the tominon fort, but alt tmalltr; jimi are futtediled by berries, of the same size with thofe of die former ibrtj wliidb ire red when ripe.

There are ftwof thefe plami in the Engliflig:ir rams, for aa they are inhabiajiw of very cold LOW rams, wherr (hqf are ooi-en-ta with fnow all die winta, and growing itjmn bogs among inols, fo when they nrerou^ht into a garden, they fcdcen continue long, nor Jo the; thirc with the utmost care; for in places where artificial bogs have been contrived, to receive these plian:, th' have been preserved two or three years, and then have perihid; so that unless the place • vhcirtJtcy nrripLintLd is naturally boggy, there is no hope of their succeeding long.

The sixth sort grows naturally upon Mount Cervin in Italy, and upon some mountains in Spain, it is hath woody liii;:; win: rite two or three feet high, dividing into many divided branches, closely garnished with roundish fleshy leaves, which are indented at the nip-, tin' (lower) arc produced in I racorus toward the • nl i>f the braneh's, which are shaped like those of the Stru• lierrj'-tree, of an li rubeaceous colour, (h-ipped with purple. The plants of this kind art very rare in Enpland, nor is this Ijwe tmsh known among botanists, most of whom have supposed the first to be the sort mentioned by Clufius, in which they are really mistaUea,

The seventh sort is very rare in England, and is this may be procured in the pagaietfciie liime manner upon the direct road to the hamori Album-, Inn as there are several plants in thii country whidb produce it; priV: it, the seeds must be procured from the Levant, whert they may be had in plenty. As the leaves of this tree are larger than those of the common Arbutus, the tree makes a late appearance, therefore observe • >ur tait 10 culti ate them, especially as they will bear i' < open air when the plants are become woody, for while they are young, they are impatient of much frost, therefore should be preserved in pots three or four years, till they have obtained strength, and may then be planted in a warm situation and on a dry soil, for this sort will not thrive in wet ground.

The two first sorts are common weeds, growing on the sides of roads and foot-paths in most parts of England, and are not admitted into gardens. The first is indeed for medicinal use by the college of physicians, therefore I have inserted it here: the second is by many supposed to be only a variety of the first, but I have for several years seen the seeds of both sorts in the Chelsea garden, where they have constantly retained their difference, so may be allowed to be distinct species. The first is cited by Caspar Bauhin ...

The third sort is not a native of England, but grows naturally on the Apennine mountains. The leaves of this are like those of the common sort, but are white on their under side; the heads are more compact, and the flowers are of a bright red colour: but die grejttel di3< ... id in Haver.

This is also supposed to be only a variety of the common sort, but I have cultivated it above forty years, during which time it has never varied, so that it is certainly a distinct species. This is by Caspar Bauhin titled, Lappa major montana capitulo pinnatis. Pin. 113. Greater Mountain Bardach and usually heads. As these plants are seldom admitted into gardens, it is needless to say any thing of their culture; but where they are troublesome weeds, it may not be amiss to mention, that their roots last but two years, so may be destroyed with less trouble than such as have perennial roots; for if they are cut up before they root, in i<1 of these years they may be entirely rooted out; for the plants which come up from seed, do not flower all the second year, and when the seeds are perfected their roots decay.

ARCTOTIS. This hath been usually known under the title of Anemoneperennis, from the circumstance the seeds of these plants have to that of the Anemone.

About the end of September following they may be opened and examined, to fee if they have taken root or not, which it is very probable they will have done, but if not, they muft be let alone, to be till the next autumn, wjcn di'y .. to be taken up, and planted in the nurfery.

This may be done to the Dutch, Wick, and Eng- iiii Elms-, the Abbe, Lime, Alder, Plane, and many forts of evergreen trees and flowering shrubs.

A R E A is the internal capacity or content of any given boundary or liij lii ., of what figure or fhape soever it be.

A K C i E M O K E ffo called from 'Afym, a fiftick in the ... caQ ... mu chrumbia a Fig, and thus in allegory J Pocky Poppo.

The CHARACTERS are, The flower hath a three lobed calycement, which falls off; it hath five trumpet petals, which spread open, and are larger than the calycement; in the center is fixated an oval five-angled germ, covered by a large shell of figus, which is perforated, divided into five parts, attended by a great number of fermen, covered by oblique oval fermen; the germes afterward become an oval leaf, having five veins, and as many ribs, which are filled with foft rough feds.

This genus of plants is ranged in Linnæus's thirteenth class, entitled Polyandria Monogyna. The flowers having many flamina and one germen.

We have but one Species of this genus, viz. AGRICOLA (Adonias) capitata quinque lobata, foliis bipinnis. Lin. Sp. 707. Agricola, which is called both for water, and the leaves are prickly, or Pocky Figs. Papanus spinosum. C. B. P. 171.

This is an annual plant, which is very common in moft parts of the Weft-Indies, and is, by the Spaniards, called Fico del Inferno, or the Devil's Fig; there is no great beauty or use in this plant than I know of, but whoever hath a mind to cultivate it, fhould low it on a bed of light earth, in the Spring, when it is ten inches high, and if it comes up too thick, the plants muft be thinned to four inches diftance, where, when once it has fixed its feed, there will not want a fupply of plants for feveral years after. I have been informed that gumbuga is made from the juice of this plant, but how true I cannot take upon me to lie ten nine.

ARGILL. [Argilla, Lat. a fort of white earth like chalk, but moft brittle.] Pocky Clay.

The firft and fecond forts grow naturally in the fourth of France, in Spain, and Italy, from whence their roots are brought for medicinal ufe. The roots of the firft fort are roundifh, and grow to the fize of fmall Turneps, in fhape and colour like the roots of the common Cyclamen *, the roots of which are frequently fold in the markets for thofe of the round Birbwort, which at firft may have been occafioned by the fuppofed virtues of the roots of the Cyclamen. This lends out three or four weak trailing branches,

which lie on the ground where they are not fupported, and extend to the length of two feet; the leaves are heart-fhaped, and rounded at their extremity; thefe are placed alternately on the ftalks, and clofe to the foot-ftalks of the leaves, the flowers come out fingly, at every leaf, toward the upper part of the ftalk. They are of a purpliih black colour, and fhaped like thofe of the other forts, and are frequently fucceeded by feed-veffels, having fix cells, which are full of flat feeds. The flowers appear in June and July, and the feeds ripen in autumn.

The fecond fort hath long tap roots, fhaped like thofe of Carrots; thefe fend out weak trailing branches, which extend little more than a foot; the leaves of f this fort are paler, and have longer foot-ftalks than the firft, placed alternately, and the flowers come out from the wings of the leaves like the other, which are not fo long, and are of a pale purple colour: they are fometimes fucceeded by oblong feed-veffels, having fix cells filled with compreffed feeds. The ftalks of both thefe forts decay in the autumn, and new ones are produced in the fpring.

They are both propagated by feeds, which fhould be fown in the autumn, in pots filled with light earth, and placed under a frame, to be fcreened from the froft; but the glaffes fhould be taken off at all times when the weather is mild. If thefe pots are put into a gentle hot-bed in March, it will bring up the plants much fooner than they otherwife would rife. As the feafon advances, the plants fhould be inured by degrees to bear the open air: when the pots are taken out of the bed, they muft be placed where they may enjoy the morning fun, but fcreened from it in the heat of the day. Gentle reffhings of water muft be in dry weather given to the plants during the fummer, but in the autumn, when their ftalks begin to decay, they muft have little wet. In the winter ^the pots muft be fheltered as before; and in March, before the roots begin to fhoot, they fhould be twnfplanted into feperate fmall pots filled with light earth, and fet under the frame, where they fhould rental till fpring; then they may be removed into the open air, and treated in the fame manner as in the former fummer, and fheltered alfo the following winter. The next fpring they may be turned out of the pots, and planted in a warm border, where, during the fummer, they will require no other care but to keep them clean from weeds; and in the autumn when their ftalks are decayed, if the border is covered with old tanners bark to keep out the froft, the roots will be fecured; but where this care is not taken, the roots are frequently killed by froft. With this management the roots will thrive much better than thofe which are kept in pots, and continue longer; and when they are three years old, they will flower and produce plenty of feeds, whereas thofe in pots feldom perfect their feeds in England.

When the feeds of thefe plants are fown in the fpring, the plants will not appear till the fpring following; fo that a whole feafon is loft, and many times they fail, therefore it fhould always be fown in the autumn.

The third fort grows naturally in France, Spain, Italy, and Hungary, but is preferved in fome of the Englifh gardens, becaufe it is fometimes ufed in medicine. This is a terrible plant for creeping at the root; fo that if once it has taken in a garden, it will be difficult to extirpate again, and will over-run whatever plants grow near it; therefore it fhould be planted in fome abjedt part of the garden by itfelf, for it will thrive in almoft any foil or fituation.

The fourth fort grows wild in Spain, Italy, and the fourth of France; but in England it is preferved, foi variety, in botanic gardens. The plants of this fart muft be planted in pots filled with iight rich earth, and fheltered from fevere cold in winter, otherwife they will not live; but they fhould have as much free air as poffible in mild weather. This produces flowers every year, but never perfects its feffils in this country.

A R I

The fifth fort grows naturally in Crete. The root of this is perennial, and sends out many trailing branches, which extend one foot and a half in length, garnished with oblong heart-shaped leaves, which are waved on their edges, and are evergreen. The flowers come out singly from the wings of the leaves, which are of a dark purple colour, in shape like the others, but the plants never produce seeds in England, so is propagated by parting of the roots: this is too tender to thrive in the open air in winter; the plants are preferred in pots, and placed under a common frame in winter, where they should have as much free air as possible in mild weather, but screened from hard frosts; in mild winters I have had this plant live abroad in a warm border, but in hard winters it will be destroyed; therefore one or two plants should be sheltered to preserve the species.

The sixth fort is the Snakeroot, which is greatly used in medicine: these roots are brought from Virginia and Carolina, where there are two species of this plant, but this fort is the best for use. There are some of these preferred in the gardens of those who are curious in collecting rare plants, but as they are sometimes killed by frost in winter, so they are not very common in the English gardens. This is propagated by seeds, which should be sown in the autumn, in small pots filled with light sandy earth, and placed under a common frame in winter, and afterwards treated in the same manner as hath been directed for the two first forts, as should the plants also, with which management they will produce their flowers, and perfect their seeds every year.

The seventh fort grows naturally in North America, and is by some called Snakeroot, but is not near so strong as the former; the branches of this grow erect, and are perennial, whereas those of the other fort decay to the root every winter; this rises about two feet high, the branches are not very woody, but are strong enough to support themselves; the leaves are oblong and heart-shaped; the flowers come out singly at the wings of the leaves. This will live abroad in warm borders, with a little protection in hard frosts. It is generally kept in pots, and sheltered in winter; but those which are planted in the full ground will thrive much better, provided they are screened from hard frosts.

The eighth fort grows naturally in Jamaica, where it is called Contrayerva, the roots are there used as such: this hath long trailing branches, which climb upon the neighbouring plants, and rise to a considerable height; the leaves are placed alternately, and are of the long heart-shaped kind; the flowers are produced in small clusters toward the upper part of the stalks, which are of a dark purple colour; the seed-vessels are oblong and smooth. This is tender, and in winter should have very little wet, therefore must be constantly kept in the stove, otherwise it will not live in England.

The ninth fort was discovered by Dr. Tournefort in the Levant. This hath some resemblance to the second fort, but the leaves are hairy, and not so deeply eared at the bottom; the flowers are also much larger. This may be propagated by seeds, in the same manner as hath been directed for the first and second forts, and the plants treated so, will thrive very well in England.

The tenth fort sends out climbing stalks, which support themselves by fastening to the neighbouring trees, and thereby rise to a very great height, the leaves are very broad and heart-shaped, having several longitudinal veins; the flowers grow in loose bunches at the extremity of the branches, each having a long foot-stalk: this is tender, so must be kept in a stove, and treated as other exotic plants. It grows naturally about Tolu in New Spain, where it was discovered by the late Mr. Robert Millar, who sent the seeds to England.

The eleventh fort was discovered by the same gentleman at Campeachy in New Spain, from whence he sent the seeds; this fort seldom climbs above three

A R M

or four feet high; the leaves are short and heart-shaped, in some measure like those of the first; the flowers come out in small clusters from the wings of the leaves, and are of a dark purple colour.

The twelfth fort was discovered at La Vera Cruz in New Spain, by the late Dr. Houtton, who sent the seeds to Europe: this rises with an upright stalk, to the height of three feet; the leaves are long, narrow, hairy, and grow close to the branches, having scarce any foot-stalk; the flowers come out singly from the wings of the leaves, which are near four inches long, of a dark purple colour, and grow erect; these are succeeded by slender vessels, about one inch long, which open into six cells, filled with flat heart-shaped seeds. This fort requires a warm stove to preserve it in this country.

The thirteenth fort was discovered by Mr. Robert Millar, near Carthagena in New Spain, who sent it to England, this hath strong climbing stalks, by which it mounts up to the top of the tallest trees; the leaves of this are four inches long and two broad, of an oval shape, rounded at their ends, and are nearly as thick as those of the common Laurel; the flowers come out in loose clusters at the ends of the shoots, each standing on a very long foot-stalk; the seed-vessels are four inches long, and as much in circumference, having six longitudinal ribs, which make so many angles, being very prominent; they open into six cells, which are filled with heart-shaped leaves.

All these forts, which are natives of the warm parts of America, are too tender to thrive in the open air in this country, therefore require a stove to preserve them. They are propagated by seeds, which must be procured from the countries where they grow naturally, for they do not produce any here. As the seeds are a considerable time in their passage, they should be brought over in their pods; for many of the forts have very thin light seeds, which are soon dried in a hot country, when they are out of their covers, which will prevent their growing. So soon as the seeds arrive, they should be sown in small pots filled with light earth; and if this happens in the autumn, or winter, the pots should be plunged into the tan in the bark-stove, between some of the pots with large plants, which will screen them from the sun; for as these plants delight in shade, so, by thus placing of the pots, the earth will not dry very fast, which will be of great advantage to the seeds, which should not be too often watered. Here the pots may remain till March, at which time they should be removed, and plunged into a hot-bed, under frames, where, if the seeds are good, the plants will appear in May; but if the seeds arrive in spring or summer, they must be immediately sown in small pots, and plunged into a moderate hot-bed, observing to shade them constantly in the heat of the day; but the seeds sown at this season seldom grow the same year, therefore if the plants do not appear, the pots should be plunged in the tan-bed of the stove in autumn, and in the spring following, treated as before directed, which will bring up the plants. When these are strong enough to transplant, they should be each put into a separate small pot, and plunged into the tan-bed in the stove, and treated as other tender plants from the same countries.

A R M E N I A C A, the Apricot.

The CHARACTERS are,

The empalement of the flower is bell-shaped, cut into five blunt segments at the top \ the flower is composed of five large roundish petals which spread open, whose base are inserted in the empalement; in the center is placed a round germen, supporting a slender style, crowned by a round stigma \ this is attended by upward of twenty awl-shaped stamina, which are crowned by short double summits. The germen afterward becomes a roundish pulpy fruit, having a longitudinal furrow inclosing a roundish nut, which is a little compressed on the sides.

Dr. Linnaeus has joined the Armeniaca, Cerasus, Laurocerasus, and Padus, to his genus of Prunus, making them only so many species of the same genus, and

ranges it in his twelfth class of plants, entitled Icosandria Monogynia; the flowers of this class have from twenty to thirty stamina fattened to the empalement, and a single style.

The joining of so many plants under the same genus, as Linnaeus has done, renders it much more difficult to ascertain their specific difference, than when they are ranged under different genera; and although most of them do agree in those parts from whence the characters according to his system are taken, yet if their fruits may be allowed as one of the characteristic notes (which surely ought not to be totally omitted) there will be reason for separating some of them, especially when we consider the boundary which nature has set between them, for it is well known that all fruits which are of the same genus, may be grafted or budded upon each other, but those of different genera will not take upon each other, nor will any two kinds of different genera impregnate each other. Now the Cherry and Plum cannot by any art be made to take when grafted or budded upon stocks of the other kind; nor will the Apricot take upon the Cherry, the Laurel, or Padus; but it will grow upon the Plum to which it is nearly allied, therefore these may be joined together according to the strict rules of botany: yet in a work of this kind, designed for the instruction of the practical gardener, were these fruits to be included under the same appellation, it would rather confound than instruct, those who had not applied themselves to the study of botany: therefore I shall continue this genus under its former title, and shall enumerate all the varieties of this fruit which are at present cultivated in the English gardens, ranging them according to the orders of their ripening. For although most, if not all those which are by the gardeners called different sorts, may have been produced by culture, so should be deemed as one species; yet as the differences may be continued for ever, by the method in which they are propagated, so it would be unpardonable in a book of gardening to omit them.

The specific title given by Linnaeus to the Apricot is, *Prunus floribus subsessilibus foliis subcordatis*. Sp. Plant. 474. i. e. *Plum whose flowers want foot-stalks* and bearl-shaped leaves*.

The VARIETIES are,

1. The Mafculine Apricot.
2. The Orange Apricot
3. The Algier Apricot.
4. The Roman Apricot.
5. The Turkey Apricot.
6. The Breda Apricot.
7. The Bruffels Apricot.

The Mafculine is the first ripe of all the Apricots; it is a small roundish fruit, of a red colour towards the sun, as it ripens, the colour fades to a greenish yellow on the other side. It is chiefly preferred for being the first ripe, and there is a quickness in the flavour of the fruit when it is not too ripe, which renders it agreeable; the tree is very apt to be covered with flowers, but as they come out early in the spring, they are frequently destroyed by the cold, unless the trees are covered to protect them.

The Orange is the next ripe Apricot; this fruit is juicy, it changes to a deep yellow colour. The flesh of this is dry and not high flavoured, it is better for tarts than for the table.

The Algier is the next in season; this is of an oval shape, a little compressed on the sides; it turns to a pale yellow, or straw-colour, when ripe; the flesh is high flavoured, and very full of juice.

The Roman is the next ripe Apricot; this is a larger fruit than the former, and not compressed so much on the sides; the colour is deeper, and the flesh is not so moist as the former.

The Turkey Apricot is yet larger than either of the former, and of a globular figure; the fruit turns to a deeper colour than the former; the flesh is firmer, and drier than those of the two former.

The Breda Apricot (as it is called from its being brought from thence into England) was originally brought from Africa: this is a large roundish fruit, changing to a deep yellow when ripe; the flesh is soft, full of juice, and of a deep Orange colour within side; the stone is rounder and larger than any of the other sorts: this is the best Apricot we have, and when ripened on a standard, is preferable to all other kinds.

The Bruffels is the latest ripe of all the Apricots, for when it is planted against a wall, it is generally the beginning of August before it is ripe, unless when it is planted to a full fourth aspect; which is what should not be practised, because the fruit is never well tasted which grows in a warm exposure. This fruit is of a middling size, rather inclining to an oval figure, red on the side next the sun, with many dark spots, and of a greenish yellow on the other side; the flesh is firm, and of a high flavour; the fruit often cracks before it is ripe. This is commonly preferred to the former sort by most people, but when the other is planted as a standard, the fruit is fuller of juice, and of a richer flavour than this.

Most people train these trees up to stems of six or seven feet high, or bud them upon stocks of that height; but this is a practice I would not recommend to the public, because the higher the heads of these trees are, the more they are exposed to the cutting winds in the spring, which too frequently destroy the blossoms; and the fruit is also more liable to be blown down in summer, especially if there should happen to be much wind at the time when the fruit is ripe, which by falling from a great height, will be bruised and spoiled; therefore I prefer half standards, of about two and a half, or three feet in the stem, to those which are much taller; or to plant them as dwarfs against an espalier, where, if they are skillfully managed, they will produce a large quantity of good fruit; and the trees in espalier may be more conveniently covered in the spring, when the season proves bad, whereby there will be a greater certainty of fruit every year.

These fruits are all propagated by budding them; Plum-stocks, and will readily take upon almost any sort of Plum, provided the stock be free and thrifty (except the Bruffels kind, which is usually budded).

3 sort of stock, commonly called the St. JULI which better suits this tree, as being generally planted for standards, than any other sort of Plum will.) The manner of raising the stocks, and budding these trees, shall be treated of under their particular articles, to which I refer the reader, and shall proceed to their planting and management.

These trees are all (except the two last sorts) planted against walls, and should have an east or west aspect; for if they are planted full south, the great heat causes them to be mealy before they are eatable.

The borders near these walls should be six or eight feet wide, at least, and if it were more, the better; but I would never advise the making of them so deep as is the general custom, for if the earth be two feet deep, or two and a half at most, it is enough.

If the ground is a wet cold loam or clay, the borders should be raised as much above the level of the surface as it will admit, laying some stones or rubbish in the bottom, to prevent the roots from running downwards; but if you plant upon a chalk or gravel, it will be better to raise the borders above either to a proper thickness, with good loamy earth, than to sink the borders by removing the chalk or gravel; for although these are removed the whole breadth of the border, which we may allow to be eight feet, and this trench filled with good earth, yet the roots of the trees will in a few years extend this length, and then meeting with the chalk or gravel, they will receive a check whereby the leaves will fall early in the season, and the fruit will be small, dry, and ill-flavoured, and the shoots of the trees will be weak. But where the borders are raised upon either to their full height, the roots will sink down

into

into the gravel or chalk, but rather extend themselves »rar the fufoc, when; they will meet with better foil: and as the trees are of long duration, ami old trees being not only more fruitful than young, but the fruit is alfo better flavoured, therefore the providing for their continuance is abfolutely neceffary.

The foil I would in general ait vile to be tiled for &££, and all other Tons of fruit-trees, is freth untried cart'i, from a pafure ground, taken about ten inches deep, widi the turf, anil laid to cot and mellow at Jeaft twelve months before it is ufrd, mixing a little rotten dung with it; this muft be often turned, to fweten and imbibe the nitrous panicles of the nir.

When the former foil of the border is taken away, tiis frich earth mould' be carried in the place; and if the borders are filled with it two months before the tree* are planted, the ground will be better fettled, and not fo liable to Jink after the trees are planted : b filling of the borders, the ground lould be railed four ur live inches above the level they are defigned, to allow for the fettling.

The borders being thus prepared, make choice of fuch trees as arc but of one year's growth from budding; and if the foil is dry, or of a middling temper, Oftuber is the befl feafon for planting, dpeoally having at that time a greater choke of trees from the nurierics, before they have been picked and drawn over by other people. The manner of preparing thefc tress for planting be in 3 the fame in common with odicr fruit trees, I (hull refer die reader to die article of FEACIIES, where he will find it largely treated of. At the time of planting no jxirt of the head of toe trees lould be cut olt, unlefi there are any frong fortnight (hoots which will not come to the wall, which may be taken quite away.

The trees being thus prepared, you muft mark out the diftances they an- to Hand, which in a good frong foil, or againft 3 low w.iil, flould be twenty feet or more ; but in a moderate one, eighteen feet is a good rcafonable uitancc; then make a hole where each tree is -0 (land, and fhut iii Ken) about four inches from the-wall, inclining the head thereto; and after having c—* die trte in die ground, nail the branches to die o prevent their fhaking, and cover the furtcc e ground round the root with rotten dung, to j out the froit i* in this tate let it remain till the d of February or the beginning of March, when if le weather is good, you muftunnail the branches of your trees, Co as not to dilurb dieir toots ; and, being ponded with a (harp knife, put your foot clofe to the item of the crec t and having placed your left-hand to the bottom of the tret, to prevent its being disturbed, with your right-liand cut orf the head of the tree, if it his but one fteit; or where it may liave two or more fhoots, each of them mull be iliortened, to about ibur or five eyes above the bud, iij that die Hoping lidc may be toward the wall.

In the fpring, if the weather proves dry, it will be neccillary to give the trees a gentle refrefhing with water ; in the duin^ of whi Ji, if tlicy Watered with a rofe to the watering-pot all over their heads, it will greatly liclp them -, anil alfu lay Tome turf, in the manner dirctcd for AppSes, Or fbmc other mulch,

Iround their roots, to prevent their dryip' during the fumrier iV.ion ; and in the fpring, as new branches are produced, obltrvc to nail them to the wall in i hoots • nul jiolition ; and Inch (lixit-, as arc produced fore-right, nouf be entirely displaced. This IE all be repeated as often as ii neccillary, to prevent their hanging from die wall. but by no incuts Hop any of the lboots in furruner.

At Michaelmas, when the trees have done growing, their branches flould be unnailtd, and (Horvn them jr proportion » » their th • ngthi a vigorous branch it-ay bt left eight or nine inches long, but a weak One /iould not be len «bovj; five or fix. J'. • • pole many i erfons will wnder at this direction, cfpecially having i lowed luca a diftmcebetween cbeccret, ai believing, • y this muling-mem, the will will never lie filled •, but my rejlon £K i';is, that I would have no part of

the wall left unfumilhed with bt-nring wood; Which muft frequently be the cafe, it 11 b anics arc left to a greater length at Krlt s for it lcldom hapns, that more buds than two or three upon each b Jhoot -, and thefe arc, for the molt part, fuch at or near the cicreme part of the laft year's wood I ftiur .ill the lower pare of the floocs btoinc naked, no will they rver after produce [hoots; and liis is tifi reafon, we fee £b many trees which have theirbi 1 rimp wood fituated only in the eKuenc part u/ the tree.

When you have Ihortncd the lbou«, be Turc to nail them as horizontally as poffible, for upon this it is that the future good of the tree chiefly depends.

The licond iimmer obltrve, as in the lift, ll fcf pkee all fore-right fhoots as they are produced, nailing in dirothcrclolcto the wall horizontally, lb that the middle of the tree may be keptopen; and never iliorten any of the llioots in fummer, unidi to fumiHi branches to fill vacant places on the wall, and never do tiis later than the ejid of April, for realons lien- aftT given in the article of Peaches. At Michaelmas ftorien thelc ihooB, as was directed for the fir/ yearj the frong ones may be left nine or ten inches, and the weak ones lix or feven at moft.

The following year's inanagement will be nearly the fame with this, but only obferve, diat Apricots produce their blofism buds, not only upon the lift yin's wood, bvit alia upon the curlbns, or lpurs, which arc produced from the two years wood; a great care mould therciore be had in the llunnicr management, not to hurt or difpiaee thefe ; obferve alfu to Ihurten the branches at the winter pruning, lb as to furnilh frch wood in every part of the tree-, and be fure lu cm uut entirely all luxuriant branches, or difplnce them as foon a3 they arc produced; which, if left 10 grow, would txhaul thenourifliment from tile bearing bunches, which in my opinion, cannot be too frong, provided they arc kindly i for the mure vigorous the l roe k, the more likely it is ro re lift the injuries of the weather) though we often fe trees brought to ib wcnlt a condition, tx lo be able onlj faintly to Wow their blofbms, and then moft of the bearing branches have died; which has liven occafion to the owner to imagine it was the cfikct u/ l blight in reality, it was only for want of right manage incut. And, I am fully ptrjmdcd, liaHtie blighti we hear complined of, proceed from nothing elie but this.

These few rules, well executed, together with a little oWervation and care, will be fulhcient, therefore to pretend to prefcribe particular directions for ail the diflerent neccitcntn, or manner of treating rniits, would be inppoJfible; Lut I believe the reader will Bnd what ha* been faid, if duly attended to, willanfwer his de-Cgn; for, without diligent oblcrvatkm, there can be no fuch thing M » Ikilivt nmngt-r, let him have ever lb many or gi»d inUrudioiii lid down to liim.

The Bruffls and Breda Apricots being, for the mnll part, planted tor (bndards, will require veiy little pruning or management; only obfinve to take out all dead wood, or luch branchei at crofs each other l thta muft be done early in autumn, or in the fpring, after the cold weather a pad, ihat the part may not canker where the incilion v; niide.

A R T

These two feet high; untill when they flowers for the spikes are generally more than a foot long, the flowers are yellow, and are propagated either by slips or (Linings in the same manner as the former, and is usually hardy.

The tenth fort produces the Semen Santonttufh, which is much used for worm in children. It grows naturally in the fields; from whence the seeds are brought to Europe; this hath the appearance of our Wild Mugwort; the stems are slender, erect, and garnished with linear winged leaves, and terminated by recurved linear spikes of flowers, which have naked receptacle*. This may be propagated by slips: cuttings in the like manner as the former but the plants should be planted in a dry soil and sheltered situation, where they will endure the cold of our ordinary winters pretty well, but it will be proper to liaw a plant or two in pot, which may be sheltered in winter under a common hot-bed frame to preserve the species.

The ninth fort is our common "Wild SaiuhrmwrH., which grows naturally in (bute parts of Norfolk, and is admitted into gardens.

The tenth fort COWS naturally in Portugal; this is a low under shrub, which grows more than two feet high, and is much of the aspect of our wild fort, and is rarely kept in gardens in this country.

The eleventh fort is the common Sea Wormwood, which grows naturally on the sea coast in most parts of the "En" land, where there are several varieties (if not distinct species) to be found. The most common is a low under shrub, which grows more than two feet high, and is much of the aspect of our wild fort, and is rarely kept in gardens in this country.

The twelfth fort grows naturally on the Alps; this is also a low under shrub, which grows more than a foot high, and is much of the aspect of our wild fort, and is rarely kept in gardens in this country.

The thirteenth fort is the true Roman Wormwood, though it has time never ultd in any of the floops; but is greatly preferred to the Sea Wormwood, because it is less nauseous: and a much pleasanter bitter, and may be had in as great plenty, provided it was cultivated by those who diligently the market with medicinal herbs. This is a low herbaceous plant, which dies in the root in autumn, and is not renewed in the spring; the stems are garnished with small divided leaves, whole underneath; and woolly, the upper part of the stalks are furnished with globular umbels which nod on one side, having naked receptacles. They appear in August, but are rarely succeeded by seeds in England.

This fort is easily propagated by its creeping roots, which may be parted in the autumn, and planted two or three feet asunder, that they may have room to spread; the best time for this is in the middle of October; it will grow in any soil which is not too wet.

The fourteenth fort grows naturally in Sicily; it is an annual plant which grows two feet high, garnished with smooth winged leaves, which have an agreeable taste; the stems are globular and nod on one side. If the seeds of this are permitted to scatter in the autumn, the plants will come up betwixt them if sown with care.

The fifteenth fort is the common Wormwood which grows naturally in lanes and uncultivated places in many parts of the island, and is not often cultivated in gardens. This is easily propagated by seeds, which should be sown in the autumn soon after they are ripe, or if they are permitted to scatter, the plants will come up without any further care.

The sixteenth fort has been supposed to be a variety

A R T

of the common Wormwood: indeed the appearance of the plants are nearly alike, but the stems of the leaves of this are broader and whiter than those of the common and the whole plant is insipid, and continues so in winter.

The seventeenth fort is commonly known by the name of Tree Wormwood; this grows naturally near the sea in Italy and the Levant, and is a woody plant, which grows to the height of six or seven feet high, and is furnished with many small flowers, which are terminated by spikes of globular flowers in the autumn, which are succeeded by seeds here. This plant is easily propagated by cuttings, which should be planted in a shady border during the summer months, and duly watered, take root readily. In autumn some of the young plants should be potted, that they may be sheltered in winter; the other may be planted in a warm border, where they will live, and in winter prove favourable.

The eighteenth fort is a low shrubby plant; the stalk is woolly, sending out a few slender branches, garnished with small leaves growing in clusters; the flowers grow in a roundish bunch, and are (taped like those of Wormwood. This grows naturally in Ethiopia. It is propagated by planting the cuttings any time in summer, and the plants must be sheltered from hard frosts in winter.

The nineteenth fort grows naturally on the Alps; this is a low plant, which grows to the height of a foot and a half high; the stalks are clothed with small white leaves which are like a hand; the flowers are globular, and are produced in clusters at the end of the stalk; these are rarely succeeded by seeds in England. This plant may be propagated by planting the seeds in a shady border during any of the summer months, which, if duly watered, will put out roots, and in autumn they may be transplanted where they are to remain.

The twentieth fort grows naturally at Wedmore is an herbaceous plant, whose stalks die in the winter; and the flowers are produced in the spring, and are succeeded by seeds in England. This may be easily propagated by parting the roots in the autumn.

ARTICHOKE a variety of the Utins Cinara.

As this plant is much better known by its English title than the Latin, I shall treat of it under this head, and refer for its characters to the Latin title of Cinara, under which the other species will be exhibited.

We have two sorts of Artichokes which are cultivated in the English gardens, which we shall distinguish here only by the names they are generally known among the gardeners, and reserve their farther distinctions to their Latin titles.

The first is what the gardeners call the Globe Artichoke. This is a large hardy plant with broad brown scales, which turn inward; the fleshy part at the bottom of the stalks is very thick, and is much preferred to the other, which is called the French Artichoke. The stems of this fort are generally grown taller, and the heads are smaller, and more conical than those of the other sort. The scales are narrower, of a greener colour, and are more outward. The fleshy part which is eaten is not near so thick, and hath a disagreeable perfumed taste; this is usually sown in the English gardens in the month of May, when the greater part of the roots of the other fort are destroyed, and many of the roots supplied the following spring with plants from the French, where they cultivate the latter sort; but since die other has been increased again, this sort has been in most gardens rooted out, to make way for the Globe Artichoke.

The manner of propagating this plant is from slips, taken from the old roots, in February or March, which, if planted in a good soil, will produce large

fur fruit the autumn following; but a» thii U \plant whi i few gardeners, that live nut been iuirrueted in the kitcn-feardfns near London, underiland to mar.../x well, 1 t:ill be die more particular in my direct ions about it.

A: the latter end of February, or in Mwch, according to die earlinels of the icafon, or t'orwardncl* of the bid Artichoke roots, will be tlie proper time for drelling them, which muft be thK performed : with your fpade remove all the earth from nbou: your Itock, down below the part from whence tile y iliofTd five pi'udu^td, clearing the earth i: om between the (hoots with the hands, la la to be able to edge of the goadnels of each, with their proper pofition upon the flock; then make choice of two of the clearcil, ilriiicIV, and molt pmciif ing plants !UB are produced from the under pwt of the tlu^k, which as* much preferable to thr ibol).

which plants which generally grow upon the Irown of the roots; for their here hard woody firms, li) never produce gaodfruit, but are generally what the market people call hogues, which have very little but; on; the scales of their head i .ire irregularly placed; in nipping oil" the i plants youi mull be careful not to injure LvS,ii whkh are to remain (fg a. crop; then «... your thumb fctce off all the other plants and bud. also clofe to the head of the (lock, from whence they art: pasdoced, being very i arical not w ILJVU any of the buds, which will foil produce plants fo as to hurt ihoic which arc Idt: then with youi fold; Jr.iv/ tin- Mth tbot: the two plants which are kit, and with your hands dof ic fait rocach nt"i hem, kpar...Jngthem as faraiunder as they can conveniently be placii without bn. long them, obferving to crap offF the tops of the kavrs •wtiirh lung down with your h... m Mpnild being levelled between the Aocks, you may few ihewon a lmall crop of Spin.idi, which will be taken off be-

the Artichoke! will tovt-r the ground, and be ; co keep them clear from weeds; and toward ilic ter end rf April, or the beginning of May, when d plants begin co (hew their fruit, yniil muft iillylook over your Itocks, and draw up all young IB froi" them; wbi h may have been pm; ticed ince their dreffine and cur off all flickers which arc produced from tneftmuof the Artichoke, !aving only the principal head, Uy which means your fruit will be the larger-, when your Artichokes are fit t» (Other, you iimtt break or cut tli^i (liiwn di... to rhe Curtice 9/the gtwa d, that your flock may make frong frch fhogts before Lhe eml of 0 tober; the ieafon ibr canhinn, or, as the gurdent-rs; erm it, land-in^ them up, ia the midJJe or lies er end of N owni- btr, which ii thus done :

Cur off'all the young flioints quite dof to the iurrice ot'the ground i then Jig between every (lock, Tilling all the earth between etc !^ row of D... 11 idge, a* is done in rlic common method of trenching ground, fo as that the row of Artiel.-... I i' t^aftly ij; the middle of ciih ii: ;e, this will be iimic fit to guard them agtinf t&oftj »nd I would here recom-jnend it to tlic public, as infinitely prdrable to long dung, which B by the uiifkMM eftoi ufcd, and 5 the ocaGon of their fruit ix'iny ihiall, and almuil without any bottom* to them; for there is not any thing fu hurtful to thele, as new dung bein^ buried near, or laiJ abotit them.

Since we hzve exprrienced, that, in very kverv friffts thefe roots are lometiims deftroyed, therefore it is proper to give lhmC direftiona LO [irevent it; chough this rarely happens in dry ground, in which v. have had fTM iril.incts 0" lhetr being k^*d, except tin ilic hard fmls of i... and 1773. In thefe two winters ivnift til"the Acrcd... were deftroyed in EnsUnd; in the lult of tlicc irr.i'-r^, it happened from the lit-tle WK which was? taken of them, then; . . . no'froit fur ID many yeau before, whith h3.* i-jjur^d thtm, thai flw [-<0>k* oied Buy can: • preserve them; but Tint* that had t'roi', many people have r:•: into the otW-; TKt ffiiv of covering all thefe roots of Arti-(huk* witti long dung every winter, which is 3 very

(ad method, becaufe: i he •ing by tign nwr the root5, it very apt to rot the belt plants) : certain I would advi: the earthing (or as it is called by the garden-ers, landing) the Artichokes to be deferred till the lat- tetendi November, or the begining of December, provided the feafon continues temperate and towards Christmas, if there is any danger of fevere froits, to lay a t

quantity of long dung, Peafe-hulls, tanners bark, or any other light covering over the ridges of earth, which will keep out the froit; and this being at a dif- tance i from the roots, will not injure them; but this covering JtiouM Lc carefully taken 08" the 1x-gt' ending of February, or tofater, provided the feafon is mild, or at leaft fo lean as the weather is fo, otherwife the plants will be injured by iu lying too long i upon them.

k will alfo be r, good method, whenever, any roots are dug up in autumn, either to bury them deep in the ground to a pit till fpring, or to lay them in a heap, fo as that they may be eafily covered in hard frofts I a and their may be a fupply, if thofe in the gro: . are deftroyed.

When you Imvj that earthed them up, you have to- thing i' are to do till February or March, by which time thry will h. the green through the ridge of the earth; ... when the weather is proper, muft be dreffed . was before dreffed.

When you have a fized t >make a ntw ptan tium, after having dugged and beat down very . . . dung in the ground "you have allotted !•• that purpose, make choice of .-ich of jrour plane as wot taken from your old Hocks, which • clear, f mnd, and not woody, having feme (ibn to their bottom .li:; i with youir knife cut off that knobbed wood.¹ part, which joined them to the I Sack; and il" thai CutScrifp and render, it is a fgti of its gwdnefs, but if tough and ftrite)', throw it fway as gaud for nothing; then cut off the large outside leaves jretty low, and the middle or hc^rt leaves nay lie above them. Voui plants being thw preparitl (it'tlie weather Li <ry dry, or the pjants have been atiy timr taken from the flock, it will becoiivD to fet them upright in a tub of water for three or four hours before they are planted, wJjith will greatly refrefh them; you muft then proceed tt planting, which muft K clone liy ranging a line ll with the ground, in order to their being placed a&5 in a row; and, with y maining flick, plintther. at two feet diftance from ... other in the r iwt, and if defigned for a full crop, five feet u'll-incivv, . from the row, your plants muft be fet about four inches d rry, and the earth chofed irery filt to their roots, I ferving, if the feafon • va dry, to keep i c m witedred wo or dii e times a week, un- til they are L. . . after which they y leldom reu>

N. D. You rzzy low 3 dan crop of Spinach upon the ground! before you plant your t plants, obferving to Clear it from about them after it is come up. Tltefe plant •, in a kindly frai m, or a fnoit foil, y ill produce die largeIV Mii beft Arch... fime time in August and September, after all the • from the uIJ flockl vtr p.ul; fo : hat if you i: tfnd to continue your Artichoke's throu; h the whole feafon, you muft make a new |... every I .it, oilimvifc'you can- not ptu&fy have fruit longer than two or three monih.

If any of the piann which are planted in the fpring fhould nut fruit in autumn, you may, at the feafon of earthing up) the roots, tie up the leaves ., ith a fmall Willow twig, &c. and by the . . . u) • . . to it, ij iii. th • top of the plant ty be alive grmtd; and wj in the froit comes on, if you wiD cover the top with 1 Gi the fraie, or Peafe-hulls, to prevent their being killed by froit, thefe of PIS will produce fruh in winter, or early in the fpnj*.* But in thiofe pi,ini;utoni where you intend to plant oilier things bct»<n your Arrjebokcs, you muft allow nine or tea feet between the mwv as it often prafticed by; the kitchen-gardeners near I .odon, who low the ground between with K; Jilley or Spinach,

ami plant two town of Cauliflowers, at four fret difl incerovil from row, an.l two fttt and a half afiinder in the rows, lii thiut there arc always five feet allowed for clir Ardchofco to grow; and in May, when the RalEflie or Span h ire taken ofij U117 fow a raw of Cucumbers fur pickling, exa&ly between the *two raws of Cauliflowers, at three Ret distance from each other i .inj Ixrwcn the rows of Cauliflowers and the Artichokes, plant a row of Cabbages or Savoy's tor winter ufc, which, when the Cauliflowers an: drii . . . and ihc Artichoke! gufaered, will have full liberty to grow, and by this tncini the ground is fully employed through the whole fealbn. This has long been the pracllce of the kUcien-e-uti-iicrs near London, who pay large rents for their land, fii arc obliged to get is mmy crops in a year from it as poJiible.

In thole which arc planted at five feet distance row from row, you may plant in every othsir tow a line of Cabbages or Savoy's for winter ufc, which will be gone by the titiu; of landing them up ; in doing oi' whid you miilil lay the whok live feet of earth into one ridge, except the ground be extreme lifif, or the fitans young in botti which cafes you may lay only three feet and a half of the ground in the ridge over the roots, and the remainder may be laid in a IIMIII ridge between ; the feme compaTs of ground miff allii be allowed wlicrc the) arc planud at a wider iliflance.

Ami if in thie Ipring you find your (locks (hoot very weak, which may have been occilionefl either by land fruit, or too much wet, you muft then uncover them, an^ witiu your fpad lootin and break the earth about them i, rjifing a final] Mil about each Hock, levelling tilt refi between the rows, which will greatly help tlicm, and in three weeks, or a month's time after, they are commonly fit to (lip.

Thoiic Artichokes which are planted in a mold ricl foil, will always produce the largdt and belt fruit; lu that where Such a foil can be obtained, it will be proper to make .1 (refi plantation every fpring, to UKceed the old Hocks, (Ud fiupply the tabU' in autumn, Bui the roots will not live through the winter [in a moft foil, fo that your (locks which you intend OuHihl remain to fupply the table early, and lo furnitii plant-! (boVM he in a drier foil. You fould always obicrvc [0 plant thefe in jin open fuatation", and flM under the drip of trees, whT: they will draw up very tall, and produce fmall iirignificant fruit.

Cowl, firojn the re- loinlilarnv the Rowa ... has in fhape to the roots of ... n by the people of this order j thi i ... leaves of theft have lhort fifta I ... the flowers growing clofe in the ground. ... flower in April, but Jcdurn pro- dacefedl in I'nglanil *, however they,multipty fafi by offe B, and fh&ukl have 3 fhury lituation. The time for tnmfplandllg (be rood is the fame as for the former. They ate preferred in liimt- pardens for the fake of variety, but huve li: ic beauty to recoon- mend I hem.

The fifth and feventh forts grow natur.illy in Vit'r, nia and Carolina, from whence I have received their roots; the leaves arife immediately from the roots, havingfearcanyfo, ... cBowen come Up be- tween their leaves, v-iivli Sove lliort foot-Hall ... they ippsci ... in May, but have little beaulty, ... the plants are only kept ... II botanic g.nilitis tül- tic In' ... of vari- ety. They will live in the open air, if they are planted in .1 fiil-ltrred firtuation, or it die furface of (hi; gr> ... is cover <d "it! tan to keep out the froit in winter, and w; ; thrive better in the full ground than ... are propagated byoRitti.

I lie tu ... are common Dragon, which is ufed in medicine. ... lad has beM generally utged in a 'tujuric [jin ... from this under the title of ... alia, in which genus Tournefort has range: ill th'de ... which have compound leaves. ... una lljofr with single leaves he has placed ... Kr Aritni.

This fort is used in medicine, fo is preferred in gar- dens to fignify the mark; it grows naturally in moil

of the southern parts of Europe. This plant hath a large, tuberous, tlehy root, which, in the I ... fpring puts up a firft ... ilaik about ilire; s'<t liigh, wli ... it is tron- tel like the belly of a snake; at the top it fpreads out into ... avej, v.IIILJI are cut into fevo ... narrow fegments ... nult to rlie bottom, which fpread open like a band>at the top of the stalk the flower is produced, which is in fhape ... the cummen Arum, having a very long ... Ltha of a dark purple colour, ftanding erect. ... ih 3 krge piltil of the fame colour, fo that when it is in flower, a mikes no unjl ... the (lower haill f ... through a feat of carrion, tl.it few perfons enn endure it for which rfalbn it hath been bsniihed moit Burden, ... but was ii ... this, a few of the plants ... 'rit n place in jjanlcits, tor the oddnels of the flower. It is very hardy, fowill grow in any foil or finitiff..

to tranl'plant it is in autumn, when thr; ; ... decay. It flowers in June or July, s: ... their stalks de- cay in Setitemljer.

The ninth fort grows natrally in moil places in Vir- ffinia and ... England, but is very diiBcttt & pre- ferve long in a garden. I received lbne root', of thii from NewEnglan ... a few years ago, when i ... continued two years j but the foil being dry, they decayed in fummer: thefe fliolild have a much thady lituation, othei wilt th*y will not thrive. The lenwj of this fort are divided like thoife of the former, but are fmaller, ant! rarely grow more thin nine indies high i the flowers are like thoje of the commori Arum, bu the piltil is longer than the Ipatia. It Bawt; ... in June, and the ftalks deciy in autumn.

The tenth fort grows naturally in Ceylon, and fome other parts of India, fo it ver' impatient of cold : ir is rA plant of humble growth: the leaves come up from the root, having foot-Ltalks about four inches biil<j theft JIT divided into three lobrf, which itr- irinate in points; the flower rife immediudy from the root, ft/witling on a very ihort foot-Hilk ; ihe (ja- tha is long, erect, and of a fine fcarlet within, ... is alfo thr j-iftil. Thi* ufualty appears in M ... and the leaves ikc.ty in Akiguit, but new ones Toon after rife iWim the r^jt. Thii plant tnuil be placed in die tsn-bedof dttbuk-tove, otbenrileit will not thri-c in EngUnd. li'ts propagated by ... m the root, which come out in plenty when ife ... plants are in health.

The eleventh thirteenth, fo ... strength, fifteenth, and fixteeith fw ... , ... roots, which are eaten by the inJ ... inhabitants of all the hot countries, where they B ... ally, and fome of the forts arc en' ... if the inhibit ... of the fugar colonies, as ... culent plants, their roon hiring c.infantly P'aten, a ... the leas ... of some of the forts, part ;,ubrly the fif- teenth, which they oil Indian Kale: the leaves of this are boiled, and fupply the want of other greens.

As there is a confiderable quantity of riidi; all the ywr, a fmall fpot of Rtmind, planted with thr::; roots, will be fufficient to fupply a large ... family. It is cald, m^ / i wholfiane gteen, and in thole countries v. i-erc many of the ... I 1 iiropon vegetable ... are with diffi- culty procured, thij provej a pi ... of fuccedaneus; but they make little diftintti ... of the fpecies, but I have received the roots of three forts, by the com- mon title of Edder; but I terpose the fourteenth fort is the moil commonly cultivated there for their ufe. The fixteenth fort has not been many years introduced among them, but iircameotii' ... from the Spanish Weft-India, where it grows as a great plant. Both thefe have larger roots than the firft, for which reafon they are preterctt ...

All thefe forts are preserved in the garden is of thefe perions, V ... are curious in collecting exotie plants, for the variety or their Iwvei ; their flowers have very little beauty, nor do they often appear in this coun- try. I he plants are propagated eafily by offsets from dieir r'ititi, which they cut out v.entrally; thcle mull bepuuted in poti lil'lei win: light earth, and plunged into i hot-bed, to promote dim r taliinii root ... and

and if they are afterward continued in the bark-IWe, they will make great pragre's, and their leavtii will be larger. They may be kept in a dry (tovc, iijon fhcvu, after drey are well eltablifhed in iht pott, but they will nut be fo frong as the other.

The twelfth fort I was favoured with by Mr. Peter Collinon, F- R. S. who procured the rout from North America, where it natural I¹ grows. ThU requires a moilt foil, and a fludy (kunnoa, but a hardy in re- ppeft of cold. It flowered two veaiS in the garden al Chclfa, but in a very dry liilin decayed. The flowers came vip before there was any appearance of leaves; the fpatha was large, and the piitil fhoit and blunt; the female flowers were ranged each between a fort of cheque work, which was diagonal to the piitil) the Rawer decayed without any appearance of Feed.

The fivenwcnth fort rifesto the height of fix or fcyen feet, with a green jointed (lullt as krge as a walking, flick; the leaves arc placed irregularly at the top of the flalks, growing in a clutter; tiefr arc oblong, and of a light green colour; from between the leav, the flowers come out on the liile ufthe flalk, having a long fpatha of a pale green colour, marked widi white foots, fitting clofe to the ftem of theplant; at their Brft appearance they find erefl, Coon alter thty art horizontal, anil in a little time they decline downward; their lower part h fwdling fo tar as the flowers we ranged on the pitil, above wliicli it is greatly contracted, and toward the top enlarges again, where it is a little open, fo as to ihew the naked part of the pill il, but is twilled again at the top. All the lower pan clofely fulds over the piitil, Jo that it is fcarce difcernible, unlrf the I fat III is opened, which can only be done on one Qde, the other adhering dofelfj to the pitil, fo far upward as the flowers extend tht, naked part of the pillil only being feparated from it; fo that the female (lowers and ftamina are ranged only upon one fide of the piitil, in which it differs from al the other fpeciei which I have ftn.

It grows naturally in the fugar i(lands, and odier warm parts of Ann-rica, chiefly in the low grounds; the whole plant abounds with an acrid juice, lb that if a leaf or part of the (talk is broken, and applied to tin tip of the tongue, it caufcs a very painful Jenfation, and otafuiuu the falivary duels to iwcll, and brings an a great defluuian of faliva; the (talks of this plant arc fometimes applied to the mouths of die at grocs by way of puniflimenc, which is indeed bad enough. This lort is propagated by cutting off the (talks into Itjiuthof threeor four joints, which mull be laid tt dry fix weeks or two months; for if die woundei part h not perfectly heakd over before the cutting, art planted, they will rot and decay: thele ihouTi be planted in linnl pots filled with light, tiidy earth, and : hmp i-i into a moderate hot-bed of tan, being careful tint they have little wet, until they have made good roots; when they are well elVablillicd at bottom, tome of them may be placed in a dry ftove, and others plunged into the uui-bed in the txark-ftove, when they will make the greatfl progrcis, ami produce more (lowers than tile odienu tt'u a cender plant, fo mull be confantly kept in the ftove, and fhwild havi very liwle wet in winter.

The eight a nih Lje is a ft indent plunt, feuding ou jooti from iht IUni and bnnche*, ae leaves Arc large, licort-ihaped, having thrtc lobts or can -. thi; flennen are indented in a lar^c Ipatha i but dwfe tie not Grun- ful In Englanti I¹hii is a tender plant, tij requ&c to be tonilantly kept in the bark ftove, and Btatec at other tender exotic plants, which come from hu countries. It h propagated by cutimji off the bran^ hei which readily put out rooM, fut all meie f)j)ie3 whic are natives of hoc countries, never produce foals in England.

The firft fort is ID very common by the G
and large Handing waters in divers parts of I,
[liar it K ntdlels for me to; iay any I
culture. This is em in autumn, when the
bigin to fall, and the Hems arc changed brov,
making hedges in kitchen -gardens, and for many
other ufej.

The fecood fort, although native of a warm coun!r>-,
yet will bear the cold of our winters in the open
ground, provided it is plumed in a loil not too wet •,
and it' the winter (houkl pruve very ievcre, a little
mulch be kid over die TOOK; it dies to the :•rface
in autumn, and rifcs again the fucceeding fpring;
and if kept fupplied with water in diy weather, will
grow ten or twelve feet high the fame lummer; mid
is very proper to intermix with trees nnd (hrubs, or
tali plants and flowers in bofquets, where, by the
od. Inefi of in appearance, it will have a g>oi effect,
:n adding to che variety. This is propagated by par:
ing the roots early in die fpring, before they begin
ro floot, and will, in a year or two, if your groin *
be good, make very large ftoots, fo that from I each
ftool you may hvvt eight or ten canei prodm • • , but
tlu, never produce* any fpikts of flowers in England.
Thettalki of this fort are brought from l'omn and
Spain, and are ufcd by the weaver*, »s allb to make
filling-rods.

The third fort is fupposed to be a variety of ihe ft-
cond, differing tjierfrom only in having variegated
leaves. But this I much doubt, becaufe die tort with
variegated leaves is much tenderer than the OII
mult be thekend from tlc ftoft, otherwie it wilrn-l
live through the winter in England. The plant n vr •
grows to a third part of ih : height of the other, in I
the leaves are narrower and much Ihorwr; \ I
thet differences may not be occafoned by the m • •
nefs of die plant, I cannot take upon me to
mine; for it is well known, th>t all thofc flants wliii
hive variegated leaves, are much weaker than the

plain, and do not grow large, nor will they resist the cold so well. But is chit a Uipped in be i native of a different country, mil by all the writers who have mentioned it luppoted 10 be different, I have enumerated it among the species-

The two of our offlamby art-of great service to the inhabitants of India, who make mull of ilitirtoitimon Ucnlls of die Items of ihelc canes, which grow to a prodigious magnitude in thiof countries.

We have planu of the fourth fan in the t'nsl'Hi g*r-dena, which are more than twenty fees high; and if lie lrtivei in which they are kept were high enough to admit them, they would, according to appearance, rise to nvice that height. The floou of thij plant are of quicker growth than any other yet known, which rises with an upright stalk j for a strong floot in the COM will rise to twenty feet in five or six weeks, as f have for several years obfervd. Some of thefc items are as large as a man's writ, but in general is big as walking-fticks and when dried nans fit for that purpose as thofc which are imported. The Itavea of this fort are much broader than thofe of the fifth, particularly at their bale-, theft U-avcs are generally put round the tea cherts in their pa, and are fattened together !b as to form * kind of irut.

TJu fifth fort is more rare at jirefent in t'urope, dio' it a the inoft common on the coalt of Mililwr.

They are both tender planu, fo will not live in this country, ualrls they are preferved in a warm ftove; and as their roots freat! very wide, they mould not be confined: therefore to have them produce frong (terns, they muft be planed in large tubs, filled with rich earth, and plunged into the hot-bed in the bark-ftove i and as they naturally grow in marmy low places, they require plenty of water, efpecially when the roots have filled die cubs in which they were planted. When the tubs decay, the brairds may be removed, and the plants permitted to root into the n, which will entourage them io grow to a larger :e-, but thru there mult be care taken when the bed refrdldc with new tan. 10 leave a fufficient quantity if the old tan about thir ram of rlic plants; for they are too much bared, and the new tan laid .. At th'm, whei that heiB, it will fcorch their roots fo that the plants are fmetfraet dcllroml by it. Both lorts are propagated by Hips tVom the foots, which fould be tjkeu off in the bring, that thij- imy be

Established before the winter. The fifth fjt is what the Turks mskr ihcir writing with !t this grows in a valley near mount ilfo on the banks of the rivrr Jordan, but here are nm;c of ilic planu in England. This fon may I .. a' the Uambu.

The first fort hath thick fleshy roots which are jointed, and fend out fibres from every part; the leaves growing upon the first fort-ftalks, arising immediately from the root, these are kidney-shaped, eared at the foot-stalk, and rounded at the top, where they are indented; they are smooth, and of a shining green colour: the flowers grow upon very short foot-ftalks close to the ground, and are hid under the leaves. They are composed of a bell-shaped empalement, of a worn-out purple colour, which is cut into three at the top, where it turns backward: in the bottom is situated the germen, attended by twelve short stamina, which afterward turns to a leathery feed-veffel, divided into six cells, which contain several roundish seeds.

The leaves of the second fort are much larger than those of the first, and stand on longer foot-ftalks, these are pointed and hairy. The flowers are like those of the other fort, growing close to the root, but are somewhat inclining to green on their outside, in all other respects they agree.

The third fort hath smooth blunt heart-shaped leaves, standing on longer foot-ftalks; these are veined and spotted on their upper surface like those of the autumnal Cyclamen, the flowers of this are shaped like die others, but stand on longer foot-ftalks, and are of a darker purple colour. These flowers in April and May, and their seeds ripen in July and August.

The first of these forts is very common, and hath been found wild in some parts of England, though but rarely; it delights in a moist shady place, and is increased by parting the roots in autumn. This is the fort which is used in medicine.

The Canada fort is equally hardy, so will endure our common winters in the open ground, being rarely hurt by frosts, if planted in a dry soil, for too much wet often occasions the roots to rot in winter. This is propagated as the other.

The third fort will also live in the open air in England, being seldom injured by frost; but if the plants are too much exposed to the sun in summer, they seldom thrive well; therefore they should be planted in a border where they may have only the morning sun, in which situation they will spread and increase. These two last grow naturally in several parts of North America.

ASCLEPIAS [so called from Esculapius the first inventor of physic, it is also called Vincetoxicum, from vincere, to overcome, and rogiā, poisons, q. d. a plant overcoming poisons,] Hirundinaria, or Swallow-wort.

The CHARACTERS are,

The empalement is of one leaf, which is cut into five acute segments; the petal of the flower is also of one leaf divided into five oval parts* which are reflexed; in the center is situated five neclarii which encompass the parts of generation these have horns which turn toward the stamina, and are joined in a truncated body inclosed by five scales, which open every way. There are five stamina which are scarce visible, which have five summits, situated between the neclarii, and inclosed by the scales of the truncated body. It hath two oval pointed germen, supporting two short styles crowned by a single stigma. The germen after several branches the large, oblong, swelling seeds ending in a point, together one end, which opens into five valves filled with compressed seeds, lying over each, other like tiles on a cube, and are crowned with a soft dozyfi.

This genus of plants is ranged in Linnaeus's second method of his fifth class, entitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. ASCLEPIAS (Alba) foliis ovatis basi barbatis caule erecto umbellulis proliferis. Lin. Sp. Plant. 314. Swallow-wort with oval leaves bearded at their base, an upright stalk, and a proliferous umbel. *Asclepias albo* flore. C. B. P. 303;
2. ASCLEPIAS (Nigra) foliis ovatis basi barbatis caule superne subvolubili. Lin. Sp. Plant. 216. Swallow-wort with oval leaves bearded at their base, and the upper part of the stalk twining. *Asclepias nigro* flore. C. B. - P. 303.

3. ASCLEPIAS (*Littea*) foliis ovatis acutis caule infirmo, umbellis simplicibus. Swallow-wort with oval pointed leaves* a weak stalk, and single umbels. *Asclepias angustifolia* flore flavescente. H. R. Par.
4. ASCLEPIAS (*Verticillata*) foliis revolutis linearibus verticillatis caule erecto. Lin. Sp. Plant. 217. Swallow-wort with narrow twisting leaves growing in whorles, and an upright stalk. *Apocynum Marianum* erectum *linariae angustifoliae* foliis umbellatum. Pluk. Mant. 17.
5. ASCLEPIAS (*Syriaca*) foliis ovalibus subtus tomentosis caule simplicissimo umbellis nutantibus. Lin. Sp. Plant. 214. Swallow-wort with oval downy leaves, a single stalk, and nodding umbels. This is the *Apocynum majus Syriacum* erectum. Corn. Canad. *Greater upright Syrian Doglance*.
6. ASCLEPIAS (*Amama*) foliis ovatis subtus pilosifolius caule simplici umbellis nectariisque erectis. Lin. Sp. Plant. 214. Swallow-wort with oval leaves, hairy on their under side, a single stalk, with upright umbels and nectarii. *Apocynum floribus amene purpureis corniculis furectis*. Hort. Elth. 31.
7. ASCLEPIAS (*Purpurascens*) foliis ovatis subtus villosis caule simplici umbellis erectis nectariis reflexis. Lin. Sp. Plant. 214. Swallow-wort with oval leaves, hairy on their under side, a single stalk, and upright umbels with inclining nectarii. *Apocynum erectum Novboracense* foliis minus incanis flore ex obsoleto dilute purpurascente. Par. Bat. 33.
8. ASCLEPIAS (*Variegata*) foliis ovatis rugosis nudis caule simplici umbellis subferrilibus pedicellis tomentosis. Lin. Sp. Plant. Swallow-wort with rough, naked, oval leaves, a single stalk, umbels growing close to the stalk, having woolly foot-ftalks. *Apocynum vetus Americanum Wifank* dictum. Hort. Elth. 32.
9. ASCLEPIAS (*Incarnata*) foliis lanceolatis caule superne diviso, umbellis erectis. Lin. Sp. Plant. 215. Swallow-wort with spear-shaped leaves, the upper part of the stalk divided, and erect double umbels. *Apocynum minus reum Canadense*. Corn. Canad. 9.
10. ASCLEPIAS (*Decumbens*) foliis villosis caule decumbente. Lin. Sp. Plant. 216. Swallow-wort with hairy leaves, and a declining stalk. *Apocynum Carolinianum aurantiacum pilosum*. Pet. H. Sic. 90.
11. ASCLEPIAS (*Tuberofa*) foliis alternis lanceolatis caule divaricato piloso. Lin. Sp. Plant. 217. Swallow-wort with spear-shaped leaves growing alternate, and a hairy divided stalk. *Apocynum Novae Angliae hirsutum tuberofa radice floribus aurantiis*. H. L. 649. commonly called *Orange Apocynum*.
12. ASCLEPIAS (*Glabra*) foliis lineari-lanceolatis glabris caule fruticofo umbellis lateralibus. Swallow-wort with smooth, narrow, spear-shaped leaves, a shrubby stalk, and umbels coming out of the sides. *Apocynum erectum Africanum villoso fructu falcis folio glabro angusto*. Par. Bat. 23.
13. ASCLEPIAS (*Fruticofa*) foliis lanceolatis glabris umbellis simplicibus lateralibus caule fruticofo. Swallow-wort with smooth spear-shaped leaves, single umbels coming from the sides of the branches, and a shrubby stalk. *Apocynum erectum Africanum folio falcis lato glabro fructu villoso*. Par. Bat. 24.
14. ASCLEPIAS (*Fillofa*) foliis lanceolatis villosis acutis umbellis simplicibus erectis caule fruticofo. Swallow-wort with hairy spear-shaped leaves, single upright umbels, and a shrubby stalk. *Apocynum erectum Africanum villoso fructu falcis folio lato subhirsuto*. Par. Bat. 24.
15. ASCLEPIAS (*Rotundifolia*) caule erecto fruticofo, foliis subrotundis amplexicaulibus, umbellis congestis. Swallow-wort with an upright shrubby stalk, roundish leaves embracing it, and close umbels. *Apocynum erectum fruticosum folio subrotundo glauco*. Par. Bat. 37.
16. ASCLEPIAS (*Nivea*) foliis lanceolatis glabris caule simplici umbellis erectis lateralibus foliariis. Lin. Sp. Plant. 215. Swallow-wort with a single stalk, smooth spear-shaped leaves, and upright single umbels, proceeding from the wings of the leaves. *Apocynum Americanum foliis Amygdali longioribus*. Plum. Cat. 2.
17. ASCLEPIAS (*Ctirajavica*) foliis lanceolatis petiolatis glabris caule simplici umbellis erectis foliariis. Lin. Sp.

tranplanting after the plants are two years old. It is propagated by feeds, which should be treated in the manner directed for the former. These flower the latter end of July and in August; and in warm seasons, sometimes ripen their feeds in England. Neither of these plants will live long in pots, for which reason I have recommended their being planted in the full ground; but they should have a warm situation.

The twelfth, thirteenth, and fourteenth sorts grow naturally at the Cape of Good Hope. I have all received feeds of the thirteenth sort from Alexandria; and Mr. Peter Collinson, F. R. S. gave me some feeds of it, which were sent him from Minorca, but it is not certain that it grows naturally there, but may have been carried thither from Africa.

These rise with upright shrubby stems to the height of seven or eight feet, and divide into many branches; those of the twelfth sort are garnished their whole length with long, narrow, smooth leaves, ending in a point; from the wings of the leaves the umbels of flowers are produced, upon long foot-stalks; the flowers are white, and grow loosely on the umbel; these are frequently succeeded by short, thick, swelling pods, ending in a point, which are thick set with hairs, and filled with compressed feeds, crowned with a foot down. These flowers from June to October, and the feeds ripen in winter.

The thirteenth sort differs from the twelfth, in having much broader leaves, which are of a darker green; the umbels of flowers are smaller, grow upon shorter foot-stalks, and the single flowers are larger. This flowers at the same time with the former.

The fourteenth sort doth not rise so high as either of the former, and the branches grow at a much greater distance, the leaves are shorter, and are covered on both sides with short hairs. The flowers grow in small loose umbels, and are white; these appear in the same season with the former.

These are propagated by feeds, which may be sown in April on a bed of light earth in the open air, and when the plants are three or four inches high, they should be each planted in a small pot filled with light earth, and shaded until they have taken new root, then they may be placed with other exotic plants in a sheltered situation till October, when they must be removed into the green-house, and during the winter should have but little water; for as they abound with a milky juice, much wet will rot them. The only care these will require, is to shift them into larger pots as they advance in their growth; but care should be taken not to put them in pots too large, and in the summer to place them abroad with other plants from the same country.

These three sorts may also be propagated by cuttings, which if planted in July or August, in a shady border, will soon take root, and may soon after be taken up and planted in pots, and managed as the seedling plants. The thirteenth sort hath lived in the open air in mild winters in the Chelsea garden, but in cold winters they are constantly destroyed.

The fifteenth sort grows with an upright shrubby stalk to the height of six or seven feet, dividing toward the top into three or four branches, garnished their whole length with stiff roundish leaves, which closely embrace them. Toward the upper part, the flowers are produced on their sides, growing in short compact umbels. These are of an herbaceous colour, so make but little appearance; they come out chiefly in autumn and winter. This grows naturally at the Cape of Good Hope, and requires the same culture as the former sorts. There is a variety of this with deep green leaves, which some have supposed to be a different species, but I have raised it from the same feeds. The sixteenth sort grows naturally in the warm parts of America, the feeds were sent me from La Vera Cruz. This rises with single stalks four feet high, garnished with smooth spear-shaped leaves, ending in a point; toward the top of the stalk the umbels of flowers are produced from the wings of the leaves,

which are white, and stand erect; these are succeeded by oblong pointed pods, filled with compressed feeds, crowned with foot down. It flowers in June and July, and the feeds ripen in October.

This plant is tender, so must be raised in a hot-bed, and transplanted into pots filled with rich earth, and plunged into the tan-bed in the stove. It must have but little water, and constantly remain in the stove, otherwise the plants will not thrive here.

The seventeenth sort is also a native of the warm parts of America, the roots of which have been sent to England for Ipecacuaná, from which it may be easily distinguished by its form, this being composed of a great number of small fibres; whereas the true Ipecacuaná hath jointed roots, which run deep into the ground, and are fleshy. There have been many accounts of the bad effects of the use of these roots, as also of the poisonous quality of the plant; so that the public should be cautioned not to make use of it, and also to be careful not to let the milky juice of the plant mix with any thing which is taken inwardly.

This plant rises five or six feet high, with upright stems, garnished with smooth oblong leaves, placed opposite; toward the top of the branches the umbels, or flowers come out, which are single, and grow erect 5 the petals of the flowers are of a scarlet colour; and the horny nectaries in the middle are of a bright saffron colour, which make a pretty appearance; these are commonly a succession of these flowers on the same plant from June to October. The flowers are succeeded by long taper pods filled with feeds, crowned by a foot down, which ripen late in the autumn.

It is propagated by feeds, which must be sown on a hot-bed in the spring, and the plants should be treated in the same manner as is before directed for the former sort; the roots of this may be continued three or four years, but after the second year the plants grow naked, and do not produce so many flowers as before; so that it is much better to raise young plants to succeed the other, especially as they produce plenty of feeds in England.

The eighteenth sort rises with upright stems six or seven feet high, which are garnished with thick oval leaves placed opposite. The umbels of flowers are single; the flowers are white, of a star figure, having five points 5 the pods of this sort are very large, in shape like an ox's testicles, and are filled with flat feeds, lying over each other like tiles on a house. I received the feeds of this sort from the Right Hon. the Earl of Northumberland, who procured it from India.

This plant is tender, so must be preserved constantly in the stove, and treated in the same manner as the two former sorts, and should have very little wet, especially in the winter.

The nineteenth sort I received from Carthage; this hath climbing stalks, which fasten themselves to the neighbouring plants, and rise to the height often or twelve feet; the joints of the stalks are pretty distant from each other; at each are produced two oblong, spear-shaped, hairy leaves, growing opposite, upon very short foot-stalks; the umbels of flowers come out from the wings of the leaves, which are very compact, and the flowers are of a sulphur colour. These appear in August, but have not been succeeded by feeds in England.

This plant is tender, so must be constantly preserved in the stove, and treated in the same way as is directed for the former sorts.

A S C Y R U M. Lin. Gen. Plant. 737. Hypericoides. Plum. Nov. Gen. 51. tab. 7. St. Peterwort.

The CHARACTERS are,

The empalement is four leaved the two outer being narrow and opposite, the two inner are broad, heart-shaped, and erect. The flower hath four oval petals, the two outer are large and placed opposite, the two inner are small. In the center is situated an oblong germen, with a very short style, crowned by a single stigma. This is attended by a great number of busily stamens, which are joined*

joined at their base into four bodies; and are crowned with round funmits. *The germen afterward becomes an oblong pointed feed-yeffel, opening in two valves, and filled with small round feeds. The feed-veffel is inclosed by the two large leaves of the empalement.

This genus of plants is ranged in the third section of Linnæus's eighteenth class, entitled Polyadelphia Polyandria, the flowers having many stamens, which are joined in several bodies.

The SPECIES are,

1. ASCYRUM (*Crux Andre**) foliis ovatis caule teretipaniculâ dichotomâ. Lin. Sp. Plant, 787. *St. Peterwort with oval leaves, a taper stalk, and flowers growing in loose spikes from the divisions of the branches.* Hypericoides ex terra mariana floribus exiguis luteis. Pluk. Mant. 104. called *St. Andrew's Crofs*.
2. ASCYRUM (*Villofum*) foliis hirsutis caule tereti &c. Lin. Sp. Plant. 788. *St. Peterwort with hairy leaves and a stiff slender stalk.* Hypericum Virginianum frutescens pilosifolium. Pluk. Aim. 189.
3. ASCYRUM (*Hypericoides*) foliis oblongis, ramis ancipitibus. Lin. Sp. 1108. *St. Peterwort with oblong leaves and a flattened stalk.* Hypericoides frutescens erecta flore luteo. Plum. Nov. Gen. 51.

The first sort is a low plant, whose (talks seldom rise more than six inches high, garnished with small oval leaves, placed by pairs -, the stalks are slender, and divide into two toward the top. From between the division of the branches, the loose spikes of yellow flowers are produced very small, to make no appearance; therefore the plant is scarce worthy of a place in gardens, except for the sake of variety. The root is perennial, and the plant may be propagated by laying down its branches; it loves a moist soil and a shady situation. This grows naturally in North America; I was favoured with this plant by the Right Hon. the Earl of Northumberland, who procured it from thence.

The second sort grows about three feet high, with upright stalks, garnished with hairy oblong leaves; the flowers are produced at the ends of the stalks, which are of the shape and colour with common *St. Johnswort*, but have only four leaves. This hath a perennial root, but the stalks decay every autumn. It may be propagated by parting the roots in autumn, when the stalks decay, and should be planted in a loamy soil; this some years will produce feeds in England. It grows naturally in Virginia.

The third sort grows naturally in South Carolina, from whence I received the feeds. This plant rises a foot and a half high, with flat stalks, garnished with oval smooth leaves growing opposite; the stalks are terminated by three or four yellow flowers, growing close together* which are larger than those of the common *St. Johnswort*, and the petals of the flowers are hollow. This sort rarely produces feeds in England, but it may be propagated by cuttings made of the young shoots in May, which, if planted in pots, and plunged into a very moderate hot-bed, will take root in five or six weeks, when they may be transplanted into a warm border, where they will endure the cold of our ordinary winters; but in severe frosts they are frequently destroyed, unless the roots are covered with tan to keep out the frost.

These plants have little beauty, so are seldom cultivated but in botanic gardens for the sake of variety.

ASCYRUM BALEARICUM. 7
ASCYRUM MAGNIFLORE. J. CUM.
ASCYRUM VULGARE. J. CUM.

ASH-TREE. See FRAXINUS.

ASHES are esteemed a good superficial dressing for corn and meadow land, as they give a new ferment to such lands as are in any degree sluggish and inactive, and enrich those which are jejune and flow, being endowed with singular qualities to make them prolific.

All sorts of ashes, indeed, contain in them a very rich fertile fait, and are the best manure of any to lay upon cold wetland; but then they ought to be kept dry, that the rain may not wash away their f^ok. Ex-

perience has shown, that the ashes of any sort of vegetable are very advantageous to land, by the improvement that has been made in moist places in England, by burning bean-stalks, fern, furze, heath, fedge, itraw, stubble, &c.

Coal ashes, or such as are made of Newcastle, Scotch, and other pit-coal, are much recommended for fomes; but the first are most approved of, because they contain a greater quantity of nitrous and sulphureous matter than the others, though the rest are good.

There is no dressing so good for grass ground as the sea-coal ashes, especially for cold wetland, and where it is subject to rushes or mosses; for these will destroy both, and occasion the grass to be much finer: but this dressing should be laid on the land early in winter, otherwise they will do harm the first summer; for when they are laid on the ground in the spring, they will cause the grass to burn as soon as the warmth comes on; whereas those that were put on early enough to receive the winter's rain, will be washed into the ground before the warm season, whereby the grass will have the benefit of it the first year. Where the land is poor and sour, producing rushes and mosses only, there should be at least twenty loads of ashes laid upon each acre; for a light dressing will not answer the design of killing weeds and mosses, nor will it be sufficient to enrich land which is cold and sluggish, therefore it will be better to lay a good dressing at first, than to do it at several intervals; for one substantial dressing will continue the land longer in heart than three light ones, besides the advantage before-mentioned.

But these ought to be applied superficially, and not too near the roots of plants; and if so, there are few plants but will receive benefit by them, by their nitrous and sulphureous qualities being washed down by the rain, which will open by the strength of water, and cause it to heave, in some degree, as lime will do when water is thrown upon it.

Wood-ashes are commended as the principal of superficial dressings for land, in that they contain a vegetative kind of fait.

Kiln-ashes, i. e. such as are made of straw, furze, &c. are, by some, accounted as good as any of the spirituous improvements of lands that are lightish; but for such as are heavy, they are looked upon as scarce solid and ponderous enough. These ashes the millers in the west country sift over their corn and grass, which are supposed, by their heat, to cause a fermentation, a hollowing and loosening in the mould; by which means the rains enter it the more easily, and dispose the earth for giving up an augmentation of its vegetative augment.

But these being light, ought never to be sowed nor sited in windy weather, because they would be blown away; and if it could be so ordered as to be done just before snow or rain, it would be the better.

Soap-ashes (i. e. after the soap-boilers have done with them) are very proper for lands that are very cold and sour, and to kill weeds of all sorts: and Sir Hugh Plat mentions one at Ware, who having a piece of land over-run with broom and furze, manured it with soap-ashes, and had an incredible crop of wheat for six years successively.

Pot-ashes, after the pot-ash men have done with them, are esteemed good for moist sorts of land; but as they have been wet, and most of the fait drawn off by the lee, they ought to be laid on much thicker than other ashes.

Turf-ashes are very good for all sorts of land, but especially for clay lands, but will be much better if mixed with lime.

But all these ashes ought to be kept dry, from the time they are made till they are used, else the rains will both wash away their goodness, and all make them clod, especially some of the last mentioned, which will prevent their spreading.

And besides, one load of ashes that has been kept dry, will go as far as two that have been exposed to the rain: and coal-ashes, if moistened with

chamber-lye or soap-suds, will greatly add to their strength.

All calcined vegetables cause a fiery heat and vegetation, and, when wet comes, set the ground to work, by a subtle insinuation unlocking the clods, and quickening the sluggishness of the earth, according to that established maxim among naturalists. That all fermentation is caused by the interposition or mixture of different qualities one with the other.

It is after this manner that coal-ashes operate so admirably in loosening and mouldering stiff clayey grounds, and, as it is usually termed, making it rough, ashy, or sandy-like: and after the same manner, sand mixed with clay does well, especially when it is impregnated with saline qualities.

ASPALATHUS. Lin. Gen. Plant. 767. African Broom.

The CHARACTERS are,

The empalemtis of one leaf which is cut into five equal segments at the top; the flower is of the butterfly kind. The standard is hairy, compressed, and blunt-pointed, the wings are blunt, moon-shaped, and spread open, being shorter than the standard; the keel is bifid, and of the same length as the wings. It hath ten stamina, nine of which are joined and covered by the standard, the other standing separate; these are crowned by oblong single stamens. In the bottom is situated an oval germen supporting a single style, crowned by a pointed stigma. The germen afterward becomes an oval oblong pod, inclosing one or two kidney-shaped seeds.

This genus of plants is ranged in the third section of Dr. Linnæus's seventeenth class, entitled Diadelphia Decandria, the flowers having ten stamina joined in two bodies.

The SPECIES are,

1. ASPALATHUS (*Cbenopoda*) foliis confertis subulatis mucronatis hispida floribus capitatis, Lin. Sp. Plant. 711. *Aspalathus with rough, pointed, awl-shaped leaves, growing in clusters, and flowers in heads. Genista Africana lutea, floribus hirsutis in capitula lanuginosa conglobatis foliis corrodæ aculeatis puberulis.* Hawn. Cat. 11. *Yellow African Broom.*

2. ASPALATHUS (*Indica*) foliis quinatis sessilibus pedunculis unifloris. Lin. Sp. Plant. 712. *Five-leaved Aspalthus growing close to the branches, and one flower on a foot-stalk. Dorycnium Indicum floribus singularibus rubris in pedicellis oblongis filiquis perexiguis.* Raii Supp. 47¹.

3. ASPALATHUS (*Argentea*) foliis trinis Knearibus fericeis stipulis simplicibus mucronatis floribus sparsis tomentosis. Lin. Sp. Plant. 713. *Aspalathus with three narrow silky leaves, single-pointed stipula, and woolly flowers growing thinly. Cytisus Africanus angustifolius fericea lanugine argentatus spica lagopode.* Pluk. Mat. 63.

These plants grow naturally about the Cape of Good Hope, from whence I have received their seeds. The first is a low shrub growing about three feet high, with slender branches, garnished with many trifoliate leaves growing in clusters, which are awl-shaped, pointed, and rough, at the ends of the branches the flowers come out, which are yellow, collected in woolly heads; these are rarely succeeded by pods in England. It is propagated by seeds, which must be obtained from the country where the plants grow naturally, and should be sown in pots filled with light earth as soon as they arrive: if this happens in the autumn, the pots should be plunged into an old tan-bed, where they may remain till spring, when they should be removed into a moderate hot-bed, which will ripen the plants. But when the seeds arrive in the spring, the pots in which the seeds are sown should be then plunged into a moderate hot-bed, and in warm weather the glasses must be shaded in the middle of the day, and the pots frequently refreshed with water. Those seeds which are sown in the spring, seldom grow the same year, therefore in the autumn the pots should be put into an old tan-bed, as was directed for those sown in autumn, and afterward put in a hot-bed the following spring.

When the plants come up, and are strong enough to remove, they should be each planted into a separate small pot filled with light earth, and plunged into a moderate hot-bed, to encourage their rooting again; and as soon as they are established in the pots, they should by degrees be inured to the open air, into which they should be removed in summer, placing them in a sheltered situation, where they may remain till autumn, when they must be carried into the green-house, and in winter should have but little water.

The second sort grows about five feet high, with slender branches, garnished with leaves growing by fives close to the branches; the flowers come out singly upon long foot-stalks, which are of a pale red colour; these appear in August, but seldom are succeeded by pods here. This is propagated as the former, and requires the same treatment.

The third sort rises about four feet high, with a shrubby stalk dividing into slender branches, garnished with silky leaves, coming out by threes; the flowers are purple, downy, and grow thinly on the branches. This is propagated as the two former, and must be treated in the same way as is directed for the first sort. It flowers late in the summer,

ASPARGUS, the first sprigs of herbs before unfolded into leaves, and the young and tender branches that are eatable, are called Asparagus.

ASPARGUS [*h&iri.a.i*], Gr. signifies a young shoot putting forth, Asparagus, Sparagus, corruptly called Sparrowgrass.

The CHARACTERS are,

There are male and hermaphrodite flowers upon different roots; the male flowers are tubulous, composed of six narrow petals, which do not spread open, having six short stamina, but no style or stigma; these are barren: the hermaphrodite flowers have six petals which spread open, six stamina surrounding the germen, and a short style crowned by an obtuse stigma which is prominent. The germen afterward becomes a round berry, having three cells, each including one or two seeds, rounded on their outside, but angular where they join.

This genus of plants is ranged by Dr. Linnæus in the first section of his sixth class, titled Hexandria Monogynia, but with more propriety should be placed in the second order of his twenty-first class, which includes those plants as have the Polygamia on different roots.

The SPECIES are,

1. ASPARAGUS caule herbaceo erecto, foliis fetaceis, stipulis duabus interioribus, una exteriore. Floh. Suec. 272. *Asparagus with an upright herbaceous stalk, bristly leaves, having two inner and one outer stipula. Asparagus fativa.* C. B. P. 489. *Garden Asparagus.*

2. ASPARAGUS (*Maritimus*) caule inermi herbaceo foliis teretibus longioribus falciculatis. *Asparagus with a smooth herbaceous stalk, and longer taper leaves growing in clusters. Asparagus maritimus crassifloro folio.* C. B. P. 490.

3. ASPARAGUS (*Acuticulus*) caule inermi fruticoso, foliis aciformibus rigidulis perennantibus mucronatis asquahbus. Lin. Sp. 449. *Asparagus with a shrubby smooth stalk and rigid leaves, with points which abide in winter. Asparagus foliis acutis.* C. B. P. 490.

4. ASPARAGUS (*Albus*) fipinis retroflexis, ramis flexuosis, foliis falciculatis angulatis muticis deciduis. Lin. Sp. 449. *Asparagus with flexible branches and chaffy leaves growing in clusters, which fall off in winter. Asparagus aculeatis fipinis horridus.* C. B. P. 490.

5. ASPARAGUS (*Retrofractus*) aculeis foliariis ramis reflexis retrofractisque, foliis falciculatis. Lin. Sp. Plant. 313. *Asparagus with single spines, reflexed branches, and leaves growing in clusters. Asparagus Africanus tenuifolius, viminalibus drgis, foliis laricis ad instar ex uno pulchro numerosis stellatis positus.* Piuk. Aim. 40. tab. 375.

6. ASPARAGUS (*Aphyllus*) aphyllus fipinis subulatis triatis inaequalibus divergentibus. Hort. Cliff. 122. *Asparagus without leaves, and awl-shaped: unequal spines which spread from each other. Asparagus aculeatus*

The lirit fort is the common Asparagus, which is cottmed for the ulc E the table, and may have probafaWbccfibuuvtit by tukurc LU da perfection; it nuw a, li DWS n. icuriJly in hire, whict tht llioots ire no larger than draws i but if (b, it in ul have been fr<n very long ailture and goo l management : tir a friTMJ of mine, » no processed some beds of the w J fort, which he cultivated wiih grea[caru, in \<... rich ground, yet could not bring the roots w \oduce moots niori- tiin half the size of the garden kind, which mew ornhe inncngromi i; i but he always found the wild fort came up 3 week or ten days earlier in the spring, and tie fhooos were exceeJin- f

1 have lately had lome tlouli whether the fort of Af-jaragiis which grows naruri in England, was the time wiili that nicniuncj by Cljilp Toume fon and Vaillam both cStat that they had cultivatd that wild fort in [he royal

garden at Paris several years, and it had never altered, therefore I procured specimens of that, which I find to be extremely different from the English fort. The leaves are much finer and : rarer, and are induced in • ch larger clutters; UK branch^ grow mud cloier together, and the foot-stalks of the flowers are longer; therefore i believe it to be a distinct species from our wild fort, which appears to me undoubttkd the same as the Giakn /Ujtaragus.

The Garden Asparagus is propagated by feeds in tin-procuring of w b £ laTfdliiii hii

in for his choice of ilit (foots, and inti • ty in fap-ping wiil the best feeds. Hut d

in potTidHn of I have good beds of Asparagus, it is much the btl

to wliirfi, a fufScic/it number ol the finest beds fhould be marktd early in ths: faring, and V< mottd

tc i run uji i the feeds; because those which are cut after the -ibn for cutting die At

nerly ijr ib backw.irtC as nui to ripen the feeds which the funnmer is wann, and the aununn vtry favour-

able. If the choice of the beds to be sown the feeds, there imift be great regard had to their size and roundness, never leaving any that are inclinable to be Hat, or th

that soon grow open headed, always choosing the rJWirleft, ami fucn .1 • . the choicest tops. Bur l

are barren, a greater numbi of beds should be KI. than might be necessary, if there could be a certainty of their being all fruitful. When the beds are left, it will be proper to thr• a flick down by ea

, but there mult bi- 'nv iinl in or injure L! the crown of the root. These beds will serve as marks to distinguish them from the others when they are all run up.

Toward the end of September tiw berries will be fully ripe, when the stalks (haul be cut • , and the berries stripped into a tub, in which they may remain three weeks or a month or more, by which means the outer hulls will be rotten, then fill the tub with water, and wash your hands

tin. • all the hulls by squeezing them between your

hands. Their hulls will all swim upon the water, but the feeds will sink to the bottom; to thereby parting off the worst quality, the hulls will be carried along with it, and by pouring fresh water two or three times, and stirring your seed about, you will make it entirely clean: then spread the seed upon a mat or cloth, and expose it to the sun and air in dry weather, until it is perfectly dry, when it may be put into a bag, and hinged up in a dry place till the beginning of February, which is the proper season for sowing it; so which time you must prepare a bed of good rich earth made very level, whereas you must dig your l

pLins to be firm; then tread the bed all over to tray the feed in the ground, and make it even smooth. The following summer keep the ground constantly cleared from weeds, which will greatly add to the strength of the plants; and toward the latter end of October, when the haulm is quite withered, you may (pread a little rotten dung over the surface of the ground, about two inches thick, which will preserve the young buds from being hurt with the frosts, &c.

The i ring following the plants will be fit to plant out in good (the plants of more than one year's growth are unfit to remove, as I have often experi- rtdCii for young plants are much better than old, ill produce their roots;) you must therefore and n your ground by treading it well, burying therein a good quantity of rotten dung at the bottom of each trench, that it may be at least six inches below the surface of the ground; then level the whole plot very exactly, taking out all large lumps; but

must not be done long before you intend to plant your Asparagus, in which you must be govern- ed according to the nature of your soil or the season; for if your soil is dry and the season forward, you may plant early in March; but in a wet soil, it is better to wait till the end of that month, or the begin- ning of April, which is about the season that the plants are beginning to shoot. I know many people have advised the planting of Asparagus at Michaelmas, but this I have experienced to be very wrong; for in two different years I was obliged to transplant large quantities at that season, but I had better have thrown away the plants; for upon examination in the spring, I found most of the roots were grown mouldy, and decaying, and I am sure, not one in five of them successful, and those which did were so weak, as not to be worth their breeding.

The season being come for planting, you must, with a narrow pointed dung-fork, carefully dig up the roots, shaking them out of the earth, and separating them from each other, observing to lay their heads down, for the more convenient planting them, which must be performed in this manner:

The plot of ground being levelled, you must begin at one side thereof, treading a line very tight with the pick, throwing out a trench exactly straight, by the line about six inches deep, being careful not to turn up the dung; into which trench you may lay your roots, spreading them with your fingers, and placing them upright against the back of the trench, that the heads may stand forward, and be about two inches below the surface of the ground, and at twelve inches distance from each other, then with a rake, draw the earth into the trench again, laying it very level, which will preserve the roots in their right position; then remove the line a foot farther back, and make another trench in the like manner, laying therein your plants as before directed, and continuing the same distance row from row, only observing between every four rows, to leave a distance of two feet four inches for an alley to go between the beds to cut the Asparagus, &c.

The plot of ground being levelled and levelled, you may sow therein a small crop of Onions, which will not hurt the Asparagus, provided the Onions are not too close, and tread in the feeds, taking the ground level.

There are some persons who plant the feeds of Aparagus in the place where the roots are to remain, which is a very good method, if it is performed with care. The way is this: after the ground has been well trenched and dunged, they lay it level, and draw a line across the ground (in the same manner as is practised for planting of the young plants;) then with a dibble make holes at a foot distance, into each of which they drop two feeds, for fear one should miscarry; these holes should not be more than half an inch deep, then cover the feeds, by striking the earth in upon it, and go on removing the line a foot back for another row; and after four rows are finished, leave a space for an alley between the beds, if it is designed to stand for the natural season of cutting; but if it is to be taken up for hot-beds, there may be six rows planted in each bed, and the distance in the rows need not be more than nine inches. This should be performed by the middle of February, because the feeds lie long in the ground; but if Onions are intended to be sown upon the ground, that may be performed a fortnight or three weeks after, provided the ground is not stirred so deep as to disturb the Aparagus-feeds, in raking the Onion-feeds into the ground.

As the roots of Aparagus always send forth many long fibres which run deep into the ground, so when the feeds are sown where they are to remain, the roots will not be broken or injured, as those must be which are transplanted; therefore will shoot deeper into the ground, and make much greater progress, and the fibres will push out on every side, which will cause the crown of the root to be in the center; whereas in transplanting, the roots are made flat against the side of the trench.

When the Aparagus is come up, and the Onions have raised their feed-leaves upright (which will be in six weeks after planting) you must with a small hoe cut up all the weeds, and thin the crop of Onions where they may have come up in bunches: but this must be done carefully, and in dry weather, that the weeds may die as fast as they are cut up, being careful not to injure the young shoots of Aparagus, as also to cut up the Onions which grow near the shoots. This work must be repeated about three times, which, if well done, and the season not too wet, will keep the ground clear from weeds until the Onions are fit to be pulled up, which is commonly in August, and is known when their greens fall down and begin to wither. When you have drawn off the Onions, it will be necessary to clean the ground well from weeds, which will keep it clean till the alleys are dug to earth the beds, which must be done in October, when the haulm is decayed; for if you cut off the haulm while green, the roots will shoot fresh again, which will greatly weaken them. This young haulm should be cut off with a knife, leaving the stems two inches above ground, which will be a guide for you to distinguish the beds from the alleys; then with a hoe clear off the weeds into the alleys, and dig up the alleys burying the weeds in the bottom, and throw the earth upon the beds, so that the beds may be about four or five inches above the level of the alleys: then a row of Coleworts may be planted in the middle of the alleys, but never sow or plant any thing upon the beds, which would greatly weaken the roots, nor would I ever advise the planting of Beans in the alleys, as is the practice of many; for that greatly damages the two outside rows of Aparagus. In this manner it must remain till spring, when some time in March, the beds should be hoed over, to destroy all young weeds; then rake them smooth, and observe all the succeeding summer to keep them clear from weeds, and in October dig up the alleys again, as was before directed, earthing the beds, &c. The second spring after planting, some persons begin to cut some of the buds of Aparagus for use, though it would be much better to stay until the third year; therefore now the beds should be forked with a flat-pronged fork made on purpose, which is commonly

called an Aparagus-fork: this must be done before the buds begin to shoot in the spring, and should be performed with care, lest you fork too deep, and bruise the head of the root; then rake the beds over smooth, just before the buds appear above ground, which will destroy all young weeds, and keep your beds clean much longer than if left unranked, or if done so soon as forked. When the buds appear about four inches above ground, you may then cut them; but it should be done sparingly, only taking the large buds, and suffering the small to run up to strengthen the roots; for the more you cut, the greater will be the increase of buds, but they will be smaller and the roots sooner decay. In cutting the buds, you must open the ground with your knife (which should be very narrow-pointed, and long in the blade, and filed with teeth like a saw) to see whether any more young buds are coming up close by it, which might be either broken or bruised in cutting the other, then with the knife saw it off about two inches under ground. This may appear a very troublesome affair to people unacquainted with the practical part, but those who are employed in cutting Aparagus, will perform a great deal of this work in a short time; but care in doing it is absolutely necessary to be observed by all who cut Aparagus.

The manner of dressing the Aparagus-beds is every year the same as directed for the second, viz. keeping them clean from weeds in summer, digging the alleys in October, and forking the beds toward the end of March, &c. only observe every other year to lay some rotten dung (from a Melon or Cucumber-bed) all over the beds, burying some in the alleys also, at the time for digging them up. This will preserve the ground in heart to maintain the roots in vigour, and by this management, a plot of good Aparagus may be continued for ten or twelve years in cutting, and will produce good buds, especially if it is not cut too long each season; for when it is not left to run up pretty early in June, the roots will be greatly weakened, and the buds will be smaller: therefore, in those families where Aparagus is required late in the season, a few beds should be set apart for that purpose, which will be much better than to injure the whole plantation, by cutting it too long.

I cannot help taking notice of a common error that has long prevailed with many people, which is, that of not dunging the ground for Aparagus, believing that the dung communicates a strong rank taste to the Aparagus, which is a great mistake, for the sweetest Aparagus is that which grows upon the richest ground; for poor land occasions that rank taste so often complained of, the sweetness of Aparagus being occasioned by the quickness of its growth, which is always proportionable to the goodness of the ground, and the warmth of the seasons. In order to prove this; I planted two beds of Aparagus, upon ground which had dung laid a foot thick, and these beds were every year dunged extremely thick, and the Aparagus produced from these beds was much sweeter than any I could procure, though they were boiled together in the same water.

The quantity of ground necessary to be planted with Aparagus, to supply a small family, should be at least eight rods, less than that will not do; for if you cannot cut one hundred at a time, it will scarcely be worth while, for you must be obliged to keep it after it is cut two or three days, especially in cold seasons, to furnish enough for one meal; but for a larger family, sixteen rods of ground should be planted, which if a good crop, will furnish two or three hundred each day in the height of the season.

But as there are several people who delight in having early Aparagus, which is become a very great trade in the kitchen-gardens near London, I shall give proper directions for the obtaining it any time in winter.

You must first be provided with a quantity of good roots (either of your own raising, or purchased from such

uch gardeners as plant for EJC.) filch ss have been
 no or three years planted out from the <...>
 and having fixed upon tin- ; one you would willingly
 have: your Afrtragu- fit to cut, about six weeks be-
 fore, you ihon- prepare a quantity of new fiddle
 hirc-dung, which liiouUl be th... in a heap for
 i Jays or more, to femr... making these into a
 after with i ;[-, thien it . ovei
 re it muft lie anothei week, when :* will
 : ht for lift. Then dig out it trench in the ground
 :id to matt the bed, the width of the
 nes tfo . • defigned :- cover it, and the length
 tion co the quantify you intend to have
 (which is defigned only to fupr . • * Im ill family, three
 or four lights at a time will be fufficknt,) but for a
 larger family, (x)r tight lights will nmlx* too much :
 i lay i lung into the trench, working
 : very regular
 norc, when the beds are made in December; then
 earth thereon noon' fix inches ;lick, break-
 ing the clods and • Ing it level; and 3E one end, be-
 gin laying your roots againft a. little ri Jgc • of earth,
 raised ab air tour inches high: your rrmrt inquit be
 mid as cluli; as }ofTibk' ont t to the other, in rows, with
 their buds flanding upright; and between every row
 ay a fmmll quantity of fine mould, obferving to keep
 the crown of the roots exoBXY lev! . VVhen you have
 nifhed I... your bed with roots, you muft lay
 bine itiff'i-lu-th up to the roots, 01... the outfides of the
 bed, whi b are bare, to keep them from drying;
 and I thruft two or three fharp-pojKcd (ticks, about
 two feet long, ' JVTI between the roots, in the
 F the bet!, at a difcance from each other. The nfc
 of thfe fticks is to inlurm j... what temper of heat
 de bed b in, which you may find by drawing up the
 fticks, and... and if, after the
 d hit. been nwdi... a week, you find it doth not heat,
 you may lay a little draw or liner round the fticks,
 and alfo upon the top, - • I will greatly help it; or
 if you find it very hot, fo as to endanger the decay
 of the roots, it will be ad... to let it remain
 wholly uncovered, and to thruft a large ftick into the
 dung, on each fide of the bed, in two or three places,
 to make holes for the great ftream of the bed to pafs
 off, which in a fhort time will... deduce the b :
 to a moderate heat.
 After the bed has been made a fortnight, vml... muft
 cover the crown of the roots with fine earth, about
 two inches thick; and when the buds begin to appear
 above ground through their earth, you muft again lay
 on a frefh quantity, about three inches thick; fo that
 in the whole, it may be five inches above the crown
 of the root, which will be fufficient.
 When you mud make a band of ftraw for Ion...
 about four inches thick, w ;.iJimuftbe... around
 the fides of the bed, that the upper part may be level
 with the furface of the ground: this muft be fattened
 with ftreak fticks about two feet long, fattened at
 the points, to... and upon this band
 you muft fix your frames, and put your glaffes there-
 on; but if, after your bed hath been made three
 weeks, you find the frame declining, you muft lay a good
 lining of ftraw... the fides of the bed,
 which will alfo... and in bad wea-
 ther, to alfo every night... keep the glaffes covered
 with mats and ftraw; but in the day time, let it be
 all taken off, especially whenever the fun appears;
 which... being through the glaffes, will give a good
 colour... w Alparagus.
 A... us made, if it works kindly, will begin to
 do for cutting, in about ii. fvc or fix...
 which, [•...
 r to !

 io that where A"]...
 until the feifon of...
 bed (koutd be i

in March, it •.l. left till the feifon of "nature!
 ragus; for the El... beds will chine a fortnight earlier
 tooitaftermzking, ihantiaai.- macit . about Chriftmas;
 and the buds will be br... and better coloured, as
 they will then enjoy a greater fhare of the fun.
 When this method of forcing early Alparagus is in-
 tended, there Ihou... be every year fuch a quantity
 pinnted, w]... which you fhall judge neceffary (unlefs you
 intend to buy the r... from fome other garden); the
 quan.:- of roots neceffary to plant one light, is com-
 monly known by the n... of the ground where they
 grow; for when there is a good cry... and few roots
 are miffing, one re... of ground will furnish enough
 for a light; but this calculation is made from the
 ground pLar, i... with some, which are defigned to be
 taken up after two or three years growth for forcing,
 in which there are fix roots in a bed, or but ten inches
 dlftanee... and the plants might be nine inches afunder
 in the row; bin... where there is a greater fpace be-
 tween the rows, and fewer roots in a bed, then there
 muft be a greater quantity of ground allotted for each
 light. Many of the kitchen gardeners about London,
 take up their Alparagus roots after two years growth
 from planting; but when the land is not very good,
 it is w... to let it have three years growth, for
 if the roots 2... week, the beds of Alparagus will be
 very fimll, to not want the trouble of forcing. The
 be ft ground... the planting Alparagus, to have large
 roots for hot... beds, is a small rich fill, but for those
 that are to remain for a natural produce, a middling
 foil, nt... other top wet not too dry; but a frefh fandy
 loin-. when well dunged, is preferable to any other.
 The forced lot is propagated to grow naturally in
 Wales, and alfo near London: I have received feeds
 from the Ifland of Portugal, which have fucceeded
 in the Chelsea garden, by which I am convinced it
 is a different fpecies from the Garden Alparagus; and
 alfo from the wild fort which grows naturally at Gibral-
 tar, and alfo near Montpellier, is different from both.
 Mr. Stappol, of Montpellier, was alfo of the op...
 nion... that it was a different fpecies, for he fays, the con...
 wild Alparagus and this grow near each other...
 in die neighbourhood of Montpellier, and the young plants
 of the former were fweet, whereas thofe of the latter
 were bitter. The fame has been confirmed to... by
 feveral gardeners, who have related many years...
 at Gibraltar and Minorca, where the forced lot g...
 naturally in plants.
 This fort is propagated by feeds in the fame manner
 as the garden kind, but muft have a warmer fituation;
 and the roots fhould be well covered in winter, to
 prevent the froft from penetrating the ground, which
 will deftroy it.
 The third fort hath white, crooked, ftrubby ftalks,
 wiitli... • four or five feet high, but have 90 ftints
 <jil til*... the leaves come out in clufters from...
 the lower part, like thofe of the Larch-tree; the... are
 very fhort, and end in fharp prickles, fo that they
 are unpleafant to handle. This fort grows naturally
 in the South of France, Spain, and Portugal. It is
 propagated by feeds as the former fort, but is too
 tender to live abroad in England, fo the roots fhould
 be planted in pots, or near a ftone wall, and fheltered
 in winter.
 The fourth fort grows with fliruliby (bills th... or
 four :... high, with very white buds, and are armed
 with thorns which are fingle, coming out juft below
 tacli I... of leaves. These ftalks continue feveral
 years, and put out many bunches, garnifhed with
 narrow fhirt leaves. These continue green all the
 winter, if the plants are fheltered from fevere froft.
 It is propagated by feeds as the former, which may
 be procured from the Mediterranean, where it grows
 naturally; fome of the plants fhould be kept in pots,
 that they may be fheltered in winter, and the others
 may be planted in the full ground in a warm fituation,
 and in hard froft covered, otherwife it will not live
 abroad in this country.
 The fifth fort grows naturally at the Cape of Good
 Hope. This hath very crooked irregular ftalks, which

are thrubby, and rise eight or ten feet high, putting out several weak fide branches, garnished with long narrow leaves, coming out in clutters like those of the Larch-tree, under each of these clutters is placed a single sharp thorn. The stalks continue several years, and the leaves keep green all the winter. This is commonly propagated by parting the roots, because the plants rarely produce seeds in this country, the best time for this is in April. The roots must be planted in pots, and removed, into the green-house in the autumn, for these plants will not live abroad in England.

The sixth fort grows naturally in Spain, Portugal, and Sicily, generally in rocky places. This sends up many weak irregular shoots, which have no leaves, but instead thereof, are armed with short stiff thorns, which come out four or five together from the same point, and spread from each other every way. The flowers are small, of an herbaceous colour, the berries are larger than those of the common fort, and are black when ripe. This is tender, so must be treated as the third fort.

The seventh fort grows naturally at the Cape of Good Hope. This sends up from the root several tender stalks, which put out weak branches, declining downward; these are dolefully garnished with brittle leaves, like those of Garden Asparagus, which continue green through the year. It hath not produced any seeds in England, so is only propagated by parting the roots, as the fifth fort, and the plants should be treated in the same manner.

The eighth fort grows naturally at the Cape of Good Hope, this sends up many weak shoots growing in clutters, which are armed with sharp spines, both on the side and ends of the shoots, the leaves come out in small clutters, which continue green all the year. This doth not produce seeds in England, so is propagated as the fifth fort, and requires the same treatment.

The tenth fort sends out from the root many weak climbing branches which rise five or six feet high, garnished with narrow spear-shaped leaves coming out single, the shoots are armed with short crooked spines, which render it very troublesome to handle the plants, for they are so closely set on, that it is difficult to touch the branches. This is propagated by parting the root, but the plants must be placed in a moderate stove, otherwise it will not thrive in this country. It grows naturally in the island of Ceylon.

These plants are preferred in the gardens of the curious, where they add to the variety; being not difficult to manage, where there is conveniency to house them in winter. They should have a place among other exotic plants.

ASPARAGUS SCANDENS. See MEDEOLA.
ASPEN-TREE. See POPULUS.

ASPEHIFOLIUS plants [asperifolius, of asper, rough, and folium, Lat. a leaf] are such plants as are rough-leaved, having their leaves placed alternately, or without any certain order, on their stalks: the class of plants so denominated by Mr. Ray, have a monopetalous flower, cut or divided into five parts; after every flower there succeed commonly four seeds. Of this class are Bugloss, Borage, Comfrey, Hounds Tongue, &c.

ASPERUGO, small Wild Bugloss.

The CHARACTERS are,

The empakment is of one leaf, cut lightly at the top into five equal parts \ the flower is of one leaf, having a short cylindrical tube, cut at the top into five small fluted parts, which are closed at their base: it hath five short stamina, pwnned by cblong fummits \ in the center there are four con-prefed germen, supporting a short slender style, crowned with a blunt stigma. The germen are four, and the seeds are four, enclosed in the mpalemi

This genus of plants is ranged in the first section of Linnaeus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one fruit?

We know but one SPECIES of this gen, which is, ASPERUGO. Fior. Lapp. 76. *S. arvensis* L. *S. arvensis* L.

Goose Grafts, or German Madwort. Buglossifolium fylestifum caulibus procumbentibus. C. B. P. 257.

This is an annual plant, which is found wild in some parts of England, as near Newmarket, at Boxley in Suffex, and in Holy Island. It is preferred in botanic gardens for variety, and may be easily propagated by seeds, which should be sown in autumn; for if the seeds are kept out of the ground till spring, they do not succeed so well. When the plants come up, they require no other culture but to keep them clear from weeds, and in May they will flower: in June their seeds will be perfected, which, if suffered to scatter, will grow again in autumn; so that when this plant is once brought into a garden, it will maintain itself, provided it be allowed a place.

ASPERULA, Woodroof.

This plant grows wild in shady woods in many parts of England, and flowers in April or May, and is sometimes used in medicine.

Dr. Linnaeus has joined to this genus the *Gallium album*, *Gallium montanum*, and *Rubia fyanthica Saxatilis*. C. B. But as these grow wild in England, and are rarely admitted into gardens, I shall pass them over with just mentioning them.

ASPHODELUS [*Asphodelus* Gr. by Pliny it is called *Asphodelus*, or *Baccillus Regius*, because when it flowers, the stalk resembles a royal scepter.] *King's Spear*.

The CHARACTERS are,

The flower has no empakment \ it is of one leaf cut into six parts, which spread open; at the bottom is inserted a globular nectarium, having six valves; it hath six awl-shaped stamina, which are inserted in the valves of the nectarium, and are crowned by oblong fummits, which are prostrate, and turn upward \ between the nectarium is placed a globular germen, supporting an awl-shaped style, crowned by a club-like stigma: the empalement afterward becomes a fleshy globular seed-vessel, having three cells, which are filled with triangular seeds.

This genus of plants is ranged in the first section of Linnaeus's sixth class, entitled Hexandria Monogynia, the flower having six stamina and one style.

The SPECIES are,

1. ASPHODELUS (*Luteus*) caule folioso, foliis triquetris fistulosis. Hort. Cliff. 127. *King's Spear with a leafy stalk, and triangular fistular leaves.* *Asphodelus luteus* & flore & radice. C. B. P. 28,
2. ASPHODELUS (*Ramosus*) caule nudo foliis ensiformibus carinatis laevibus. Lin. Mat. Med. 172. *King's Spear with a naked branching stalk, and smooth, sword-shaped, carinated leaves.* *Asphodelus albiis ramosus* mas, C. B. P. 28.
3. ASPHODELUS (*Albus*) caule nudo simpliciter foliis lineari-ensiformibus. *King's Spear with a single naked stalk, and narrow sword-shaped leaves.* *Asphodelus albus non ramosus*. C. B. P. 28,
4. ASPHODELUS (*Fistulosus*) caule nudo foliis frigidis subulatis triatis fistulosis. Hort. Cliff. 83. *King's Spear with a naked stalk, fistular awl-shaped leaves, and an annual root.* *Phalangium parvo flore ramosum foliis fistulosis annuum*. H. L.

The first fort is the yellow Asphodel, which is used for use in medicine, this hath roots composed of many thick, fleshy, yellow fibres, joined into a head at the top; from whence arise strong, round, single stalks, near three feet high, garnished their whole length with long triangular leaves, which are boat-shaped, of a sea-green colour the upper part of the stalk is adorned half way with yellow star-shaped flowers, which begin opening from the bottom, and are followed by others above; so that on the same spike, there is often a succession of flowers for a month. It flowers in June, and the seeds ripen in autumn;

There is a variety of this with a larger flower, mentioned in the catalogue of the Royal Garden at Paris, by the title of *Asphodelus spiralis luteus*. Italicus magno flore, the seeds of which I received from the garden at Pisa, some years ago, and the first year of the plants flowering in Chebea garden, the flowers were larger, and the spikes longer than those of the common

A S P

Common fort -, but in two years time, they were [a like the common fort as not to be distinguished from it, as were also the young plants which were raised from the feed sowed at Chelsea, therefore it should be esteemed an accidental variety.

The second fort hath roots composed of many thick fleshy fibres *, to each of which is fattened an oblong tuber, as large as small potatoes *, the leaves are long and flexible, having acute edges; these grow in irregular clutters, from the crown of the root *, between these come out the stalks, which rise more than three feet high, sending out several side branches, which are naked; the upper part of these are adorned with many white star-shaped flowers, consisting of one leaf cut into six parts, each having a purple line running lengthways on the outside of each segment. The flowers grow in long spikes, flowering gradually upward. They appear the beginning of June, and the feeds ripen in autumn.

The third fort hath roots like the second, but the leaves are longer and narrower; the stalks of this are single, never putting out any side branches; the flowers are of a purer white, and grow in longer spikes. This flowers at the same time with the former.

The fourth fort is an annual plant, the roots of this are composed of many fleshy yellow fibres, the leaves are spread out from the crown of the root, close to the ground, in a large cluster; they are convex on their under side, but plain above, and hollow like a pipe; the flower-stalks rise immediately from the root, and grow about two feet high, dividing into three or four branches upward, which are adorned with white starry flowers, with purple lines on the outside. These flower in July and August, and their feeds ripen in October, soon after which the Plants decay. It grows naturally in the south of France, Spain, and Italy.

The first fort grows naturally in many of the islands of the Archipelago, and also in Sicily. The second, third, and fourth forts grow naturally in Portugal, Spain, and Italy; the third fort is not quite so hardy as either of the other, so in very severe winters it is sometimes killed, unless the roots are covered in winter. The yellow fort multiplies very fast by roots, and will soon overpread a large border, if suffered to remain unremoved, or the side roots are not taken off; but the other forts are not so productive of shoots from their sides, and are much better kept within bounds.

The second and third forts do not increase very fast by their roots, nor should they be often transplanted, for that will weaken them, so that their flower-stems will not rise so tall, or produce so many flowers, as when they are left undisturbed for some years * therefore the best way is, to propagate these by feeds.

These three forts of Asphodel are very pretty ornaments for a flower-garden, and, requiring very little trouble to cultivate them, are rendered more acceptable. They may be all propagated by feeds, which should be sown soon after they are ripe, on a warm border of light fresh earth: in the spring the plants will appear, when you should carefully clear them from weeds, and in dry weather they must be frequently watered: if this be duly observed, the plants will have acquired strength enough to be transplanted by the Michaelmas following; at which time you must prepare a bed of fresh earth in the flower nursery, into which you should plant the roots, at about six inches distance every way, observing to plant them so low, as that the top of the roots may be three or four inches under the surface of the bed; and some old tan, or dung, should be spread over the surface of the ground, to keep out the frost: in this bed they may remain one year, during which time they should be kept clear from weeds; by which time, the roots having acquired strength enough to produce flowers the following year, they should, in autumn, when their leaves are decayed, be carefully taken up, and transplanted into the flower-garden, observing to place them in the middle of the borders, amongst

A S T

other hardy kinds of flowers, where being properly intermixed, they will make an agreeable variety, and continue a long time in flower.

The fourth fort is an annual plant, so is only propagated by feeds *, these should be sown in the autumn, when they will more certainly grow than if sown in the spring: when the plants are up, they will require no other trouble but to keep them clean from weeds, until they have put out four or five leaves, when they should be carefully removed to the places where they are to remain for good. If the feeds of this plant are permitted to scatter, the plants will come up without care, and those which are not removed, will be the strongest plants, and produce a greater number of flowers.

ASPLENIUM, or Ceterach [is so called from a privative, and *Asplen* the spleen, because good against diseases of the spleen.] Spleenwort or Miltwaffe.

The CHARACTERS are,

The leaves are like those of the Polypody, but less and pretty round* notched toward the side* downy on their under side, having aqueous dust* in which* by the help of a microscope* membranous capsule* or seed pods* lying close to one another* are perceived* every one furnished with a little round cord* which by its contraction opening the fruit into two parts* pours forth certain very small seeds: the root is fibrous. This plant thrives in stony places* as in walls* 67r.*

This plant is of the Fern kind, and grows upon old moist shady walls in divers parts of England; but is never cultivated in gardens. There are several species of this plant in America, but they have not been introduced into England.

ASTER [*Astris*, Gr. a Star-, so called because the flower is radiated with little leaves after the manner of a star.] Starwort.

The CHARACTERS are,

It hath a compound flower composed of several female and hermaphrodite florets* included in one common scaly empalement; the rays or border of the flower is composed of several female florets* whose upper parts are stretched out on one side like a tongue* and indented in three segments at the end the hermaphrodite florets form the disk or middle 1 which are Jewel-shaped* and divided at the top into five parts* spreading open* and have each five short slender juncos* crowned with cylindrical Juncos* in the bottom is placed a crowned germen* supporting a slender style* crowned by a bifid stigma* the germen afterward becomes an oblong feed* crowned with down: the female flowers have a germen supporting a slender style* crowned by two oblong stigmas, which turn backward. These have no stamina* but in other respects are like the hermaphrodite flowers.*

This genus of plants is ranged in the second edition of Linnaeus's nineteenth class, entitled Syngenesia Polygamia superflua, from the same flower having female and hermaphrodite florets included in the same empalement.

The SPECIES are,

1. **ASTER** (*Alpinus*) foliis lanceolatis hirtis, radicalibus obtusis, caule simplicifloro unifloro. Lin. Sp. Plant. 872. Starwort with hairy spear-shaped leaves* those at the root blunt* and a single stalk* having one flower. After montanus caeruleus magno flore foliis oblongis. C. B. P. 267.
2. **ASTER** (*Amellus*) foliis lanceolatis obtusis scabris trinerviis integris, pedunculis nudiusculis corymbosis squamis calycinis obtusis. Lin. Sp. Plant. 873. Starwort with rough* blunt* spear-shaped leaves* which are entire* having three veins* naked foot-stalks* flowers in a corymbus* and blunt scales to the empalement. After atiticus caeruleus vulgaris. C. B. P. 267. vulgarly called Italian Starwort.
3. **ASTER** (*Tripolium*) foliis lanceolatis integerrimis carnosis glabris ramis inaequalis, floribus corymbosis. Lin. Sp. Plant. 872. Starwort with smooth* fleshy* spear-shaped leaves* which are entire* unequal branches* and flowers in a corymbus. After maritimus Tripolium di&us. Raii Hilt. 270.
4. **ASTER** (*Linifolius*) foliis linearibus acutis integerrimis, caule corymboso ramofliformi. Hort. Cliff. 408. Star-

The firft fort grows naturally upon the Alps, where it feldom rifes more than niffe inches high, and when tranfplanted into a garden, not above fixteen. It fends up fingle ftalks from the root, which are thinly garnifhed with oblong leaves; at the top of each ftalk is one large blue flower, fomewhat like thofe of the Italian Starwort. This flowers in June; the root is perennial, but muft be planted in a fhady fituation, and a moift foil. It is propagated by parting the roots, which fhould be done in autumn.

The fecond fort is the Italian Starwort, which was fome years paft more common in the gardens than at prefent, for fince the great variety of American Starworts have been introduced into England, this fort hath nor been fo much cultivated, though it is by no means inferior to the beft of them, and, in fome refpe&ts, preferable to moft of them; for it is not fo fubjeft to creep by the root, as many of the American forts do, whereby they often become troublefome in fmall gardens, nor do the ftalks require fupporting as they do, for thefe feldom grow more than two feet high, and the ftalks are generally ftrong, foare very rarely broken by the wind. Thefe grow in large clufters from the root, and each of them branch at the top into eight or ten foot-ftalks, each of which is terminated by a fingle large flower, having blue rays, with a yellow difk. It flowers in October, and, in mild feafons, will often continue till the middle of November, during which time they are very ornamental plants in a garden. This fort is propagated by parting the roots, the beft time for this work is foon after they are out of flower, for thofe which are removed in the fpring v/ill not flower fo ftrong the fucceeding autumn. Thefe roots fhould not be removed oftener than every third year, wherethey are expected to produce many flowers.

It grows naturally in the vallies of Italy, Sicily, and Narbonne, and is generally fuppofed to be the Amellus mentioned by Virgil in his fourth Georgick, to grow in the paftures; the leaves and ftalks being rough and bitter, die cattle feldom browfe upon it, fo that whenever there are any of thefe roots in the fields, they fend up a thick tuft of ftalks, which, being left after the grais is eaten bare, thefe being full of flowers, make a fine appearance, and therefore might engage the poet's attention.

The third fort grows naturally in fait marfhes, which are flowed by the tides, and is feldom admitted into gardens. It flowers in July and Auguft.

The fourth fort is a native in North America, but has been many years in the Englifh gardens. It fends up many ftrong fhoots from the root every fpring, which rife between two and three feet high, garnifhed with oblong leaves, placed alternately, and half embrace the ftalk with their bafe; from the main ftalks,

many fide branches are put out, for near half their length, thefe are garnifhed with fmaller leaves, which diminifh in their fize to the top, where there is a fingle flower, terminating the ftalk, of a blue colour* This flowers in Auguft and September; it is eafily propagated by parting the roots, foon after the flowers are paft, and will thrive in almoft any foil or fituation.

The fifth fort fends up many ftalks from the root* which rife five feet high; garnifhed with fpear-fhaped leaves which are entire, and half embrace the ftalks, which are terminated by large purple violet flowers, growing in ajoofe panicle: it flowers in Auguft, and is very hardy, fo may be planted in any foil or fituation, and is propagated by parting the roots.

The fixth fort grows naturally in North America. This hath broad heart-fhaped waved leaves at the bottom, the ftalks rife between two and three feet high, which fend out fmall fide branches, upon which the flowers come out in loofe fpikes, which are of a very pale blue colour, inclining to white. This flowers in the fame feafon as the former, and may be propagated in the fame manner.

The feventh fort fends up feveral ftrong ftalks, upward of two feet high, which are of a purple colour, garnifhed with fpear-fhaped fmooth leaves, whofe bafe embrace the ftalks half round; the flowers grow upon fingle foot-ftalks, forming a corymbus at the top, and are of a pale blue colour, thefe appear the latter end of September. This comes from North America, and may be propagated in the fame way as the former.

The eighth fort rifes with flender ftalks, upward of three feet high; fending out many weak branches on every fide, garnifhed with very fmall leaves, the flowers come out on fhort foot-ftalks, on every fide of the branches, thefe are fmall, with white rays and a yellow difk. They appear in November, and often continue part of December. This comes from the fame country with the former, and may be propagated as is before direfted for them.

The ninth fort rifes near four feet high, having broad leaves at the bottom which diminifh gradually to the top; the flowers are produced in a loofe kind of umbel at the top of the ftalks, which are of a pale blue colour, thefe appear the latter part of Auguft. This is hardy, and may be propagated as the former.

The tenth fort grows naturally in the fourth of France and Italy; the ftalks of this divide into a great number of branches, which divide again toward the top into feveral fmaller, fully garnifhed with very narrow leaves their whole length; the flowers grow in large clufters at the top, forming a fort of corymbus; they are of a pale bluiſh colour, and appear the beginning of Auguft. This is hardy, and may be propagated by parting the roots, as the former.

The eleventh fort rifes four feet high, with a fingle ftalk, and oval leaves growing clofe to the ftalks, which are terminated by flender loofe fpikes of pale blue flowers, which appear about Michaelmas. This grows naturally in North America, and is propagated as the forts above-mentioned.

The twelfth fort fends up flender ftalks three feet high, which fend out flender fide branches moft of their length, fo as to form a thick bufh; thefe are garnifhed with very narrow leaves their whole length, and are terminated by fingle flowers.

The thirteenth fort grows about two feet high, having flender ftalks, garnifhed with oblong, pointed, heart-fhaped leaves, which are harply fawed on their edges; the upper part of the ftalks is divided into feveral fmall branches, which are terminated by white flowers growing in loofe panicles. This flowers in September, and may be propagated as the former.

The fourteenth fort fends up ftalks five feet high, which put out many flender fide branches, garnifhed with narrow fpear-fhaped leaves, and are terminated by fpikes of fmall white flowers, which appear the end of O&ober. This fort fpreads greatly at the root, fo is apt to over-run the borders.

The fifteenth fort hath narrow, oblong, liary leaves at the bottom; the stalks rife three feet high, garnished with flnsH, narrow, tough leaves, which mm backward; the stalks lend nut many ikle branches, each being terminated by a single large blue flower.

Tkii fort flows: i tin: end in Ocitol, and is iinus most part of November; when ic makes a Bre Ltiptar-ace. It d'jii nut multiply M by its i... fcn I may be propagated plenty, by cuttings nisue from the young shoots in i'-. which, if planted in a bed H EgjK MTib, and (hided from iln; inn, will take toot, ~anJ flnrcr the Sum year. It is commonly culled by the gardeners Gurityj Sturwort, from Mr. Catelby, who brought it from Virginia.

The fixic-ndi fort lends up ftvcal Italia u foot and a half high, garnished with rough (pear-flaped leaves, lending out many iite branches which diverge from the stalk: every way; thdfe art; terminated for the mod part by one large blue flower, (imcwhai like thole of the Italian Starwort, bilL paler, and comes earlier to flower. It grows naturally on the Alps, and is propagated by outing the root.

The fevntWHfi fore riles to the height of five feet, with branching ftulkt, gsmilhed with obkmg fpear-flwpcd team which arc (awed on ihuir trd'ces. Each of the tide branches are divided at the top into feve-iiHitflilk*, which are terminated by Sarge, pale, Mas flower, and are in beauty in October. This is prupigactd by parting the roots, as the forts beforementenciJ. It grows naturally in North America,

The eighteenth fort was brought from Virginia many years ago, by Mr. John Truk-tt snt, who was a great collector of rarities; ami from his garden it was foon dipried, and became commun. Jc is generally known by the title of Michaelmas Daifry, iVom its (lowering eixml old Michaelmas day. The ftalks of thisfon arc numerous, and lile about three feet and a liiif high, being fully garnilhed with ublong leaves ending in a point, whole bale linl embrace the ftalks. Thefc fhoat out many lateral brant lies, which are terminated by pretty large flowers, of a very pale bluilh colour, tending to white. The roots of this multiply very fait, and the (ceds often are blown about, to that it propagates lb much as often to be

...iildamc; it will thrive jc any iituation. The nineteenth lbrt lends ufi leucral (bone hairy (talks, which rife * foot and a half high, naving many oblong rough leaves ending in a poinr, whole bale half"embrace the (talks, which divide into many final branches ai dte top, forming n kind of corymbus, each being terminated by oiui large blue flower, hiving a very liary einpalement. This Bowers the latter end **; Juty. It grows naninilly on lite Alps, fo ia very hardy, bur mould have a nwift foil and a Qndy taaDDn. It is propagated by parting the roots.

The twntJeLi fon rifes with ltrong liary ibJks, do the height of etghr or nine ftef, which art upright, unbranchtd, anaginitihed wtli (jblong hairy leaves, agin* poiui; dicir baiehaif lurrjunili tin I stalks, which are for the molt part terminated by three large pi!rple flowers inclining to rat, and fit dole to the top of the iUlK, furroiroded by a few namv i... This lore Howcri in November, Ic came from Pht-Jadflphtf, where it naturally grows, and is propagated by parting die roots-, it dcligto in a niouli toil.

The twnty-firft fort liath (ender purpiih Mks, which rife about three t'ett hish, (ending out many fide branches almoU the whole length, which ipreaii horizontally, giimilhed. with narrow, fmall, (pt-ar-Diapcd l'itvsv the flower* are produced in a fort of looie fpikc, groving one t b m another en etch fide die talk. Thefe arc fmalr, of a \>zh: putplith CO-loin', and appear in NovemtKir. It grows naturally in North America, tuid U colily propagated by pnri-ina dKroob.

The twenty-Onond ton I received from Philadelphia, where it grows naturally. Tlvi; fends up (tiff char-

nished stalks about two feet high, garnished with rough lpear<ft>apeil>leave9 ending in i. point, plated atetii... only on every fide the stalks; the flowers are white, and grow in a fort of umbel u the top of the stalks. It flowers the end of September, ant) in (iro-pagated by parting the roots.

The twenty-third fort I received from Mr. l'cter Col-inton, I . K. v... it from Penfyhnuia. Thu bach much tbeaj... former... fort, but tht leaves arc narrower, vfuft... on their under fide, and have three longitudinal veins; the flowers are alfo larger and whiter. It grows about... fiefimc being... and liuwitJ at the (atuc time witi the tor-ten.

The twenty-fourth fort riles four feet high, the bot- tom leaves are ova) and half III mm ml the lilk nt their ha&t the upper leaves are fmall and tjtar flap- ed j the ltalks put out fide branches toward rh... which grow creel, forming a loofe fpikc, each being - terminated by one large blue flower, with a leaf... tbot- llilk; diis flowers allot ir EILL- end of October. It TMws naturally in North America, and is propagated by parting the roots.

The twenty-firth iort fends Dp from the met feveral flentcr Ualks near three feet high, jramilhed by many very narrow lores, and puts out iide branches, cath being terminated by one white flawrn This grows naturally in Philadelphia! it flowers iti November, and is cacity propagated by parting the roots.

The twenty-finji (brt riles about a foot and it half high; the (talks tire garnilhed with narrow, ipar- iliajicd, (mouth leaves: the end of theftlks are ter- minated by tiNji-thll. on every fide, rath having one pale blue Bower. This grow* morally in Ca- nada, and is propagated by pining the roots. It is tilled Alter Canjdenfis linarkc folio. Hort. R. Par.

(he iwenty-frventh fort grtws about rwofeit high, with ureft (talks, garniflicd with u... Siaped leaves, which cotnt out im'iiliirU' in iittllets; fVim the upper part of die l'talis, there are a few fide branches nmdecod, which arc guniilhed with tmrow leavsv the flowers are piDiUiceti !*... paficde, which are of n pale blue colour, and appear in Sept'... This is propagated by parting the roots.

The twenty-eighth lort is an mnual plant, which when once introduced into a garden, die iceds will (rather, and the pburtl conn* up wirlmuc care- This lends up (trait (talks about cwo iect hi^h, which are termi- nated by white Be infi in Sana of a corytn- bui. It flowers in Ausult, and the IK-ds rijen in Oc- tober, and grnws naturajly in North Awenea.

The iwenty-nimh fort grows natm-jly at the Cape of Good Hope. This rifes with a woody item about three feet high, (ending out fide branches which arc ligneous, garnilhed with narrow leaves coming out ill cluftcr! from one point, like thole of the Larch- tree; the flowers arc produced from tile fide of the branches, upon long (kmli-r tW-Ltalks Unely; thriu arcofapii!... r, and appear the beginning of March; as th... t produces &eds i... rope, it is only i... This ion is at prelent but ip few linglifli gardens.

The thirtieth fort is a native of China, from whence the feeds were sent to France by the missionaries, where the plants were first raised in Europe. In the year 1731, I received feeds of this, from which I raised plants with red, and some with white flowers; and in 1736, I received feeds of the blue flower, but these were all single. They came by the title of La Reine Marguerette or the Queen of Daifies, by which title the French still call it. In 1752, I received feeds of the double flowers both red and blue, and in 1753* the feeds of the double white fort, from my worthy friend Dr. Job Batter, F. R. S. of Zirkzee. These have retained their difference from that time without variation, yet as they are generally supposed to be only varieties, I have not inserted them as different species.

As these are annual plants, they are only propagated by feeds, which must be sown in the spring upon a gentle hot-bed, just to bring up the plants; for they should be inured to the open air as soon as possible, to prevent their being drawn up very weak: when the plants are big enough to remove, they should be carefully taken up and planted in a bed of rich earth at six inches distance each way, observing to shade them from the sun till they have taken new root, and if the season proves dry, they must be often refreshed with water. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flower-garden where they are designed to remain; the plants should be taken up carefully, with large balls of earth to their roots, and the ground dug up and well broken with the spade, where the holes are made to receive the plants: after they are planted, and the earth doled about their roots, there should be some water given them to settle the earth. This work should, if possible, be done when there is rain, for then the plants will soon take new root, after which time they will require no other care but to keep them clear from weeds.

In August these plants will flower, by which time if the ground is rich in which they are planted, they will be two feet high, and furnished with many fine branches, each of which is terminated by a large radiated flower, some white, some red, and others blue. These are some of the greatest ornaments in the flower-garden in autumn, during their time of flowering. The feeds ripen the beginning of October, which should be gathered when it is perfectly dry; and in order to preserve the kinds with double flowers, those which grow upon the fine branches, which are commonly fuller of leaves than the flowers on the main stem, should always be preserved for feeds.

The thirty-first fort was discovered by the late Dr. Houtton in the year 1731, at La Vera Cruz in New Spain. This is an annual plant, which rises with an upright stalk about one foot high, garnished the whole length with winged leaves, each consisting of two or three pair of lobes, terminated by an odd one: each of these lobes are heart-shaped, and sowed on their edges; at the top of the stalk is produced one large Orange-coloured flower, having a single empalement, cut into many slender segments which end in points. After the flower is past, each floret is succeeded by an oblong angular seed, crowned with long down. This is propagated by feeds, which should be sown on a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot filled with rich earth, and plunged into the tan-bed, observing to shade them until they have taken new root, as also to refresh them with water, and in warm weather admit free air to the plants. When these pots are filled with their roots, the plants should be carefully shaken out* and after paring off the outside roots, put into larger pots, filled with light earth, and plunged into the hot-bed again, where they may remain to flower and perfect their feeds, for they will not thrive in the open air. This fort flowers in July, and the feeds ripen in September.

The thirty-second fort was discovered by the late Dr. William Houtton, in the year 1729, growing in plenty in the sandy ground about Vera Cruz, in America, where he drew the figure, and made a description of the plant upon the spot; which he sent to England with the feeds, some of which grew in the Chelsea garden, and the plants flowered the following summer, but did not perfect their feeds.

It hath bushy fibrous roots, which creep in the ground, and send out many slender round stalks, which bend and incline to the ground. These are about four or five inches long, destitute of leaves, each sustaining one flower, in shape and size of those of the common Field Daifey, of a whitish purple colour, but the rays are narrower. The disk is composed of several florets, which are succeeded by small feeds crowned with a pappous down. The empalement which includes the flowers, is fealy.

As this plant is a native of a warm climate, it will not live in the open air in England; therefore the feeds must be sown in a hot-bed, and the plants will require a stove to maintain them through the winter.

The thirty-third fort is a native of North America. This hath upright stalks about three feet high, garnished with spear-shaped sowed leaves; the flowers are produced in bunchy panicles, having rough empalements. It flowers the end of August, and is propagated by parting the roots in autumn.

The thirty-fourth fort grows naturally in Siberia; the stalks are striated about two feet high, sending out side branches, garnished with rough, veined, spear-shaped leaves; the foot-stalks of the flowers are woolly, each supporting one large blue flower. This flowers in August, and is propagated by parting the roots in autumn.

The thirty-fifth fort sends up rough stalks about two feet high, dividing toward the top into many forked branches, diverging from each other, garnished below with oval sowed leaves; but the flowering stalks have entire obtuse leaves which embrace them with their base; the flowers are growing almost in an umbel; these appear the beginning of September. It is propagated by parting the roots as the former.

A S T E R I S C U S. See BUPHTHALMUM.

A S T E R O I D E S, Bastard Starwort. See INULA.

A S T R A G A L O I D E S. See PHACA.

A S T R A G A L U S, Wild Liquorice, Liquorice Vetch, or Milk Vetch.

The CHARACTERS are,

It hath a butterfly flower, whose empalement is of one leaf cut into five acute segments at the top. The standard (or vexillum) is upright, blunt, and reflexed on the sides; the wings are oblong, and shorter than the standard; the keel is the same length with the wings, and bordered. It hath ten stamina, nine of which are joined, and one stands singly; these are crowned by roundish funnels. At the bottom of the flower is situated a taper germen, supporting an awl-shaped flye, crowned by a blunt stigma. The germen afterward becomes a pod having two cells, each having a row of kidney-shaped feeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class of plants, entitled Dialectica Decandria, from the flower having ten stamina joined in two bodies.

The SPECIES are,

1. ASTRAGALUS (*Gfycyphyllos*) caulescens prostratus leguminibus subtriquetis arcuatis foliis ovalibus pedunculo longioribus. Lin. Sp. Plant. 758. *Stalky prostrate Milk Vetch, with crooked pods almost triangular, and oval leaves longer than the foot-stalk. Astragalus luteus perennis procumbens vulgaris sylvestris. Mor. Hist. 2. 107. sometimes called Wild Liquorice.*
2. ASTRAGALUS (*Hamosis*) caulescens procumbens, leguminibus subulatis recurvatis glabris. Hort. Upfal. 226. *Stalky trailing Milk Vetch, with smooth awl-shaped pods bending inward. Astragalus luteus annuus M'upeliacus procumbens. Mor. Hist. 2. 108.*

- 3}. **ASTRAGALUS** (*Aldpecuroides*) caulefcens, fpicis cylindricis fubfeffilibus, calycibus leguminibufque lanatis. Lin. Sp. Plant. 755. *Stalky Milk Vetch with cylindrical fpikes-growing clofe to the ftalks, and woolly pods and empalements.* Aftragalus Alpinus procerior Alopecuroides. Tourn. Inft. 416.
4. **ASTRAGALUS** (*Cicer*) caulefcens profratitii, leguminibus fubglobofis inflatis riucronatis pilofis. Hort. Upfal. 226. *Milk Vetch with a profrateftalk, and a globular, fwelling, hairy pod) ending in a point.* Aftragalus luteus perennis filiqua gemella rotunda veficam referente. Mor. Hift. 2. 107;
- j. **ASTRAGALUS** (*Epiglottis*) caulefcens procumbens, leguminibus capitatis cordatis acutis reflexis complicatis. Lin. Sp. Plant. 759. *Milk Vetch with trailing ftalks, and pods growing in heads, which are heart-ftiaped, pointed, reflexed, and complicated.* Aftragalus Hifpanicus filiqua epiglottidi fimili flore purpureo major. H. L. 74.
- c. **ASTRAGALUS** (*Montanus*) fubcaulos fcapis folio longioribus, floribus laxè fpicatis ere&is, leguminibus ovatis acumine inflexo. Prod. Leyd. 392. *Low Milk Vetch with flower-ftalks longer than the leaves, and flowers growing in loofe upright fpikes.* Onobrychis floribus vicie majoribus caeruleo-purpurafcentibus five foliis tragacanthæ. C. B. P. 351.
7. **ASTRAGALUS** (*Bosticus*) caulefcens procumbens, fpicis pedunculatis, leguminibus prifmaticis reddis triquetris apice uncinatis. Hort. Cliff. 225. *Milk Vetch with trailing ftalks, fpikes of flowers with foot-ftalks, and upright triangular pods Jhaped like a prifm pointed at the top.* Aftragalus annuus maritimus procumbens latifolius floribus pediculo infidentibus. Tourn. Inft. 416.
8. **ASTRAGALUS** (*Arenarius*) fubcaulefcens procumbens floribus fubratemofis ereftis foliis tomentofis. Lin. Sp. Plant. 759. *Low trailing Milk Vetch with branching flowers growing ere&is, and woolly leaves.* Aftragalus incanus parvus purpureus noftras. Pluk. Aim. 59*
9. **ASTRAGALUS** (*Pbyfodes*) acaulos fcapis folia fequantibus leguminibus inflatis fubglobofis nudis. Lin. Sp. Plant. 760. *Low Milk Vetch with flower-ftalks as long as the leaves, and naked, globular, fwelling pods.* Aftragalus acaulos leguminibus inflatis fubglobofis. Amce nit. Acad.
10. **ASTRAGALUS** (*CbriftiaHus*) caulefcens ere&ctus floribus glomeratis fubfeffilibus ex omnibus axillis foliaceis. Lin. Sp. 755. *Milk Vetch with upright ftalks, and glomerated flowers growing clofe to them, proceeding from all the wings of the leaves.* Aftragalus Orientalis maximus incanus ere&ctus, caule ab imo ad fummum florido. Tourn. Cor. 29.
11. **ASTRAGALUS** (*Mgyptiacus*) caulefcens fcapis folio longioribus floribus laxè fpicatis ere&is, leguminibus arcuatis. *Stalky Milk Vetch with flower-ftalks longer than the leaves, upright flowers growing in loofe fpikes, and arched pods.* Aftragalus iEgyptius floribus fpicatis purpurafcentibus filiquis incurvis. Juff!
12. **ASTRAGALUS** (*Sefameus*) caulefcens diffufus capitulis fubfeffilibus lateralibus leguminibus ere&ctis fubulatis acumine reflexis. Hort. Cliff. 361. *Milk Vetch with diffufedftalkf, flower-heads growing clofe to the fides of the ftalks, and awl-Jhaped upright pods reflexed at their points.* Aftragalus annuus foliis & filiquis hirtutis plurimis in foliorum alis feffilibus. Pluk. Aim. 60.
13. **ASTRAGALUS** (*Galegiformis*) caulefcens ftri&us glaber, floribus racemofis pendulis, leguminibus triquetris utrinque mucronatis. Lin. Sp. 1066. *Milk Vetch with fmooth flender ftalks, hanging branching flowers, and three-cornered pointed pods.* Aftragalus Orientalis altiffimus folio galegae, flore parvo flavefcente. Tourn. Cor. 29.
14. **ASTRAGALUS** (*Uralenfis*) acaulos fcapo ere&cto foliis longiore leguminibus fubulatis inflatis villofis ere&ctis. Hort. Upfal. 226. *Low Milk Vetch, with upright fcoot-ftalks to the flowers longer than the leaves, and awl-Jhaped, upright, fwoln, hairy pods.* Aftragalus non ramofus villofus & incanus fpicatus floribus purpuro-violeis. Amman. Ruth. 167. p. 126.
15. **ASTRAGALUS** (*Carolinianus*) caulefcens ere&us laevis pedunculis fpicatis leguminibus ovato-cylindricis ftylo acuminatis. Lin. Sp. Plant. 757. *Smooth, upright, ft alky Milk Vetch, with fpikedftalks, and oval cylindrical pods ending injharp points.* Aftragalus procerior non repens flore viridi flavefcente. Hort. Elth, 45.
16. **ASTRAGALUS** (*Canadenfis*) caulefcens diffufus, leguminibus fubcylindricis mucronatis foliolis fubtus fubvillofis. Lin. Sp. Plant. y&sy. *Milk Vetch with diffufed ftalks, pointed cylindrical pods, and thefmall leaves hairy on their under fide.* Aftragalus Canadenfis flore viridi flavefcente. Tourn. Inft. 416.
17. **ASTRAGALXJS** (*Pilofus*) caulefcens ere&ctus pilofus floribus fpicatus leguminibus fubulatis pilofis. Lin. Sp. Plant. 756. *Milk Vetch with hairy upright ftalks, flowers growing in fpikes, and awl-Jhaped hairy pods.* Aftragalus villofus ere&ctus fpicatus floribus flavefcentibus. Amman. Ruth. 166.
18. **ASTRAGALUS** (*Procumbens*) incanus caulibus procumbentibus fcapis folio aequantibus floribus glomeratis. *Hoary Milk Vetch with trailing ftalks, foot-ftalks equal with the leaves, and glomerated flowers.* Aftragalus fupinus filiquis villofis glomeratis. ToUrn. Inft R. H. 417.
19. **ASTRAGALUS** (*Incanus*) caulefcens ineanus, leguminibus fubulatis recurvatis incanis. *Hoary ft ally Milk Vetch, with awl-Jhaped recurved pods which are hoary.* Aftragalus incanus filiqua recurva. Bot. Monfp.
40. **ASTRAGALUS** (*Capitatus*) caulefcens capitulis globofis, pedunculis longiffimis, foliolis emarginatis. Hort. Cliff. 360. *Stalky Milk Vetch with globular heads, very long foot-ftalks, and thefmall leaves crenated at their points.* Aftragalus Orientalis villoffiffimus capitulis rotundioribus floribus purpureis. Tourn. Cor. 29.
21. **ASTRAGALUS** (*Chinenfis*) caulefcens procumbens, capitulis pedunculatis, leguminibus prifmaticis re&is triquetris apice fubulatis. *Milk Vetch with trailing ftalks> the foot-ftalks terminated by flowers cotefted in beads* and three-cornered pods. Jhaped like prifms.*
12. **ASTRAGALUS** (*Uncatus*) acaulis exfeapus, leguminibus fubulatis hamatis folio longioribus, foliolis obcordatis* Lin. Sp. 1072. *Milk Vetch without ftalks awl-Jhaped hooked pods longer than the leaves, and the final leaves almoft heart-jhaped.*

The firft fort grows wild upon chalky ground in many parts of England, fo is not often admitted into gardens. The root of this is perennial, but ihe ftalks decay every autumn : it creeps at the root, fo that it is too apt to fpread where it is fuffered to grow. It flowers in June, and the feeds ripen in September.

The fecond fort is annual; the branches of this trail upon the ground, which are ftriated; the leaves are winged, compofed of about eight pair of lobes, terminated by an odd one; thefe are crenated at their points. The foot-ftalks of the flowers arife from the wings of the leaves, which are about three inches long, garnifhed toward the top with a few pale yellow flowers rifing one above another *, thefe are fucceeded by oblong pods, which bend in form of a fickle, being round on their outer fide, but flatted on the oppofite, ending in a point, opening in two cells, each having a row of fquare feeds. It flowers in June, and the feeds ripen in September. The feeds of this fhould be fown in April, in the place where they are to remain, and require no other care but to draw die plants out where they come up too thick, leaving them a foot and a half afunder, and keep them clean from weeds.

The third fort is a biennial plant, which grows naturally on the Alps. This rifes with an upright hairy ftalk near three feet high, garnifhed with long winged leaves, each having eighteen or twenty pair of oval lobes, terminated by an odd one. The flowers are produced in large cylindrical fpikes from the wings of the leaves, fitting very clofe to the ftalks, which are entirely covered with down, out of which the yellow flowers juft peep; thefe are fucceeded by oval

Pods shut up in the woolly empalements, having two cells, containing three or four square feeds in each. It flowers in June and July, and the feeds ripen in autumn, soon after which the plants decay. The feeds of this should be sown in April, on an open border, where the plants are designed to remain; and when the plants come up, they should be thinned, leaving them at least two feet asunder, and keep them clean from weeds; the second year they will flower, and produce feeds.

The fourth fort hath a perennial root, which sends out several striated stalks near three feet high, which, if not supported, prostrate themselves towards the earth. These are garnished with winged leaves placed alternately, at two inches distance, which are composed of about ten pair of oval small lobes, terminated by an odd one. The flowers arise from the wings of the leaves, upon foot-stalks two inches long, in small loose spikes, which are yellow* and shaped like the rest of this genus, and are succeeded by hairy, globular, swelling pods* ending with a sharp point, opening in two cells, in each of which are contained two or three hard reddish feeds. It flowers in July, and the feeds ripen in autumn. This grows naturally in the south of France and Italy. It is easily propagated by feeds, which should be sown upon an open border in the spring; and when the plants come up, they must be thinned and kept clean from weeds till autumn, when they should be transplanted to the place where they are to remain, and will afterward require no other culture, but to keep them clean from weeds. One or two of these plants in a garden by way of variety, may be admitted, but they have little beauty.

The fifth fort is annual. This sends off from the root two or three hairy trailing branches, which are garnished with winged leaves, composed of ten or twelve pair of blunt lobes, terminated by an odd one: the flowers come out from the wings of the leaves upon naked foot-stalks, four or five inches long, and are gathered into a round head. These are flapped like the others, but are pretty large, and of a deep purple colour, which are succeeded by short pods rough on their out-fides, and when opened, are shaped like a heart, ending in a sharp point, containing three or four feeds.

The feeds of this should be sown on an open border in April, where the plants are to remain, and treated as the other annual forts before-mentioned. It flowers in July, and the feeds ripen in autumn. It grows naturally in Spain and Portugal, from whence I have received the feeds.

The sixth fort is a perennial plant, which grows naturally upon the mountains in Spain, from whence I received it. This is a low plant, seldom rising with a stem more than three inches high, sending out winged leaves on every side, which are composed of many pairs of narrow lobes, set very close together on the midrib, terminated by an odd one. The flowers grow upon long foot-stalks, which rise above the leaves. These are large and of a purple colour, growing in a loose spike, and straggled, and are succeeded by oblong crooked pods opening in two cells, filled with square feeds. It flowers in June, and the feeds ripen in August. This is propagated by feeds, which should be sown, and the plants treated in the same manner as the fourth fort, but should have a shady situation and a stronger foil.

The seventh fort is annual. This sends out several trailing branches near two feet long, which are garnished with winged leaves, composed of about ten pair of blunt lobes, set thinly on the midrib, terminated by an odd one: at the wing of each leaf comes out a foot-stalk near two inches long, sustaining four or five yellow flowers at the top, which are succeeded by triangular brown juxts, shaped like a prism, growing erect, and open in two cells filled with greenish square feeds. It flowers in July, and the feeds ripen in autumn, soon after which the plants decay.

This may be treated in the same manner as the second.

The eighth fort is a perennial plant, which grows naturally upon hills in several parts of England, particularly in the North. This is a low plant, seldom rising more than two or three inches high, having many winged leaves composed of narrow woolly lobes, placed close on the midrib, the flowers are pretty large, of a purple colour, growing in loose spikes. It flowers in June, and the feeds ripen in August. This may be propagated as the fourth fort, and should have a shady situation.

The ninth fort hath a perennial creeping root, sending out leaves, which are composed of many pair of oval lobes, terminated by an odd one. The foot-stalks are as long as the leaves, which support a cylindrical spike of yellow flowers, which are succeeded by swollen pods, opening in two cells, containing several greenish feeds. This may be propagated as the fourth fort, and must have a shady situation. It flowers in June, and grows naturally in Siberia.

The tenth fort was discovered by Dr. Tournefort in the Levant, who sent the feeds to the royal garden at Paris, where they succeeded, from whence I was furnished with them. This sends up stalks near three feet high, which are large at bottom, and gradually diminish to the top; the leaves also at bottom are very long, and diminish upward, so as to form a sort of pyramid; these are winged, and composed of many large oval pair of lobes, which are placed thinly on the midrib, and terminated by an odd one; the flowers come out in clusters from the wings of each leaf, beginning near the root where the foot-stalks are the longest, and continuing upward, diminishing in their number. These are large, of a bright yellow colour, and are succeeded by cylindrical pods opening in two cells, filled with square yellow feeds. It flowers in July, and in very favourable seasons will perfect feeds in England. It is propagated by feeds, which should be sown, and the plants afterward treated as hath been directed for the fourth fort; with this difference only, to plant them in a warm border and a dry foil, otherwise the plants will not thrive well in this climate. The third year from seed the plants will flower, and continue many years in a proper foil.

The eleventh fort grows naturally in Egypt, from whence the feeds were sent to the royal garden at Paris, and Dr. Jussieu was so good as to send me part of the feeds: this is an annual plant, which rises with upright stalks a foot and a half high, thinly garnished with winged leaves, composed of about twelve pair of oval lobes, terminated by an odd one; the foot-stalks of the flowers arise from the wings of the leaves, and are extended beyond them; these are terminated by loose spikes of yellow flowers, which are succeeded by fickle-iliaped pods. It flowers in July, and the feeds ripen in autumn, soon after which the plants decay. It may be propagated by feeds in the same manner as hath been before directed for the annual forts, putting the feeds in a warm border and a dry foil, where the plants will perfect their feeds very well.

The twelfth fort grows naturally in Italy, and the south of France, from whence I received the feeds. This is an annual plant, which sends out several weak stalks without any order, garnished with winged leaves, composed of ten or twelve pair of lobes, and sometimes terminated by an odd one; these are hairy; at the foot-stalks of the leaves the flowers come out in small chillers, fitting close to the sides of the stalks, which are of a copper colour, and are succeeded by awl-shaped pointed pods growing erect, and reflected at their points. This is propagated by feeds in the same manner as the other annual forts before mentioned. It flowers in July, and the feeds are ripe in autumn.

The thirteenth fort was discovered by Dr. Tournefort, in the Levant, who sent the feeds to the royal garden

»t Paris, where they succeeded, and produced few feeds, so that many of the European gardens have been since supplied with it, this hath a perennial root, which sends out many upright stalks upward of five feet high, which are garnished with winged leaves, composed of about fourteen pair of oval lobes* terminated by an odd one, from the wings of the leaves the foot-stalks of the flowers arise, which are garnished with small yellow flowers-, growing in loose spikes, and are extended beyond the leaves; these are succeeded by very short triangular pods, ending in a point, which open in two cells, filled with ash-coloured square seeds. This flowers in June or July, and the seeds ripen in autumn. It is propagated by seeds, which may be sown in the spring, upon a border of light earth, and treated in the same manner as the fourth sort, till the following autumn, when the plants should be removed to an open situation and a dry soil, and when they have taken root, will require no farther culture. I have a root of this sort growing in the Chelsea garden, which is too old than thirty years old, and produces plenty of seeds every year.

The fourteenth sort grows naturally upon the mountains in Germany; this never rises with a stalk, but sends out divers winged leaves from the root, which are composed of many blunt lobes, placed by pairs, and terminated by an odd one the foot-stalks of the flowers arise immediately from the root, and are longer than the leaves, being terminated by spikes of blue flowers, which are succeeded by swelling awl-shaped pods, which are erect and hairy, having two tells which are filled with greenish seeds. It flowers in July, and the seeds ripen in autumn. The root is abiding, and the plant is propagated by seeds as the fourth sort, but should have an open situation.

The fifteenth sort grows naturally in Carolina, from whence I received the seeds, this hath a perennial root, but an annual stalk, which decays in autumn; from the root arise several upright stalks three feet high, garnished with winged leaves, composed of eighteen or twenty pair of oval smooth lobes, terminated by an odd one; from the wings of the leaves arise the foot-stalks, which are terminated by spikes of greenish yellow flowers, which are succeeded by oval cylindrical pods, to which adhere the style, which extends beyond the pods in a point. This flowers in August, but unless the season is warm, the plants seldom ripen their seeds in England. It is propagated by seeds, which should be sown upon a moderate hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a small pot filled with earth from the kitchen-garden, and plunged again into the hot-bed, to forward their making new roots; and when they are established in the pots, they must be inured to the open air, into which they should be removed the end of May, placing them in a sheltered situation, where they may remain till October, when they should be placed under a common frame to shelter them in winter; and in the spring they may be turned out of the pots, and planted in a warm border, where they will thrive and flower; and if the winter proves very severe, a little old tan should be laid over the roots, which will effectually preserve them.

The fifteenth sort grows naturally in most parts of North America; this hath a perennial root, which sends out many irregular stalks about two feet high, garnished with winged leaves, composed of many pair of oval lobes, hairy on their under side, from the wings of the leaves come out the foot-stalks, supporting spikes of greenish yellow flowers, which are succeeded by cylindrical pods, ending in a point. This flowers in July, and the seeds ripen the beginning of October. It is propagated by seeds, which should be managed as those of the fifteenth sort, but the plants are hardier, so will live thro' the winter in a common bed of light earth without covering. The seventeenth sort rises With upright, hairy stalks

two feet high, garnished with winged leaves, composed of many pair of oval woolly lobes* terminated by an odd one -, from the wings of the leaves arise the foot-stalks, which are terminated by close spikes of yellow flowers, these are succeeded by hairy awl-shaped pods, having two cells, filled with brown seeds. This flowers in June, and the seeds ripen in autumn. It grows naturally in Siberia, from whence the seeds were sent to Dr. Amman, at Peterburgh, who communicated them to me. It is a perennial plant, and propagated by seeds in the same manner as the fourth sort.

The eighteenth sort is a biennial plant: the seeds of this were sent me from Spain, where the plant grows naturally; This sends out many trailing stalks, which are divided into many smaller branches, garnished with many pair of narrow lobes, terminated by an odd one -, the flowers are collected into heads, which terminate the foot-stalks, and are white; the foot-stalks are about the same length as the leaves, the pods are short and triangular, and the whole plant is covered with a silvery down. The seeds of this should be sown upon an open bed of light earth, where the plants are to remain, and the plants afterward treated in the manner directed for the annual sorts: the second year they will flower and perfect their seeds, after which they seldom continue.

The nineteenth sort grows upon the hills near Verona, from whence I received it. This sends up an upright stalk, seldom more than six inches high, garnished with small, winged, hoary leaves; the foot-stalks arise from the wings of the leaves, supporting three or four pale flowers, which are succeeded by fickle-shaped hoary pods. This is a biennial plant, and should be treated in the same manner as the last.

The twentieth sort was discovered by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris. This hath a perennial root, which sends up several erect stalks, garnished with winged leaves, composed of several pair of lobes, indented at the top, from the wings of the leaves come out long foot-stalks, supporting a globular head of purple flowers, these are rarely succeeded by pods in England. It flowers the end of July. It is propagated by seeds, which should be sown upon a moderate hot-bed in the spring, and the plants treated in the same manner as hath been directed for the fifteenth sort.

The twenty-first sort grows naturally in China: the plant is annual -, the stalks spread on the surface of the ground, which are closely garnished with winged leaves, composed of eight or ten pair of oval smooth lobes, fitting close to the midrib; these are slightly indented at their end. The foot-stalks of the flowers are produced from the wings of the stalk, two of them generally arising at each place, and are equal to the leaves in length, supporting a globular head of purple flowers, which are succeeded by three-cornered pods growing erect in a compact head, opening in two cells, filled with small triangular seeds. This plant flowers in July and August, and the seeds ripen in autumn.

The seeds of this sort should be sown upon a hot-bed in March, and when the plants come up and are fit to transplant, they should be each put into a small pot filled with light earth, and plunged into another moderate hot-bed, being careful to shade them from the sun until they have taken new root; after which they should have free air admitted to them daily, proportional to the warmth of the season, and frequently but gently watered, with which management the plants will flower and produce seeds.

The twenty-second sort grows naturally about Aleppo, from whence the seeds were brought by Dr. Ruffel. The plant is annual, sending out a few branching stalks which trail upon the ground, garnished with narrow winged leaves, whose lobes are broader at their points than their base, and are indented so as

to become almost hemispherical, the flowers produced in the wings of the ...

The first fort is the Cimarron, which is very common in the mountains of New Mexico, and by the inhabitants there is called Bald-Money, or David-Money, by some it is called Meum.

This may be propagated by parting the roots, or from seeds sown soon after they are ripe, the plants should have a sandy situation and moist soil, it flowers in June, and the fruit ripens in August.

The second fort is the Daucus Crotaria, of which there are two sorts, which are differently used in the shops, one of which is annual, but that here mentioned is a perennial plant, which kinds are very common.

: stalks, garnished with slender narrow leaves like those of Fennel, irregularly disposed. The flower-stalk rises about two feet high, sending out many branches, garnished the whole length with the same compound capillary leaves, and at the top are terminated by compound umbels, composed of near twenty small ones, these have white flowers with five petals, which are succeeded by oblong, hairy, channelled fruit, divided into two parts, each containing one oblong hairy seed.

This sort is propagated by seeds, which should be sown in autumn on an open bed of light dry ground; and when the plants come up in the spring, they should be kept clean from weeds, and thinned where they are too close, so that they may have room to grow till the following autumn, when they should be carefully taken up, and planted at about a foot distance in a bed of light sandy earth, where the roots will continue several years, and annually flower and produce ripe seeds. It flowers in June, and the seeds are ripe in September. This grows naturally in Candia, but is rarely injured by cold in this country.

The third sort is a perennial plant; this sends up from the root several upright stalks, near three feet high, which are terminated by compound umbels, these, at their first appearance, are very close and compact, but afterward spread open, and divide into several smaller umbels; the foot-stalks or rays of these are short and hairy. The flowers are composed of five white petals, which are not quite equal, and are succeeded by oblong woolly fruit, divided into two parts, each containing one oblong channelled seed.

This may be propagated in the same manner as the former, and is equally hardy; it grows naturally in Sicily, and some parts of Italy.

The fourth sort is a perennial plant, which grows naturally in some particular parts of England, France, and Germany; the leaves of this are linear, and acutely cut into oblong segments; the stalks rise two feet high, dividing toward the top into three or four branches, each being terminated by an umbel of white flowers, which are succeeded by oblong striated seeds. It flowers in July, and the seeds ripen in autumn.

The fifth sort grows naturally in the south of France, and in Austria: this hath a perennial root, the stalks rise three feet high, garnished with winged leaves, which are cut into angular segments; they are terminated by umbels of white flowers, which are succeeded by naked seeds. This flowers in July, and the seeds ripen in autumn.

These two sorts are seldom admitted into any gardens but those of botanists, for the sake of variety, being plants of little beauty or use. They are propagated by seeds, which should be sown in autumn soon after they are ripe, and the plants will appear the following spring, when they will require no other care but to thin them where they are too close, and keep them clean from weeds. The second summer they will flower and produce ripe seeds, but the roots will abide several years where they are desired.

ATHANASIA. Lin. Gen. 943. Baccharis. Vaill. Aft. Gall. 1719. Goldylocks.

The CHARACTERS are,

The empalement is imbricated, oval, and the scales are spear-shaped; the flower is of the compound kind, the florets are uniform and longer than the corolla; the hermaphrodite stamens are funnel-shaped, cut into five segments, which are erect, they have each five short hair-like filamina, with cylindrical tubulose summits, and an oblong germen with a slender style, terminated by an obtuse bifid stigma, each floret has an oblong seed with a chaffy down between them.

This genus of plants is ranged in the first order of Linnaeus's nineteenth class, entitled Syngenesia Polygamia Equalis; the florets of this order are all hermaphrodite.

The SPECIES are,

1. ATHANASIA (*Dentata*) corymbis impositis, foliis in-

ferioribus linearibus dentatis, superioribus ovatis ferratis. Lin. Sp. 1181. *Athanasia with a compound corymbus, the lower leaves linear and indented, the upper oval and fawed.* Coma aurea Africana frutescens, foliis inferioribus incisis, superioribus dentatis. Com. Rar. Pl. 41.

2. ATHANASIA (*Trifurcata*) corymbis simplicibus, foliis trilobis cuneiformibus. Lin. Sp. 1181. *Athanasia with a Jingle corymbus, and wedge-shaped leaves with three lobes.* Coma aurea Africana fruticans, foliis glaucis & in extremitate trifidis. Hort. Amft. 2. p. 97.

3. ATHANASIA (*Crithmifolia*) corymbis simplicibus, foliis femitrifidis linearibus. Lin. Sp. 1181. *Athanasia with a Jimple corymbus, and linear femitrifid leaves.* Coma aurea fruticans foliis angustifimis trifidis. Burm. Afr. 186.

4. ATHANASIA (*Pubescens*) corymbis simplicibus, foliis lanceolatis indivisis villosis. Amcen. Acad. 4. p. 329. *Athanasia with a Jimple corymbus, and Jpear-shaped, undivided, hairy leaves.* Coma aurea Africana fruticosa, omnium maxima, foliis tomentosis & incanis. Hort. Amft. 2. p. 93.

5. ATHANASIA (*Annua*) corymbis simplicibus coarctatis, foliis pinnatifidis dentatis. Lin. Sp. 1182. *Athanasia with a Jimple corymbus, and winged indented leaves.* Elichryium inodorum glabrum, coronopi folio glabrum. Magn. Montp. 307.

6. ATHANASIA (*Maritima*) pedunculis unifloris subcorymbosis, foliis lanceolatis indivisis crenatis obtusis tomentosis. Lin. Sp. 1182. *Athanasia with Jingle flowers on each foot-stalk formed like a corymbus, and Jpear-shaped, obtuse, woolly leaves.* Gnaphalium vmitimum. C. B. P. 263.

The first sort grows naturally at the Cape of Good Hope: this hath a low, shrubby, branching stalk, which seldom rises three feet high; the branches are garnished with two sorts of leaves, those toward the bottom are linear and indented, but the upper arc oval and fawed on their edges: the flowers are disposed in a compound corymbus at the end of the branches; they are of a pale yellow, and appear early in summer, and if the season proves favourable, will be succeeded by ripe seeds in autumn.

The second sort is a native of the Cape of Good Hope: this rises with a shrubby stalk five or six feet high, dividing into many irregular branches, garnished with flat glaucous leaves cut at their extremity into three segments; these have an agreeable odour when bruised. The flowers are produced in a simple corymbus at the extremity of the branches; they are of a bright yellow colour, and appear in August, but are seldom succeeded by ripe seeds in England.

The third sort grows naturally at the Cape of Good Hope: this hath a shrubby branching stalk like the former; the leaves are linear, and divided more than half their length, some into three, and others into five narrow segments: the flowers are produced at the extremity of the branches in a simple corymbus, like those of the former sort in shape and colour, of which there is a succession on the same plant great part of summer, but unless the season is warm, they are rarely succeeded by ripe seeds in England.

The fourth sort rises with a shrubby stalk six or seven feet high; the branches are garnished with hairy, spear-shaped, entire leaves, the flowers are yellow, and produced in a simple corymbus at the extremity of the branches, but are not succeeded by good seeds in England.

These four sorts are easily propagated by cuttings during the summer months. If these are planted either in pots or upon an old hot-bed, and closely, covered with glasses, shading them in the heat of the day, and refreshing them with water when they require it, they will put out roots in five or six weeks; and in two months they may be taken up and planted in pots filled with light earth, and placed in a shady situation until they have taken new root; after which they should be removed to a sheltered situation, mixing them with other exotic plants, where they may remain till the middle or end of October, according as the season proves

proves favourable, then should be removed either into a green-house, or a glass case, where they may enjoy as much free air as possible, but secured from frost, with which management they will thrive and produce plenty of flowers, but where they are drawn weak in winter, they will not appear freely.

The fifth sort is an annual plant, which grows naturally in Africa. This hath an herbaceous stalk about nine inches high, which divides toward the top into three or four branches, garnished with smooth leaves, divided into segments like those of Buckhorn Plantain; the flowers are large, of a bright yellow colour, and are produced at the extremity of the branches in a compact simple corymbus; these appear in July and August, but are rarely succeeded by ripe seeds in this country.

- This is propagated by seeds when they can be obtained good, which should be sown on a moderate hot-bed the latter end of March; when the plants are come up they should have air in proportion to the warmth of the season admitted to them, to prevent their drawing up weak; and so soon as they are big enough to remove they should be transplanted on another gentle hot-bed, at three inches distance, observing to shade them until they have got fresh root; after which they must have air and water, and by the end of May, the plants will have acquired strength enough to be transplanted into the open air; when some may be planted in pots to place among other exotic plants in summer, and the others into warm borders, where they will flower all the autumn, but unless the season is very warm, they will not ripen seeds.

The sixth sort grows naturally on the sea coasts in the warm parts of Europe, and also in some parts of Wales, from whence I have received plants. The stalks trail on the ground, seldom growing more than seven or eight inches long, garnished closely with woolly leaves, which are spear-shaped, entire, and obtuse; the flowers are of a bright yellow, each produced on a single foot-stalk, forming a kind of corymbus; they appear in June and July, but rarely ripen seeds in the garden.

This may be propagated by planting slips or cuttings during the summer months, in the same way as the African sorts; some of the plants should be put into pots to be placed under a hot-bed frame in winter, the other may be planted in a warm border, where if the winter proves favourable they will live, but they rarely survive cold winters.

A T M O S P H E R E [of 'flippif, a vapour, and *fy a. 7g*** Gr. a sphere] is an appendage of the earth* which consists of a thin, fluid, elastic substance, called air, surrounding the terraqueous globe to a considerable height.

The whole mass, or assemblage of ambient air, is commonly understood to be the atmosphere.

But the more accurate writers refrain the term atmosphere to that part of the air which, is next to the earth, which receives the vapours and exhalations, and which is terminated by the refraction of the light of the sun.

Those spaces that are higher, and beyond these, are called aether; and, being supposed to be possessed by a finer substance, are called the aethereal regions, though these, perhaps, are not destitute of air.

This atmosphere insinuates itself into all the vacancies of bodies, and by that means becomes the great spring of most of the mutations here below, as generation, corruption, dissolution of vegetables, &c. to the pressure of the atmosphere, plants owe their vegetation, as well as animals do their respiration, circulation, and nutrition.

ATRACTYLIS. Lin. Gen. Plant. 837. Distaff Thistle.

The CHARACTERS are,
// bath a radiated compound flower, composed of many hermaphrodite florets* which are included in a common scaly unarmed empalement. // this hath a permanent involucrum* composed of several narrow plain leaves* which cavitybarjipnes on their sides. The hermaphrodite florets

which compose the rays* or border* are fireched out on one side like a tongue* and are slightly indented in five parts. Those which compose the disk* or middle* are funnel-shaped* cut at the top into five parts; these have both five slender filamina in each* which are Jhort* and crowned by cylindrical summits; in those of the disk is situated a Jhort crowned germen* supporting a slender style* crowned by a bifid stigma. The germen afterward becomes a turbinated* compressed seed* crowned with a plume of down* Jhut up in the empalement.

This genus of plants is ranged in the first section of Linnseus's seventeenth class, entitled Syngenesia Polygamia JEquis, from the florets of the border and disk being hermaphrodite.

The SPECIES are,

1. **ATRACTYLIS** (*Cancellaria*) involucris cancellatis ventricosis, linearibus dentatis calycibus ovatis, floribus floiculosis. Lin. Sp. Plant. 830. Distaff Thistle with a bellied netted involucrum* an oval* indented* linear empalement* and flosculous flowers. Cnicus exiguus capite cancellato femine tomentoso. Tourn. Inf. R. i }.
2. **ATRACTYLIS** (*Humilis*) foliis dentato-finuatis, flore radiato obvallato involucro patente, caule herbaceo. Lin. Sp. Plant. 829. Distaff Thistle with finuated indented leaves* a radiated flower strongly guarded by its spreading involucrum* and an herbaceous stalk Cnicus aculeatus purpureus humilior. Tourn. Inf. R. H. 451.
3. **ATRACTYLIS** (*Gummifera*) flore acaule. Lin. Sp. Plant. 829. Distaff Thistle with a flower without a stalk. Cnicus Carlinae folio acaulos gummifer aculeatus. Tourn. Cor. 33.

The first sort grows naturally in Spain, Sicily, and other warm parts of Europe. This is an annual plant which seldom rises more than eight or nine inches high, with a slender stem, thinly garnished with narrow hoary leaves, having spines on their edges; at the top of the stalk there are two or three slender branches sent out, each being terminated by a head of flowers, like those of the Thistle, with an involucrum composed of several narrow leaves, armed with spines on their side, which are longer than the head of flowers. The empalement is curiously netted over, and is narrow at the top, but swelling below, containing many florets of a pyrplish colour. These are each succeeded by a single downy seed; it flowers in July, and, if the season be warm and dry, it will ripen its seeds in September, but in cold years never perfects seeds here.

It is propagated by seeds, which must be sown upon an open bed of light earth, where the plants are to remain, and will require no other care but to keep them clean from weeds, and thin the plants where they come up too close together.

The second sort rises with a stalk near a foot high, which is garnished with indented leaves, having small spines on their edges; the upper part of the stalk is divided into two or three slender branches, each supporting a head of purple flowers, paving rays in the border, and florets in the disk, inclosed in a scaly empalement. The roots of this will live two or three years; it flowers in June, but unless the summer is warm and dry, it will not perfect seeds in England. The seeds of this sort should be sown where they are to remain, and will require no other culture than the former. It grows naturally about Madrid, from whence I received the seeds.

The third sort grows naturally in Italy, and the islands of the Archipelago, and is what the College of Physicians have placed among the medicinal simples, by the title of Carline Thistle; the root of this is perennial, and sends out many narrow leaves, which are deeply finuated, and armed with spines on their edges. These lie close on the ground, and between them the flower is situated, without stalk, having many florets, inclosed in a prickly empalement. Those on the border are white, but those which compose the disk are of a yellowish colour. It flowers in July, but never perfects seeds in England.

It U propagated by feeds, which mull be obtained from the countries where it grows naturally; these should be fown upon a border of light earth, in a warm situation, early in April, and when the plants come up, and are fit to transplant, they should be thinned, and those which are drawn out may be transplanted, leaving the other two feet asunder; after which the only culture they require is, to keep them clean from weeds in summer, and in winter to cover the roots with some old tanners bark, to prevent the frost from penetrating the ground.

The fourth sort grows naturally at the Cape of Good Hope; this sives with a shrubby stalk near three feet high, garnished with oblong leaves, indented on their edges, which have weak spines at each indenture, there are several weak branches sent out on the sides, each of which are terminated by a single head of flowers, inclosed in a common empalement, which spreads open, and are of a golden colour, but are never succeeded by feeds in England. This is propagated by slips, taken from the flower-stalks in June, and planted in pots filled with light earth, and plunged into an old bed of tanners bark, where the heat is gone, and shaded with mats in the heat of the day, until they have taken root; after which time they may be exposed in the open air till October, when they must be removed into shelter, and, during the winter, should have little water, and in summer exposed with other hardy exotic plants in a sheltered situation.

ATRAPHAXIS. Lin. Gen. Plant. 405. We have no English name for this.

The CHARACTERS are,

The flower hath a permanent empalement, composed of small coloured leaves placed opposite. The flower hath two roundish situated petals, larger than the empalement, which are permanent; it hath six capillary stamina, which are the length of the empalement crowned with roundish summits; in the center is situated a compressed germen, having no style, but crowned by two stigma-, the germen afterward becomes a roundish compressed seed, shut up in the empalement.

This genus of plants is ranged in the second section of Linnæus's sixth class, entitled Hexandria Digynia, the flower having six stamina and two stigma.

The SPECIES are,

1. ATRAPHAXIS ramis spinosis. Hort. Cliff. 138. *Atrophaxis with prickly branches.* Atriplex orientalis frutescens flore pulchro. Tourn. Cor. 38.
2. ATRAPHAXIS inermis. Lin. Sp. Plant. 333. *Atrophaxis without spines.* Arbutula Africana repens folio ad laterce crasso, ad Polygonia relata. Hort. Elth.

The first sort grows naturally in Media, from whence Dr. Tournefort sent the feeds to the royal garden at Paris.

This is a shrub which rises four or five feet high, sending out many weak lateral branches, which are armed with spines, and garnished with small, spear-shaped, smooth leaves, of an Ash-colour. The flowers come out at the ends of the shoots in clusters, each consisting of two white leaves tinged with purple; and are included in a two leaved empalement, of a white herbaceous colour; these appear in August, but the feeds never ripen here, so the plant is propagated by cuttings, and must be screened from hard frost, which commonly destroys those which are planted in the open air.

The second sort sends out many tender branches, which trail on the ground when they are not supported, garnished with small oval leaves, about the size of those of the Knot Grass, waved and curled on their edges, embracing the stalk half round at their base, and are placed alternate. The flowers come out from the wings of the leaves, and have much the appearance of an apetalous flower, being composed of four herbaceous leaves, two of which are the empalement, the other two the petals; in the center is situated the compressed germen, attended by six stamina, but the feeds are never produced in

this shrubby. It flowers in June and July. This is a native of the country about the Cape of Good Hope, from whence it was brought into the gardens in Holland, and has been several years in the English gardens, where it is allowed a place more for the sake of variety, than its beauty. It may be easily propagated by cuttings any time in the summer, and in winter the plants must be screened from frost.

ATRIPLEX, Orach, or Arach.

The CHARACTERS are,

It hath female and hermaphrodite flowers on the same plant. The hermaphrodite flowers have a permanent empalement of five oval concave leaves, with membranaceous borders; they have no petals, but five awl-shaped stamina placed opposite to the leaves of the empalement, supporting double summits. In the center is placed the orbicular germen, with a short bipartite style, crowned with a reflexed stigma. The germen afterward becomes an orbicular compressed seed, shut up in the five-cornered empalement. The female flowers have a two-leaved empalement, which are large, plain, erect, and pointed. They have no petals nor stamina, but in the center a compressed germen, supporting a bipartite style, crowned by a reflexed stigma. The germen afterward becomes an orbicular compressed seed, inclosed in the heart-shaped valves of the empalement.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, entitled Polygamia Monœcia, the same plants having female and hermaphrodite flowers.

The SPECIES are,

1. ATRIPLEX caule erecto herbaceo foliis triangularibus. Hort. Cliff. 469. *Orach with an upright herbaceous stalk, and triangular leaves.* Atriplex hortensis alba live pallide virens. C. B. P. 119.
2. ATRIPLEX caule fruticoso foliis deoidibus integris. Hort. Cliff. 469. *Orach with a shrubby stalk and entire leaves, shaped like the Greek delta.* Atriplex latifolia five Hahmus fruticosus. Mor. Hist. p. 2. 207. commonly called Sea Purslane-tree.

3. ATRIPLEX caule fruticoso foliis obovatis. Flor. Suec. 829. *Orach with a shrubby stalk and oval leaves.* Atriplex maritima fruticosa, Halimus & Portulaca marina dida angustifolia. Rail Syn.

There are several other species of this genus, some of which grow naturally in England, but as they are plants of no beauty, they are rarely admitted into gardens, for which reason I shall not enumerate them here.

The first of these plants was formerly cultivated in the kitchen-gardens as a culinary herb, being used as Spinage, and is now, by some persons, preferred to it; though, in general, it is not esteemed amongst the English; but the French, at present, cultivate this plant for use.

There are three or four different sorts of this, whose difference is only in the colour of the plants; one of which is of a deep green, another of a dark purple, and a third with green leaves and purple borders. These are supposed to be only accidental varieties which have come from the same feeds, but in forty years which I have cultivated these sorts, I have never yet observed them to vary. But as there is no other essential difference, I have not enumerated them here.

These plants are annual, so must be sown for use early in the spring, or at Michaelmas, soon after the feeds are ripe; at which time it generally succeeds better than when it is sown in the spring, and will be fit for use at least a month earlier. These plants require no other culture, but to hoe them when they are about an inch high; to cut them down when they are too thick, leaving them about four inches asunder, and to cut down all the weeds. This must be done in dry weather, otherwise the weeds will take root again, and render the work of little or no use. When the plants are grown about four inches high, it will be proper to hoe them a second time, in order to clear them from weeds; and, if you observe the plants are left too close in any part, they should then be cut out. If this be well performed, and, in dry

weadicr, the ground will remain clean ttt all the plant is Te for uic. Where ihefc plants nre Town on • rich foil, and allowed a gooddi

ance, the leaves will be very large, in which the goodnefs of ihe herb confifts. This mift be eaten while it is young; for, when the ftallu become tou«ii, it is good for nothing. Some few plants uf cadl kind may be j i

rotted to ftud for lied, to preferve thier kind:, which will ripen in Auguft, and may then be cut, and lEKl on i cloth to dry •, after which the Iceds may be beaten out, and put up tor life. The nrlr fun is ordered by the College of l'hyfitians for medicinal life

The (econd lui i was forme dy cultivated in gardens as a •irub i and, by lame perlbn, they were l'urmed into hedges, and confantly fharcil, to kwp them diicl; but chia plant a by no mews fit tor iuch purpofes, on many iL^um?;, lor it grows too vigorous i the llirijis, in one mondt, at ihe growing feafon of the year, will be two feet long, provided they have a good loll - . To that u h<|> of this mi CMUKK be kept in tolerable order, nor will it tier Sana 4 thick hedge. BJt a worft inconvenience attends this plant i lbr, in very hard winter, i a often destroyed; as allb, in very dry fumujers. many of te plants will ilei

by, whereby thietc will become large gaps in the huige. But although this plantwillnotbc proper for hedg«, yet it may have a place Li wiUirmelk quarters, where it will i'crvetutii ckern, and the filver«V>urcd leaves will add to the variety, amoiif; uchr lbnbs of the lame growth. Tills wij; grow eighi or icn f<t ligh, and, if fuficred to grov wild, without pruning, will l'pri^il iei-cral fecc in coinpals, and will (bmctiinu produce Ek»ers. h may be propagated by cuttings, which may bt plantw in any d the fure am months, on 3 [had] border; where, if illy are duly watered, dx y will loon take root, and be fit i> transplant ihe Michaelmas following, irhin they l'hciculO be planted when: diey arc to icmain; for they dj tin; H^ivrJ wll in n.ir.jijilinting, clpcciolly wlien they an! grown pretty lir^c and woody.

The third furt gnjws wild in divers parts of I; gland, on p • • • • • hence the plants may be [p>ro-cured; or it may be propiL ated by cuttings, in the lame manner as the former IU:L. This is a l. under ill rub, fcldoni riCng above two feet and a bail, or at null three fa t high, but become) ver) bushy. The leaves of this kind art narrow, and of a whitilh colour, but are not fo white as thofe I th& former. This may have a place amongst odier luv l'brubs-, and, if planted on a poor gravelly lull, will abide le-verjl years, and make a pretty djverfity.

The belt time for fowing of Oaw is in February or
 Marclv, Ktording as the featn is eirly or la; and
 fntmchnes t have known it (own in April upon cold
 land, and has been early ripe. The bbek and ted
 Oatt may be lbwn R momh earlier than the white,
 bsaufe they are tardier.

Oau are often fown on land which has the former
 yeau produced Wheat, Rye, or il • ley. The com-
 mon method is to pto gh in the stubble abent the
 liL-girtnng of February, and fow tin- Otto, and har-
 row them in; but then they irmii :e harrowd the
 lame wsy as ilic furrows htv, for If it ix- done croiT-
 ways, the :ubble will be raised or i the filrfta; but
 Illl5 I 9d method of Iiu(bamir> for when
 people have mne to plough the stubble in autumit,
 It will rot in winter; and tin -i giving the land another
 ploughing and a gond harm- ing juft before the Oau
 are born, it will make the ground finer and better
 to receive th' grain. Mort people allow rour bufheb
 of oats to an acre, but I im Llinvired three bulheb
 arc mnre tltin enough; the nTual produce u ^buut
 twenty-five Liilhels to an acre, though I have fume-
 Dma known more than thirty tiufliiek on an acre.

Oats are alfo fown upon; land when it u hrj broken
 up, before the ground is brouplit caa iUUh fortlier
 grain, ami Is frequently fown upon the fwarti with one
 ploughing; but it is much better to give the fwart
 tune la r"i before die <Jzxi are limn, for the roots of
 the graft will prevent thofe of the Corn from I striking
 down. and.

 and, if it be carried fomr. ees through trees, and
 it-ijmiin! in an any natural way, it will be much
 more beaivutl than any ftiff formal avenue, how large
 love; mad-

But as there may be some persons who are much wedded to the old way of laying out small plantings, as I prefer the avenue to the molt be...

The usual width of the avenues was generally as much as the width of the road, but if they are planted in a narrow way, they will be better...

And as to such avenues to woods or proficients, &c. they ought not to be more than thirty feet in width, and because such walks are a long time before they are shaded, it will be better to plant another row on each side...

As to the trees proper for planting streets, they may be the English Elm, the lime-tree, the Horse Chestnut, the common Chestnut, the Beech, and the Alder.

The English Elm is approved for all places where it will succeed, in that it will do in any soil, except in a very wet or cold situation...

Secondly, the Lime-tree: this is approved by others, because it will do well in any soil, and because of its regular shape it has in growing, and the beautiful colour of its leaves.

Thirdly, the Horse Chestnut is also to be used in such places as are very well defended from the wind, because wherever it grows freely, if it be not killed by any means now and then by cutting, the branches are subject to split...

Fourthly, the common Chestnut will do well in any soil, but wherever these are planted in a cold soil, they will not be so fruitful, and therefore they should be planted in a warm soil...

Fifthly, the Beech is recommended by some; but this kind is not so well as the other, and therefore it is not to be planted in a cold soil, but in a warm soil...

Sixthly, the Alder: this is indeed a very useful tree, and will grow in any soil, but it is not so beautiful as the others, and therefore it is not to be planted in a cold soil, but in a warm soil...

Seventhly, the Oak: but this is seldom used in plantings, because it is not so useful as the others, and therefore it is not to be planted in a cold soil, but in a warm soil...

As to the Aider, Ath, Etano*, and others, they are not so useful as the others, and therefore they are not to be planted in a cold soil, but in a warm soil...

It rarely suffices for planting avenues.

AURANTIA: T-IUM I this plant is so called from aurum, Lat. gold, on account of its golden colour, the Orange-tree.

The Orange-tree is small, of one leaf, divided into five parts. The leaves are green, spreading out, and many jointed in Juratjiparafa bediti 1:1...

This genus of plants is by Dr. Linnæus joined to the Citrus, to which he has also added the Lemon, making them a single species of the Eune genus, and ranges it in his eighth method, entitled Juratjiparafa bediti 1:1...

vica produce fruit with a pale yellow fleth, and by confiantly railing thefe trees from feeds, they degenerate the fruit continually *, whereas, if they would bud from the good fort, they might have it in as great plenty as they pleafed; but there are few perfons in that part of the world who underftand the method of grafting or budding fruit trees, and if they did, they are fo negligent of their fruits, &c. as to leave the whole to nature, feldom giving themfelves any farther trouble than to put the feeds into the ground, and leave them* to grow as nature fhall incline.

In proof of what I have here faid, I cannot omit to mention, that a few years ago, I lent two fmall trees of the true Seville Orange to Jamaica, where this fort was wanting; and from thefe many other trees were budded, which have produced plenty of fruit, fome of which were fent to England a few years paft *, and although they were long ip their paffage, yet when they arrived here, they were greatly fuperior to any of thofe fruit which are imported hither from Spain or Portugal, one of thofe affording three times the quantity of juice, that a fruit of equal lize from either of thofe countries does.

All the forts of Orange-trees with ftriped leaves are tender, therefore muft be placed in a warm part of the green-houfe in winter, and muft be treated with more care than the common fort, otherwife they will not thrive. Thefe are varieties which fome perfons are fond of, but they never produce good fruit, nor are the flowers produced in fo great plenty, therefore a few only fhould be preferred for the fake of variety.

The horned Orange differs, from the other forts in # the fruit dividing into parts, and the rind expanding in form of horns: this and the diftorted Orange are preferred by fome curious perfons for variety, but are not fo beautiful as the common Orange. There is alfo a great variety of fweet Oranges both in the Eaft and Weft-Indies, fome of which are much more efteemed than thofe we now have in Europe; but as they are much tenderer, they will not thrive in this country with the common culture; therefore I (hall not enumerate them, but fhall proceed to give dire&ions for the management of Orange-trees in England.

Whene the trees are to be raifed for docks to bud Oranges, you fhould procure fome Citron-feeds which were duly ripened *, for the flocks of this kind are preferable to any other, both for qu cknefs of growth, as alfo that they will take buds of either Orange, Lemon, or Citron; next to thefe are the Seville Orange feeds. The beft feeds are ufually to be had from rotten fruits, which are commonly eafy to be procured in the fpring of die year *, then prepare a good hot-bed! of either horfe-dung or tanners bark; the laft of which is much the better, if you can eafily procure it. When this bed is in a moderate temper for heat, you muft fow your feeds in pots of good rich earth, and plunge them into the hot bed; obferving to give them water frequently, and raife the glaffes in the great heat of the day, to give proper air, left the feeds fhould fuffer by too great heat: in three weeks time your feeds will come up, and if the you:g plants are not ftinted, either for want of proper heat or moiiure, they will be in a month's time after their dpearance, fit to tranfplant into fingle pots: you muft therefore renew your hot-bed, and having prepared a quantity of fmall halfpenny pots (which are about five inches over at the top,) fill thefe half full of good frefh earth, mixed with very rotten cow-dunpr *, and then fhafce out the young plants from the large pots, with all the earth about tjem, that you may the better feparate the plants without tearing their roots *, and having half filled the pots with earth, put a fingle plant into t ach of the fmall pots; then fill them up with the fame earth as before dire&ed, plunging the pots into the new hot-bed, giving them a good watering to fix the earth to their roots; and obferve to repeat the fame very often (for this plant, when in a hot-bed, requires much water,) but be fure

to fcrcen them from the fun in the heat of the day, In this method, with due care, your plants will grow to be two feet high by July, when you muft begin to harden them by degrees, in railing your glaffes very high, and when the weather is good, take them quite off; but do not expofe them to the open fun in the heat of the day, but rather take off the glaffes, and fliaide the plants with mats, which may be taken off when the fun declines; for the violent heat in the middle of the day would be very injurious to them, epecially while young. Toward the end of September you muft houfe them, obferving to place them near the windows of the green-houfe, to prevent the damp from moulding their tender fhoots. During the winter feafon they may be often refrelhed with water, and in March or April, wafh their heads and ftems, to clear them from the filth that may have fettled thereon, during their being in the houfe; and you muft alfo give them a moderate hot-bed in the fpring, which will greatly forward them'; but harden them by the beginning of June, that they may be in * right order to bud in Auguft; when you fhould make choice of cuttings from trees that are healthy and fruitful, of whatever kinds you pleafe, obferving that the fhoots are round; the buds of thefe being much better and eafier to part from the wood, than fuch as are flat. When you have budded the flocks, you fhould remove them into a green-houfe, to defend them from wet, turning the buds from the fun; but let them have as much free air as poffible, and refrefh them often with water. In a month's time after budding, you will fee which of them has taken *, you muft then untie them, that the binding may not pinch the buds, and let them remain in the green-houfe all the winter-, then in the fpring, prepare a moderate hot-bed of tanners bark *, and, after having cut off the flocks about three inches above the buds, plunge their pots into the hot-berc, obferving to give them air and water, as the heat of the weather fhall require; but be fure to fcreen them from the violence of the fun during the heat of the day. In this management, if your buds fhoot kindly, they will grow to the height of two feet or more, by the end of July *, at which time you muft begin to harden them before the cold weather comes on, that they may the better ftand in the green-houfe the following winter. In the firft winter after their fhooting, you muft keep them very warm *, for, by forcing them in the bark-bed, they will be fomewhat tenderer; but it is very neceffary to raife them to their height in one feafon, that their ftems may be ftrait: for in fuch trees, which are two or more years growing to their heading height, the ftems are always crooked. In the fucceeding years, their management will be the fame as in full grown trees, which will be hereafter treated of: I fhall therefore, now, proceed to treat of the management of fuch trees as are brought over every year in chefts from Italy; which is, indeed, by much the quicker way of furnifhing a green-houfe with large trees y for thofe which are raifed from feeds in England, will not grow fo large in their ftems under eighteen or twenty years, as thefe are when brought over; and although their heads are fmall when we receive them, yet in three years, with good nagement, they will obtain large heads and produce fruit.

In the choice of thefe trees obferve firft, the difference of their fhoots and leaves (if they have any upon them) to diftinguifh their different forts, for the Shaddock and Citrons always make much ftronger fhoots than the Orange *, for which reafon, the-Italiaa gardeners, who raife thefe trees for fale, generally propagate thofe forts, fo that they bring few of the Seville Orange-trees over, which are much more valuable both for their flowers and fruit *, alfo prefer thofe that have two good buds in each flock (for many of them have but one, which frill always produce an irregular head:) the ftraitnefs of the ftem, frefhnefs of the branches, and plumpnefs of the bark, are nceffary obfervations.

A U ft

When you have furnifted yourfelf with a parcel of trees, you mud: prepare a moderate hot-bed of tanfers bark, in length and breadth according to the number of trees to be forced; then put your trees intp a tub of water upright* about half way of the items, leaving the head and upper part of the ftem out of the water, the better to draw and imbibe the moifture. In this fituation they may remain two or three days (according to tKeir plumpnefs when you received them;) then take them out, and clean their roots from all filth, cutting off all broken or bruifed roots, and all the fmall fibres, which are quite dried by being fo long out of the earth, and fcrub the ftems with a hard hair-bruff, cleaning them afterwards with a cloth; then cut off the branches about fix inches from the ftem, and having prepared a quantity of good frelh earth, mixed with very rotten neats dung, plant your trees therein, obferving never to put them into large pots; for if they are but big enough to contain their roots, it is fufficient at firft planting *, and be fure to put fome pottherds and large ftones in the bottom of each pot, to keep the holes at the bottom of the pots from being (topped with earth, that the water may freely pafs off, and wrap fome haybands round their ftems, from bottom to top, to prevent the fun from drying their bark; then plunge thefe pots into the bark-bed, watering them well to fettle the earth to their roots, frequently repeating, the fame all over their heads and items, being very careful not to over-water them, efppecially before they have made good roots; and obferve to fcreen the glaffes of your hot-bed from the fun in the heat of the day.

If your trees take to grow kindly (as there is little reafon to doubt of, if the direftions given be duly obferved,) they will have made ftrong fhoots by the beginning of June; at which time you ihould (top their fhoots, to obtain lateral branches to furnift their heads; and now you muft give them air plentifully, and begin to harden them, that in the middle of July they may be removed into the open air, in fome warm fituation, defended from the great heat of the fun, and from winds, that they may be hardened before winter. About the end, of September you ihould houfe thefe plants, fetting them at firft in the front of the green-houfe, near the glaffes, keeping the windows open at all times when the weather will permit; and about the later end of Odtober, when you bring in the Myrtles, and other leis tender trees, you muft fet your Oranges in the warmeft and beft part of the houfe, placing lower plants or trees in the front, to hide their ftems. During the winter, let your waterings be frequent, but give them not too much at a time; for now their heads are but fmall, and therefore incapable to difcharge too great a quantity of moifture, and take great care to guard them from froft.

In the fpring, when you begin to take out fome of your hardieft forts of plants to thin your houfe, wafh and cleanfe the ftems and leaves of your Orange-trees, taking out the upper part of the earth in the pots, filling them up again with good, frelh, rich earth, laying thereon a little rotten neats dung round the outfide of the pots, but do not let it lie near the ftem of the trees; then place them at wider diftances in the houfe, that the air may circulate round their heads, giving them air difcretionally, as the weather grows warm; but do not remove them into the open air until the latter end of May, that the weather is fettled; for mafly times, when they are removed out too foon, the mornings often proving cold, give them at leaft a great check, which will change the colour of their leaves, and many times kill the extreme weak part of the fhoots. Let the fituation for your Orange-trees, during the fummer feafon, be as much defended from the fun in the heat of the day, and ftrong winds, as poffible, by tall trees or hedges; both of which, if they are expofed thereto, are very hurtful to them.

As thefe trees advance, it will be neceffary in the

A u R

fummer td ftop-ftrong fhoots where they grow irrègularly, to force out lateral branches to fill the head; but do not pinch off the tops of all the fhoots (as is the practice of fome,) whictwill fill the tree with fmall fhoots too weak to ilupport fruit; but endeavour to form a regular head, and obtain ftrong fhoots* taking away weak trifling branches where they are too clofe.

During the fummer feafon, your Orange-trees will require frequent waterings in dry weather, efppecially if they iare large; therefore you ihould endeavour to have the water as near the trees as poffible, to feve the trouble of carrying it, which, in a large quantity of trees, takes up much time. Your water ihould be foft, and expofed to the air, but never add dung of any fort thereto; which, although by many frequently recommended, yet has always been found deftrudlive to thefe, and ail other trees, if much ufed; it being like hot liquors to human bodies* which, at firft taking,, feem to add vigoifr, yet certainly leave the body weaker after ibme time than before.

Your Orange-trees will require to be ihifted arid new potted eveiy other year, therefore you muft prepare a quantity of good earth, at leaft a year before you intend to ufe it, that it may be well mixed and perfectly rotten. The beft feafon for this work is about the end of April, that they may have taken freih root before they are removed out of the green-houfe; and when this work is performed, it will be neceffary t* let them remain in the houfe a fortnight longer than ufual, to be well fettled.

In the performing this work, after you have drawn the trees out of the pots, you muft cut off alUthe roots round the outfide of the ball of earth, and take away all mouldy roots (if any fuch be;) then with a iharp iron inftrument, get as much of the bid earth from between the roots as poffible, being careful not to break or tear the roots; then fet the root of the tree into a large tub of water for about a quarter of an hour, to foak the under part of the ball of earth; and afterwards fcrub the ftems of the trees with a hard hair-bruff, cleaning them and the heads with water, and a foft woollen cloth. Your pots being prepared, with feme pottherds and large ftones in the bottom*, put fome of your frelh earth into the po(^ about three or four inches thick; and having placed your tree thereon, in the middle of the pot, upright, fill it up with the fame rich earth* preffing it down hard with your hands \ then water the tree all over the head, with a watering-pot that has a rdfe upon the fpout, to let the water fall light and thick (as in a ihower of rain;) and in watering thefe trees, do it in the fame manner, during the time they abide in the houfe after fhifting \$ this will greatly refreih their heads, and promote their taking freih roots.

When you firft fet thefe trees abroad after ihifting, jrou ihould place them near the fhelter of hedges, and fatten their items to ftrong ftakes, to prevent their being difturbed by winds, which fometimes will blow freih planted trees out of the pots, if too much expofed thereto, and thereby greatly injure their new roots.

If old Orange-trees have been ill managed, and their heads become ragged and decayed, the beft method to reftore them, is to cut off the greateft part of their heads early in March, and draw them out of the tubs or pots, and ftiake off the earth from their roots, cutting away all fmall fibres and mouldy roots; and then foak and clean their roots, ftems, and branches, planting them in good earth, and fetting them into a hot-bed of tenners bark, as was directed for fuch trees as came from abroad* managing them in the fame manner: by this method they will produce new heads, and in two years time become good trees again. But if thefe are large trees, and have grown in tubs for fcvtral years, your beft way will be to prepare a parcel of rough baikets (fuch as ire ufed for bafketing Evergreens, when fcntto adiftant place:) let thefe be fomewhat lefs than the tubs you defign to plant your trees into; then plant your trees

herein, plunging them into the hot-bed, and about the beginning of July, when your trees have made good shoots, you may remove them into the tubs, with their baskets about them, filling the empty space with the same good earth: this will preserve your tubs from rotting in the bark, and the trees will do equally well as if planted into the tubs at first, provided you are careful in removing the baskets, not to disturb their roots, and also let them remain in the green-house a fortnight or three weeks after planting, before you set them abroad.

These trees being new potted or tubbed every other year, those years in which they are not shifted, you must in April observe to take out as much of the old earth from the tops of the pots and tubs, and also round the sides of them, as possible, without injuring the roots of the trees, and fill them up with fresh earth & you must also wash and clean their stems and leaves from filth, which will greatly strengthen their flowering, and cause them to shoot vigorously the following summer.

In the management of Orange-trees which are in good health, the chief care should be to supply them with water duly, and not (as is sometimes practiced) starve them in winter, whereby their fibres are dried, and become mouldy, to the great prejudice of the trees; nor to give them water in too great abundance, but rather let their waterings be frequent, and given in moderate quantities. You must also observe, that the water has free passage to drain off for if it be detained in the tubs or pots, it will rot the tender fibres of the trees. During the winter season, they must have a large share of air when the weather is favourable, for nothing is more injurious to these trees than stifling of them, nor should they be placed too near each other in the green-house but set them at such distance, that their branches may be clear of each other, and that the air may circulate freely round their heads. In summer they should be placed where the winds are not violent, and to have the morning and evening sun; for if they are too much exposed to the mid-day sun, they will not thrive. The best situation for them is near some large plantation of trees, which will break the force of the winds, and screen them from the violent heat of the sun. In such a situation they may remain until the beginning of October, or later, according as the season proves favourable; for if they are carried into the green-house early, and the autumn should prove warm, it will occasion the trees to make fresh shoots, which will be weak and tender, and so liable to perish in winter; and sometimes it will occasion their flowering in winter, which greatly weakens the trees; nor should they remain so long abroad as to be injured by morning frosts. The best compost for Orange-trees is two thirds of fresh earth from a good pasture, which should not be too light, nor over stiff, but rather a hazel loam; this should be taken about ten inches deep with the spade, which should be mixed with the earth to rot, and one third part of neat's dung, these should be mixed together, at least twelve months before it is used, observing to turn it over every month, to mix it well, and to rot the spade, this will also break the clods, and cause the mould to be finer. Before you make use of this earth, you should pass it through a rough screen, to separate the great stones and the roots of the spade therefrom, but by no means sift the earth too fine, for this is very prejudicial to most plants, but particularly to Orange-trees.

Of late years there have been many of these trees planted against walls, against which frames of glass are made to fix over them in winter, and some few curious persons have planted these trees in the full ground, and have erected moveable covers to put over the trees in winter, which are so contrived as to be all taken away in summer: where these have been well executed, the trees have made great progress in their growth, and produced a much larger quantity of fruit, which have ripened so well, as to be extremely good for eating. If these are planted either against walls with

design of training the branches to the walls, or in borders at a small distance, so as to train them up as standards, there should be a contrivance of a fire-place or two, in proportion to the length of the wall, and flues carried the whole length of the wall, to warm the air in very cold weather, otherwise it will be very difficult to preserve the trees in very hard winters alive; or, if they do live through the winter, they will be so much weakened by the cold, as not to be recovered the following summer to a proper strength for bearing, so that wherever the trees are intended to be placed against or near old walls, the flues should be built up against the front, allowing four inches thickness of the brick-work on each side the flues, observing to fasten this with irons, at proper distances, to secure it from separating from the old wall: the manner of making these flues, is fully explained under the article of HOT WALLS. Where this contrivance is made, there will be no hazard of losing the trees, be the winter ever so severe, with a little proper care; whereas, if this is wanting, there will require great care and trouble to cover and uncover the glasses every day, when there is any sun; and if the wall is not thicker than they are usually built, the frost will penetrate through the walls in severe winters, so that covering and setting the glasses of the front will not be sufficient to preserve the trees, be it done with ever so much care & therefore the first expence of the walls will have great trouble and charge, and be the securest method.

If the ground is wet, or of a strong clay, so as to detain the moisture, the borders should be raised above the level of the ground, in proportion to the situation of the place & for where the wet lies in winter near the surface, it will greatly prejudice, if not totally destroy the trees, so that lime rubbish should be laid at least two feet thick in the bottom of the border, to drain off the wet; and the earth should be laid two and a half or three feet thick thereon, which will be a sufficient depth for the roots of the trees. In these borders there may be a few roots of the Guernsey and Belladonna Lilies and, Hsemanthus planted, or any other exotic bulbous-rooted flowers, which do not grow high, or draw too much nourishment from the borders; and these, producing their flowers in autumn or winter, will make a good appearance, and thrive much better than if kept in pots.

The management of the Orange-trees in these places, is nearly the same as hath been directed for those in pots or tubs, excepting that the borders in these places should be dug, and refreshed with some very rotten dung every year.

AURICULA MURIS, or Pansy. Mouse Ear.

This is a sort of Hawkweed with small hairy leaves, which are white underneath: the plant trails upon the ground, taking root at the joints, by which means it will soon spread over a large compass of ground.

This is very common in England; it grows chiefly on dry barren places, or upon old walls, and is too often a troublesome weed in grass-plats in gardens.

AURICULA URSI [i.e. Bear's Ear, so called because the ancients fancied it resembled the ear of a bear.] Bear's Ear, or Auricula.

Dr. Linnaeus has joined this genus to the Primula veris of Tournefort, making this one species under the title of Primula.

To enumerate the diversities of this plant, would be almost endless and impossible; for every year produces vast quantities of new flowers, differing in shape, size, or colour of the flowers, and also in the leaves of these plants there is as great a variety, so that the skilful florist is oftentimes capable of distinguishing many of the particular sorts thereby.

But as it seldom happens, that such of these flowers as are at one time in great esteem, continue to be regarded a few years after, (their being still finer or larger flowers produced from seeds, which are what the florists chiefly seek after) it would be needless to mention any of them; wherefore I shall proceed to give the characters of a good Auricula.

- i. *The stem of the flower should be lofty and strong.*
 1. *The foot-stalk of the flower should be short, that the umbel may be regular and close.*
 3. *The pipe or neck of each flower should be short, and the flowers large, and regularly spread; being no ways inclinable to cup.*
 4. *That the colours are very bright and well mixed.*
 5. *That the eye of the flower be large, round, and of a good white, or yellow and that the tube or neck be not too wide.*

All the flowers of this kind that want any of the above-mentioned properties, are now rejected by every good florist for as the varieties every year increase from seeds, the bad ones are turned out to make room for their betters, but in some people the passion for new flowers so much prevails, that, supposing the old flower greatly preferable to a new one, if it is of their own raising, the latter must take place of the old one.

In order to obtain good flowers from seeds, you must make choice of the best flowers you have, which should be exposed to the open air, that they may have the benefit of flowers, without which, they seldom produce good seeds: the time of their ripening is in June, which you will easily know, by their seed-vessel turning to a brown colour, and opening; you must therefore be careful to scatter the seeds out of the vessel, for it will not be all fit to gather at the same time.

The time for sowing this seed is commonly in August, but if it be sown any time before Christmas, it will be time enough.

The best soil for this seed is good, fresh, light, sandy mould, mixed with very rotten neat's dung, or very rotten dung from the bottom of an old hot-bed: with this you should fill your pots, boxes, or baskets, in which you intend to sow your seeds: and having levelled the surface of the earth very smooth, sow your seeds thereon, covering it very lightly with rotten Willow mould taken out of the stems of decayed hollow Willow-trees; then cover the box, &c. with a net or wire, to prevent the cats, birds, &c. from scratching out, or burying the seeds too deep; for whenever this happens, the seeds will remain a year in the ground before the plants appear, if it should grow at last; for which reason many persons never cover these seeds, but leave them upon the surface of the earth, in the boxes, for the rain to wash them into the ground, which is often the best method: let these boxes, &c. be placed so as to receive half the day's sun, during the winter season; but in the beginning of March, remove them where they may only have the morning sun till ten of the clock; for the young plants will now soon begin to appear, which, if exposed to one day's whole sun only, will be all destroyed.

During the summer season, in dry weather, often refresh them with water, but never give them too great quantities at once. In the July following, your plants will be large enough to transplant, at which time you must prepare a bed, or boxes, filled with the above-mentioned soil, in which you may plant them about three inches square; and (if in beds) you must shade them everyday, till they are thoroughly rooted, as also in very hot dry weather, but if they are in baskets or boxes, they may be removed to a shady place.

When the seedling Auriculas are planted in beds, there should be some rotten neat's dung laid about ten inches under the surface, and beaten down close and smooth: this will prevent the worms from drawing the young plants out of the earth, which they generally do where this is not practised. This dung should be laid about half a foot thick, which will entirely prevent the worms getting through it until the plants are well established in the beds; and the roots of the Auriculas will strike down into the dung by the spring, which will make their flowers stronger than usual: these beds should be exposed to the east, and screened from the south sun.

When you have taken all your plants, which are now come up, out of your boxes or pots, level the earth gently again; for it often happens, that some of the seeds will lie in the ground two years before they appear, especially if they were covered too deep when sown, as was before observed.

The spring following many of these flowers will show, when you may select such of them as have good properties, which should be removed each of them into a pot of the same prepared earth, and preferred until the next season, at which time you will be capable to form a judgment of the goodness of the flower; but those that produce plain-coloured or small flowers, should be taken out, and planted in borders in the out-parts of the garden, to make a show, or gather for nosegays, &c. the others, which do not produce their flowers the same year, may be taken up, and transplanted into a fresh bed, to remain till you see how they will prove.

The manner of propagating these flowers when obtained, is from offsets, or slips, taken from the old roots in April, when the flowers are in bloom: these offsets must be planted into small pots filled with the same sort of earth as was before directed for the seedlings, and, during the summer season, should be set in a shady place, and must be often (but very gently) refreshed with water; but in the autumn and winter should be sheltered from violent rains: The spring following these young plants will produce flowers, though but weak; soon after they are past flowering, you must put them into larger pots, and the second year they will blow in perfection.

But, in order to obtain a fine bloom of these flowers, you must observe the following directions.

First, Preserve your plants from too much wet in winter, which often rots and spoils them; but let them have as much free open air as possible; nor should they be too much exposed to the sun, which is apt to forward their budding for flower too soon, and the frosty mornings, which often happen in March, thereby destroy their buds, if they are not protected therefrom. To prevent which, those who are very curious in these flowers, place their pots in autumn under a common hot-bed frame, where, in good weather, the plants may enjoy the full air, by drawing off the glasses; and in great rains, snow, or frost, the plants may be screened by covering them. Where this method is practised with judgment, the flowers will be much stronger, and the plants will increase faster than when they are exposed abroad.

Secondly, In the beginning of February, if the weather is mild, you must take off the upper part of the earth in the Auricula pots, as low as you can without disturbing their roots, and fill up the pots with fresh rich earth, which will greatly strengthen them for bloom, as also prepare your offsets for transplanting in April, by causing them to push out new roots.

Those plants which have strong single heads, always produce the largest clusters of flowers, therefore the curious florists pull off the offsets as soon as it can be done with safety to their growing, to encourage the mother plants to flower the stronger; they also pinch off the flowers in autumn, where they are produced, and suffer them not to open, that the plants should not be weakened thereby.

Thirdly, You must cover your pots with mats in frosty weather, during this time of their budding for flower, lest the sharp mornings blight them, and prevent their blowing.

Fourthly, When your flower-stems begin to advance and the blossom buds grow turgid, you must protect them from heavy rains, which would wash off their white mealy farina, and greatly deface the beauty of their flowers; but at the same time observe to keep them as much uncovered as possible, otherwise their stems will be drawn up too weak to support their flowers (which is often the case when their pots are placed near walls) give them gentle waterings to strengthen them, but let none of the water fall into the center of the plant, or among the leaves.

Fifthly

A Z A

-fifthly, When your flowers begin to open, you should remove¹ their pots upon a stage (built with rows of shelves, one above another, and covered on the top, to preserve them from wet: this should be open to the morning sun, but sheltered from the heat of the sun in the middle of the day :) in this position they will appear to much greater advantage, than when the pots stand upon the ground, for, their flowers being low, their beauty is hid from us; whereas, when they are advanced upon shelves, we see them in a full view. In this situation they may remain until the beauty of their flowers is past, when they must be set abroad to receive the rains, and have open free air, in order to obtain feeds, which will fail if they are kept too long under shelter. When your feed is ripe, observe to gather it when it is perfectly dry, and expose it to the sun in a window upon papers, to prevent its growing mouldy, and let it remain in the pots till the season for sowing it.

AURICULA URSI MYCONL See VERBASCUM.

AXIS of a plant. Axis is properly that round smooth cylinder, about which a wheel is turned whence, by way of metaphor, that long, round, smooth part, placed in the center of the tuft, or cat tails, on Nut-trees, &c. about which the male organs are disposed, may be called the Axis. The French call it Ame, Noyau, or Poinçon.

AZALEA. Lin. Gen. Plant. 195. American upright Honeyfuckle.

The CHARACTERS are,

It hath a small coloured empalement which is permanent into five acute parts at the top. The flower is juncif-shaped having a long naked tube* cut into five parts; the two upper segments are reflexed backward* the two sides are bent inward* and the lower one turns downward. It hath five slender stamina of unequal lengths*, which have oblong erect summits. The round germen supports a long slender style* crowned with an obtuse stigma i the germen afterward becomes a roundish capsule* having five cells* which are filled with roundish small seeds.*

This genus of plants is ranged in the first section of Linnaeus's fifth class, entitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

I. AZALEA (*Vicofa*) foliis margine scabris, corollis pilofo glutinosis. Lin. Sp. Plant. 151. *Azalea with leaves having rough edges* the petals of the flower hairy and glutinous.* Cistus Virginiana flore & odore periclymeni. Pluk. Phyt. tab. 161. f. 4.

£. AZALEA (*Nudiflora*) foliis ovatis corollis pilq/is ftaminibus longiflimis. Lin. Sp. Plant. 150. *Azalea with oval leaves* hairy flowers* and the longest stamina.* Cistus Virginiana periclymeni flore ampliori minus odorato. Pluk. Mant. 49.

There are three or four other species of this genus, two of which grow naturally upon the Alps, chiefly on bogs; these are low plants, which have little beauty, and very difficult to keep in gardens. The others grow one in the east, near Pontus, and the other in India, but as neither of these are in the English gardens, I shall not enumerate them.

A Z E

The first of these here mentioned, is a low shrub, rising with several slender stems near four feet high. The leaves come out in clusters at the ends of the shoots, without order: they are spear-shaped, but narrow at their base, their edges are set with very short teeth, which are rough. The flowers come out in clusters between the leaves, at the extremity of the branches, which are white, with a mixture of dirty yellow on their outside: they have a tube an inch long, and at the top are pretty decaly cut into five segments, the two upper are reflexed, the two side ones are bent inward, and the lower one is turned downward. There are five slender stamina, which are a little longer than the petals of the flower, supporting oblong Saffron-coloured summits. The style is much longer than the stamina, and crowned by an obtuse stigma. These flowers have much the appearance of those of the Honeyfuckle, and are as agreeably scented. They appear the middle of July, but are not succeeded by seeds in England.

The second sort grows taller than the first, and in its native country frequently rises to the height of fifteen feet, but in England is never more than half that height. This sends out several stems from the root, which are garnished with oblong smooth leaves, placed alternately, having foot-stalks. The flower-stalks arise from the division of the branches, which are long and naked, supporting a cluster of red flowers, which are tubulous, swelling at their base like those of the Hyacinth, and contracted at their neck; they are divided at the top into five equal segments, which spread open. The five stamina and the style are much longer than the petals, and stand erect. This flowers about the same time as the former, but is not so well scented.

These plants grow naturally in shade, and upon moist ground in most parts of North America, from whence many of the plants have been sent of late years to England, and several of them have produced their beautiful flowers in many curious gardens.

They must have a moist soil and a shady situation, otherwise they will not thrive. They can only be propagated by shoots from their roots, and laying down their branches, for they do not produce seeds here; and if good seeds could be obtained, they would be difficult to raise, and a long time before they would flower. But when they are in a proper situation, their roots extend, and put out shoots, which may be taken off with roots, and transplanted. When any of them are laid down, it should be only the young shoots of the same year, for the old branches will not put out roots. The best time for this is 19 at Michaelmas, and if they are covered with some old tan, to keep out the frost, it will be of great use to them. The autumn is also the best time to remove the plants, but the ground about their roots should be covered in winter to keep out the frost, and if this is every year practiced to the old plants, it will preserve them in vigour, and cause them to flower well.

Ploughman's Spikenard, vulgu.
Be CfAIUcruts arc,
efouin- if eemped ef wax y law.

This genus of plants is ranged in the second section of Linnaeus's plantarum class, intitled Syngnesia Polygamia superflua, the flowers being composed of hermaphrodite and female florets, which are both fruitful.

1. **BACCARIA (Trifolia)** foliis lanceolatis tongicudnalter dentato- serratis. Ljn. • lor., I. Inf. Ploughman's Spikenard with four-shaped leaves, which are longitudoinally indented and serrated. Senecio Africana serotinent folia serrata. Boerh. Ind. ab. v. 117.
2. **BACCARIA (Aurea)** foliis lanceolatis superne uno altero dentato- serratis. Hort. Cliff. 404. Ploughman's Spikenard with four-shaped leaves, which are longitudoinally indented and serrated. Senecio Africana serotinent folia serrata. Boerh. Ind. ab. v. 117.
3. **BACCARIA (Haloifolia)** foliis obovatis superne emarginato- serratis. Hort. Cliff. 405. Ploughman's Spikenard with four-shaped leaves, which are longitudoinally indented and serrated. Senecio Africana serotinent folia serrata. Boerh. Ind. ab. v. 117.
4. **BACCARIA (Folia)** foliis lanceolatis serratis dentatis, corymbis bifidis. Flor. Virg. 121. Ploughman's Spikenard with four-shaped leaves, which are longitudoinally indented and serrated. Senecio Africana serotinent folia serrata. Boerh. Ind. ab. v. 117.

The English name of Ploughman's Spikenard has been always applied to the *Coccyza naja*, or greater Pheasant, but since most of the modern botanists have applied the name of *Baccaria* to this genus, I have added the old English name to it; Ploughman's Spikenard, rather than leave it without an English title. The first sort was brought from the Cape of Good Hope, but grows naturally in Peru, and in other parts of America. This plain has been long preserved by the curious in their gardens. It grows to the height of five or six feet, and is a remarkable shrub, which may be propagated by cuttings, which should be planted in a shady border during any of the summer months, or by seeds sown in a common border in the spring of the year. These seeds ripen well in this country; and, if permitted to sower on the ground, the plants will come up the following spring. It is very hardy, and will live abroad in mild winters, if planted in a warm situation; but it is usually kept in green-houses, and placed abroad in summer; it requires much water in warm weather.

The second sort is also a native of Africa; it hath a soft fleshy stalk, which rises to the height of eight or ten feet, pushing out side branches toward the top, garnished with six four-shaped leaves, having a few indurated toward their tops; these are placed without order; the flowers are produced at the extremity of the branches in a close spike, consisting of female and

B A N

bennapbrodte Sum included in the common emplacement they art- <ffan herl njr, C> m.ick ippewance, and arc not succeeded by seeds in England.

This plant is difficult to propagate, for the cuttings do with it with a difficulty take root; and it is very rare to find flowers near the root to lay down, so that in Uolhuui they lay down the entire head of young plants; flitting the (mallet branches in the same manner as is practised for Camassoot, laying them near the ground and forcing each down to prevent their rising; these when duly watered put out roots in six or seven years, when they may be taken off, and planted in small pots filled with light earth, and placed in the fire till they have taken new roots; after which they may be placed in a sheltered situation in summer, but in winter must be kept in a green-house.

The third is very common in the mountains of London, where it is usually called the Ground-Tell-ur; this is a native of Virginia and other parts of North America; it grows to be a shrub of five or six feet high, and flowers in October; the flowers are white, and not very beautiful; but the leaves continuing green through the year, by enclosing the stems into many small garden*.

This sort may be propagated by cuttings, which should be planted in the end of May, upon a shady soil, and in dry weather, and at Michaelmas, they will be so transplanted where they are to remain; they will live in the open air, and never is injured by frost of our tirdinury mnttr; but severe frost will sometimes deflmy it.

The fourth is found in North Carolina, and in other parts of North America; it rises with a lignous (i. e. six or seven feet high, garnished with long pear-shaped leaves, which are heavy in their under side, having a disagreeable smell when handled; the stalks are terminated by loose clusters of flowers, which appear late in the autumn, but are not succeeded by seed in this country.

It may be propagated by cuttings, which should be planted toward the end of May, which if sowed and watered will put out roots in two months; when they should be potted, that they may be sheltered under a frame in winter.

BACCIFEROUS (Baccifer, Lat. of Baccia, a berry, and ferre, to bear) is an epithet applied to trees, shrubs, or plants, that bear berries, as Briony, Lily of the Valley, Alparagus, Butchers Broom, Nightshade, Solomon's Seal, and many others.

BALAUUSTIA. See **PERSEA**.
BALAUUSTIUM is the cup of the flower of the wild Pomegranate.

BALLOTE (ballot, Gr.) Black Honeysuckle.
This is a common weed, growing on the sides of banks in most parts of England, or a frigid shewed a place in gardens; there are two sorts of it, one with a white, and the other a purple flower. As these are not cultivated, I shall not trouble the reader with a further description of them.

BANISTERIA. Houft. MSS. Lin. Gen. 509.
Acer Scandens. Sloan. Cat. 137. Plum. Cat. 18.

The CHARACTERS are,

It hath a small permanent empalement, cut into five acute segments to the bottom; the flower hath five petals, which are fhaped like thofe of the papilionaceous tribe, but fpread open, having infome fpecies one, in others two, and in feme, feveral neftarious glands. It hath ten fhort ftamina, crowned with fimple fummits. There are infome fpecies three, and, in others but one grmen, each fupporting a fingle flyk, crowned by an obtufe ftigma \ the germen afterward become Jo many winged fruit, likethat of the Maple, each containing a Jingle feed.

The title *6i* this genus was given by the late Dr. Houftoun, in honour to the memory of Mr. Banifter, a curious botanift, who loft his life in the fearch of plants in Virginia.

The Doftor ranged this genus in the clafs of papilionaceous flowers, to which 'it has great affinity by the form of its flower; but the ten ftamina ftanding feperate, induced Dr. Linnaeus to place it in his tenth clafs; but although he has put it under his third fection, yet it would with greater propriety come under his fecond, the greater number of fpecies having but two ftyles.

The SPECIES are,

1. BANISTERIA (*Angulofa*) foliis ovato-oblongis rigidis racemis terminalibus caule fruticofo fcandente. *Banifteria with oblong, oval, ftiff leaves, fpikes of flowers terminating the branches, and afhruddy climbing ftalk.* Sir Hans Sloane titles it, *Acer fcandens foliis Laurinis.* Qfcjam. 137.
2. BANISTERIA (*Fulgens*) foliis ovatis glabris, floribus corymbofis terminalibus, caule fruticofo fcandente. *Banifteria with oval fmoother leaves, flowers growing in a corymbus at the extremity of the branches, and afhruddy climbing ftalk.* *Acer fcandens minus Apocyni facie folio fubrotundo.* Sloan. Cat: 138.
3. BANISTERIA (*Brachiata*) foliis ovatis acuminatis floribus laxè fpicatis, ramis diffusis fcandentibus. *Banifteria with oval pointed leaves, flowers growing in loofe fpikes, and climbing diffufed branches.* *Banifteria fcandens & frutefcens folio fubrotundo, flore ex aureo Coccineo.* Houft. MSS.
4. BANISTERIA (*Laurifolia*) foliis ovatis nervofis fubtus incanis, floribus lateralibus, caule fruticofo fcandente. *Banifteria with nervous heart-Jhaped leaves, hoary on their under fide, flowers growing from the fide of the branches, and a Jhrubby climbing ftalk.* *Acer Americanum fcandens foliis fubrotundis fubtus pubefcentibus.* Millar. Cat.
5. BANISTERIA (*Benghalenfis*) foliis ovato-oblongis acuminatis rr.cemis lateralibus feminibus patentibus. *Flor. Zeyl. 1761 Banifteria with oblong, oval, pointed leaves, fpikes of flowers growing from the fide of the branches, and fpreading feeds.* *Acer fcandens foliis Citrei flore cseruleo fpicato.* Plum. Cat. 18.
6. BANISTERIA (*Aculeata*) foliis pinnatis, foliolis oblongis obtufis, floribus fpicatis caule ramofo aculeato. *Banifteria with winged leaves, whofe fmall leaves are oblong and blunt, flowers growing in a fpike, and a prickly branching ftalk.*
7. BANISTERIA (*Purpurea*) foliis pinnatis foliolis ovatis fpicis lateralibus feminibus eredbis. *Banifteria with winged leaves, whofe fmall leaves are oval, fpikes of flowers growing from the fide of the branches, and ereff feeds.* *Banifteria foliis ovatis fpicis lateralibus feminibus ereffis.* Lin. Sp. Plant. 427.

The firft grows naturally in Jamaica. This hath a woody ftalk, which twifts itfelf round the neighbouring trees, and riles to their top. It is garnifhed with leaves as large as thofe of the Bay-tree, and of the fame thicknefs, growing oppofite* the flowers are produced in long branching fpikes at the ends of the branches, which are yellow, compofed of five fmall leaves; thefe are fucceeded by two or three winged feeds like thofe of the greater Maple.

The fecond fort grows naturally in Jamaica, at Campeachy, and feveral other parts of America. This hath flender winding ftalks, which rife five or fix feet

high, and are thinly garnifhed with oval fmoother leaves; the flowers grow in a round bunch at the extremity of the branches, which are of a browniff yellow colour, and are fucceeded by winged feeds like the former, but fmaller, and have narrower wings.

The third fort was fent me from Carthage, where it naturally grows. This, fends out many branches, which divide again into others, gracing without order, and become very bufhy upward, fending out tendrils by which they fatten themfelves to the neighbouring trees, and mount to a grqat height; thefe are garnifhed with oval ftiff leaves, ending in a point. The flowers are produced in loofe fpikes at the ends of the branches, which are firft of a gold colour, and fade to a fcarlet. Thefe are fucceeded by feeds of the fame fhape with the former, but are flender, thin, and for the moft part fingle.

The fourth fort was fent me from Campeachy, by Mr. Robert Millar; this hath many irregular climbing ftalks, which fatten themfelves to the neighbouring trees, and rife to a great height, garnifhed with oval leaves, which are hairy on their under fide, where they have many tranfverfe ribs. The flowers come out thinly from the fide of the branches, which are of a pale yellow colour; and are fucceeded by large winged feeds, of which are double.

The fifth fort hath ftrong woody ftalks, which twine about the trees which grow near it, and rifes twenty feet high, garnifhed with oblong pointed leaves like thofe of the Bay-tree, growing oppofite; from the wings of the leaves the flowers are produced in loofe fpikes, upon long foot-ftalks, which are blue, and are fucceeded by flender winged feeds, which fpread open from each other.

The fixth fort was fent me from Tolu in New Spain, where it grows naturally. This hath climbing ftalks, which divide into many branches, garnifhed with long winged leaves, compofed of about twenty pair of fmall, oblong, blunt pinnae, each having a deep furrow on the under fide. At the wings of the leaves the ftalks are armed with fhort ftrong fpines, a little crooked. The flowers grow in long loofe fpikes at the end of the branches, which are fucceeded by fingle feeds, as large as thofe of the greater Maple.

The feventh fort hath ftrong ligneous ftalks, covered with an Afh-coloured bark, and divide into many branches, garnifhed with winged leaves, compofed of five or fix pair of oval fmall leaves, nearly of the fize with thofe of the common Acacia, but are whitiff on their under fide; from the wings of the leaves are produced flender bunches of flowers, growing in a racemus like thofe of the Currant-buff, of a purpliff colour; thefe are fucceeded by broad winged feeds, growing erect. It was fent me from Campeachy, where it grows naturally.

Thefe plants are all of them natives of warm countries, fo'c jnnot be preferred in England, unlefs they are kept in a bark-ftove. They are propagated by feeds, which muft be procured from the countries where they grow naturally. Thefe feeds fhould be fully ripe when gathered, and put into fand or earth, in which they fhould be fent to England, otherwife they will loofe their vegetative quality *, for from a large parcel of thefe feeds which were fent over in papers, as freffh as they could poffibly arrive here, there was very few plants raifed, and thofe did not appear till the fecond year *, for thefe feeds are not only in fhape like thofe of the Maple, but alfo are of the fame quality, requiring to be fown as foon as poffible when they are ripe, or preferred in fand or earth till they are fown, otherwife they rarely fucceed; therefore when die feeds arrive, they fhould be immediately fown in pots, and, if it happens in autumn or winter, the pots fhould be plunged into a hot-bed of tanners bark, where the heat is very moderate, and fe cured from froft and wet, till fpring, when they muft be removed to a freffh hot-bed, which will bring up the plants; but if they fhould not appear the firft year, the pots fhould be preferred till the next fpring,

B A R

to see if the feeds will grow. When the plants come up, they must be planted in separate pots, filled with light earth, and plunged into the bark-bed, after which they must be treated like other tender plants from the same countries.

BARLERIA.

The name was given to this genus of plants by father Plumier, in honour of Jacobus Barlier, of Paris, who was a famous botanist.

The CHARACTERS are,

*It hath a permanent empalement, divided into four parts, two large and two smaller, opposite. The flower is of the lip kind, of one leaf, funnel-shaped and divided into five parts at the top, the upper figment being broad and entire, the two side ones narrower, and the under one which turns downward is divided into two. It hath four slender filaments, two of which are very short, the two upper are longer, crowned by oblong summits. In the center is placed the oval germen, supporting a slender style, crowned by a bifid stigma. *The germen afterward becomes an oblong, quadrangular, membranaceous vessel, with two cells, which is very elastic, containing two or three roundish compressed seeds.*

This genus of plants is by Dr. Linnaeus ranged in the second order of his fourteenth class, titled Didymia Angiofermia, whose flowers have two long and two short stamens, and their seeds are included in a capsule.

The SPECIES are,

1. BARLERIA (*Solanifolia*) spinis axillaribus foliis lanceolatis denticulatis. Lin. Sp. 887. *Barleria with spines on the side of the branches, and pear-shaped indented leaves.* Barleria aculeata foliis angustioribus flore casruleo. Plum. N. G. 31.
2. BARLERIA (*Prionitis*) spinis axillaribus quaternis foliis integerrimis. Lin. Sp. Plant. 636. *Barleria with spines growing by fours from the side of the branches, and entire leaves.* Coletta-veetla. Hort. Mai. 9. p. 77.
3. BARLERIA (*Buxifolia*) spinis axillaribus oppositis foliatis, foliis subrotundis integerrimis. Lin. Sp. 887. *Barleria with spines at the wings of the stalk, and roundish entire leaves.* Barleria Americana spiniflora frutescens, buxi folio parvo flore. Amm. Herb. 104.
4. BARLERIA (*Coccinea*) inermis foliis ovatis denticulatis petiolatis. Lin. Sp. 888. *Barleria without spines, and oval indented leaves having foot-stalks.* Barleria foliis ovatis, flore coccineo. Plum. Nov. Gen. 31.

The first fort rises with upright square stalks three feet high, garnished with two oblong entire leaves at every joint, above which the flowers come out in whorls surrounding the stalks, and under each whorl there are six sharp spines, which are as long as the empalement of the flowers. These joints are about three inches distance; the flowers are blue, and have more of the form of the labiated flowers, than any of the other species. I received this from Panama.

The second fort has been long in the curious gardens in Holland, but has not been many years in this country. This sends out many slender stems from the root, which rise eight or nine feet high, garnished with oval pointed leaves, two growing opposite at each joint, which are attended by four long spines standing cross-ways. This plant hath not as yet flowered in England, though there are large plants of it in the Chthia garden.

The third fort hath shrubby stalks which rise five or six feet high, garnished with roundish entire leaves placed opposite, under which are placed strong spines; the flowers are produced in whorls toward the upper part of the stalk; these are succeeded by short seed-vessels, containing three or four flat seeds. This grows naturally in Jamaica.

The fourth fort grows naturally in the warm parts of America. The stalks of this are smooth, they rise

B A R

four feet high, are garnished with two oval indented leaves standing opposite, the flowers are scarlet, and are placed in whorls at the joints of the stalks; these appear in July, August, and September, and are succeeded by short pods inclosing flat seeds.

The roots of the first fort will continue three or four years, but after the second year, the plants grow too rambling, and the lower part of the branches are naked, so are not so fitly as the young plants; therefore a succession of these should be raised, and the old ones turned out. They are propagated by seeds, which will sow themselves in the pots which are near them in the stove, when the plants are once obtained; but where the seeds are received from abroad, they must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, and plunged into a hot-bed of tanners bark, where they must constantly remain, and managed in the same manner as other tender exotics from the same countries, giving them water frequently in summer, and letting the fresh air to them every day in warm weather, but in winter they should have less water and be kept warm. They flower from June to November, and their seeds ripen soon after.

The second fort hath flexible perennial stalks, which if cut off during the summer months, and made into lengths of six or eight inches, and planted in pots, plunging them into a hot-bed, and duly watered and shaded from the sun, will soon put out roots, so may be planted each in a small pot, and plunged into the tan-bed in the stove; for although this fort may be kept in a dry stove through the winter, yet the plants will not grow near so fast, nor will their leaves be so large as those which are plunged into bark. By this method the plants may be propagated in plenty, but as they rarely produce flowers in England, two or three plants will be sufficient to maintain the species.

The third and fourth forts will produce seeds in England, provided the plants are kept in the tan-bed in the stove, so these may be propagated by seeds, which should be sown in the hot-bed, and the plants afterward treated in the same manner as the first fort.

B A R O M E T E R [from *Barys*, a weight, and *metron*, a measure,] is an instrument or machine for measuring the weight of the atmosphere, or the minute variation of the weight or pressure of the incumbent air, in order to determine the changes of weather.

This machine is founded on the Torricellian experiment, so called, from the inventor Torricellius.

1. It consists of a long tube of glass, hermetically sealed at one end; and being filled with quicksilver, is inverted so as to have one end of it immersed in a basin of stagnant quicksilver, and the other hermetically sealed, which is exposed to the pressure of the outward air, out of which open end (after such immersion) the quicksilver in the tube being suffered to run as much as it will into the stagnant quicksilver, in which that mouth or open end is immersed, there is wont to remain a cylinder of quicksilver suspended in the tube, about twenty-eight, twenty-nine, or thirty inches high, measuring from the surface of the stagnant quicksilver perpendicularly, but more or less within such limits, according as the weight or pressure of the air incumbent on the external stagnant quicksilver exposed to it, is greater or lesser, leaving the upper part of the tube void, or at least empty of common air.

The phenomena of the barometer are various, and the causes assigned for them, by several authors, are various; nor is the use of it in predicting the weather, yet perfectly ascertained.

The greatest height the mercury has been known to stand at in London, is thirty inches three-eighths, and its least, twenty-eight inches: and though, as Mr. Boyle observes, the phenomena of the barometer are so very precarious, that it is very difficult to form any general rules about the rise and fall thereof, since

in thit which seems to hold most univerfally, vk. that when the liGH winds-Mow, tht mercury is the lower, they fometim.e fail ; as the following obllv-varium iffic been made by feveral authors.

Dr. Hstley obferves, th.i: in calm weather, when the air •3 iiclinu! to r.-in, the mercury h comi; usually low ; in fercne guod fettled weather, high.

That on great vrinils, clough the incompinied with rain, ilit; mercury u lowdt of all, with regard to the point of the compali the wind blows on; this , se-irit pariimi, the grtstcft heights of 11 it mercury arc oneiik-rlly aml north-carter! after great ftrms of wind, when the mercury his bten low, it lifts agnin vet; fall.

That in culm troffy weather it fhnds high.

That the more northerly places find greater ;:ltera-tions than the more fothern , and ili nt within the tropics, and near chcin, iliere bliafcornovari sion of the mercury at all.

Dr. B?il obfervei, that, e*firis paribm, the mercury is higher in cold weathw than in warm, and usually higher !n morning and even in p th >n ?s :i • < i • I ;iy.

That the mercury i; higher in iettled jfel i'ir we.nher, than either a link benire, or alter, or in tltit nun ; ami tltut I: generalW deteeads lower afrer win, than if it chance to rife higher after rain, it is ;ra% followed by a fetti

Th;it thsre arc frequ: I great changes in tte (Ur, withiout iBiv | acceptable ftrations f) tlic baramer.

As in the pord, ••• as from iht; barometer, Dr. Hnt-ky hi^ (bund,

That the r; ingof the mercury forebode* iair weather after fool, and an eafterly or north-tatkrlly wind.

Thai the filling of the mercury porrends fe- arly weitrllly winds, with i rains, or ltormy wind.i. or both.

That in a ftrnm tlic mercury beginning to riic, is a pretty fure ligh that it begins [OIEste.

Mr. Patrick obferves, that the falling of the in- cihotweath! perhaps thunder j that when foul wea-ther happens after trie i ill of the mercury, it Idom iiohk long) ^n d the lame is dbferved, if hir weather ftrceeds ;Fifty utter ii

Here • Mr. Pointer conceives, time the principal e-ife of rlv rife and fall of the mercury, is in the varu) y winds which are ftrted in the temperate zont-s, uul whose great iriconftant: here in England h molt notori

A iteond enufe he takes co be, the uncertain exhalation and perfp. tion of the vap- mrs lodging in the air, whereby It come] to be at one tim*¹ much more crowd d than at another, and conicqnc'ly heavier; but this latter, in a great meafure, depends • >n cic former.

And t'roni thec principles, he endravouj to explain tlic feveral phi-non'cni c* the baroiv

1. Tlic raercury J being bw, inclints it to nin; be- caufe the air being light, the vapours are no longer fup- ported thefdy, being become fpecifically heavier than the medium wherein they are floated; fo that they c'clend towards the earth, and in their fall rntet- ing with < air aqueous particles, they incorporate tughttth, a i i form little drops of i ijn , but ito mercury's being at Dre rimt lower than another, is the efieft of two con'ary winds blowing from the place where the barometer ftands , whereby ch

place is carried both ways from it, and confequently the incumbent cylinder of air is diminished, and ac- cordingly the mercury linloi. As • influence, if in rhe German occ.;; it fhould blow a gale of westerly wind, and lj the fame rime an L-iltterly wimi

in the Irish fea, or if in France . . • Ill blow n northerly wind , and in Scotland J fiju' rity, it muft be grant- ed, that that p n air l ft- atmol j'herc imjondc... over England, would thereby be rthaufted and atte- nuated, and the mercury would rife; and the vap- p mrs which before floated in Th'e part of thepif,

Of K! . lvo, would fink to the carrh.

••. The gw r h rfit of tlic barometer ii occaGoncd

by two contrary winds blow raj towards the plate of obfervation, whereby the air • other places is hrughr fufier and accumulated ; fo that the incumbent cy- linder of air being increased both in height and weight, the mercury prefied thereby muft needs rife and lli'Ui i> i' l' , •• long is the winds continue in d blo.v ; and then the air being fpecifically heavier, the vapours are better kept fufpended, fo that they have

110 in dination to precipitate and i Abr.vn in drops, which is the reafon of the fervat good weather, which attends the greater heights of the mercury.

% The mercury finkj tin- bwef of all by die very rapid wofon of r-x air in iorins of i mls.

For the tract of the region of the earth's furface, wherein tin ic winds rage, not exten • out a] round the globe, that ftagnant air which ii left behind, as it were that on the fides • cannot c • meinfofaiUsto fupply the evacuation made by li • meinfofaiUsto rtwit a current i fo tliati;

the air muft neceffarily be ftirred up and where the fide winds continue to blow, and thal more or lefs, according to their violence; add to which, that L: horizontal motion of the air being fo quick as it is, may, in all probability, take off fome part of die J- pendiculae pressure it exerts ; and the gre a g J- tation of its particles is the reafon why th • vapours are diflipatcd, .. d do not condense into drops, fo as to form rain, i ftrvice the natural confequence jf tlic air's rarefaction.

+ The mercury rids the high; uptm an eafterly or north-eafterly wind; becaufe, in the great Ath- latic ocean, on this fide the thirty-fifth degree of north latitude, the eafterly and westerly winds blow almoft always trade : fo that whenever here the winds come up at east and north-east, it is fure to be checked by a contrary gale as foon as it reaches the ocean ; whether, according to what is faid • out in the se- com i remark, the air muft needs be heaped over this ihu \ and CDiiletjueml , the mercury muft ftand high, as often as thec winds Wow.

5. In calm froiVf Meat tier, the mercury generally itanui high, beca • as he conceives, it seldom freezes bin: when : be winds come out of the northern or north-eaftern quarters, or at leaft, unlefs thofe winds blow at no great diftance of.

For the northern parts of Germany, Denmark, Swe- den, Norway, and all that tract, from whence north- eaftern winds come, are fubject to almoft continual froft all the irinrer, r.nd therdy the IOWL: air is very much conditced, and in that rate is brought higher- ward by thofe winds; and, being accumulated by the oppofition of the westerly wind blowing in the ocean, the mercury muft needs be perfid to a more ordinary height; and, as a concurring caufe, the ftirking of the lower parts of the air into better room by cold, muft needs caufe a defcent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an equilibrium.

6. After great ftorms of winds, when the mercury htut l rize very low, it generally rife again very fall: he fays, he once obferved it to rife an inch and a half in Idi thrji l' hours, after a long continued ftorm of i both-weH wind. The reafon is, ¹ becaufe the air being very much rare- fied by the great evacuations that fuch continued ftorms make thereof, the neighbouring air runs in more fwiftly, to bring it to an equilibrium, as we fee wate run the fides of having a greater density.

7. The variations are greater in the more northerly places, as at Stockholm greater than at Paris (com- pared by Mr. Falch); becaufe the more northerly parts have usually greater ftrms of wind ill in the more fotherly, whereby the mercury fhould fink low < Tin : air expanoixhe and rty be winds bringing

the condensed and pondicous air from the neighbour- hood of the pole, and that a gun being checked by a fotherly wind, at no great diftance, and fo heaped up, muil i' neceffary, make the mercury in fuch cafe land higher in the other extreme.

8. Th' remark, that there is little nr no variation ntai the ctju inctual, is : • , tbovcall other?, tuiinrm the

the hypothesis of the variable winds being the cause of these variations of the height of the mercury, for in the places above-named, there is always an easterly gale of wind, blowing nearly upon the same point, viz. E. N. E. at Barbadoes, and E. S. E. at St. Helena; so that there being no contrary currents of the air to exhaust or accumulate it, the atmosphere continues much in the same state.

Mr. Patrick gives us the following rules and observations for the rising and falling of the mercury, in order to foreknow the weather by the barometer.

1. It has been observed, that the motion of the mercury does not exceed three inches in its rising or falling in the barometer of the common form.
2. That its least alterations are to be minded, in order to the right finding of the weather by it.
3. The rising of the mercury prefaces in general fair weather, and its falling, foul, as rain, snow, high winds, and storms.
4. In very hot weather, the falling of the mercury foretells thunder.
5. In winter, the rising of the mercury prefaces frost; and in frosty weather, if the mercury falls three or four degrees, there will certainly follow a thaw; but if the mercury rises in a continued frost, it will certainly snow.
6. When foul weather happens soon after the falling of the mercury, you may expect but little of it; and you may judge the same, when the weather proves fair shortly after the mercury has risen.
7. When the mercury rises much and high in foul weather, and continues so for two or three days before the foul weather is over, you may expect a continuance of fair weather to follow.
8. When the mercury falls much and low in fair weather, and continues so for two or three days before the rain comes, then you may expect a great deal of wet, and probably high winds.
9. The unsettled motion of the mercury denotes uncertain and changeable weather.
10. You are not so triflingly to mind the words engraven on the plates, though for the most part they will agree with them, as the rising and falling of the mercury; for if it stands at much rain, and rises up to changeable, it prefaces fair weather, although not to continue so long as it would have done, if the mercury were higher, and so on the contrary.

These rules and observations are sufficient to instruct persons who are unacquainted with this instrument, how to make their observations; and with constantly remarking what alterations happen in the weather on the variations of the mercury, a person may nearly predict the great alterations of the weather a day or two before they happen, which is frequently of great use to the gardener and farmer, but particularly to the latter, who may begin to mow his grass when he finds there is a prospect of fair weather, or postpone it a few days until he foresees a likelihood of such. The same also may be of great moment in reaping his corn, as also in sowing his grain, and mowing his other business. Therefore the use of this instrument should be more generally known by the practical farmer and gardener.

B A R T R A M I A. See TRIUMFETTA.

B A S E L L A, or climbing Nightshade from Malabar.

The CHARACTERS are,

The flower hath no empalement; it is shaped like a pitcher, fleshy at the base and swelling, but closed toward the brim, where it is divided into six parts, two of which are larger than the others. It hath five awl-shaped Stamina, which are equal, fastened to the petal, crowned with roundish summits. The globular germs, which is situated in the center, supports three slender styles, crowned by oblong stigma. The petal of the flower remains, and incloses a roundish fleshy berry, including one round seed.

This genus of plants is ranged in the third section of Linnæus's fifth class, entitled Penwondria Trigynia, the flower having five stamens and three styles.

The SPECIES are,

1. BASELLA (*Alba*) foliis planis, pedunculis simplicibus.

bus. Lin. Sp. 390. *Bafella with plain leaves and finite foot-stalks.* Cicutia. foliis iuscordatis. Hort. CUE 39. *Climbing Nightshade.*

2. BASELLA (*Alba*) foliis ovatis undatis, pedunculis simplicibus folio longioribus. Lin. Sp. 390. *Bafella with oval waved leaves, and foot-stalks longer than the leaf.* Bafella Sinica, foliis & caulibus viridibus minus fuculentibus fructu minore. Just.

The first sort has thick, strong, succulent (talks and leaves, which are of a deep purple colour. The plant requires to be supported, for it will climb to the height of eight or ten feet, when the plants are kept in a stove or glass-case, and produce a great number of side branches: but if they are exposed to the open air, they will not grow so large, nor will they perfect their seeds, except it be in very warm seasons, when they are placed in the bark-stove, they will often live through the winter, and produce great quantities of flowers and seeds. The flowers of this plant have no great beauty, but the plant is preserved for the odd appearance of the stalks and leaves.

The seeds of the second sort I received from Dn Juslieu of Paris, from whence I have obtained two varieties, one of which hath purple stalks and leaves, and the other hath leaves variegated with white, but both of them retain their small stalks, and oblong; flaccid leaves, smaller flowers and fruit, in which they essentially differ from the first.

These plants are propagated by seeds, which should be sown in a hot-bed in the spring, and when the plants are fit to remove, they should be each planted into a separate pot filled with rich earth, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotics. They may also be propagated by cuttings, which should be laid to dry a day or two after they are taken from the plants, before they are planted, that the wound may heal, otherwise they will rot. These cuttings must be planted into pots filled with light fresh earth, and plunged into a moderate hot-bed of tanners bark, where they will take root in a fortnight or three weeks time, when they should be treated in the same manner as the seedling plants. But as these rise so easily from seeds, it is seldom they are propagated any other way, because they are plants of short duration. These flowers from June to autumn, and the seeds ripen in September and December.

These plants will climb to a considerable height, and send forth a great number of branches, so that they should have a place near the back of the stove, where they may be trained up to a trellis, or fattened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them, and be very injurious to the other plants; whereas, when they are regularly trained to a trellis, they will have a good effect in adding to the variety.

From the berries of the first sort, I have seen a beautiful colour drawn, but when used for painting, did not continue very long, but changed to a pale colour; though I believe there might be a method invented, whereby this beautiful colour might be fixed, so as to become very useful; for I have been assured, that the juice of these berries has been used for staining of calicoes in India.

BASILICUM, or BASIL. See OCYIMUM.

BASONS or fountains, &c. which serve either for the ornament or use of gardens, are made in divers forms, some round, some oblong or oval, others square, octangular, &c. but their most common form is circular; and, if the ground will permit, the larger they are the better, and when they exceed in size, they are called pieces of water, canals, fish ponds, pools, and reservoirs.

In making these, care ought to be taken to avoid both the extremes, and not to make them either too big or too little, that a water work may not take up the best part of a small spot of ground; nor to make too little a basin in a large spot. This must depend entirely on the judgment of the designer of the garden.

Some would have the fize of a bafon to be proportioned to the Jet d' Eau, that the water thrown up in the air, may not, by being blown by the air, be carried beyond the edge of the bafon, but all fall down without wetting the walk.

As to the depth of baibns it is ufually from two to three feet, this depth being fufficient to fecure the bottom of the bafons from froft, and to dip watering pots.

But if they are to fcp/e for refervoirs, or to keep fifh in, then they may be made four or five feet deep, which will both hold water enough, and be deep enough for the fifh to breed in, and alfo to bear a boat.

Deeper than this they need not be, and if they were deeper, they would be dangerous as to the drowning of perfons who might chance to fall in.

In making bafons, great care ought to be taken in making them at firft-, for die water always naturally endeavouring to run away, and by its weight and preffure in a bafon, making its way out at the lead cranny, it will grow confantly bigger and bigger; fo that if it be not well made at firft, it will be very difficult to repair it.

Bafons are made either with clay, cement, or lead; they are mod: ufually made of clay; in making fuch, at the marking out the dimenfions, the diameter ought to be four feet bigger on each fide, yet the bafon will not be the wider, for it will be taken up with the walls on each fide; and the clay-work, which is to fill the fpace between; the bafon muft alfo be dug two feet deeper than the depth of the water is defigned to be, becaufe it is to be laid over eighteen inches thick with clay, and fix inches with gravel and paving.

The clay ought to be well wrought with the hands and water, and when it is fspread, fhould be trodden in with the naked feet, that the water of the bafon may not dilute through it, and the roots of any trees that may grow near, may not penetrate into the outward wall, which may be made of fhards, rubble, or flints, with mortar made of the natural earth, and is called the ground wall, becaufe it is only made to refift the preffure of the ground about it. The inward wall ought to be made with good rubble ftones that will not fcale and come off in flafhes in the water, or elfe of flints and ftones from the hills, which will make durable work, but will not look fo neat as the pointed rubble *, and there ought to be laid here and there ftones, the thicknefs of the wall, to render it the more fubftantial.

The method of making bafons of cement is as follows: after you have marked out the dimenfions of the bafon, as before, if you enlarge it one foot nine inches, it will be fufficient, and the fame depth deeper at the bottom will be enough.

This being done, you muft begin to back up and raife againft the ground *, cut perpendicularly a wall of malbnry a foot thick, which muft go to the bottom, and fhould be built with fhards and rubble ftones laid in mortar of lime and fand.

When the wall is finifhed round the circumference, then the bottom is to be wrought .a foot thick with the fame materials *, and the folid work or lining of cement is to be backed up againft the walls nine inches thick, including the plaftering and inward furface. This folid ought to be made of fmall flints, laid in beds of mortar made of lime and cement.

When this folid is eight inches thick, it ought to be plaftered over the whole furface of the bottom with cement well fitted before it be tempered with lime *, and with this it fhould be wrought over fsmooth with the trowel.

The proportion of this cement fhould be two thirds of cement or powdered tile to one third of lime.

This cement has the property to harden fo underwater, that it will be as hard as fstone or marble, and the body will be fo folid as never to decay.

After the finifhing of the bafon, the plaftering fhould be for four or five days fucceffively anointed over with

oil, or bullock's blood, to prevent it from ttackirtg or flawing; this being done, the water fhould be let into the bafon as fcon as may be.

Thofe bafons which are made of lead, are to be thus wrought *, the outlines ought to be enlarged one foot of a fide, and digged half a foot deeper than the bafon is to be.

The wall muft be made a foot thick, that it may be able to bear up againft the earth lying againft it -, but the bottom will not require to be miffe than half a foot thick.

Thefe walls muft be built in rubble laid in mortar all of plafter, becaufe the lime will eat the lead, and then the lead muft be laid on the walls and bottom, and be feamed with folder.

But bafons of lead are not much in ufe, becaufe of their great charge in making, and the danger of the lead being ftolen.

Great care ought to be taken to keep the upper edge and fuperficies of a bafon upon a level, that the water may cover all the walls equally.

As to the wafte pipes of bafons, whether at the bottom or fuperficies, they ought not to be made too fmall, left they fhould be choked, notwithstanding the cawls that are drawn before them.

When this wafte water is only to be loft in finks iftd common fewers, it is carried away in drains or earthen pipes -, but when it ferves to pLy the bafons that lie below it, it muft pafs through leaden pipes.

Thefe bafons are now pretty generally rejected by perfons of good tafte, as being no ways ornamental; therefore where there is a neceffity to make refervoirs for water for the ufe of gardens, they are commonly dug in the loweft part of gardens, or where the fpot is moft convenient for receiving the water, which may run from the adjacent grounds in hard rains; thefe ponds fhould have their fides made very eafy, for, if they are too upright, the earth frequently breaks down by the water wafhing, and making it hollow below; the fides and bottoms of thefe ponds fhould be laid nine or ten inches thick with well wrought clay *, and, as the clay is finifhed, it fhould be well covered to prevent the fun arid wind from cracking it before the water is let in. The figures of thefe ponds fhould not be regular, for the fhape of the hollow, where they are made, fhould be followed, which will fave expence, and have a better appearance.

B A S T E R I A . Nov.Gen. All-fpice.

As this plant had no proper title given to it, I have given it this in honour of my worthy friend Dr. Job Bafter, F. R. S. of Zurick Zee, in Holland, who is a gentleman well skilled in botany, and has a fine garden ftored with rare plants, of which he is very communicative to his friends, as I have many years experienced.

The CHARACTERS are,
The empalement of the flower is Jhort, of one leaf, and cut into five narrow fegments at the top. It hath a double ftries of narrow petals, which fpread open, and turn inward at their extremity. Under the receptacle is fituated an ovalgermen, having noftyle, but five ftigma refiting upon it, and is furrounded by many Jhort Jiamina, crowned by obtufe fummits. Thegermen afterward becomes a roundijh fruit, compreffed at both ends, having cells, containing oblong feeds.

We have but one SPECIES of this genus at prefent in England, which is,

BASTERIA foliis ovatis oppofitis, floribus lateralibus caule fmitcofo ramofo. *Bacteria with oval leaves placed oppofite, flowers coming from the fides oftbeftalki, and a branching fhrubby ftalk.* Frutex Corni foliis conjugatis floribus Anemones ftellatae, petalis craffis rigidis coloris fordiderubente, cortice Aromatico. Catefb. Hift. Carol. Vol. I. p. 46. *commonly called in Carolina All-fpice.*

This fhrub grows naturally in America. *Mr. Catefby, who firft introduced it into the EngKfh gardens, procured it from the continent, fome hundred miles on the back of Charles Town, in Carolina.

It seldom rifts more than four feet high in this country, (finding into many kinder branches near the ground, which are garnished with two oval leaves placed opposite at every joint, which are entire; these have three foot-stalks). Uw (lowers grow Tingle at the extremity of the foot-stalk, which comes out from the iriogi of the leaves, they hav. two leaves > narrow thick petals, which sprai open, and iurn inward at the lop, like thole of the Starry Anemone, or the Virgin's Bona: there are of a fuilen purple colour, and have a disagreeable scent i they appur in May. The embryo fit* beneath the flower, and supports five figroa-, thu afterward appears to have five cells, but it never comes to perfection in this country, therefore I can only give a delciption of it from an imperfect rudiment, which a few years pall, was fairer than any I have before fern. The bark of this flrub is brown, and has a vtry strong atomatic scent; from whence tin-inhabitants of Cam Una gave it the title of Allfpic, by which it is generally known in the nurseries near Loton.

This Jirab will thrive in the open air in England, if it is pnted in a warm fiigaibn and a dry loil. It h propagated by laying down the young branches, which will take root in one year, and may tictn be taken from the mother plant, and planted where they are designed to remain, for they do not bear (ranplanting well, after they are grown to any fi-ve. When the layers are iranfpnrtti, the surfact of the ground should be covered with mulch, to prevent the drying winJs from pendrating the ground to their roots j and if the leafon proves dry, they mull be watered once a week, but ihould not have too much wet, for that will destroy their tender fibres.

The best time for laying down the branches, is in the autumn, but they shoud not be tranip! until the spring twelve months arier, for the iprii is the safest time to remove ride plants. Afta the "branchj arc laid down, there shoud be (bmc ukl tanners birti laid upon the; furt'ace of the ground, to keep out the tin It, which shoud abb be i every winter, while the plants are young, which will prevent the froft from pi-nerming to their root, and thereby ferure them.

This plant was very scarce in England, till within a few years nfti thate any of them have been brought from Carolina, where they have been greatly increased in the gardens near Charles Town.

Dr. Kcnpier has givrn a figure and deicriptdon of a phnt, in his Amrenitatea Exoticarum, which seems to be of this genus i but he mentiort i'ie fruit n> be composed of eight cells; whereat, th tar as I have been able to examine this, it appears to have but Jive; however, the flower and general fruftun; eff the plan: agrees very well with this, but I suppose it to be a distinct species, the leaves of this Wing much longer, and the flower stand upon naked foot-stalks, whereas thoi; of our fort have commonly n small leaves, which are nitrower, and more pointed than those upon the brandies: but I find Dr. Linnsua a'd Monfieur Du Hamel, both fuppofe dieyart tiejame plant.

After I had given a figure of tills plant, in plate LX. of my Figures of Plants, I received Monfieur Du Hamel's book of the tree* and flrubs, which will grow in the open air about Paris, in which he has given a bad figure of this plant, under die iit(- of Bateria; but as my plate was frft published, and I was not apprised of his title, I have continued my tick la n; not from my attachment to it, as being my own, but rather to avoid confusion, which must attend the frequent alteration of tic names of plants, which is too much in E^itanat pteicnt.

B A U 111 X 1 \, Mountain Ebony, -Jibb. This plant was fo named by falter Plumter, in honour of the boranifts, John and Cafpar li

This genus of plants is ranged in the first section of Linnæus's fifteenth class, in the class Pentandria Monogynia. M. The flowers having five stamens and one pistil.

We have but one species of this genus, viz.

BELLONIA. Lin. Sp. Plant. 472. *Bellonia frumifera* Hi. folio nudo...

This plant is very common in several of the warm islands in America, from whence I have received the seeds.

It hath a lignous stalk, which rises ten or twelve feet high, sending out many lateral branches, garnished with oval rough leaves, pierced opposite; the Bowers are five in the wings of the leaves, in small panicles, which are of the wheel shape, of one leaf, divided into six parts, these are succeeded by oval capsules, ending in a point, which are full of small seeds.

It is propagated by seeds, which should be sown either in the month of March or April, in a hot-bed of pannes bark, observing to water it frequently, as the plants appear dry; but you must be careful not to wash the seeds out of the ground. When the plants are come up half an inch high, they should be carefully transplanted in a pot filled with light fresh earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root, after which they may be removed to a cooler place, where they may be frequently watered. When the plants have attained to the height of six or seven inches, they should be carefully flaken out of them, and their roots trimmed, and put into a pot filled with light earth, and plunged into the hot-bed again. In warm weather they should have free air admitted into the hot-bed, but in autumn they must be plunged into the bark stove, and watered in the usual manner of tender exotic plants. The second year these plants will bear a cold winter, but they will produce good seeds in this climate; however, they may be propagated by emulsion in the summer months, provided they are planted in a moderate hot-bed.

The cure fitly watered until they have taken root. These plants must be constantly kept in the stove, and should have a free air in warm weather; but if they are taken abroad, they will not thrive in this climate.

TilL i down the beginning of March, upon an open fpot (... ground, not too cold; the feeds fhould be town th... because the plants require room to fpread; for when they are too thick, the leaves will be fmall and full of fibres, fo unfit for the purpofes defign'd. When the plants have put out four leaves, the ground fhould be hoed, as is praftis'd for Carrots, i

plants which they are too near each other, leaving them at leaft four inches ftander; if this is performed in dry weather, all the perfect weeds will be deftroy'd; but as young weeds will foon appear, fo in three weeks or a month's time, the ground fhould be a fecond time hoed over, to cut up the weeds, and thin the plants to a greater diftance, for by this time they will be full danger, fo fhould not be left more than

tuc inches, if r... of their leaves; and if it is of the third kind, with broad leaves, the plants fhould not be nearer than nine or ten inches, h tu- fecond hoeing is well performed, and in dry weatier, the ground will require clean a month longer, when it fhould be hoed over a third time; which, if properly done, will deftroy all the weeds; fo th!

after this, the plants will fpread, and prevent tlr WEI... from growing, therefore will want but little clearing for a confiderable time, and the leaves will loon t... when the outer large leaves fhould be cut gathered, leaving the fmall inner leaves to grow larger; fo that a fmall crop of ground will fupply a moderate family, and will furnish a new fupply of leaves for two years, provided the plants are not permitted to run up to feed, for after that, their leaves will not be good; therefore thofe who

ire cu v... in their herbs, muft fow a fufficicnt quantity of thefe, and although the roots may be continued longer, yet the leaves will not be fo large or tender upon their roots, ai uMj

The Reil Beet is frequently feen with Carrots, Parsneps, or Onions, by the kitchen gardeners near Londn, who <... up their Carrots or Onions when they are young, whereby the Beets will have room to grow, when the other crops are gathered; but when the crops are not timely removed from them, it will be A lwi... method to fow them feparately. This fort requires A >... light foil, for as their roots run deep in the ground, fo in shallow ground they will be flo.T... The feeds fhould be fown in March, and muft be treated in the fame manner as the former fort; but the plants fhould not be left

neai 1... than a foot diftance, or at good land a foot and . half; for the leaves will cover the ground at that diftance. The roots will be fit for ufe in the autumn, and continue good all the winter; but in the fpring, when they begin to fow, they will be hard and stringy. A few roots may be left for feed, or lbm; of the fecond fort transplanted in a furrow'd (ym' ground, where they may be defended from

many weeds, which frequently break down their ftalks, if they are not well fupported, efpccially when the feeds are fow'd, which becoming heavy as it increafes in bulk, it apt to weigh down the tender ftalks upon which they grow. The feed will ripen in September, when the ftalks fhould be cut off, and fpre: d on mats to dry, and afterward threfted out and cleant, and put up in bags for ufe.

RETONICA (or Venonice, is called from the Venetians, an antient people of Spain, who firt uled ihia plant), Herby.

The CHARACTERS are, It hath a perennial expofure of one leaf, which is re- fectus, cut at the base into five parts. The flower is of one leaf, of the lip kind, with a cylindrical recurved calyx; the upper lip is roundish, plain, veal, and entire; the lower lip is cut into three parts, the middle being long, broad, roundish, and indented at the end. It hath four... flowers, one long and two fhort, which in- creafe in the upper lip; thefe have roundish flowers. The grmen :> quadrangular, fupporting a ftalk of the length

B E T

AHd figure of the flaming crowned by a bifid stigma. The germen afterward becomes four naked oval feeds, lodged in the empalement.

This genus of plants is ranged in the first section of Linnaeus's twelfth class, intitled *Didynamia Gymnospermia*, the flower having two long and two shorter stamens, which are succeeded by naked feeds.

The SPECIES are,

1. *BETONICA (Officinalis) spica interrupta*, corollarum laciniâ labii intermediâ emarginatâ. Flor. Leyd. Prod. 316. *Betony with an interrupted spike, and the middle segment of the lower tip of the flower indented at the end.* *Betonica purpurea*. C. B. P. 235. *Purple or Wood Betony.*

2. *BETONICA (Danica) foliis radicalibus ovato-cordatis, caulinis lanceolatis obtusis spicâ crassiore. Betony whose under leaves are heart-shaped, those on the stalks spear-shaped and obtuse, and a thicker spike of flowers.* *Betonica major Danica*. Park. Theat. 615. Mor. Hist. 3. 365.

3. *BETONICA (Alpina) foliis triangularibus obtusis spicâ brevior. Betony with obtuse triangular leaves, and a shorter spike of flowers.* *Betonica minima Alpina Helvetica*. Park. Theat. 650.

4. *BETONICA (Orientalis) spica integrâ, corollarum laciniâ labii intermediâ integerrimâ. Flor. Leyd. Prod. 316. Betony with a whole spike, and the middle segment of the lower lip entire.* *Betonica Orientalis angustiflora & longiflora folio, spicâ florum crassiori.* Tourn. Carol. 13.

5. *BETONICA (Incana) foliis lanceolatis obtusis incanis spicâ florum crassiori. Betony with obtuse, spear-shaped, hoary leaves, and a thicker spike of flowers.* *Betonica Italica incana flore carneo.* Barrel. Icon. 340.

The first sort grows naturally in woods and on shady banks in most parts of England, so is seldom cultivated in gardens. This is the sort which is used in medicine, and is greatly esteemed as a vulnerary herb. There is a variety of this with a white flower, which I have often found growing naturally in Kent.

The second sort grows naturally in Denmark. This differs greatly from our common sort, the lower leaves being much broader and heart-shaped, those upon the stalks are spear-shaped and rounded at the end, and the stalks are larger, stand upright, and are terminated by thicker spikes of flowers. These differences are constant, for I have many years propagated them by feeds, and have never found the plants so raised to vary.

The third sort grows naturally upon the Alps, where it seldom rises more than four inches high, and when cultivated in a garden, not above seven or eight. The leaves of this are much broader at the base than those of the common sort, and are very different in their shape, being triangular and blunt at the end. The flowers grow in very short close spikes, on the top of the stalks. These differences constantly hold in the plants raised from feeds.

The fourth sort was discovered by Dr. Tournefort in the Levant. The leaves of this are very long, narrow, and hairy, and are neatly crenated on their edges. The flowers grow in very close thick spikes at the top of the stalks, which are larger, and of a lighter purple colour than those of the common sort.

The fifth sort grows naturally in Italy, upon the hills, from whence I received the feeds. The leaves of this sort are broader, and not so long as those of the common sort, and are hoary; the stalks are shorter and much thicker, as are all the spikes of flowers, than those of the common, and the flowers are larger and of a flesh colour. This sort constantly keeps the same from feeds.

There is another sort which Tournefort and others mention, by the title of *Betonica rubicundiflora flore montis aurei*; which differs but little from the fifth, except in the colour of the flower, so I doubt of its being specifically different from that.

All the sorts are perennial plants, which may be propagated by feeds, or parting of their roots. They are all very hardy, but require a shady situation and

B E T

a moist stiff soil, in which they will thrive better than in rich ground. The best time to transplant and separate the roots is in the autumn, but the feeds should be sown in the spring upon a shady border, and when the plants come up, they will require no other care but to keep them clean from weeds, and to thin them where they are too close.

These all of them flower in May and June, and the feeds ripen in August.

BETONICA AQUIJATICA. See *SCROPHULARIATA.*

BETONICA PAULL. See *VERONICA.*

BETULA, the Birch-tree,

The CHARACTERS are;

It hath male and female flowers, at separate distances on the same tree; the male flowers are collected in a cylindrical catkin, which is scaly, loose, and imbricated on every side, each scale having three flowers, which have two minute scales on the side. The flower is composed of three equal florets, fixed to the empalement by a single scale, each floret is of one leaf, divided into four oval segments which spread open, these have four small stamens, crowded by double stamens. The female flowers grow in a catkin, in the same manner as the male. The common catkin is imbricated, having three scales which are every way opposite, fastened to the central firing or axis, having two heart-shaped flowers pointing toward the apex, where it is situated. They have no visible petals, but a short oval germen, supporting two bristly styles, which are the length of the scales of the empalement, and crowned with a plain stigma. It hath no pericarpium, but the feeds are included in the scales of the catkin, which are oval and winged.

This genus of plants is ranged in the fourth section of Linnaeus's twenty-first class, intitled *Monoecia Tetrandria*, there being male and female flowers on the same plant, and the male having four stamens.

The SPECIES are,

1. *BETULA (Alba) foliis ovatis acuminatis ferratis.* Hort. Cliff. 442. *Birch-tree with oval fawed leaves ending in points \ the common Birch-tree.* 1

2. *BETULA (Nana) foliis orbiculatis.* Flor. Lap. 266. *Birch-tree with round crenated leaves.* *Betula pumila foliis subrotundis.* Amman. *Dwarf Birch.*

3. *BETULA (Lenta) foliis cordatis oblongis acuminatis ferratis.* Lin. Sp. Plant. 983. *Birch-tree, with oblong pointed, heart-shaped, fawed leaves.*

4. *BETULA (Nigra) foliis rhombo-ovatis acuminatis duplicato-ferratis.* Lin. Sp. Plant. 982. *Birch-tree with rhomboid, oval, pointed leaves, which are doubly fawed.* *Betula nigra Virginiana.* Pluk. Aim. 6j. *Black Virginia Birch-tree.*

The first is the common Birch-tree, which is so well known as to need no description. This is not much esteemed for its wood, but however it may be cultivated to advantage upon barren land, where better trees will not thrive; for there is no ground so bad, but this tree will thrive in it for it will grow in moist springy land, or in dry gravel or sand, where there is little surface: so that upon ground which produced nothing but moss, these trees have succeeded so well, as to be fit to cut in ten years after planting, when they have been sold for near 10l. per acre standing, and the after produce has been considerably increased. And as many of the woods near London, which were chiefly stocked with these trees, have been of late years grubbed up, so the value of these plantations have advanced in proportion. Therefore those persons who are possessed of such poor land, cannot employ it better, than by planting it with these trees, especially as the expence of doing it is not great.

The best method to cultivate this tree, is to furnish yourself with young plants from the woods where they naturally grow, and are generally found there in great plenty; but in places where there are no young plants to be procured near, they may be raised from feeds, which should be carefully gathered in the autumn, as soon as the scales under which they are lodged begin to open, otherwise they will soon fall out and be lost: the feeds are small, so should not be buried

B E T

deep in the ground The autumn is the best season to sow them, and in a shady situation, the plants will thrive better than when they are exposed to the full sun -, for in all places where there are any large trees their seeds fall, and the plants come up well without care ; so that if the young plants are not destroyed by cattle, there is generally plenty of them in all the woods where there are any of these trees. These wild plants should be carefully taken up, so as not to destroy their roots. The ground where they are to be planted, will require no preparation; but that is necessary to be done, is to loosen it with a spade or mattock, in the places where the plants are to stand, making holes to receive their roots, covering them again when the plants are placed, and doling the earth hard to their roots. If the plants are young, and have not much top, they will require no pruning; but where they have bulky heads, they should be flintened to prevent their being shaken and displaced by the wind. When, the plants have taken root, they will require no other care, but to cut down the great weeds which would over-hang the plants which may be done with a fickle, being careful not to cut or injure the young trees. This need not be repeated oftener than two or three times in a summer the two first years, after which time the plants will be strong enough to keep down the weeds, or at least be out of danger from them.

These may be planted any time from the middle of October till the middle of March, when the ground is not frozen, but in dry land the autumn is the best season, and the spring for moist. The distance which they should be planted, is six feet square, that they may soon cover the ground, and by standing close, they will draw each other up ; for in situations where they are much exposed, if they are not pretty close, they will not thrive so well.

If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterward they may be cut every seventh or eighth year, if they are designed for the broom-makers only *, but where they are intended for hoops, they should not be cut oftener than every twelfth year.

The expence of making these plantations in places where the young plants can be easily procured, will not exceed forty shillings per acre, and the after expence of cleaning about twenty shillings a year more; so that the whole will not be more than 3*l.* and if the land so planted be of little value, the proprietor cannot make better use of his money *, for when the wood is cut, it will repay, the expence with interest, and a perpetual stock upon the ground. I have seen several of these plantations made upon land which would not let for one shilling per acre, which has produced from 10 to 12*l.* an acre, clear of the expence in cutting, and this every twelfth year. The broom-makers are constant customers for Birch, in all places within twenty miles of London, or where it is near water carriage; in other parts the hoop-benders are the purchasers ; but the larger trees are often bought by the turners, and the wood is used for making ox-yokes, and other instruments of husbandry.

In some of the northern parts of Europe, the wood of this tree is greatly used for making of carriages and wheels, being hard and of long duration. In France it is generally used for making wooden shoes. It makes very good fuel.

In some places these trees are tapped in the spring, and the sap drawn put to make Birch wine, which has been recommended for the stone and gravel, as is also the sap unfermented. The bark of the Birch-tree is almost incorruptible, In Sweden the houses are covered with it, where it lasts many years. It frequently happens, that the wood is entirely rotten, and the bark perfectly sound and good.

The second sort grows naturally in the northern parts of Europe, and upon the Alps; this seldom rises above two or three feet high, having slender branches, garnished with round leaves, but seldom produces either male or female flowers here. It is preserved in some

B I D

curious gardens for the sake of variety, but is a plant of no use.

The third and fourth sorts grow naturally in North America, from whence their seeds have been brought to Europe, and many of the plants have been raised, which thrive very well here. In Canada these trees grow to a large size, where the third sort is called Merrier. The natives of that country make canoes of the bark of these trees, which are very light, and of long duration.

Both these sorts may be propagated by seeds in the same manner as the first, and are equally hardy -, some of the trees now begin to produce their catkins in England, so that we may hope to have plenty of their seeds of our own growth, for at present we are supplied with them from America. As these grow more vigorously than the common sort, and thrive on the moist barren ground, they may be cultivated to great advantage in England, for their wood is much esteemed in Canada, where the trees grow to a large size: and they are by no means an unprofitable tree in parks, for their stems are straight, the bark smooth, and their leaves are much larger than those of the common Birch, so may be planted in such places where few other trees will thrive.

BIDENS. Tourn. Inf. R. H. 362. tab. 262. Lin. Gen. Plant. 840. Water Hemp Agrimony.

The CHARACTERS are,

The common empalement is erect, and often equal, composed of finally oblong, concave leaves 5// bath a compound flower 5 the middle or disk is composed of hermaphrodite florets which are funnel-shaped and quinquefid. These have five short capillary flaming with cylindrical funnels, and an oblong germen supporting a single style the length of the flange crowned by two oblong reflexed stigma. The female florets which compose the border are naked these are all succeeded by a single, angular, obtuse seed, having two or more bristles or teeth, by which they fasten themselves to whatever passes by them when ripe.

This genus is ranged in the first section of Linnæus's nineteenth class, intitled Syngenesia Polygamia æqualis, the flowers being composed of hermaphrodite and female florets, which are succeeded by seeds.

There are several species of this plant, which are seldom admitted into gardens, some of which are common weeds in England, therefore I shall only mention those which are frequently preserved in the gardens of the curious.

1. BIDENS (*Frondoza*) foliis pinnatis ferratis feminibus erecto-constantibus calycibus frondosis corollis radiatis. Lin. Sp. Plant. 832. Water Hemp Agrimony with winged sawed leaves, seeds standing erect, a very bushy empalement, and radiated flower, Bidens Canadensis latifolia flore luteo. Tourn. Inf. 362. *
2. BIDENS (*Nodiflora*) foliis oblongis integerrimis caule dichotomo floribus foliariis sessilibus. Lin. Sp. Plant. 832. Hemp Agrimony with oblong entire, leaves, a forked stalk, and a single flower growing close to the stalk. Bidens nodiflora brunellæ folio. Hort. Elth. 52.
3. BIDENS (*Nivea*) foliis simplicibus subhastatis ferratis petiolatis, floribus globosis, pedunculis elongatis feminibus sessilibus. Lin. Sp. Plant. 833. Hemp Agrimony with single sawed leaves having foot-stalks, globular flowers with longer foot-stalks, and smooth seeds. Bidens scabra flore nivea, folio trilobate. Hort. Elth. 55.
4. BIDENS (*Frutescens*) foliis ovatis ferratis petiolatis, caule fruticoso. Hort. Cliff. 399. Hemp Agrimony with oval sawed leaves having foot-stalks, and a shrubby stalk.
5. BIDENS (*Scandens*) foliis ternatis acutis ferratis caule scandente floribus paniculatis. Three-leaved Hemp Agrimony, with pointed sawed lobes, a climbing stalk, and flowers growing in panicles. Chrysanthemum trifoliatum scandens, flore litteo femine longo rostrato bidente. Sloan. Cat. Jam. 125.
6. BIDENS (*Bullata*) foliis ovatis ferratis, inferioribus oppositis, superioribus ternatis intermedio majore. Lin.

B I D

Sp. Plant. 833. *Hemp Agrimony with oval fawed leaves, the kwer ones growing oppofite, but the upper having three lobes, the middle of which is the largeft.* Cryfanthemum conyzoides nodiflorum femine roltrato bidente. Sloan. Cat. Jam. 126.

The firft fort grows naturally in Virginia, Maryland, and Canada, where it is often a troublefome weed. It rifes about three feet high, fending out many horizontal branches, garnifhed with trifoliate leaves, deeply fawed on their edges; the flowers are produced at the end of the branches in fmall clutters, which are yellow, and fucceeded by oblong fquare feeds, having two crooked horns, by which they fatten themfelves to the clothes of thofe who pafs near them. There are two forts of this, one whole flowers have a fhort empalement, which is Tournefort's broad-leaved Canada Bidens; the other hath a leafy empalement, and is by Juffieu diftinguifhed by the title of Capite foliofo. But I am not very fure of their being diftinct fpecies, though I have many years cultivated both; for their feeds when ripe fpread fo far, that in a fmall garden they cannot be kept feparate. It is eafily propagated by feeds fown in the fpring, in an open fituation, where, if the feeds are permitted to fcatter, the plants will come up the following fpring, and two or three of them may be tranfplanted where they are to grow, and after they are rooted, will require no farther care. This is an annual plant, fo decays foon after the feeds are ripe.

The fecond fort grows naturally in warm countries. This is an annual plant, which rifes near three feet high, dividing upward into feveral branches, which are garnifhed with oblong entire leaves; the flowers come out fmgle at the divifions of the branches, fitting clofe 5 thefe are white, and fucceeded by fmooth feeds.

This fort muft be fown upon a moderate hot-bed in the fpring, and afterward treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June, and their feeds ripen in autumn, foon after which the plants will decay.

The third fort grows naturally in South Carolina, and alfo at Campeachy. This is alfo an annual plant, which rifes three feet high, dividing upward into many flender branches, whole joints are far afunder; the leaves come out by pairs at each joint upon long flender foot-ftalks, which are oval, ending in a point. The flowers grow at the extremity of the branches in fmall globular heads, which are very white, ftanding upon very long foot-ftalks, and are fucceeded by fmooth feeds. This muft be fown upon a hot-bed, and treated as the former. It flowers and feeds about the fame time.

The fourth fort rifes with a fhubby ftalk to the height of fix or feven feet, dividing into many branches, whole joints are very diftant, at each of which are placed two oval leaves, flightly fawed on their edges, and have fhort foot-ftalks. The flowers are produced at the end of the branches in fmall clutters, each ftanding upon a long naked foot-ftalk; thefe are fucceeded by flat feeds, having two fhort teeth at their extremity. I received the feeds of this fort from Carthagpna in New Spain. This is propagated by feeds, which fhould be fown on a hot-bed in the fpring, and when the plants are fit to remove, they muft be each planted into a feparate fmall pot, and plunged into a freih hot-bed, and treated as other tender plants from the fame countries, and in autumn placed in the ftove: the following fummer they will abide fome years with proper management.

The fifth fort rifes with a climbing flender ftalk to the height of ten feet, dividing into many branches, garnifhed with trifoliate fawed leaves: the flowers grow in large panicles at the end of the branches; they are yellow, and are fucceeded by flat feeds having two teeth. This plant grows naturally in Jamaica, from whence I received the feeds. It muft be treated in the fame manner as the former fort, and will continue two or three years.

B I G

The fixth fort is annual. This rifes about two feet high, and fends out feveral lateral fhoots, which at the bottom have oval leaves placed by pairs at the joints, but upward they are trifoliate, the middle lobe being very large, and the two fide ones fmall; the flowers are produced at the wings of the leaves upon fhort leafy foot-ftalks, and are yellow, but very fmall. It flpwers in July, and the feeds ripen in autumn; the feeds of this muft be fown upon a hot-bed, and treated as the fecond fort.

BIFOLIUM, Twyblade. See OPHRYS.

BIGNONIA. Tourn. Inf. 164. Lin. Gen. Plant. 677. [M. Tournefort called this plant Bignonia, in memory of abbot Bignon, librarian to Lewis XIV. king of France, he being a great encourager of learning.] The Trumpet Flower, or Scarlet Jafmine.

The CHARACTERS are,

"The empalement is cup-fhaped* quinquefid, and of one leaf "The flower is of the ringent, or grinning kind, tubulous, with long chaps, which are fwelling, and bell-fhaped, divided into five parts at the top; the two upper fegments are reflexed, and the under fpread open 5 it hath four awl-fhaped ftamina fhorter than the petal, two longer than the other, having oblong reflexed fummits. In the center is an oblong germen, fupporting a flender fyle, crowned by a roundifh ftigma. Thegermen afterward becomes a bivalve pod, with two cells, filled with compressed winged feeds, lying over each other imbricatin.

This genus of plants is ranged in the fecond divifion of Linnseus's fourteenth clafs, intitled Didynamia-Angiofpermia, the flower having two long and two fhort ftamina, and the feeds included in a capsule.

The SPECIES are,

1. BIGNONIA (*Radicans*) foliis pinnatis, foliolis incifis, caule geniculis radicatis. Lin. Hort. Cliff. 217. *Bignonia with winged leaves, which are cut on their edges* and roots coming out at the joints of the ftalk.* Bignonia Americana Fraxini folio flore amplo Phoenicio. Tourn. Inf. 164.
2. BIGNONIA (*Catalpa*) foliis fimplicibus cordatis, caule erecto, floribus diandris. Lin. Sp. Plant. 622. *Bignonia with Jingle heart-fhaped leaves, an upright ftalk* and flowers with two ftamina.* Bignonia Urucu foliis, flore fordide albo, intus maculis purpureis & luteis adfperfo, filiqua longiflima & anguftiflima. Catefh. Carol. 1. p. 49.
3. BIGNONIA (*Frutescens*) foliis pinnatis, foliolis lanceolatis acutis ferratis, caule erecto, floribus paniculatis erectis. *Bignonia with winged leaves, having acute fawed lobes, an upright ftalk, and flowers growing in panicles erect.* Bignonia arbor flore luteo Fraxini folio. Plum. Sp. Plant. 5.
4. BIGNONIA (*Pubescens*) foliis conjugatis cirrhofis foliolis cordato-lanceolatis foliis imis fimplicibus. Vir. Cliff. 59. *Bignonia with conjugated leaves having tendrils, the leaves fpear-fhaped, and the lower leaves Jingle.* Bignonia Americana Capreolis donata filiqua brevior. Breyn. Ic. 33.
5. BIGNONIA (*Unguis Cati*) foliis conjugatis, cirrho breviffimo arcuato tripartito. Lin. Sp. Plant. 623. *Bignonia with conjugated leaves, and port arched tendrils* divided inter three parts.* Bignonia Americana capreolis aduncis donata, filiqua longiffima. Tourn. Inf. 164.
6. BIGNONIA (*Mquinottiatis*) foliis conjugatis cirrhofis, foliolis ovato-lanceolatis, pedunculis bifloris filiquis linearibus. Lin. Sp. 869. *Bignonia with conjugated leaves, having tendrils* whole lobes are oval, fpear-fhaped, and linear pods.*
7. BIGNONIA (*Sempervirens*) foliis fimplicibus lanceolatis caule volubili. Lin. Sp. Plant. 623. *Bignonia with Jingle fpear-fhaped leaves, and a twining ftalk.* Gelfeminum five Jafminum luteum odoratum Virginiae fcandens & fempervirens. Park. Catelb. 1. P. 53.
8. BIGNONIA (*Pentaphylla*) foliis digitatis foliolis integerrimis obovatis. Hort. Cliff. 497. *Bignonia with fingered leaves* whole lobes are entire.* Bignonia arbor pentaphylla flore rofeo. Plum. Sp. Plant. 5.

9. BIGNO-

9. *BIGNONIA (LecutyUn)* foliis digitatis foliolis integerimis ovatis acuminatis. Lin. Sp. Plant. 870. *Bignonia with fingered leaves, whose lobes are oval, pointed, and entire.* Leucoxydon arbor filiquiosa, quinquefolia, floribus Nerii, alato femine. Pluk. Aim. 215. tab. 200. f. 4. commonly called in America Tulip Flower.
10. *BIGNONIA (Paniculata)* foliis conjugatis cirrhosis, foliolis cordato-ovatis, floribus racemosis-paniculatis. Lin. Sp. Plant. 623. *Bignonia with conjugated leaves, having tendrils, the lobes oval and heart-shaped, and flowers in branching panicles.* Bignonia bifolia scandens, flore violaceo odore, fructu ovato duro. Plum. Cat. 5.
11. *BIGNONIA (Carulea)* foliis bipinnatis foliolis lanceolatis integris. Lin. Sp. Plant. 625. *Bignonia with double winged leaves, which are entire and spear-shaped.* Arbor Guajaci latiore folio, Bignoniae flore cseruleo, fructu duro in duas partes diffilente feminibus alatis imbricatis. Cateb. Carol. 1. p. 42.
12. *BIGNONIA (Crucigera)* foliis conjugatis cirrhosis foliolis cordatis; Vir. Cliff. 60. *Bignonia with conjugated heart-shaped leaves, having tendrils, and a stalk having tendrils.* Pseudo Apocynumbiliculis maximis obtusis feminibus ampliflimis alis membranaceis. Mor. Hist. 3. p. 62.
13. *BIGNONIA (Capreolata)* foliis conjugatis cirrhosis foliolis cordato-lanceolatis, foliis imis simplicibus. Lin. Sp. 870. *Bignonia with conjugated heart-shaped leaves, having tendrils, whose lower leaves are single, growing in panicles, and long compressed pods.*
14. *BIGNONIA (Triphylla)* foliis ternatis glabris, foliolis ovatis acuminatis, caule fruticoseo. Lin. Sp. 870. *Smooth three-leaved Bignonia, with oval lobes ending in a point, and a brubby stalk.* Bignonia frutescens triphylla glabra, filiquis longis compressis. Houft. Cat.

The first sort grows naturally in Virginia and Canada. It hath large rough stems, which send out many trailing branches, putting out roots at their joints, which fatten themselves to the trees in their natural places of growth, whereby they climb to a great height, and in Europe, where they are generally planted against walls, they fall themselves thereto by their roots, which strike into the mortar of the joints so strongly, as to support their branches, and will rise to the height of forty or fifty feet. The branches are garnished with winged leaves at every joint, placed opposite, composed of four pair of small leaves, terminated by an odd one; these are sawed on their edges, and end in a long sharp point. The flowers are produced at the ends of the shoots of the same year, in large bunches, these have long swelling tubes, shaped somewhat like a trumpet, from whence it had the appellation of Trumpet flower. They are of an Orange colour, and appear the beginning of August.

This sort is very hardy, so will thrive in the open air, but as the branches trail, they must be supported, therefore are usually planted against walls or buildings, where, if the branches have room, they will spread to a great distance, and rise very high, so are very proper for covering of buildings, which are unfitly. They may all be trained up against the stems of trees, where they may be so managed, as to make a fine appearance when they are in flower.

This is propagated by seeds, but the young plants so raised do not flower in less than seven or eight years, therefore those which are propagated by cuttings or layers from flowering plants, are most esteemed, because they will flower in two or three years after planting. The old plants also send out many suckers from the roots, which may be taken off, and transplanted where they are to remain, for these plants will not transplant easily if they are old.

The necessary culture for these plants after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to about two feet long, that young shoots may be obtained for flowering the following summer; these plants are of long duration. There are some in gardens which have been planted more than sixty years, which are now very vigorous, and produce flowers in plenty every season.

If the plants are propagated by seeds, they should be sown upon a moderate hot-bed to bring them up, which should be so managed to the open air, to prevent their being drawn up weak; and the first winter these young plants should be screened from hard frosts, which will kill their tender shoots; but the spring following they may be planted in the full ground, in a nursery-bed, at a foot distance from each other, where they may remain one or two years to get strength, and afterwards be planted where they are designed to grow.

The second sort was brought into England by Mr. Cateby, about forty years past, who found it growing naturally on the back of South Carolina, at a great distance from the English settlements. It is now very plenty in the English gardens, especially near London, where there are some of them near twenty feet high, with large stems, and have the appearance of trees.

This sort rises with an upright stem, covered with a smooth brown bark, and sends out many strong lateral branches, garnished with very large heart-shaped leaves, placed opposite at every joint. The flowers are produced in large branching panicles toward the end of the branches, of a dirty white colour, with a few purple spots, and faint tinges of yellow on their inside. The tube of the Mower is much shorter, and the upper part more expanded, than those of the former sort, and the segments deeper cut, and waved on their edges. The flowers are in America succeeded by very long taper pods, filled with flat winged seeds, lying over each other like the scales of fish. In England there has not as yet been any of the pods produced, but the seeds are annually brought over from South Carolina. These should be sown in pots, and plunged into a moderate hot-bed to bring up the plants, which should be sown to the open air by degrees; and, in the beginning of June, placed abroad in a sheltered situation till autumn, when they should be placed under a common frame to screen them from frost in winter but in mild weather they must be fully exposed to the open air. The following spring these may be taken out of the pots, and planted in a nursery-bed, in a warm situation, where they may remain two years to get strength, and afterwards planted in the places where they are designed to remain. These plants, when young, are frequently injured by frost, for they shoot pretty late, in the autumn, so that the early frosts often kill the extremity of their branches; but as the plants advance in strength, they become more hardy, and are seldom injured but in very severe winters. It is late in the spring before these trees come out, which has often caused persons to believe they were dead; and some have been so imprudent, as to cut them down on that supposition, before the tree was well known.

It may also be propagated by cuttings, which should be planted in pots in the spring before the trees begin to push out their shoots, and plunged into a moderate hot-bed, to serve to shade them from the sun in the middle of the day, and refresh them occasionally with water, which must not be given to them in too great plenty. In about six weeks these will have taken root, and made shoots above, so should have plenty of air admitted to them constantly, and hardened by degrees to bear the open air, into which they should be removed, and treated in the same manner as the seedling plants, and the spring following planted out into a nursery-bed, as is before directed.

As these trees have very large leaves, they require a sheltered situation, for where they are much exposed to strong winds, their leaves are often torn and rendered unfitly, and many times their branches are split and broken by the winds, their leaves being so large, as that the wind has great force against them. These produce their flowers in August. They delight in a light moist soil, where they make great progress, and in a few years will produce flowers. It is generally known in the gardens by the Indian title of Catalpa.

B I G

The third fort is a native of the warmer parts of America, where it was discovered by father Plumier, who made a drawing of it, and gave the title of *Clematis* to it, which he afterward altered to *Bignonia*, when he became better acquainted with Tournefort's System of Botany. This rises with an upright stem, to the height of twelve or fourteen feet, sending out many side branches, garnished at every joint by two long winged leaves placed opposite; the small leaves which compose these, are long and spear-shaped, ending in a point, and lightly fawed on their edges, each leaf being composed of six pair, terminated by an odd one. The flowers are produced in loose panicles at the ends of the branches, and are shaped like those of the other species, but (spread open more at the top.) These are yellow, and succeeded by compressed pods about six inches long, having two rows of flat winged seeds, like those of the other species.

I received this fort first in 1719, from La Vera Cruz, in New Spain, where the late Dr. Houffton found it growing naturally in great plenty; since which time I have received the seed from the island of Bermuda, by the title of Candle Wood.

It is propagated by seeds, which must be sown on a hot-bed, and the plants afterward transplanted into separate small pots, filled with light fresh earth, and plunged into a fresh hot-bed to bring them forward, that they may obtain strength before winter; in the autumn they must be removed into the bark-stove, and during the winter should have but little water, but in summer they must be frequently refreshed with it, but not given in too great plenty. The plants should constantly remain in the bark-stove, and be treated in the same manner as other tender plants from those countries. The third year from seed, they will flower, but they do not produce seeds in England.

The fourth fort grows naturally in Virginia, and several other parts of America; this hath very slender trailing (stalks, which must be supported; in the places where it naturally grows, the branches fatten themselves by their tendrils to whatever plants are near them, and extend to a great distance. In this country they require the assistance of a wall, and to have a good aspect, for they are impatient of much cold, so should be sheltered in severe frost; the branches are garnished with oblong leaves, which are green all the year; these are often single at bottom, but upward are placed by pairs opposite at each joint; the flowers are produced at the wings of the leaves, which are yellow, and shaped like those of the Foxglove. These appear in August, but are not succeeded by pods in this country. This is propagated by seeds, which (should be sown on a moderate hot-bed, and treated in the same manner as the first fort. When these plants are planted in the full ground against walls, the ground about the roots should be covered in the autumn with some old tanners bark to keep out the frost in winter; and in very severe frost, the branches should be covered with mats, to prevent their being destroyed. With this management I have had the plants flower very well in the Chelsea garden.

The fifth fort hath slender (stalks like the former, which require the same support; these are garnished with small oval leaves, which are entire, placed opposite at every joint; at the same places come out the tendrils, by which they fasten themselves to the plants which grow near them. These end in three distinct parts; the flowers come out from the wings of the leaves, which are (shaped like those of the former fort, but are smaller, and are not succeeded by seeds in this country. This grows naturally in Carolina and the Bahama Islands, but will live in the open air, if it is planted against a wall to a fourth aspect, and sheltered in very severe frost. It is propagated in the same manner as the former fort.

The sixth fort hath very weak slender branches, which put out tendrils at the joints, by which they fasten themselves to the neighbouring plants: at each joint

B I G

there are four leaves, two on each side opposite; these are oval pointed, and waved on their edges, of a bright green, and continue through the year; the branches ramble very far where they have room; the flowers are large, yellow, and are produced at the joints of the stalks, but are not succeeded by pods in this country. I received this fort from La Vera Cruz, in New Spain, but it thrives against a warm wall in the open air very well, with the same treatment as the two former forts.

The seventh fort grows naturally in South Carolina, where it spreads over the hedges, and at the season of flowering, perfumes the air to a great distance, it also grows in some parts of Virginia, but not in so great plenty as at Carolina. The inhabitants there call it Yellow Jasmine, I suppose from the sweet odour of its flowers.

This rises with slender stalks, which twist themselves round the neighbouring plants, and mount to a considerable height; the branches are garnished with oblong pointed leaves, which come out single and opposite to each other at every joint; these remain green through the year. The flowers come out from the wings of the leaves at every joint, sometimes but two, at other times four at each joint; these stand erect, are trumpet-shaped, yellow, and have a very sweet scent; and in the countries where they naturally grow, they are succeeded by (short taper pods, filled with small winged seeds.

The plants of this fort, when young, are impatient of cold, so must be sheltered in the winter until they have obtained strength, when they should be planted against a warm wall, and in winter protected from frost by coverings of mats, and the ground about their roots covered with tan. With this management I have had them flower very well in the Chelsea garden. It is propagated by seeds in the same manner as the former forts.

The eighth fort was sent me from Jamaica by the late Dr. Houffton. This rises with an upright stem near twenty feet high, sending out many lateral branches, covered with a white bark. The leaves come out opposite at the joints upon long foot-stalks; they are composed of five oval stiff leaves, which are joined in one center at their base, where they are narrow, but widen toward the top, where they are rounded and obtuse. They are of a pale green, inclining to white on their under side, the flowers are produced at the ends of the branches four or five together, on very short foot-stalks; they are narrow at bottom, but the tube enlarged upward, and at the top (spreads open wide, of a pale bluish colour, and smell sweet; they are succeeded by taper crooked pods about four inches long, which are filled with oval compressed seeds, with wings of a silver colour.

This fort is a native of the warmer parts of America, therefore will not thrive in this country, but in a stove. It is propagated by seeds, which must be sown on a hot-bed, and the plants treated in the same manner as the fourth fort.

The ninth fort I received from Barbadoes, by the title of White Wood. This rises with an upright stem to the height of forty feet, in the natural country of its growth, and the seeds are dispersed by wind to the neighbouring lands, where the plants come up in great plenty. This and the former fort have been generally confounded, and supposed to be the same, but the growing plants are extremely different, for the under leaves of this are sometimes composed of five, at other times of four oval leaves; and on the upper part of the branches, they come out single, placed by pairs opposite: these are as large as those of the Bay-tree, and of equal thickness, rounded at their end; each of these have a long foot-stalk, whereas those of the former join at their base to one center. The flowers of this fort are produced single at the wings of the leaves, which have a narrow tube near two inches long, but spread open very wide at the top, where they are cut into five unequal segments, which are fringed on their borders. The flowers are

white,

B I G

white, ind have an agreeable odour, but the pod I have not fecE.

The plan's muft be prefirvct in the bark-ftovc, and treated as the fourth fort. I is propagated by feeds, and will idfo take rotic from cutting™ in the fuminT, it' they an' planted in por>, am' plunged into a bark-bed. It has (o) several years in the Chell-a garden, in Au;.

Jiic tenth fort was fent me from La Vera Cruz, by the lateDr. Houftoun; this riles ft-itli ligneous (talks, which put out teuirils ar the milts, wherV they fnten themfclvcs to the neighbouring plants; the leaves come out on each fide the brand us, upon pretty long foot-ilalk; two at each joint oppofite, which arc h<Mt-fhamd and cniirt-, having a line hairy down on their under fide. The Howers grow in loofc (pikes at the end of the branches, which are tubulous, and du not fprarl much ut the topi they arc of a Violet colour, and fmell very fwect. Tittfe in their native country tin: fuccceded by oral, bard, ligneous feed-vefTds, which open in four parts, and arc ft ill of comprfid winged (ceds.

TMi fort ii propagated by feeds, which rtllfi b- fven on a hot-bed, and cbe plants in R be treated in the fame manner as the third fan, for they will not thrive in this country unlth they are placed in the bark-ftovc.

The eleventh fort grows naturally in the Bahama lilandi, from whence Mr. Caicby lent the fi eds in i 724-, and many of the plants were railed in tfo gardens near London. This, in the country where it grows naturally, rifts to die hright of twenty feet, lending our many lateral branches^ garnillhti with compound winged leave*, each having eleven alternate wings, with lpcar-iliapcd finall lobes, which grow alternate, and arc entire; at the end: of the branches the flowerJ arc produced in very loofo panicles; the foot-Italks brandling into three or •••, each containing a (ingle blue flower, with a km feeding tube, cut into five unequal legmcnB at the tap, where it frcads u'zen. The (lowers arc filer; y ova, feed-vcficK which opep tn two parts, on3 arc filled with fhi winged feeds.

The t-wlth fort luril a woody Sera, fending out many L.rinch?, which have four narrow borders nr wings running lngituiinally, fb as w eefemble .t tquare IWK; tire letrm arc' produced by pair<, on each fil. the branchei; they arc hent-ihapLf, Jmnath, anl hive ffon fooD-ftnlks) theft: nave tendrils coming out by the foot-Italks, which faller lhi-r.flyes to the plints wiith grow near them, ami thereby rife to a great height. The flowers arc Ennuced in finall clutters from the witi;j of the fawes, which have preti: bng talcs, fpical open at die top, and *te of a pile yet low colour; thre arc fuccceded by (lai pods a too' in length, which I hve two rows of flat winjrd fecdi, joined to dw intermediate partition.

This fort wwfent me from Campcadiy, whew naturally grow; and rifs W the tops of the tailed trees, (o whole branches tiefc plants feften Chen by their tendrils or, laper:; and arc thereby fup- rced. This is propagated by feeds, which miift a hot-bed,

B I S

the feeds, and dried samples of the plant, which are not more than six inches high, though they are the entire plants with their roots, but in the garden they grow almost two feet high*. This hath many long, narrow, hairy leaves, spreading near the ground, which are deeply indented on each side, resembling those of Hawkweed; from the center arises the stalk, which divides upward into many small branches, having no leaves on them, and are terminated by loose panicles of yellow flowers, composed of four petals, placed in form of a cross. These are succeeded by round compressed feed-vessels like the former, but are smaller, and the style of the flowers bends from them.

The third sort sends out many oblong hairy leaves, * which are (lightly indented on their edges; from among these there arises a hairy branching stalk, which grows two feet high, and at each joint is placed one oblong indented leaf, which half embraces the stalk at the base; each branch is terminated by a close spike of pale yellow flowers, which are succeeded by round compressed feed-vessels like the other sorts, but the style of the flower, which is joined to them; is shorter than those of the other species.

These are all annual plants, which perish soon after they have perfected their feeds. These should be sown either in spring, or the autumn, upon a border of light earth, in an open situation, where they are to remain for good. Those which are sown in autumn will come up in about three weeks, and the plants will live through the winter without any protection, so will flower earlier the following summer, whereby good feeds may always be obtained; whereas those which are sown in the spring, do, in bad seasons, decay before their feeds are ripe. The autumnal plants flower in June, and the spring in July, and their feeds ripen about six weeks after; which, if permitted to scatter, there will be plenty of young plants produced without any care.

These require no farther culture, but to keep them clean from weeds, and thin the plants where they are too close, leaving them eight or nine inches asunder. They are preserved in the gardens of those who are curious in botany, but they have no great beauty to recommend them, I have cultivated these sorts many years, and have never observed either of them to vary, therefore make no doubt of their being distinct species.

BISERRULA. Lin. Gen. Plant. 800. Pelecinus. Tourn. Inf. 417. tab. 234.

The CHARACTERS are,

The flower hath a fabulous empdement of one leaf, which is erect, acutely indented at the top in five equal parts, the two upper standing at a distance. The flower is papilionaceous, having a large roundish standard, whose edges are reflexed. The wings are oblong, but shorter than the standard and the obtuse keel is of the same length with the wings, bending upward. It hath ten stamina, nine of which are joined, and the other single, with their ends pointing upward. In the center is situated an oblong compressed germen, supporting an awl-shaped style, crowned by a single stigma; these are included in the keel. The germen afterwards becomes a flat narrow pod, indented on both edges like the jaw of the swordfish, having two cells, filled with kidney-shaped feeds.

This genus of plants is ranged in the third section of Linnaeus's seventeenth class, intitled Diadelphia Decandria, the flower having ten stamina, joined in two bodies*.

We have but one SPECIES of this genus, which is, **BISERRULA.** (*Pelecinus.*) Hort. Cliff. 361. We have no English name for this plant. *Pelecinus vulgaris.* Tourn. Inf. 417.

This is an annual plant, which grows naturally in Italy, Sicily, Spain, and the south of France. It sends out many angular stalks, which trail on the ground, subdivided into many branches, garnished with long winged leaves, composed of many pair of lobes, terminated by an odd one; these are heart-shaped: toward the Upper part of the branches come out the

B I X

foot-stalk of the flowers, which sustains several small Butterfly flowers, of a purplish colour, collected together, which are succeeded by plain pods, about one inch long, indented on both sides the whole length, divided in the middle by a longitudinal nerve, containing two rows of kidney-shaped feeds.

It is propagated by feeds, which in this country should be sown in the autumn, on a bed of light earth, where the plants will come up in about three weeks, and will live in the open air very well. These should be sown where they are designed to remain, or transplanted very young; for when they are large, they will not bear removing. When the plants are come up, they will require no other care, but to keep them clean from weeds; and where they are too near, they should be thinned to about a foot distance from each other. They flower in June, and the feeds ripen in September.

The feeds of this plant may also be sown in the spring, and treated in the same manner as before directed; but these will not flower till the middle or end of July, so unless the autumn improves warm, they will not ripen feeds; for which reason I have directed their being sown in the autumn, as soon as they are ripe. Two or three of these plants may be allowed a place in gardens for the sake of variety, but they have not much beauty.

BISLINGUA. See *Ruscus.*

BISTORTA [so called, because the root is turned or wreathed into various rings or spirals,] *Bistorta*, or *Snakeweed.*

This genus joined to the *Polygonum* by Dr. Linnaeus. This plant flowers in May, and if the season proves moist, will continue to produce new spikes of flowers till August: it may be propagated by planting the roots in a moist shady border, either in spring or autumn, which will soon furnish the garden with plants, for it greatly increases by its creeping roots.

The roots of this plant have been recommended for tanning of leather, but the trouble of procuring them in a sufficient quantity is too great to answer the intention.

BIVALVULAR, or *Bivalve* [of *bivalvis*] *Huffia*, is one that opens and gapes the whole length, like a door that opens in two parts.

BIXA. Lin. Gen. Plant. 581. *Urucu.* Sloan. Cat. Jam. Orleana. H. L. *Mitella.* Tourn. Inf. 242. *Anotta*, by the French *Roucou.*

The CHARACTERS are,

It hath a plain, small, obtuse empdement, which is permanent; the flower hath a double series of petals, the outer consisting of five, which are large, oblong, and equal, the inner of the same number and shape, but narrower. It hath a great number of brittle stamina, which are but half the length of the petals, terminated by ere stamens. In the center is situated an oval germen, supporting a slender style of the same length with the stamina, crowned by a bifid, compressed, parallel stigma. The germen afterwards becomes an oval heart-shaped capsule, a little compressed, covered with sharp bristles, opening with two valves, with one cell, and filled with angular feeds, adhering to a linear receptacle, which runs longitudinally through the capsule.

This genus is ranged in the first section of Linnaeus's thirteenth class, intitled Polyandria Monogynia, the flower having many stamina and one style.

We have but one SPECIES of this genus, viz.

BIXA. (*Orellana.*) Hort. Cliff. 211. *The Arnotta*, or *Anotta*, by the French *Roucou.* *Mitella Americana maxima tinctoria.* *Acbiotti of Hernandez.*

This shrub grows naturally in the warm parts of America, where it rises with an upright stem to the height of eight or ten feet, sending out many branches at the top, forming a regular head. These are furnished with heart-shaped leaves ending in a point, which have long foot-stalks, and come out without any order. The flowers are produced in loose panicles at the end of the branches, of a pale Peach colour, having large petals, and a great number of brittle stamina of the same colour, in the center. After the

I flower is pafi, the gertncn becomes a tican Ihaped, or rather a. mitrt-'fliajwd fced-veiTel, covered on the uitTd? with brittle', opening with two valves, and tilled wicii angular ietJs, covered with a red pulp or pafe, which colours 'be hands of tht>:c who

is thereby acquired-, which scorches the tender flowers, and other parts of plants.

But that blights are frequently no more than an inward weakness or distemper in trees, will evidently appear, if we confide? how often it happens, that trees against the same wall, exposed to the same aspect, and equally enjoying the advantages of sun and air, with every other circumstance which might render them equally healthy, yet very often are observed to differ greatly in their strength and vigour*, and as often we observe the weak trees to be continually blighted, when the vigorous ones, in the same situation shall escape very well; which must, therefore, in a great measure, be ascribed to their healthy constitution. This weakness, therefore, in trees, must proceed either from a want of a sufficient supply of nourishment to maintain them in perfect vigour, or from some ill qualities in the soil where *they* grow, or, perhaps, from some bad quality in the stock, or inbred distemper of the buds or cyons, which they had imbibed from their mother tree, or from mismanagement in the pruning, &c. all which are productive of distempers in trees* and of which they are with difficulty cured. Now, if this is occasioned by a weakness in the tree, we should endeavour to trace out the true cause; first, whether it has been occasioned by ill management in the pruning, which is too often the case; for how common is it to observe Peach-trees trained up to the full length of their branches every year, so as to be carried to the top of the wall in a few years after planting, when at the same time the (shoots for bearing have been so weak, as scarcely to have strength to produce their flowers: but this being the utmost of their vigour, the blossoms fall off, and, many times, the branches decay, either the greatest part of their length, or quite down to the place where they were produced; and this, whenever it happens to be the case, is ascribed to a blight.

Others there are, who suffer their trees to grow just as they are naturally disposed, during the summer season, without flogging of shoots, or disburdening their trees of luxuriant branches* by which means two, three, or four shoots shall exhaust the greatest part of the nourishment of the trees all the summer*, which shoots, at the winter pruning, are entirely cut out; so that the strength of the tree was employed only in nourishing useless branches, while the fruit branches are thereby rendered so weak, as not to be able to preserve themselves. The remedies to this evil shall be explained in the article of PRUNING Peach-trees, &c.

But if the weakness of the tree proceeds from an inbred distemper, it is the better way to remove the tree at first -, and after renewing your earth, plant a new one in its place.

Or if your soil be a hot burning gravel or sand, in which your Peach-trees are planted, you will generally find this will be constantly their case, after their roots have got beyond the earth of your borders^ for which reason, it is much more advisable to dig them up, and plant Grapes, Figs, Apricots, or any other sort of fruit, which may dwell in such a soil, rather than to be annually disappointed of your hopes; for, by a variety of experiments, it hath been found, that Apricots attract and imbibe moisture with a much greater force than Peaches and Nectarines -, and consequently, are better able to attract the nutritive particles from the earth, than the other, which require to be planted in a generous soil, capable of affording them a sufficiency of nourishment without much difficulty : and it is in such places we often see Peaches do wonders, especially if assisted by art; but as for the Vine and Fig-tree, they perspire very slowly, and are very often in an imbibing state (so that a great part of that fine racy flavour, with which their fruits abound when planted in a dry soil, is probably owing to those refined aerial principles, which are collected when in a state of respiration;) and therefore, as these trees delight not in drawing much watery nourishment from the earth, so they will much

better succeed in such a soil, than in one that is more generous: we should therefore always endeavour to suit the particular sorts of fruits to the nature of our soil, and not pretend to have all sorts of fruit good in the same.

But there is another sort of blight, against which it is very difficult to guard our fruit-trees*, this is sharp, pinching, frosty mornings, which often happen at the time when the trees are in flower, or while the fruit is very young, and occasion the blossoms or fruit to drop off; and, sometimes, the tender parts of the shoots and leaves are greatly injured thereby.

The only method yet found out to prevent this mischief, is, by carefully covering the walls, either with mats, canvas, reeds, &c. which being fattened so as not to be disturbed with the wind, and suffered to remain on during the night, and taking them off every day, if the weather permits, is the best and surest method that hath yet been found successful* which, although it has been flighted, and thought of little service by some, yet the reason of their being; not so serviceable as has been expected, was, because they have not been rightly used, either by suffering the trees to remain too long covered; by which means the younger branches and leaves have been rendered too weak to endure the open air, when they are exposed to it; which has often proved of worse consequence to trees, than if they had remained entirely uncovered, or by incautiously exposing them to the air, after having been long covered.

Whereas, when the covering before-mentioned has been performed as it ought to be, it has proved very serviceable to fruits; and many times, when there has been almost a general destruction of fruits in the neighbouring gardens, there has been a plenty of them in such places where they have been properly covered: and though the trouble may seem to some very great, yet, if these coverings are fixed near the upper part of the wall, and are fastened to pulleys, so as to be drawn up, or let down, it will be soon and easily performed -, and the success will sufficiently repay the trouble.

But there is another sort of blight that sometimes happens later in the spring, viz. in April or May, which is often very destructive to orchards, and open plantations, - and against which we know of no remedy. This is what is called a fire blast*, which, in a few hours, hath not only destroyed the fruit and leaves, but, many times, parts of trees, and, sometimes, entire trees have been killed by it.

This is supposed to be effected by volumes of traitparent flying vapours, which, among the many forms they revolve into, may sometimes approach so near to an hemisphere, or hemicylinder, either in their upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays.

The learned Boerhaave, in his Theory of Chemistry; observes, " That those white clouds which appear in summer time, are, as it were, so many mirrors, and occasion excessive heat: these cloudy mirrors are sometimes round, sometimes concave, polygonous, &c. When the face of the heavens is covered with such white clouds, the sun, shining among them, must, of necessity, produce a vehement heat; since many of his rays, which would otherwise, perhaps, never touch our earth, are hereby reflected to us: thus, if the sun be on one side, and the clouds on the opposite one, they will be perfect burning glasses: and hence the phenomenon of thunder.

cc I have sometimes, continues he, observed a kind of hollow clouds, full of hail and snow, during the continuance of which the heat was extreme; since, by such condensation, they were enabled to reflect much more strongly: after this came a sharp cold, and then the clouds discharged their hail in great quantities, to which succeeded a moderate warmth. Frozen concave clouds therefore, by*

** - their

" their great reflexions produce a vigorous heat, and the lime, when resolved, occelive cold." Whence (as Dr. Hides obferves) we fee, that blasts may be occuoned by the tvfkions of the clouds, as well as by tiic above-mentioned refraction of denfe ranparent vapours.

The first and second sorts grow naturally in both Indies, where they arrive to a great magnitude; being some of the tailed trees in those countries; but the wood is very light, and not much valued, except for making of canoes, which is the chief use made of them. Their trunks are so large, as when hollowed, to make very large ones. In Columbus's first voyage it was reported, there was a canoe seen at the island of Cuba, made of the hollowed trunk of one of these trees, which was ninety-five palms long, and of a proportional width, which would contain a hundred and fifty men: and some modern writers have affirmed, that there are trees of these sorts now growing in the West-Indies, so large, as not to be fathomed by sixteen men, and so tall as that an arrow cannot be shot to their top.

These trees generally grow with very straight stems, those of the first sort are closely armed with short strong spines, but the second hath very smooth stems, which in the young plants are of a bright green, but after a few years, they are covered with a grey, or ashy-coloured bark, which turns to a brown as the trees grow older: they seldom put out any side branches till they arrive to a considerable height, unless their leading shoot be broken or injured. The branches toward their top are garnished with leaves composed of five, seven, or nine oblong smooth lobes, which are spear-shaped, and join to one center at their base, where they adhere to the long foot-stalk. These fall away every year, so that for some time the trees are naked, and before the new leaves come out, the flower-buds appear at the end of the branches, and soon after the flowers expand, which are composed of five oblong purple petals, with a great number of stamens in the center; when these fall off, they are succeeded by oval fruit larger than a swan's egg, having a thick ligneous cover, which, when ripe, opens in five parts, and is full of a dark (hort cotton, inclosing many roundish seeds as large as small Pease.

The down which is inclosed in these seed-vessels is seldom used, except by the poorer inhabitants to stuff pillows or chairs, but it is generally thought to be unwholesome to lie upon.

These two species have been supposed the same by many writers on natural history, who have affirmed, that the young trees only have prickles on their trunks, and as they grow old, their trunks become smooth; but from many years experience I can affirm, that the seeds which have been sent me of the two sorts, have always produced plants of the different kinds for which they were sent, and continue the same in plants, which are more than twenty years growth.

There was a few years past a fine plant of another sort in the garden of the late Duke of Richmond, at Goodwood, which was raised from seeds that came from the East-Indies. The stem of this was very straight and smooth; the leaves were produced round the top upon very long foot-stalks, each being composed of seven or nine long, narrow, silky, small lobes, joined at their base to the foot-stalk, in the same manner as those of the two former, but they were much longer, and reflexed backward, so that at first sight it appeared very different from either of them. This may be the species, titled by Jacquin, *Bombax floribus pentandris, foliis septenatis*. Amer. 26.

The third sort was sent me from the Spanish West-Indies, where it grows naturally, but I do not know to what size; the plants which have been raised here, have soft herbaceous (stalks very full of joints, and do not appear as if they would become woody, for the plants of several years growth have soft pithy stems. The leaves come out on long hairy foot-stalks toward the top of the plants; these have the appearance of those of the Mallow-tree, but are larger, and of a thicker consistence; on their under

B O N

side are covered with a short, brown, hairy down, and are cut on their edges into five angles. These plants have not as yet flowered in England, nor have I received any information what flower they produce, but by the pods and seeds, it appears evidently to be of this genus. The down inclosed in these pods, is of a fine purple colour; and I have been informed that the inhabitants of the countries where the trees grow naturally, spin it, and work it into garments, which they wear without dyeing it of any other colour.

I received a few years since, a few pods of another sort from Panama, which were not so large as those of the common, but were rounder. The down of these was red; but the plants raised from the seeds were like those of the third sort, & not to be distinguished from them, so I doubt of their being distinct species. I also received some seeds from Siam, which produced plants of the same kind, so that these trees may be common to many of the hot countries.

The plants are propagated by seeds, which must be sown on a hot-bed in the spring; if the seeds are good, the plants will appear in a month, and those of the two first sorts will be strong enough to transplant in a month after, when they should be each planted in a small pot, filled with fresh loamy earth, and plunged into a moderate hot-bed of tanners bark, being careful to shade them from the sun till they have taken fresh root; after which they should have a large (share of air admitted to them when the weather is warm, to prevent their being drawn up weak; they must also be frequently refreshed with water, which must not be given in large quantities, especially the third sort, whose stalks are very subject to rot with much moisture. In this bed they may remain till autumn (provided there is room for the plants under the glasses) but if the heat of the bed declines, the tan should be stirred up, and fresh added to it; and if the plants have filled the pots with their roots, they should be shifted into pots a little larger; but there must be care taken not to over-pot them, for nothing is more injurious to these plants, than to be put into large pots, in which they will never thrive. In the autumn they must be removed into the bark-stove, where they must constantly remain, being too tender to thrive in this country in any other situation. In winter they must have but little wet, especially if they call their leaves; but in the summer they should be frequently refreshed with water, and in warm weather must have plenty of fresh air admitted to them. With this management the plants will make great progress, and in a few years will reach the glasses on the top of the stove, especially if the building is not pretty lofty.

The plants make an agreeable variety in a large stove where they have room to grow, their leaves having a different appearance from most other plants; but as they are several years old before they flower in the countries where they grow naturally, there is little hopes of their producing any in England.

B O N D U C. See GUILANDINA.

B O N T I A. Lin. Gen. Plant. 709. Plum. Nov. Gen. 23. Hort. Elth. 49. Barbadoes Wild Olive.

The CHARACTERS are,

// bath a small erect empalemt, which is quinquefid and permanent. The flower is of the ringent kind, having a long cylindrical tube, gaping at the brim; the upper lip is erect and indented, the lower lip is trifid and turns backward. It hath four awl-shaped stamens, which are as long as the petal, and incline to the upper lip, two of them being longer than the other, having single summits. In the center is situated the oval germen, supporting a slender style the length of the stamens, crowned by a bifid obtuse stigma. The germen afterward becomes an oval berry with one cell, including a nut of the same form.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled *Dynamia Angiosperma*, the flower having two long and two short stamens, and the seeds are included in a cover.

The SPÆCES are,
 I. BONTIA. (*Dapnoides*.) Lin. Sp. Plant. *Barbadoes Wild Olive*. *Bontia arborefcens thymelaeae facie*. Plum. Nov. Gen. 32.

z. BONTIA (*Gertmanns*) foliis oppofitis, pedunculis fpi-catis. Lin. Sp. Plant. 891. *Bontia with leaves growing oppofite, and fpiked foot-ftalks of flowers*. Avicennia. Flor. Zeyl. 57.

The firft fort is greatly cultivated in the gardens at Barbadoes, for making of hedges, than which there is not a more proper plant for thofehot countries, it being an Evergreen, and of quick growth. I have been informed, that from cuttings (planted in the rainy feafon, when they have immediately taken root) there has been a complete hedge, four or five feet high, in eighteen months. And as this will Very well bear cutting, it is formed into a very clofe thick hedge, which makes a beautiful appearance. In England it is preferred in ftoves, with feveral curious plants of the fame country. It may be raifed from feeds, which fhould be fown on a hot-bed early in the fpring (that the plants may acquire ftrength before winter.) When the plants are come up, they muft be tranfplanted out each into a feparate half-penny pot filled with light frefh earth, and plunged into a moderate hot-bed of tanners bark, obferving to water and fhade them until they have taken root; after which they muft have a large fhare of air in warm weather, and be often refrefhed with water. In winter they muft be placed in the ftove, where they fhould have a moderate degree of warmth, and but little water during that feafon. In fummer they muft have a great fhare of air, but will not do well if expofed abroad, efppecially in cold fummery; fo that they fhould remain in the ftove among plants which require a great fhare of air, which may be admitted by opening the glaffes in very hot weather. With this management, thefe plants will produce flowers and fruit in three or four years from feed. They may alfo be propagated by cuttings, which fhould be planted in the fummer. They muft be put into pots filled with light rich earth, and plunged into a moderate hot-bed, obferving to water and fhade them until they have taken root; after which they muft be treated as hath been directed for the feeding plants. Thefe plants being evergreen, and growing in a pyramidal form, make a pretty variety in the ftove amongft other exotic plants.

The fecond fort is fuppofed to be the Anacardium Orientale; but whether this is the true fort, I cannot determine, having feen only the feeds of that plant, which are frequently brought to Europe for marking nuts; and thofe have been too old to grow, fo I cannot take upon me to determine how far Mr. Jacquin is right.

BONUS HENRICUS. See CHENOPODIUM.

BORBONIA. Lin. Gen. Plant. 764.

The CHARACTERS are,

It hath a turbinated empalement of one leaf cut at the top into five acute fegments, which are ftiff, pungent, and about half the length of the petals. The flower hath five leaves, and is of the butterfly fhape. The ftandard is obtufe and reflexed. The wifigs are heart-fhaped andjherte than theftendard. The keel hath obtufe lunulated leaves. It hath nine ftamina joined in a cylinder, and one upper ftanding fingle, turning up its point. Thefe have fmall fummits. In the center isftuated an awl-fhaped germen, fupporting ajhortfyle, crowned by an obtufe indented ftigma. The germen afterward becomes a round pointed pod terminated with a fpine, having one cell, inclojing a kidney-fhaped feed.

This genus of plants is ranged in the third order of Linnasus's feventeenths clafs, intituled Diadelphia Decandria, the flower having ten ftamina, nine of which are joined, and the other Hands feparate.

The SPECIES are,

j. BORBONIA (*Lanceolata*) foliis lanceolatis multinerviis integerrimis. Lin. Sp. Plant. 707. *Borbonia with entire fpear-fhaped leaves having many nerves*. Genifta Africana irutefcens rufci nervofis foliis. Rail Hift. 3. 107.

2. BoRBONIA (*Cordata*) foliis cordatis multinerviis integerrimis. Lin. Sp. Plant. 737. *Borbonia with entire heart-fhaped leaves having many nerves*. Spartium Africanum frutefcens rufci folio caulem amplexante. Com. Hort. Amft. 2. 195.

3. BORBONIA (*Trinervia*)¹ foliis lanceolatis trinerviis integerrimis. Lin. Sp. Plant. 707. *Borbonia with entire fpear-floped leaves, having three veins*.

Thefe plants grow naturally at the Cape of Good Hope, from whence I received their feeds. In the natural place of their growth, they rife to the height often or twelve feet; but in Europe they feldom are more than four or five, having flender ftems divided into feveral branches, which are garnifhed with ftiff leaves, placed alternately; thofe of the firft fort are narrow, long, and end in a fharp point. The flowers cctne out from between the leaves at the end of the branches in fmall clutters; thefe are yellow, and fhaped like thofe of the Broom. It flowers in Auguft and September, but doth not perfect feeds in England.

The fecond fort hath broader leaves than die firft: the ftalks of this are flender, covered with white bark. The leaves embrace thefe at their bafe, where they are broadeft, and are terminated by fharp points like thofe of Kneeholm, or Butchers Broom. The flowers are produced in fmall clutters at the end of the branches, which are the fame fhape and colour as thofe of the former, but larger. This flowers at the fame time with the former, but never produces feeds here.

The third fort hath ftronger ftalks than eitlier of the former, garnifhed almoit their whole length, as arc alfo the branches with ftiff fpear-fhaped leaves, having three longitudinal nerves on each; thefe are placed clofer together than thofe of the other fpecies. The flowers are produced at the extremity of the branches, each (landing on a feparate foot-ftalk: they are of the fame fhape and colour with the former, but larger.

As thefe plants do not perfect their feeds in this country, they are with difficulty propagated here. The only method by which I have yet fucceeded, hath been by laying down their young fhoots; but thefe are commonly two years before they put out roots fit to be feparated from the old plant. In laying of thefe down, the joint which is laid in the ground fhould be flit upward, as is praftifed in laying Carnations, and the bark of the tongue at bottom taken off. The beft time to lay thefe down, is in the beginning of September; and the fhoots moft proper for this purpofe, are thofe which come out immediately, or very near the root, and are of the fame year's growth, not only from their fituation being near the ground, and thereby better adapted for laying, but thefe are alfo more apt to put out roots than any of the upper branches.

But where good feeds can be procured, that is the more eligible method of propagating the plants; for thofe raifed from the feeds make the ftraiteft plants, and are quicker of growth. When good feeds are obtained, they fhould be fown in pots filled with light loamy earth, as foon as they are received; which, if it happens in the autumn, the pots fhould be plunged into an old bed of tanners bark, under a frame, where they may remain all the winter, being careful that they are fecured fromfroft, and have not much wet. In the fpring, the pots fhould be plunged into a hot-bed, which will bring up the plants in five or fix weeks. When thefe are fit to remove, they fhould be each planted into a feparate fmall pot, filled with the like loamy earth, and plunged into a moderate hot-bed, obferving to fhade them until they have taken frefh root, as alfo to refrefh them with water, as they may require it. After this they muft be degrees be inured to the open air, into which they fhould be removed in June, and placed in a fheltd ftuation, where they may remain till autumn, when they muft be removed into the green-houfe, and place J Where they may enjoy the air and fun \ during the

winter

winter feafon, thefe plants muft be fparingly watered; but in fummer, when they are placed abroad, they will require to be frequently refrefhed, but muft not have too much water given them each time.

Thefe plants make a pretty variety in the green-houfe in winter, and as they do. not require any artificial heat to preferve them, they are worthy of a place in every garden where there is conveniency for keeping them.

B O R D E R S. The ufe of thefe in a garden, is to bound and inclofe parterres, to prevent them being injured by walking in them: thefe are commonly rendered very ornamental by means of the flowers, ihrubs, &c. that are planted in them.

Thefe ought to be laid with a rifing in the middle, becaufe, if they are flat, they are not agreeable to the eye.

As for their breadth, five or fix feet are often allowed for the largeft, and four for the leffer.

Borders are of four forts: thofe are the moft common, that are continued about parterres without any interruption, and are wrought with a gentle rifing in the middle, like an afs's back, and planted with flowers.

The fecond fort of borders is fuch as are cut into compartments, at convenient diftances, by fmall paffages -, and being alfo raifed in the middle, as before-mentioned, are likewife fet off with flowers.

The third fort is fuch as are laid even and flat without flowers, having only a verge of grafs in the middle, being edged with two fmall paths, raked fmoother and fanded. Thefe are fometimes garnifhed with flowering fhubs, and flowers of large growth, or with vafes and flower-pots, placed regularly along the middle of the verge of grafs.

The fourth fort is quite plain, and only fanded, as in the parterres of orangery, and is filled with cafes ranged in a regular order along thofe borders which are edged with Box on the fides next to the walks; and on the other, with verges and grafs-work next the parterre;

Borders are either made ftrait, circular, or in cants, and are turned into knots, fcrolls, and other compartments.

Florifts alfo make borders either along walks, or detached, and in thefe they raife their fineft and choicett flowers. Thefe are frequently encompaffed with border-boards painted green, which make them look exceeding neat.

But, in large parterres, this is not to be expected, fince, if they be ftocked with flowers fucceeding one another in their feveral feafons, it is fufficient, fo that nothing appears bare and naked.

It is ufualto difcontinue the borders at the ends next to the houfe, that the embroidery and rife of the parterre may not be hidden by the fhubs and flowering plants, and that the defign may be better judged of.

Since the modern way of gardening has been introduced in England, all the French tafte of parterres, fcroll-borders, and fret-work in Box, has been juftly banifhed our gardens: therefore I have only mentioned them here, to expofe the tafte of thofe architect-gardeners, who have no idea of the noble fimplicity of an open lawn of grafs, properly bounded by plantations, but, inftead of this, divide the part of the garden near the houfe, into various forms of borders edged with Box, with fand, fhell, or gravel-walks leading about them, by which the ground is cut into, many angles, fcrolls, &c. which is very hurtful to the eyes of a judicious perfon: therefore, where flowers are defired, there may be borders continued round the extent of the lawn, immediately before the plantations of fhubs, which, if properly planted with hardy flowers to fucceed each other, will afford a much fapre pleafing profpect than the ftiff borders made in fcrolls and compartments, after the French tañner, can poffibly do.

Thefe borders may be made fix or eight feet wide, in proportion to the extent of the garden and fize of

the lawn: for a fmall lawn fhould not have very broad borders, nor ought a large lawn to be bounded by fmall borders; fo that a due proportion fhould be always obferved in the laying out of gardens.

B O R R A G O [or Borago, which fignifies much the fame as courage, becaufe it is a good raifer of the foirit.] Borage.

The CHARACTERS are,

The empalment is divided into five parts at the top, and is permanent. The flower is of one leaf, having afhort tube, fpread wide open above, being divided into five acute fegments at the brim. The chaps of the flower are crowned by five prominences, which are obtufe and indented. It hath five fiamina which are joined together crowned by oblong fummits. It hath four germen fituated in the center, and a Jingle ftyk longer than the fiamina, fupporting a Jingle ftigma. The four germen afterward become fo many roundijh rough feeds, inferted in the cavities of the receptacle, and included in the large fwollen empalement.*

This genus of plants is ranged in the firft fedtion of Linnseus's fifth clafs, intitled Pentandria Mono* gynia, the flower having five ftamina and a fingle ftyle.

The SPECIES are,

1. **BORRAGO** (*Officinalis*) foliis omnibus alternis, calycibus patentibus. Hort. Upfal. 34. *Borage with all the leaves grafting alternate, and a fpreading flower-cup** Borrago floribus cseruleis. J. B.
2. **BORRAGO** (Ön*) calycibus tubo corollas brevioribus, foliis cordatis. Hort. Cliff. 45. *Borage with a flower-cup Jhorter than the tube of the flower, and heart-Jhaped leaves.* Borrago Conftantinopolitana flore reflexo cseruleo calyce veficareo. Tourn. Cor. 6.
3. **BORRAGO** (*Africana*) foliis ramificationum oppofitis petiolatis, calycinis foliolis ovatis acutis ere&is. Lin* Sp. 197. *African Borage with leaves growing appoiteto the branches upon foot-ftalks, and the leaves of the empalement oval, pointed, and ereff.* Cynogloffium Boraginifolio & facie iEthiopicum. Pluk. Aim.
4. **BORRAGO** (*Indica*) foliis ramificationum oppofitis calycinb foliolis fagittatis. Lin. Sp. Plant. 137. *Borage with oppofite leaves on the branches, and fpear-Jhaped leaves to the flower-cup.* Cynogloffoides folio caulem amplexante. Ifnard. A& Scien. 1718.

The firft is the common Borage, whose flowers are ufed in medicine, and the herb for cool tankards in fummer. Of this there are three varieties, which generally retain their difference from feeds; one hath a blue, the other a white, and another a red flower; and there is one which hath variegated leaves. Thefe variations have continued feveral years in the Chelfea garden, with very little alteration; but as they do not differ in any other refpect frogi the common, I have only mentioned them as varieties.

This is an annual plant, which, if permitted to fcatter its feeds, the plants will come up in plenty without care; the feeds may alfo be fown either in fpring or autumn, but the latter feafon is preferable, on a fpot of open ground where the plants are defigned to remain; when the plants have obtained a little ftrength, the ground fhould be hoed to deftroÿ the weeds, and the plants muft be cut up where they are too near each other, leaving them eight or ten inches afunder. After this they will require no farther care, unlefs the weeds fhould come up again; then the ground fhould be a fecond time hoed over to deftroÿ them, which, if well peformed, and in dry weather, will clear the ground from weeds, fo it will require no more cleaning till the Borage is decayed, the plants which are raifed in the autumn, will flower in May, but thofe which are raifed in the fpring, will not flower till June; fo that where a continuation of the flowers are required, there fhould be a fecond fowing in the fpring, about a month after the firft *, but this fhould be on a fhady border, and if the feafon fhould prove dry, the ground muft be watered frequently, to bring up the plants 5 this latter fowing will continue flowering till the end of fummer.

t

t

P

>>

The second fort was brought from Constantinople, which it grows naturally. This is a perennial plant, having thick fleshy roots, which spread under the surface of the ground, and is thereby propagated with great facility. The stems out many oblong heart-shaped leaves from the root, without any order, having lone hairy foot-stalks; from the lower part of the stem, which is more than two feet high when fully grown, having at the joints a fleshy leaf without a foot-stalk. The upper part of the stem is terminated by a pale blue colour, and the flowers are small, and are left naked. After the flowers are fallen, the four germs become so many rough seeds, smaller than those of the common Borage. It flowers in March, and the seed ripens in May. When the Borage first appears, the seeds fall into a hole, and are of such a nature, that they often spread open before the seed is six inches high; but as the seed advances, they divide into many loose spikes.

It is easily propagated by the root, which may be parted in the autumn: they should have a dry soil and a warm situation, for as the flowers appear early in the spring, so when they are much exposed, they are often killed by the frost, and thereby prevented flowering. If the plants are planted in dry rubbish, they will not grow too luxuriant, so will not be in danger of rotting. Some of the seeds of this have straggled into the joints of an old wall in the Chelsea garden, where the plants have grown without care for some years, and are never injured by cold or heat.

The third and fourth forts grow naturally in Africa; the first is an annual plant, which rarely rises above high, leaving rough stalks; those of the third fort are fit on by pairs opposite, with (short foot-stalks, but the leaves of the fourth chiefly embrace the stalks at their base; the Bowers come out on short foot-stalks from the wings of the stem, and are at the top of the stalks. Those of the third fort are white, and those of the fourth a pale flesh colour. The first is seldom cultivated but in botanic gardens for variety.

The seeds of these plants (which are sown in a hot-bed in March, and when the plants are strong enough to be removed, they should be each planted in a small pot filled with light earth, and plunged into a new situation to bring them; and when they are well rooted, they should be transplanted into a larger pot, and when they are grown up weak, and fall before the seeds are ripe.

BOSEA, Yervamora, or Shrubby Golden-rod. The Character is, that it has five ream Ubb, equal to the cereal; five aul-ftit; and the Roman xgtr than tin mpaUmfj tmimaa l figh fummiri; ex l-x eirbs, evn/ pcutndgen; if ibfi upen is. It is a small plant, which grows in the fields, and is very common in the mountains of the Alps.

The genus of plants is ranged in the first section of Jussieu's first class, under the Vntaidria Diognia, the flower having five petals and two stamens. We have but one species of this plant, viz. **Bosha**, (Yervamora.) Lin. Hort. Cliff. 4. Arb. Tbxeci lora Cacardilla, fringie carula folia, purpuratis vena, fructu monoepetalo Yervamora Hispanorum. Pluk. Phys. Cosemopolit. called Golden-rod. This plant is a native of the islands of the Canaries, and has also been found in some of the British islands in America, but was first brought into England from the Canaries, and has been long an ornament of the English gardens; but I have never seen any of these plants in flower, though I have had many old plants under my care more than forty years: it makes a pretty flower, which grows

with a stem as large as a miti. The branches came out very irregular, and strikingly different from the former, which should be fixed every spring to prevent the heads of the plants in any tolerable order: they retain their leaves till towards the spring, when they fall away, and new leaves are produced soon after: they are propagated by cuttings planted in the spring and will plant in the open air through the year, in this country.

BOSQUETS are little groves; so called from Bof-L'nii J, Italian, which is a diminutive of Buteo, a wood or grove.

They are found in gardens, which are formed of trees, shrubs, or tall large growing plants, planted in quarter; and are either disposed regularly in rows, or in a more wild or accidental manner, according to the fancy of the owner: these quarters are commonly surrounded with Evergreen hedges, and the entrance formed into regular porticos with Vews, which are by far the best and most useful for the purpose. In the inside of these quarters may be made some walks, either straight or winding; which, if the quarters are large, should be five or six feet broad, and kept well mowed and ruffled, which will render the walking much easier and pleasanter than if the walks are only the common earth; which in smaller quarters cannot be otherwise, but if the trees are close, and the walks narrow, so as to be shaded and over-hung by the trees, the walks will not grow.

The quarters may be also furrowed with hedges of Unit, Elm, Hornbeam, or Beech; which should be lit; and if the quarters are large, should be five or six feet broad, and kept well mowed and ruffled, which will render the walking much easier and pleasanter than if the walks are only the common earth; which in smaller quarters cannot be otherwise, but if the trees are close, and the walks narrow, so as to be shaded and over-hung by the trees, the walks will not grow.

In the planting of these bosquets, you should observe to mix the trees, which produce their leaves of different shapes, and various shades of green, and hoary or mealy leaves. It is also to be observed, that the plants should be planted in the autumn; of little or no effect, that we know of, yet hath good effect, in autumn, variety the foliage after the leaves are gone; as the Eilonyr, or Spindle-tree, the Poplar, or Mnrth Elder, the Caxik-fur Hawi, and many other furs, too numerous to mention in this place; the hedges are a good roof for the birds, so that they will be there invited to lay and harbour in the little groves, which by their discourse notes, will render the place very agreeable; in the spring. Evit j would advise never to mix Evergreens with deciduous trees; for, betide the ill effect it hath to the sight (especially in winter,) they seldom thrive well together. In the quarters, where you intend to have Evergreens, should be wholly planted therewith; and in the quarters, which call for a variety of different trees, which call for a variety of the largest growing flowers (especially near the OVIILL: of the quarters,) which will add greatly to the variety, if they have but air enough to grow; but if any of the Evergreen trees are mixed with the deciduous, it should lie only to border the wood.

Thele bosquets are to be planted only for spaciousness, but if they are to be used for the purpose of keeping, they should be planted in the autumn; of little or no effect, that we know of, yet hath good effect, in autumn, variety the foliage after the leaves are gone; as the Eilonyr, or Spindle-tree, the Poplar, or Mnrth Elder, the Caxik-fur Hawi, and many other furs, too numerous to mention in this place; the hedges are a good roof for the birds, so that they will be there invited to lay and harbour in the little groves, which by their discourse notes, will render the place very agreeable; in the spring. BOI & **Y S**. See **CHEKOPODIVM**. **BOX-TREE**. Sec **Btn**. **BRABEJUM**, African Almond, s-ulg6. The CHARACTER is, ETC.

Tb: four half an ounce. It is a tree of four narrow elongated seeds which are white, forming a tube, but the seeds are not backward in top, it hath four slender branching roots: they are inserted in the bottom of the stalk, and are of the same length, having small furrows. The stem is a small hairy cylinder, supporting a slender, cylindrical leaf; the leaves are small, the flowers are small, and are of a white colour, the fruit is a round, fleshy, green, berry.

this genus of plants is ranged in the first section of Linnaeus's fourth class, intitled Tetrandria Monogynia, the flower having four stamens and one style.

We have but one SPECIES of this plant, viz.

BRABEJUM. (*Stellatifolium*.) Hort. Cliff. Amygdalus^a thipica, fructu holoferico. Breyn. Cent. African* or Ethiopian Almond.

This tree is a native of the country about the Cape of Good Hope.

In Europe it seldom grows above eight or nine feet high, but in its native soil it is a tree of middling growth; but as it must be kept in pots, or tubs, being too tender to live through the winter in the open air, so we cannot expect to see it grow to a great size. It rises with an upright stem, which is soft, and full of pith within, covered with a brown bark. From the stem are sent out horizontal branches at every joint, the lower being the longest, and every tier diminishing to the top, so as to form a sort of pyramid. The branches are garnished with leaves at each joint, which are from four to five inches long, and half an inch broad in the middle, of a deep green on their upper side, but of a pale rufous colour on their under, indented on their edges, standing on very short foot-stalks. The flowers are produced toward the end of the shoots, coming out from between the leaves quite round the branches, which are of a pale colour, inclining to white; these appear early in the spring, and fall away without any fruit succeeding them in this country.

This plant is, with difficulty, propagated by layers; being often two years before they make roots strong enough to be taken from the old plants; when the branches are laid down, it will be a good method to flit them at a joint (as is practised in laying Carnations) which will promote their taking root.

These must have but little water given them, especially in winter, for as the young shoots are chiefly pith within, so they are very subject to rot with much moisture. The best time to make the layers is in April, just as the plants are beginning to shoot; the layers must always be made of the former year's shoots. As this plant is very difficult to propagate, it is very scarce in Europe, there being very few in the Dutch gardens at present.

The plants must have a good green-house in winter, but in summer should be set abroad in a sheltered situation, where they will thrive, and annually produce flowers in the spring, so will make a pretty variety among other exotic plants in the green-house.

BRANCA URSINA. See ACANTHUS.

BRASSICA, the Cabbage.

The CHARACTERS are,

The empalement is composed of four upright spear-shaped small leaves which are convex at their base and fall off. The flower is cross-shaped having four oval plain petals which spread open and are entire. It hath four oval nefarious glands, one being situated on each side of the short stamens and pistil and one on each side the empalement. It hath six stamens which are awl-shaped and erect two of which are opposite and the length of the empalement the other four are longer; these have erect pointed summits. It hath a taper germen the length of the stamens having a short style thicker than the germen and crowned by an entire stigma. The germen afterward becomes a long taper pod depressed on each side and is terminated by the apex of the intermediate partition which divides it into two cells filled with round seeds.

This genus of plants is ranged in the second section of Linnaeus's fifteenth class, intitled Tetradynamia Siliquosa, the flowers having four long and two short stamens, and are succeeded by long pods.

I shall first enumerate the species, which are distinct, and afterward mention the varieties, which are cultivated for the table, for although most of these may be continued distinct by proper care, without alteration, yet as they are liable to vary when planted near each other for seeds, so we must admit of their being different species. To this genus Dr. Linnaeus

has joined the Turnep, Navew, and Rocket, which by their general characters, may in a system of botany, come under the same title; but in a treatise of gardening, it may occasion confusion; therefore I shall treat of them under their former titles, by which they are generally known.

The SPECIES are,

1. BRASSICA (*Oleracea*) radice caulescente tereti caritosa, Hort. Cliff. 338. Cabbage with a taper fleshy stalk. Brassica capitata alba C. B. P. 111. The common white Cabbage.
2. BRASSICA (*Napobrassica*) radice caulescente orbiculari caritosa, foliis feffilibus. Cabbage with a round fleshy stalk and leaves growing close to the stalks. Brassica radice napiformi. Tourn. Inf. R. H. 219. Turnep rooted Cabbage.
3. BRASSICA (*Botrytis*) radice caulescente tereti caritosa, floralibus multicaulis. Cabbage with a taper fleshy stalk at the root and many branching flower-stalks. This is the Brassica Cauliflora. Caip. Bauh. Pin. in. The Cauliflower.
4. BRASSICA (*Sylvestris*) radice cauleque tenui ramis perenni foliis alternis marginibus incisif; Cabbage with a branching perennial stalk, and root and leaves growing alternate which are cut on their edges. Brassica maritima arborea five procerior ramosa. Mor. Hist. 2; p. 208. Taller Jhrubby Sea Cabbage.
5. BRASSICA (*Violacea*) foliis lanceolato-ovatis glabris indivisis dentatis. Hort. Upf. 191. Cabbage with entire oval spear-shaped smooth leaves which are indented.
6. BRASSICA (*Purpurea*) foliis oblongo-cordatis amplexicaulis, integerrimis. Cabbage with oblong heart-shaped leaves embracing the stalks which are entire. Brassica campestris perfoliata flore purpureo. C. B. P. 112.
7. BRASSICA (*Orientalis*) foliis cordatis amplexicaulis glabris. Lin. Sp. 931. Colewort with heart-shaped smooth leaves which embrace the stalk. Brassica Orientalis perfoliata flore albo filiqua quadrangula. Tourn. Cor. 16.
8. BRASSICA (*Gongyodes*) radice caulescente tereti, foliis inferioribus petiolatis superioribus femiamplexicaulis. Cabbage with a taper stalk the under leaves with foot-stalks and the upper half embracing the stalk. Napus Sylvestris. C. B. P. 95. The wild Navew, or Cole Seed.

The VARIETIES of the first sort are,

1. BRASSICA (*Sabauda*) fabauda hyberna. Lob. Icon. The Savoy Cabbage commonly called Savoy.
2. BRASSICA (*Rubra*) capitata rubra. C. B. P. in. The Red Cabbage.
3. BRASSICA (*Pyramidalis*) capitata alba pyramidalis. The Sugar-loaf Cabbage.
4. BRASSICA (*Pracox*) capitata alba praecox. The early Cabbage.
5. BRASSICA (*Peregrina*) peregrina moschum olens. H. R; Par. Foreign Mujk Cabbage.
6. BRASSICA (*Muscovitica*) capitata alba minor Muscovitica. H. A. Small Ruffia Cabbage
7. BRASSICA (*Capitata*) capitata alba compressa. Boerh. Ind. alt. 11. The large sided Cabbage.
8. BRASSICA (*Viridis*) capitata viridis fabauda. Boerh. Ind. 11. The green Savoy.
9. BRASSICA (*Laciniata*) fimbriata. C. B. P. in. The Borecole.
10. BRASSICA (*Selenifia*) fimbriata virefcens. Boerh. Ind. 2.12. Green Borecole.
11. BRASSICA (*Fimbriata*) fimbriata Siberica. Boerh. Ind. 2. 12. Siberian Borecole called by some Scotch Kale.

The second sort is undoubtedly a distinct species, for I have always found the seeds produce the same, with this difference only, that in good ground the stalks will be much larger than in poor land.

The VARIETIES of the third sort are,

1. BRASSICA Italica purpurea Broccoli difta. Just! Purple Broccoli.
2. BRASSICA Italica alba Broccoli difta. Just! White Broccoli.

The second sort, I believe, never varies, for I have cultivated it many years, and have not found it to

alter.

alter. This grows naturally on the sea-shore, near Dover. It hath a peculiarly initial branching stalk, in which it differs from the other species. I have continued it for four years, and have eaten the young flowers after they had been much frozen, when they were very sweet and goodly but at other times they are very (bong and rfriny. In very fevete winters, when the other raysed, out this b a neteffiry

Just, for the small severe frosts do not injure it. The rays of the leaves are inclining to a purple colour, and placed alternately on the branches. The (lower- The brandies, and ppttutl (n n m ill- <cn> ults, growereil, and feltiom put OUE

The third sort, which is the Cauliflower, has been improved a variety of ways. I have had more than fifty years experience in cultivating these plants, I could never find the least appearance of either species appearing together, and the difference is so different in their leaves, when the plants are young, that there is one essential difference between them in their growth. The common Cabbage puts out one upright stem from the center of the Cabbage, which afterward divide into several branches, whereas the Cauliflower tends out many flower-stems from the part which is eaten, which is only a compact collection of the heads of the stalks, which Biarmwri divides into many stems, branching out in many directions. It is as to form 3 Impre fprcative hew wlica in flower, but never rises pyramidically like the Cabbage

The two sorts of Broccoli I take to be only varieties of the same plant, in which the one may be distinguished by the leaves being kept distinct, yet I (loujt, if they were the same, near each other. I have seen it in the garden, and I am the either inclined to believe it is, from the YERiot! changes which I have observed in all these plants, for I have frequently had Cauliflowers of a green colour, with flower-buds regularly formed at the ends of the stalks, as in the white Broccoli, though the tototir was different and the white Broccoli approaches so near to the Cabbage, as to be with difficulty distinguished. I have seen it in the garden, and I am the either inclined to believe it is, from the YERiot! changes which I have observed in all these plants, for I have frequently had Cauliflowers of a green colour, with flower-buds regularly formed at the ends of the stalks, as in the white Broccoli, though the tototir was different and the white Broccoli approaches so near to the Cabbage, as to be with difficulty distinguished.

The Cauliflower was first brought to England from the island of Cyprus, where it has been cultivated long since, yet it was not brought to any degree of perfection, till about 1500, at least not to be sold in the markets, and since the year 1500, they have been so much improved in England, as that such of them as before were greatly admired, would at present be little regarded.

This plant has been much more improved in England, than in any other parts of Europe. In France they rarely have Cauliflowers till now, and in Italy, and in Holland, it is generally supplied with seeds from England. In many parts of Germany there was not one cultivated till within a few years past, and most parts of Europe are supplied with seeds from hence.

The eighth sort, which is generally known by the name of Rape or Cole Seed, is much cultivated in the Isle of Jersey, and some other parts of England for its

seed, from which the Rape Oil is made. It hath been cultivated of late years in other places, for feeding of cattle, to great advantage. This hath been lately joined to the Napus Sentiia, or Garden Rape, supposing them to be the same species, but I have cultivated both for more than twenty years, and could never observe a difference in them to vary; indeed the white Rape, which is the Rape, is distinguished to determine them as different species, but is the Garden Rape approaches near to the Rape than the Cabbage, for I will treat of Rape under the title of Rape.

The Cole Seed, which is cultivated for feeding of cattle, should be sown about the middle of June. The ground for this Rape should be prepared in the same manner as for Turneps. The quantity of seed for one acre of land, is from 8 to 10 pounds, and as the price of the seed is not great, it is better to allow eight pounds for an acre, if the plants are to be any part, they may be easily thinned when the ground is level. When the plants have put out their leaves, they will be lit to hoe, which must be performed in the same manner as is practised for Turneps, with this difference only, of leaving their stalks nearer together; for as they have very few roots, they do not require neat in much row. These plants should be sown a second time, about five or six weeks after the first, which, if well prepared in the ground, will entirely destroy the weed, so that they will require no further culture. By the middle of November the Rape will be grown to the height of 1 foot, when, if there is a scarcity of food, it may be either cut or fed down; but where there is not an immediate want of food, it had better be kept as a Rape, and be sown, or sown feed, when there may be a scarcity of other green food. If the heads are cut off, and the stalks are left in the ground, they will flourish again in the spring, and produce a good second crop in April, which may be either cut, or permitted to stand to feed, as is the practice when the Rape is sown for the feeds: but if the Rape is cut down, there will be no second crop.

do not destroy the Rape items, or pull the Rape ground. As the Rape is a hardy plant, it is not destroyed by frost, but is very great for the Rape for the feeding of ewes, for when the ground is frozen, as it is in the winter, it cannot be taken up, and the Rape may be cut off for the Rape supply. In several places where I have seen this Rape, I have found that one acre of Rape will produce as much Rape (buds, is sown, and the Rape will produce as much Rape; it is sown for the Rape, and the Rape will produce as much Rape, and the Rape will produce as much Rape.

Partridges, Hens, and turkeys, and the Withcreeper, are very fond of the Rape; for if there is any Rape in the neighbourhood, they will constantly be among them. The seeds of this Rape are sown in gardens for winter and spring salads, and is being one of the Rape.

The common Rape, which is sown in the garden, is not so early cultivated for winter use, as the Rape of these sorts must be sown the end of March, or beginning of April, in beds of good fresh earth; and in May, when the young plants will have about eight leaves, they should be packed out into shady beds, about three inches square, that they may acquire strength, and to prevent the Rape from being stunted.

About the beginning of June you must transplant them out, when they are so near to the Rape, as to be sown in the garden near London, a commonly between Cauliflowers, Artichokes, &c. at about two feet and a half distance in the rows; but they are planted for a Rape crop in a clear spot of ground, the distance from row to row should be three feet and a half, and as the rows two feet and a half distance, if the Rape should prove dry when they are transplanted

happens, the decayed leaves will render the soil very noxious, and the plants perished: pretty much at that time, are often destroyed in vast quantities.

In the beginning of February, if the wnatlier proves mild, you may begin to plant your plants by degrees, that they may be prepared for transplantation: and the ground where you intend to plant your Cauliflowers, or for gone! (which it would be quiet to have been well lunged and dug. It should be far advanced, with a week or fortnight before you intend to plant out your Cauliflowers: sometimes their destruction, is not, viz. that if there are not some fresh ones amongst them, and the ground is not hot and dry, as it sometimes happens, the frost will freeze your Cauliflowers, and their leaves full of holes]

Z Radishes upon the spot, the fits will not be long in coming, and the Cauliflowers, to long as they last. Indeed, the Radishes, die sooner near London than Spinach with their Radishes, and for a double crop, which is an advantage where ground is dear, or when the ground is not so good, otherwise it is better to have only one crop amongst the Cauliflowers, and the ground may be cleared in time.

Ynpr grotinri Iyring about the end of February, you may plant out your Cauliflowers: the distance which is generally allowed by the gardeners near London, is to plant other crops between their Cauliflowers, as Cucumbers for pickling, and winter Cabbages, in every other row, and a half an inch apart, and in the middle of the row, and a half an inch apart, and two feet two inches distance in the rows. In the latter end of May, or beginning of June, when the Radishes and Spinach are cleared off, you may put in a row of Cucumbers for pickling, in the middle of the wide rows, ... three feet and a half square, and in the narrow rows, plant Cabbages for winter use, at two feet two inches distance, so that there stand each of them exactly in the middle of the square between four Cauliflower-plants, and these, after the Cauliflowers are gone off, will have full room to grow, and the crop be thereby well increased in a successful year.

About three weeks or a month after your Cauliflowers are planted out, the Radishes, which will be fit to hoe, at which time, when you are hoeing out the Radishes where they are too thick, you should cut out all such as grow immediately about the Cauliflowers, and would prove hurtful to them, by drawing them up tall, and also at that time, draw up the Leeks up to the stems, and the plants, being careful not to let any get into their hearts, as was before directed, and when your plants are fit to pull, be sure to clear round the Cauliflowers first, and keep drawing the earth up to their stems as they advance in height, whirri nil!!!, rep their stems from being hurt by the weather, and be of singular service to your plants.

Benrcn, u onii ivo: driv the Leeks up to the stems, and the plants, being careful not to let any get into their hearts, as was before directed, and when your plants are fit to pull, be sure to clear round the Cauliflowers first, and keep drawing the earth up to their stems as they advance in height, whirri nil!!!, rep their stems from being hurt by the weather, and be of singular service to your plants.

Tin i are many people who are very fond of Cauliflower-plants in summer, but the gardeners near London have almost wholly laid aside this practice, and find it deal of trouble and charge with little purpose, for if the ground be so very dry as not to produce tolerable good Cauliflowers without water, it is better to have them, that watering them renders them nutd better, and when once they have been watered, if it is not constantly continued, it had been much better for them if they never had any, as also if it be given them in the middle of the day, it rather helps to fink them: so that, upon the whole, it can be taken to keep the earth drawn up to their stems, and clear away from every thing that grows near them, that they may have free open air, you will find that they will succeed better without than with water, when any of these cautions are not strictly observed.

When your Cauliflowers begin to form, you must often look over them, to turn down their leaves, as was before directed, to preserve their bottoms, and when they are full grown, observe the former directions in pulling them, &c. but wherever you meet with an extraordinary good Cauliflower, whose root is hard and white, and perfectly free from any frinkness about the edges, you should suffer it to remain for food, keeping the leaves close down upon it until the flower hath beat out stems, and then remove the leaves from them by degrees, but do not expose them too much to the open air at first. As the flowers advance, you must take the leaves quite away, and when they begin to branch out, you should cut three pretty strong stakes, at equal angles, about it, surrounding them with pickered, &c. to support their branches, which would be otherwise liable to break with the wind.

When your plants begin to be formed, if the weather grows dry, you should give them a little water all over (with a watering-pot that hath a rise to it) which will promote the growth of the seeds, and preserve them from rotting, which is often hurtful to the seeds, and when your seeds are ripe, you must cut it off, and hang it up to dry, and use it as it was directed for Cauliflowers, and although your flowers do not produce so much food as those which were of a later or frisky nature, yet the goodness of such seeds will sufficiently recompense for the quantity, and any person who was to purchase his seeds, had better give his fillings an ounce for such seeds than two for the seeds commonly found the sale, as the gardeners about London have experienced, who will never buy any seeds of this kind, if they do not know how they were sowed.

But in order to have a third crop of Cauliflowers, you should make a slender hot-bed in February, in which you should sow the seeds, covering them with a mat of an inch thick with light mould, and covering the bed with glass-frames: you should now and then gently refresh the bed with water, observing to raise the glasses with bricks or pumps in the day-time, to let in fresh air, and when the plants are come up, and I have seen four or five leaves, you should prepare another hot-bed to prick them into, which may be about two inches square, and in the middle of April harden them by degrees, to fit them for transplanting, which will be done the middle of that month, at the distance directed for the second crop, and will be managed accordingly: this (if the soil is good where they are planted, or the land cool and moist) will produce good Cauliflowers about a month after the second crop is gone, whereby their season will be greatly prolonged.

There is also a fourth crop of Cauliflowers, which is raised by sowing the seed about the end of May, and being transplanted, as has been before directed, will produce good Cauliflowers in a kindly season, and good food, after Michaelmas, and continue thro' October and November; and, if the season permit, thro' a great part of December.

The reason why I fix particular days for the sowing of this seed, is because two or three days often make a great difference in their plants, and because these are the days usually fixed by the gardeners near London, who have found their crops to succeed best when sown at those times, although one day, more or less, will make no great odds. I have also, in this edition, altered the days to the new style.

BREYNIA. See CAPPARIS.
BROMELIA. Plum. Nov. Gen. 46. tab. 1. Lin. Gen. Plant. 306.

THE CHARACTERS ARE,
It hath a three-angled permanent capsule, which is three-angled, upon which the ground is smooth. The leaves are long narrow, and are not, such having a distinct joint to it above the leaf. It hath for its fruit the length of the petals, which are terminated by a long filament. The pistil is situated upon the receptacle supporting a slender style, crowned by a bright orange stigma. The capsule is situated between

nn oblong capful, divided by a partition in the middle, to which the feeds are fixed quite round -, these are smooth, and almost cylindrical.

This genus of plants is ranged in the first section of Linnaeus's sixth class, intitled Hexandria Monogynia, the flower having six stamens and one style. Dr. Dillenius has supposed this to be the same with Plumier's Karatas, which mistake he was led into by Plumier's drawing, where the flower of his Caraguata is joined to the fruit of his Karatas, and *vice versa* and from hence Dr. Linnaeus has been induced to join these and the Ananas together, making them only species of the same genus.

The SPECIES are,

1. *BROMELIA (Nudicaulis)* foliis radicalibus dentato-spinosis caulibus integerrimis. Lin. Sp. Plant. 286. *Bromelia with lower leaves indented and prickly, and those of the stalks entire.* Bromelia pyramidata, aculeis nigris. Plum. Nov. Gen. 46.

2. *BROMELIA (Lingulata)* foliis ferrato-spinosis obtusis, spicis alternis. Lin. Sp. Plant. 285. *Bromelia with fawed, prickly, obtuse leaves, and spikes of flowers growing alternate.* Bromelia ramosa & racemosa foliis Arundinaceis ferratis. Plum. Nov. Gen. 46.

The first sort hath leaves very like some of the sorts of Aloes, but not so thick and succulent, which are sharply indented on their edges, where they are armed with strong black spines; from the center of the plant arises the flower-stalk, which is near three feet high, the lower part of which is garnished with entire leaves, placed alternately at every joint. The upper part of the stalk is garnished with flowers, set in a loose spike or thyrse, these have three narrow herbaceous petals fitting upon the germen, and six slender stamens, with the style, which are shorter than the petals. These flowers in the country where they naturally grow, are succeeded by oval seed-vessels, having a longitudinal partition, in the center of which are fattened cylindrical seeds on every side, which are smooth.

The second sort hath shorter leaves than the first, which stand erect, and are narrow at the base, increasing in width gradually to the top, where they are broadest, these are sharply fawed on their edges, and are of a deep green colour. The flower-stem arises from the center of the plant, which divides upward into several branches; the upper part of these are garnished with spikes of flowers, which come out alternately from the sides of the branches, each having a narrow entire leaf just below it, which is longer than the spike. The flowers are placed very close on the spikes, each having three short petals situated upon the globular empalement, when these decay, the empalement turns to an oval pointed seed-vessel, including seeds of the same shape with the former.

Both these plants grow naturally in very warm countries. Father Plumier, who gave this title to the genus, found them growing in the French Islands in America; and the late Dr. Houftoun observed, them growing in Jamaica, and in several parts of the Spanish West-Indies. The first sort also grows on the coast of Guinea, from whence I received the seeds; and the second sort was sent me from St. Christophers.

These plants are propagated by seeds, which must be procured from the country where they grow naturally, for they do not produce any in England. These must be sown in small pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark; the earth in these pots should be sprinkled over with water two or three times a week, according to the heat of the weather, but must not have too much moisture. If the seeds are good, the plants will appear in about five or six weeks, and in a month after will be fit to transplant, when they should be carefully shaken out of the pots, and each planted in a separate small pot filled with the same earth as before, then they must be plunged again into a moderate hot-bed, observing frequently to sprinkle them over with water, but be cautious of giving them too much, lest the roots should be thereby rotted.

During the summer season the plants should save a moderate share of air, in proportion to the heat of the weather; and, in autumn, they must be removed in the bark-trove, and treated in the same manner as the Ananas, or Pine Apple, with which management they will make good progress; but after the first winter, they may be placed upon stands in the dry stove, though they will thrive much better if they are constantly kept in the tan-bed, and treated like the Ananas, and will flower in three or four years; whereas those in the dry stove will not flower in twice that time.

The other parts of their culture is only to fluff them into fresh earth when they require it; but they should by no means be put into large pots, for they will not thrive if they are over-potted; unless they have much wet, especially in winter.

These plants make a pretty variety in the hot-house, for those who have room, may allow a plant or two of each sort to have a place in their collection of exotic plants.

BROOM, the common. See SPARTIUM.

BROOM, the Spanish. See SPARTIUM and GENISTA.

BROWALLIA. Lin. Gen. Plant. 691. Hort. Cliff. 318.

The CHARACTERS are,

The empalement is fabulous of one leaf, and indented at the top in five unequal parts. The flower is funnel-shaped, of one leaf having a cylindrical tube twice the length of the empalement, the upper part is spread open, and divided into five parts, the upper segment or lip being a little larger than the others, which are equal. It hath four stamens included in the chaps of the petal, the two upper being very short, and the two under broad, longer, and reflexed to the mouth of the tube, which inclose them, these are terminated by single incurved summits. In the center is situated an oval germen, supporting a slender style the length of the tube, crowned by a thick, compressed, indented stigma. The empalement afterward becomes an oval obtuse vessel with one cell, the top in four parts, and filled with seeds.*

This genus of plants is ranged in the * of Linnaeus's fourteenth class, intitled * Angiospermia, the flower having two long a, short stamens, and the seeds included in a capsule

The SPECIES are,

1. *BROWALLIA (Demija)* pedunculis unifloris. Hort. Cliff. 318. *Browallia with one flower on a foot-stalk.* The title of Browallia was given to it by Dr. Linnaeus, in honour of professor Browall, of Amsterdam.

2. *BROWALLIA (Elata)* pedunculis unifloris multiflorisque. Lin. Sp. 880. *Browallia with one flower on each foot-stalk, and sometimes many.*

The seeds of the first sort were sent me by Mr. Robert Millar, from Panama, in the year 1735 which succeeded in the Chelsea garden, where it has continued to flower, and produce seeds every year, but the plants are annual, so perish in autumn: the seeds of this plant must be sown upon a hot-bed in the spring, and the plants brought forward on another otherwise they will riot perfect their seeds in England. Some of these plants may be transplanted in June into the borders of the flower-garden, where, if the season prove warm, they will flower and perfect seeds; but lest these should fail, there should be two or three plants kept in the stove for that purpose. The plants usually grow about two feet high, and spread out into lateral branches, garnished with oval leaves which are entire, ending in a point, having short foot-stalks. Toward the end of the branches the flowers are produced singly, upon pretty long foot-stalks, arising from the wings of the leaf. These have a short empalement of one leaf, which is cut into five parts; out of the center of the empalement the flower arises, which is crooked and set downward; the top of the tube is spread open, and the brim, or open part of the flower, has some resemblance to a lipped (lower, being irregular. It is of a bright

BRU

bright. lje colour, ibmctm* inclining to a purple or red, and oftn there are flowers of these colours on tilt limit plant. When these fall away, the green in the cenL-r become:- an oval capsule of one cell, filled with smll, brown, anjgi for seeds, it flowers in July, August, and September, and the fruits are ripe in iivc or lix week I after.

When this plant was ii derailed in the Cht lles garden, I p ^ is the tiik of Ualea, in hcnior to Mr, 13ale, an eminent botunifr, and a great mend of Mr. Ray's. By this tide ic was delivered to the Royal Society, and printed in the Philofophical Transitions, and abb m ihe dialogue of the Chcllea garden : g as by the name I communknted tire feeds w Doctor Liri-iaiaus, who afterward clianged the name to Browallii, and printed it in the catalogue of Mr. Clifford's garden; wheie there is a figure of it exhibited, fo that this litter title is become -Umiitt univerial among lifts.

The fscond fiirt grows naturally in Peru, from whence the younger Julius fent the feeds; this plant rifts about the (iimc height as ifit firr, but hath ft ranger Italics, nnti finds out a greater number of breaches, fo much more bulhy than rltat; the flower?; are produced upon foot-lblks, which proceed from the wings cf theU^wcs; fonic of dicfc foor-ftdles fufnin one, others three, ormore floweis, of a dark blue twlourj thd'c are fuccceded by oval capiiile*, likltl with JJamll anguljr feed

 - 6. Bryonia (Bosniaca) foliis palmatis quinquepartitis herbatis, lacinis obtusis. Briony with hairy palmated leaves divided into five parts, and sharp segments. Bryonia Bosniensis lic fide. Hort. Ethn. 24.
- The first sort grows upon dry banks, under hedges in m.v y parts of England; but may be cultivated in den for use, by sowing the berries, in the spring of the year, in t dry pour I d; where they will in run years time, grow to be large roots, provided they are not too clost. The roots of this plant have been

tcyrt fvyierly, by impoilurs, brought in:o an human
shape, and carried about the country, and shown for
Monstrous to the common people, who were easily
imposed on by their credulity, and their not good
livings thereby. The method which these people
practised, was to find a young living Briony plant,

then they opened the earth all round the plant, being
careful not to disturb the lower fibres; and (being
prepared with such a mould, as is used by the people
who make plaster figures) they heap the mould close
to the root, fastning it with wire, to keep it in its
proper situation; then they filled the earth about the
root, leaving it to grow in the shape of the

...Mild,
which is sowed in not January, so that it may be
done in March, by September it will have the shape.
The leaves of this plant are otherwise disposed on the
people in the market for Maraculose leaves, although
there is no resemblance between them; nor any agree-
ment in quality.

The second and fourth sorts are perennial plants, their
roots remaining several years, but their branches de-
cay every winter. These roots must be preserved in
pots filled with fresh light and in winter must
be placed in the green-house, to protect them from
frost and great rains, which would destroy them,
if they were exposed thereon. During the winter
season, they should have very little water given them,
but in summer, when they are exposed to the sun,
they must be frequently refreshed with water, in
dry weather. They flower in July, and in warm
situations will perfect their seeds.

The third, fifth, and sixth sorts are annual plants,
their seeds must be sowed in a hot-bed early in the spring,
and when the plants are about three inches high,
they should be each transplanted into a small pot filled
with fresh light earth, and plunged into a hot-bed of
tanners bark, observing to water and shade them
till they have taken root. When the plants are
grown to large, as to ramble about on the surface of
the soil, and begin to tangle with other plants, they
should be shifted into larger pots, and placed in the
bark-flow, where their branches may be raised to
the wall, or against an espalier, that they may have
sun and air, which is absolutely necessary for their
producing fruit. When these plants are full of fruit,
they make a pretty variety in the stove among other
exotic plants.

The second and fourth sorts are also propagated from
seeds, which should be sown in a hot-bed; and when
the plants are fit to transplant, they should be put
into pots, and when they have taken root, should be
covered below the open air by degrees, when they
may remain during the summer season, but in winter
they must be sheltered under a hot-bed frame. The
second sort is much easier than the former.

BRYONIA NIGRA. See TABLE.

BUBON. Lin. Gen. Plant. 748. Apun. C. B. 154.
Fons. Herp. Pat. 102. Maccedonia Parlay.

The Bubon is a large tree, the greatest, or several
times, diameter of some individuals, which when they
stand in the middle of the forest, the trees which
are near them die. The young branches are of a
pale green colour, which turn brown and are
covered with small, round scales, which are very
hard to be taken off. The leaves are of a
dark green of the true shape, and the veins are
very plain. The fruit is a small, round, red
apple, which is very hard and of a greenish red
colour, and is very hard and of a greenish red
colour. The seeds are small, round, and of a
greenish red colour. The plant is very hard
and of a greenish red colour. The seeds are
small, round, and of a greenish red colour.

The genus of Bubon is named in the second section
of Linnaeus's method, under the name of Bubon,
the first having five flowers and two styles.

The SPECIES are,

- 1. **Bubon** (Macedonia) foliis rhombicis mbcn-m'at'r rre-
natis, umbellis numerabilibus. Hort. Cliff. 32. Bubon
with oval, rhombic, crested leaves, and many umbels.

(. D-) **Bubon** (Guazuma) foliis glabra inferioribus rhom-
bicis serratis, superioribus pinnatifidis tridentatis. JWJ.
Lepl. 100. Bubon with serrated and pinnatifid
leaves, and many umbels.
Ferd. Africanus gallicantia folia em-
pyreticis. Hort. Amst. p. 115.

The first sends out many leaves from the root, the
lower growing almost horizontally, increasing near the
surface of the ground: the first stalks of each leaf di-
vide into several other smaller, furnished with smooth
rhomboid leaves, which are of a bright, pale
green colour, inclined on their edges. In the center
of the plant arises the flower-stem, which is
more than a foot high, dividing into many branches,
each being terminated by an umbel of white flowers,
which are succeeded by oblong hairy seeds. It flowers
in July, and the seeds ripen in autumn, soon after
which the plant decays.

This plant in warm countries is biennial, the plants
which rise from seeds the first year, produce now is mid
(tedi : the next, 'id then the plants: but in England,
they seldom flower till the third or fourth year from
first sown but whenever the plant becomes, it always dies.

It is propagated by seeds, which should be sown on
a bed of soil (andy tan is, rather early in the autumn,
or in April -, and if the soil is not very warm and dry,
the seeds should be covered with a little earth, and
frequently watered with water, which is a sure
method to bring up the plants; for when this is not
practised, the seeds often fail, or remain long in the
ground. When the plants are up, they will re-
quire no other care but to be kept clear from weeds,
till the beginning of October, when they should be
carefully taken up, and planted in a warm border of
dry ground; and a few of them should be put into
pots, that they may be sheltered under a frame in
winter: for in severe frosts, those which are exposed
to the open air, are frequently killed; though, in
moderate winters, they will live abroad without cov-
ering; but it is a secure way to preserve the species,
to keep two or three plants in pots, in shelter, during
the winter, lest those abroad should be destroyed.

The Venice Titace.

The second sort grows naturally in Sicily, from whence
I received the seeds. This is a low perennial plant,
having short stiff leaves, which are very narrow: the
flower-stalks rise one or two feet high, which is terminated
by an umbel of small white flowers, which are suc-
ceeded by small, oblong, channelled seeds. It flowers
in June, and the seeds ripen in September. It is
propagated by seeds, and should have a dry soil and
a warm situation, where the plants will continue sev-
eral years. It is a plant of little beauty or use, fit
only to be preserved for the sake of variety.

The third sort rises with an upright stalk to the
height of eight or ten feet, which is termined by
several, having a purplish bark, covered with a whitish
powder, which comes off when handled; the upper
part of the stalk is furnished with leaves; every year,
the lower stalks having extending them as their hair,
leaving two lines several inches, like those of the
common Parsly, and so far with them, like those
of Linnen, but smaller, of a grey colour; the top
of the stalk is terminated by an umbel of yellow
flowers.

H

flowers, which are succeeded by oblong channelled feeds, having a thin membrane or wing on their border. It flowers in August, but hath not produced feeds in England. When any part of the plant is broken, there issues out a little thin milk of a cream colour, which hath a strong scent of Galbanum.

The fourth sort rises with a ligneous stalk about two feet high, garnished with leaves at each joint, which branch out like the former; but the small leaves or lobes are narrow and indented, like those of Bastard Hemlock. The stalk is terminated by a large umbel of small white flowers, which are succeeded by feeds like those of the former sort.

These plants are both natives of Africa. They are propagated by feeds, which should be sown in pots filled with light loamy earth, as soon as they arrive, which, if it happens toward autumn, should be plunged into a bed of tanners bark, where the heat is gone, and screened from frost in winter; In the spring the plants will come up, and by the middle of April will be fit to remove, when they should be carefully shaken out of the pots, being careful not to tear off their roots, and plant them each into a separate small pot, filled with the same earth as before; then plunge the pots into the tan again, and water them to settle the earth to the roots of the plants, and shade them from the sun in the day time, until they have taken new root; after this they must be inured gradually to bear the open air; into which they should be removed in June, and placed with other exotic plants in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house, and placed where they may enjoy as much of the sun and air as possible, but defended from frost.

In winter these plants should have but little water given them, for much wet is very injurious to them: in summer, when they are exposed to the open air, they must be frequently refreshed with water in dry weather; but at no time should have too much wet, for that will rot their roots.

These plants make a pretty variety in the green-hedley in winter, and when they are placed abroad in the summer with other green-house plants, they have a good effect, especially when they are grown to a large size. They generally flower the third year from feeds, but their flowers are produced so late in summer, that the feeds have seldom time to form before the cold comes on in the autumn; at least for some years past, as the seasons have been cold and moist, but in warm summers, the fourth sort will perfect feeds, if they stand in a warm sheltered situation.

The Galbanum of the shops is supposed to be procured from the third sort, for upon breaking the leaves the juice which flows out from the wound, hath a strong odour of the Galbanum, which is a confirmation of it.

BUCKSHORN, or HARTSHORN. See ¹LANTAGO.

BUDDING. See INOCULATING.

BUDDLEJA. Houft. MSS. Lin. Gen. Plant. 131.

The CHARACTERS are,

It hath a small permanent empalement, which is slightly cut at the top into five acute parts. The flower is of one leafy bell-shaped, and quadrid, the petal being stretched out beyond the empalement it hath four short stamina, which are placed at the divisions of the petal terminated by short funnels. The oblong germen is situated in the center supporting a short style, crowned by an obtuse stigma the germen when it opens becomes an oblong capsule having two cells filled with small feeds.

This genus of plants is ranged in the first part of Linnæus's fourth class, entitled Tetrandria Monogynia the flower having four stamina and but one style.

The SPECIES are,

1. BUDDLEJA (*Americana*) foliis ovatis ferratis oppositis ferribus spicatis racemosis, caule fruticoso. *Buddleja with oval fawed leaves growing opposite flowers growing in branching spikes, and a shrubby tall Buddleja fru-*

tefcens foliis conjugatis & ferratis floribus spicatis luteis. Houft. MSS.

2. BUDDLEJA (*Occidentalis*) foliis lanceolatis acuminatis integerrimis oppositis, spicis interruptis. *Buddleja with pointed spear-shaped leaves which are entire placed opposite and broken spikes of flowers. Buddleja frutescens foliis oblongis mucronatis, floribus spicatis albis. Houft. MSS.*

The first sort grows naturally in Jamaica, arid midst of the other islands in America, where it rises to the height of ten or twelve feet, with a thick woody stem, covered with a grey bark; this sends out many branches toward the top, which come out opposite; as are also the leaves so placed, which are oval and covered with a brown hairy down. At the end of the branches the flowers are produced in long clove (spikes, branching out in clusters, which are yellow, consisting of one leaf, cut into four segments; these are succeeded by oblong capsules, filled with small feeds. This was sent me by Dr. Houftoun, from Jamaica, in 1730, under the title Verbaſci folio minor arbor, floribus spicatis luteis tetrapetalis feminibus-fingulis oblongis in fingulis vasculis ficcis. Sloan. Cat. Jam. 139. But as this was a vague title, the doctor afterward constituted a new genus, and gave it the title of Buddleja, in memory of Mr. Buddie, an eminent English botanist.

The second sort the same gentleman sent me from Carthage, where it grows naturally. This is the Ophioxylon Americanum, foliis oblongis mucronatis, leviter ferratis bardanae infar, subtus lanuginosis. Pluk. Aim. 270. tab. 210. fig. s. and was by Plukenet supposed to be the same with the former, which was denied by Sir Hans Sloane in his History of Jamaica.

This sort rises much taller than the first, and divides into a great number of slender branches, which are covered with a russet hairy bark, garnished with long spear-shaped leaves, ending in sharp points: these grow opposite at every joint; at the end of the branches are produced branching spikes of white flowers, growing in whorls round the stalks, with small spaces between each. It hath long, narrow, spear-shaped leaves growing between the spikes, whereas those of the other sort are naked. The leaves of this are much thinner than those of the first sort; and have scarce any down on their under side; the spikes of flowers grow more erect, so form a large loose spike at the end of every branch.

The plants grow naturally in gullies or other low sheltered spots, in the West-Indies, their branches being too tender to resist the force of strong winds, so are rarely seen in open situations;

They are propagated by feeds, which should be obtained from the countries where they naturally grow, for they do not perfect them in England. These should be brought over in their capsules or pods, for those which are taken out before they are sent seldom grow. They should be sown in small pots, filled with rich light earth, and very lightly covered with the same; for as these feeds are very small, so if they are buried deep in the ground, they perish. The pots should be plunged into a moderate hot-bed and must be every third or fourth day gently watered, being very careful not to wash the feeds out of the ground, by too hafty watering them. If the feeds are fresh and good, the plants will come up in about six weeks, provided they are sown in the spring; and if they grow kindly will be large enough to transplant in about two months after. Then they should be carefully separated, and each planted into a small pot, filled with light rich earth and plunged into the hot-bed again, observing to shade them from the sun until they have taken new root, as also to refresh them with water when they require it. After the plants have taken fresh root in the pots, there should be fresh air admitted to them every day, in proportion to the warmth of the season, they must also be frequently, but moderately, refreshed with water. If the plants thrive well, they will have filled these

finest pots with their roots by the middle of August, at which time it will be proper to shift them into pots one size larger, that they may have time to take good root again, before the cold weather comes on. When these are new potted, the tan should be turned over to renew the heat; and if it is wanted, some fresh tan must be added to the bed, to encourage the roots of the plants. In this bed they may remain till autumn, when they must be removed into the stove, and plunged into the tan-bed, where they must constantly remain, for they are too tender to thrive in this country, if they are not so treated. During the winter they must have but little water, and should be kept warm, but in summer they should have fresh air admitted to them constantly when the weather is warm, and frequently sprinkled all over with water. With this management, the plants will flower the fourth year from seeds, and continue so to do every year after, and will make a good appearance in the stove.

8 U G L O S S U M. See ANCHUSA, and LYCOPSIS.
BUGULA. Tourn. Inf. R. H. 208. tab. 98. Ajuga.
Lin. Gen. Plant. 624. Bugle.

The CHARACTERS are,
It hath ajhort permanent empakment of one leaf, which is slightly cut into five parts \ the flower is of one leaf of the lip kind, having an incurved cylindrical tube > the upper lip is very finally erect, and bifid 1 the under lip or beard is large, open, and divided into three obtuse segments, the middle being large, and the twojidei finally it hath four erect stamina, two of which are longer than the upper lip) and two porter terminated by double fummits. In the center, isfluated the four germen, supporting a slender flyle the length of the stamina, crowned by two slender stigma. The germen afterward become four naked feeds inch fed in the empakment.*

This genus of plants is ranged in the first section of Linnseus's fourteenth dais, intitled *Didynamia Gymnopermia*, the flower having two long, and two short (lamina, and is succeeded by naked feeds.

The SPECIES are,

1. BUGULA (*Reptans*) foliis caulinis femiamplexicaulis, stolonibus reptatricibus. Bugle whose leaves half embrace the stalks, and shoots which put out roots. Bugula. Dod. Pempt. 135. Common Bugle.
2. BUGULA (*Decumbens*) foliis oblongo-ovatis, caulibus decumbentibus, verticillis distantibus. Bugle with oblong oval leaves, declining stalks, and the whorls of flowers wide asunder. Bugula folio maximo flore pallide caeruleo. Boerh. Ind. alt. 1. 184.
3. BUGULA (*Pyramidalis*) foliis obtuse-dentatis, caule simpliciter. Bugle with blunt indented leaves* and a single stalk. Ajuga tetragono pyramidalis. Lin. Sp. Plant. 561.
4. BUGULA (*Genevifis*) foliis oblongis tomentosis, calycibus hirsutis. Bugle with oblong woolly leaves* and hairy flower-cups. Bugula carneo flore. Cluf. Hist. 2. P. 43.
5. BUGULA (*Orientalis*) villosa, foliis ovato-dentatis sessilibus, floribus reflexis. Hairy Bugle with oval indented leaves, placed close to the stalks, and inverted flowers. Bugula orientalis villosa flore inverfo candido cum oris purpureis. Tourn. Cor. 14.

The first sort grows naturally in woods, and shady moist places, in moist parts of England, where it spreads and increases greatly by the side shoots, which put out roots at their joints. There are two varieties of this, one with a white, and the other a pale purple flower, which I observed growing in several parts of Westmoreland \ but these do not differ in any other respect than in the colour of their flowers from the common, therefore I have only mentioned them as varieties.

The common Bugle is greatly esteemed as a vulnerary herb, and is used both internally and externally; it enters as an ingredient into the vulnerary decoctions of the furgeons, and is commended externally, applied to ulcers. This is constantly mixed with the vulnerary herbs, imported from Switzerland. It is titled *Conibida Media*, or *Middle Confound*. As

this grows naturally wild in great plenty, so it is seldom admitted into gardens.

The second sort grows naturally on the Alps; the leaves of this are much longer than those of the common Bugle, the stalks are weaker, and decline on every side, and the whorls of flowers are much smaller, and are ranged at a greater distance. This is admitted into some gardens for the sake of variety, and propagates in plenty by its trailing stalks. This requires a moist shady situation.

The third sort grows naturally in France, Germany, and other countries, but is not a native in England. This grows about four or five inches high, with a single stalk, which is garnished with leaves at each joint, placed opposite; these are oval, and indented bluntly on their edges. The flowers grow in whorls round the stalks, and toward the top form a close thick spike, and are of a fine blue colour.

The fourth sort grows naturally in many parts of Europe. This approaches near to the common Bugle, but the leaves of this are woolly, and the flower-cups are very hairy, in which the chief difference consists. There are two varieties of this, one with a white, and the other a red flower.

The fifth sort was brought from the Levant by Dr. Tournefort, and is preferred by those who are curious in collecting rare plants. There are two or three varieties of it, which only differ in the colour of their flowers.

This sort requires a little protection in winter, therefore the plants should be planted in pots filled with a loamy soil, and placed in a shady situation in summer, but in the winter they must be removed under a common frame, where they may enjoy as much free air as possible in mild weather, but in hard frost should be covered, otherwise they will not live through the winter in this country, unless it proves very favourable.

This may be propagated by seeds, which should be sown soon after it is ripe, in a pot filled with loamy earth, and placed in a shady situation till autumn, when it should be removed under a frame, where it may be freed from hard frost. In the spring the plants will come up, which should be transplanted into separate pots as soon as they are strong enough to remove, and, in summer, placed in the shade, and treated as the old plants. It flowers in May, and the seeds ripen the latter end of July. It may also be increased by offsets, but this is a slow method, because the plants put out but few of them, especially while they are young, so the other method is chiefly practised.

All the other sorts are hardy enough, and are easily multiplied by their side shoots; these delight in a moist shady situation, where they are apt to spread too much, especially the two first sorts.

B U L B [Bulbus, Lat. of Boxes, Gr. - \ Bulbous roots are of two sorts, viz. tunicated (or coated) and squamous (or scaly.) A tunicated root consists of many coats, involving each other, as in the Onion, Tulip, &c. whose roots, if cut through the middle, plainly shew the several coats. A squamous root consists of many scales, lying over each other like tiles upon a house, or scales on fish of this kind are the Lily, Martagon, &c.

The CHARACTERS are*

The great or general umbel is composed of near twenty rays or small umbels, zybicb are port, *ni clofe together. The involucrum of the great umbel is composed of many Jhortnarrow leaves, thofe of thefmaller are the fame, but are as long as the umbels. The proper c}npalement of the flower is fearcē discernible. The rays of the great umbel are uniform. The flowers .have five heartfshaped petals which are equal, and turn inward; they have five Jiamina which are Jhorter than the petals, terminated by Jingle fummits\ the oblong germen is fituated below the receptacle, fupporting two reflexed ftyles, crowned by a blunt figma: The germen afterward becomes an oval fruit, dividing in two parts, containing two oval feeds, plain on one fide, and. convex on the other.

This genus of plants is ranged in the fecond fection of Linnaeus's fifth clafs of plants, intituled Pentandria Dig^nia, the flower having five ftamina and two ftyles.

The SPECIES are,

1. BUNIU (Bulbocastamm)bxL\bo£obofo.Stoiv. Monfp. 256. Earth Nut with a globular root. Bulbocastantum majus folio Apii. C. B. P. 162.
2. BUNIU (Creticum) radice turbinato. Earth Nut with a turbinated root. Bulbocastantum Creticum radice nafi-formi. Tourn. Cor.
3. BUNIU (Saxatile) foliis tripartitis filiformibus linearibus. Earth Nut with very narrow tripartite leaves. Bulbocastantum minus faxatile Peucedani folio. Tourn. Inf. 312.

The firft fort grows naturally in moift paffures, and in woods, in many parts of England. Of this there is a variety, fuppofed to be larger than that which grows commonly here, but I could never obferve any effential difference between them; for in fome places it is found much larger than in others, but when they have been tranfplanted into a garden, they have proved to be the fame. This hath a tuberous folid root which lies deep in the ground, and puts out fibres from the bottom and fides. The leaves are finely cut, and lie near the ground. The ftalk rifes a foot and a half high; which is round, channelled, and folid, the lower part being naked; but above, where it branches out, there is one leaf placed below every branch, which are cut into finer fegments than thofe below. The flowers are white, and lhaped like thofe of other umbelliferous plants; the feeds are fmall, oblong, and when ripe are channelled. It flowers in May, and the feeds ripen in July, foon after which, the whole herb decays to the ground.

The roots of this fort are frequently dug up, and by the poorer fort of people are eaten raw, having much refemblance in tafte to the Chefnut, from whence it had the title of Bulbocastantum. Thefe roots, when boiled* are very pleafant and delicious, and are fuppofed to afford great nourifhment. The fwine are very fond of thefe roots, and will root them up, when they are admitted where they grow, and will foon become fat with feeding on them.

The fecond fort was difcovered by Dr. Tournefort in the ifland of Crete, but it grows naturally in many other parts of the Levant. I received dried famples and feeds of this from Zant, where it grows plentifully.

The third fort I received from the Alps. This is a very low plant, feldom rifing above fix inches high. Thefe plants delight to grow among grafs, fo cannot be made to thrive well long in a garden.

BUPHTHALMUM. Lin. Gen. Plant. 876. Afterifcus. Tourn. Inf. R. H. tab. 285. Ox-eye.

The CHARACTERS are,

The empalernent* is different in the feveral fpecies. It hath a compound radiated flower, composed of h'ertnaphrodite and female florets. The hermaphrodite florets compofe the difk *, thefe are funnel-fhaped, and cut into five parts at the brim, which fspread open, and, have five JUnder ftamina* which are Jhort, terminated by cylindrical fummits. In the center is fituated an oval compreffed germen, fupporting a Jknderftyk, crowned by a thick figma. The germen afterward becomes an oblong feed, whofebor-

der is cut into many parts; the female flowers which compofe the rays (or border) are fretched out on one fide like a tongue, which fspreads open, and is indented at the top in three parts; thefe have no ftamina, but a double-headed germen, fupporting a flender jtyle, crowned by two oblong figma. The germen becomes a Jingle comprejhd feed, cut on each fide.

This genus of plants is ranged in the fecond fection of Linnaeus's nineteenth clafs, intituled Syngenefia Polygamia iuperflua, the flowers having hermaphrodite and female florets, included in one common empalement, which are both fruitful.

9. BUPHTHALMUM (Arborefcens)io\\% oppofitis lanceolatis craffis, glabris utrinque viridibus floribus pedunculatis. Ox-eye with thick, fsmooth, fpear-Jhaped leaves growing oppofite, green on both fides, flowers having foot-ftalks, and a tree-like ftalk. Afterifcus frutefcens leucoii foliis viridibus & fplendentibus. Hort. Elth. 43. tab. 38.
10. BUPHTHALMUM (Incanum) foliis oppofitis lineari-lanceolatis craffis incanis, floribus feffilibus caule fruticofo. Ox-eye with thick, hoary, narrow, fphzn-Jhaped leaves placed oppofite, flowers growing clofe to the branches* # end a Jhrubby ftalk. Afterifcus frutefcens leucoii foliis anguftiflimis fereceis & incanis. Lnd. Hort. Chelf. 27.

The firft fort grows naturally in Northr America. This hath a perennial root and an annual ftalk: from the root there arifes many ftalks, in number proportional to the fize of the roots 5 thefe grow upward of

fix feet high, garnished at each joint with two oblong heart-shaped leaves placed opposite, which have three longitudinal veins, the base on one side being shorter than the other. The flowers come out at the extremity of the branches, having a leafy empalement, they are radiated, of a bright yellow colour, resembling a small Sun-flower, from whence the inhabitants of America have given it that appellation. It flowers in August, and when the autumns prove favourable, the seeds will ripen in England; but as it propagates easily by parting the roots, there are few persons who are solicitous about the seed. The best time to transplant and part the roots, is toward the end of October, when the stalks begin to decay. These should be removed every other year, to prevent their spreading too far; they are very hardy, and will thrive in any situation: but as the roots are apt to extend, they are not proper for the borders of small flower-gardens; but in large borders, on the sides of rural walks, or in spaces between shrubs, they will be ornamental during their season of flowering.

The second sort grows naturally on the Alps, as also in Austria, Italy, and the south of France. This hath a perennial root, and an annual stalk; it grows near two feet high, with slender branching stalks, garnished with oblong smooth leaves ending in a point; the flowers grow at the extremity of the branches, which are of a bright yellow colour, radiated round their borders like those of the Starwort. It flowers in June and July, and the seeds ripen in autumn. There are two or three varieties of this, differing in the breadth of their leaves and size of their flowers, but from the same seeds all these have been produced.

This sort is generally propagated by parting the roots, which may be performed at the same time, and in the same manner as is directed for the first sort. As this doth not spread so much as the former, a few roots may be allowed room in the borders of the flower-garden, especially those which have little sun, where these will continue a long time in flower.

The third sort is somewhat like the second, but the leaves are broader and obtuse; the stalks and leaves are also hairy, in which consists their difference. This flowers at the same time with the former, and is propagated in the same manner.

The fourth sort rises a foot and a half high: the stalks divide into many branches upward; the side branches rise much above the middle stalk, garnished with spear-shaped hairy leaves, placed alternately; the flowers are produced at the forks of the branches on short foot-stalks; the empalement consists of seven long, stiff, spear-shaped leaves, ending in a sharp point, these spread out beyond the rays of the flower in form of a star. The flower fits close upon the empalement, the border or rays being composed of many female florets, which have one side stretched out like a tongue, and indented at the end in three parts, the middle or disk of the flower is composed of hermaphrodite flowers, which are tubulous, funnel-shaped, and (lightly indented in five parts at the brim; they are of a bright yellow colour, and are succeeded by oblong compressed seeds. The plants flower in June and July, and their seeds ripen in September, soon after which the plants decay.

The seeds of this should be sown the beginning of April, on open borders, where they are to remain, and will require no other care, but to keep them clear of weeds, and thin them to the distance of a foot and six inches, that their branches may have room to spread. If the seeds are sown in the autumn, or are permitted to fall when ripe, the plants will come up soon after, and these will more certainly ripen seeds than the spring plants.

The fifth and seventh sorts are also annual plants, which grow naturally in the same countries with the last. These seldom grow more than one foot high in gardens, and where they are wild not so high, but send out many spreading alternate branches near the

root: their leaves, which are oblong, blunt, and hairy, are placed alternate, growing close to the branches without any foot-stalks, the leaves of the empalement of the fifth sort end in a very sharp spine, and are much broader at their base than either of the other. The flowers of all these have much the appearance of those of the last, but some are smaller, and those of the seventh sort have an agreeable odour. They flower at the same season, and are propagated in the same manner.

The sixth sort is a low perennial plant with a shrubby stalk, which rarely rises a foot high, sending out many spreading branches from the stem, garnished with hairy leaves, which are narrow at their base, but broad and roundish at their extremity; the flowers are produced at the end of the branches, they are yellow, and shaped like those of the former sorts, but the leaves of the empalement are soft and obtuse. These are seldom succeeded by seeds in England, but the plant is easily propagated by slips during the summer season; if the cuttings are planted in a bed of fresh loamy earth, and covered with a hand-glass, observing to shade them from the sun in the heat of the day, and frequently refreshed with water, they will take root in about six weeks, when they should be carefully taken up, and each planted in a separate small pot filled with fresh undunged earth, and placed in a shady situation till they have taken fresh root, after which they may be removed to a sheltered situation, where they may remain till the end of October, when they must be removed to a frame for the winter season, being too tender to live abroad in winter in this country, but as they only require protection from hard frosts, they will thrive better when they have a great share of air in mild weather, than if confined in a green-house; therefore the best method is to place them in a common frame, where they may be fully exposed in mild weather, but screened from the frost. This sort grows naturally in Sicily. It flowers great part of the year, which renders it the more valuable.

The eighth sort rises with several woody stems from the root, which grow to the height of eight or ten feet, garnished with leaves very unequal in size, some of which are narrow and long, others are broad and obtuse; these are intermixed, sometimes coming out at the same joint, and often at the intermediate one; they are soft, hoary, and placed opposite. The foot-stalks of the larger leaves have, on their upper side, near their base, two sharp teeth hanging upward, and a little higher there are generally two or three more, growing on the edge of the leaves. The flowers are produced at the ends of the branches singly; these are of a pale yellow colour, and have scaly empalements. It grows naturally in America. I received another sort of this from the Havannah, which was found growing naturally there by Dr. Houftoun, who sent it by the following title, *Chrysanthemum fruticosum maritimum, foliis glaucis oblongis, flore luteo*. Sloan. Hist. Jam. i. p. 125. The leaves of this are shorter and thicker than those of the tenth sort, and have no teeth on their foot-stalks, but in other respects are very like it; the plants are not so hardy. The eighth has been long preferred in the English gardens, and was originally brought from Virginia, as I was informed by the Bishop of London's gardener, who raised it in 1606 at Fulham.

The ninth sort grows naturally in the Bahama Islands, from whence I have several times received the seeds. This seldom grows much more than three feet high, sending out many stalks from the root, which are succulent, except near the root, where they are ligneous, garnished with thick, succulent, spear-shaped leaves placed opposite; the flowers are produced at the end of the branches upon foot-stalks which are two inches long. These flowers are larger than those of the eighth sort, of a bright yellow colour. They appear in July, August, and September, but often continue till the end of October.

The tenth fort grows in the Bahama iflands, from whence I received the feeds. This fends out many {lender (talks from the root, which rife near three feet high, garnifhed with long, narrow, thick, fucculent leaves, which are very hoary, growing oppofite, embracing the ftalk at their bafe; the flowers are yellow, and are produced at the end of the fhoots, having very fhort foot-ftalks. Thefe appear at the fame time with thofe of the ninth fort.

As thefe three forts do not perfedl their feeds in this country, they are propagated by cuttings. They fhould be planted in July, when the plants have been for fome time expofed to the open air, whereby their {hoots will be hardened and better prepared to take root, than when they firft come abroad. The cuttings fhould be planted in fmall pots filled with light loamy earth, and plunged into a very gentle warmth, obferving to fhade them from the fun in the heat of the day, and gently refrefh them with water, but it muft be given to them fparingly, for much wet will rot them. In about fix weeks thefe will have taken root, when they muft be gradually inured to bear the open air, and foon after they fhould be each planted in a feparate fmall pot filled with light loamy earth, and placed in the fhade until they have taken frefh root; after which they may be removed to a fheltered fituation, where they may remain till the middle of October, when they muft be removed in the green-houfe. The eighth fort being hardier than either of the other, may be placed in a common green-houfe; but the other two will thrive better in a warm glafs-cafe, where they will receive more fun, and have a drier air. During the winter, they fhould have but little moifture, and in very mild weather they fhould have frefh air admitted to them. In the fummer they muft be placed abroad in a fheltered fituation, and treated in the fame manner as other exotic plants.

BUPLEUROIDES. See PHYLLIS.

BUPLEURUM [fo called, from Bofe Bos, and *κρυπτον*, *cofta*, *ktus*, becaufe it is commonly believed, that if cows eat of it, it will burft their bellies.] Lin. Gen. Plant. 291. Hare's-ear.

The CHARACTERS are,

// is a plant with an umbellated flower; the rays of the principal umbel are thirty confifting of ten fmaller umbels which are ere ft and fpread. The involucrium of the great umbel is compofed of many oval pointed leaves, thofe of the fmall have five. The flower hath five fmall heart-fhaped petals, which are inflexed \ it hath five flender flannrina, which are terminated by roundifh fummits. The germen is fituated below the flower, fupporting two fmall reflexed Jyles, crowned by a fmall ftigma. The germen afterward becomes a roundifh compreffed fruit which is channelled, dividing in two parts, containing two oblong channelled feeds, convex on one fide, and plain on the other. This genus of plants is ranged in the fecond fegtion of Linnaeus's fifth clafs, entitled Pentandria Digynia, the flower having five ftamina and two ftyles.

The SPECIES are,

1. BUPLEURUM (*Rotundifolium*) involucris univerfalibus nullis, foliis perfoliatis. Hort. Upfal. 64. *Harts ear, whofe greater umbel hath no involucrium, and the flalks growing through the leaves. Perfoliata vulgatifima five arvenfis.* C. B. P. 277.
2. BUPLEURUM (*angulofum*) involucellis pentaphyllis orbiculatis, univerfali triphylo ovato, foliis amplexicaulibus cordato-lanceolatis. Lin. Sp. Plant. 236. *Harts-ear with the fmaU involucrium compofed of five orbicular leaves, the larger of three oval ones, and heart fpear-fhaped leaves embracing the ftalk. Perfoliata Alpina anguftifolia major folio angulofo.* C. B. P.
3. BUPLEURUM (*Odontitis*) involucellis pentaphyllis acutis, univerfali triphylo, flofculo centrali altiore, ramis divaricatis. Lin. Sp. Plant. 237. *Harts-ear with finaller involucrii, compofed of five pointed leaves which arc acute, thofe of the larger three-leaved, the flower in the center* taller, and the branches fpreading from each other. Perfoliata minor anguftifolia, Bupleuri folio.* C. B. P. 277.

4. BUPLEURUM (*Rigidum*) caule dichotomo fubnudo, involucris minimis acutis. Lin. Sp. Plant. 238. *Harts-ear with flalks growing from the division of the branches, which have no leaves below, and a very fmall pointed involucrium. Bupleurum folio rigido.* C. B. P. 278.
5. BUPLEURUM (*Tenuiffimum*) umbellis fimplicibus alternis pentaphyllis fubtrifloris. Lin. Sp. Plant. 238. *Hare's* ear with Jingle umbels growing alternate, and five leaves under each three flowers. Bupleurum anguftiflimo folio.* C. B. P. 278.
6. BUPLEURUM (*Fruticofum*) frutefcens, foliis obovatis integerrimis. Lin. Sp. Plant. 238. *Shrubby Harts-ear with oblong oval leaves which are entire. Bupleurum arborefcens falicis folio. Tourn. Inft. 310. Sefeli Mthiopicum frutex. Dod, Pempt. 312. Shrubby Hartwort of ^Ethiopia.*
7. BUPLEURUM (*Difforme*) frutefcens, foliis vernalibus decompofitis planis incifis, aeftivalibus filiformibus angulatis trifidis. Lin. Sp. Plant. 238. *Shrubby Harts-ear, whofe fpring leaves are decomposed, plain, and cut, and the fummer leaves are narrow, angular, and trifid. Bupleurum frutefcens foliis ex uno punfto plurimis junceis tetragonis. Burman. Afr. 195. tab. 71. fol. i.*

The firft fort grows naturally upon chalky land among wheat, in feveral parts of England, fo is feldom admitted into gardens. The leaves and keds of this plant are ufed in medicine; the herb is efteemed good for diflblving fcrophulous tumours, and is by fome ufed for internal ailments, ruptures, and bruifes from a fall. It is called Thoroughwax in Englifh.

The fecond, third, fourth, and fifth forts are annual. The fifth fort grows naturally in feveral parts of England, the others are natives of the Alps and Pyrenees; thefe are feldom cultivated but in botanic gardens for the fake of variety. Thofe who are defirous to have any of thefe fpecies in their gardens, fhould fow their feeds in autumn, where the plants are defigned to remain, for they do not bear tranfplanting well; and keep the plants clean from weeds, which is all the culture they require. They flower in June and July, and their feeds ripen in September.

The fixth fort hath a woody ftem, which fends out many branches, fo as to form a large head or bufh, covered with purplifh bark, and garnifhed with oblong, oval, ftiff leaves, which are very fmooth, of a fea-green colour 5 the ends of the branches are terminated by umbels of yellow flowers fomewhat like thofe of Fennel. Thefe come out in Auguft, but are feldom fucceeded by perfedl feeds in England. It grows naturally in the fourth of France and Italy, near the borders of the fea.

It is commonly known among gardeners by the title of Shrubby ^Ethiopian Hartwort, and is now propagated in the nurfery-gardens for fale. This grows five or fix feet high, forming a large regular bufh, the leaves continuing green through the year render it more valuable. It is hardy, fo will thrive in the open air, and may be intermixed with other ever-green fhrebs of the fame growth, in the front of taller trees, where their ftems are defigned to be excluded from fight. It is propagated by cuttings, which fhould be planted in pots filled with frefh loamy earth, and in winter fheltered under a hot-bed frame, in the fpring the cuttings will put out roots, but they will not be fit to tranfplant till the autumn following; fo the pots fhould be placed in a fhady fituation in fummer, and in dry weather they muft be refrefhed with water. The young plants may be planted in a nurfery-bed at two feet diftance for a year or two to get ftrength, and then tranfplanted where they are to remain.

The feventh fort grows naturally at the Cape of Good Hope, from whence it was introduced to the gardens in Holland. This rifes with a fhubby fcalk to the height of five or fix feet, fending out fome fide branches, which in the fpring have their lower parts garnifhed with leaves compofed of many fmall plain lobes, which are finely cut like thofe of Coriander,

BUR

of a fei-green colour, thidc leaves thon fall off, am the upper part of the branches arc clulely eperet widi long ruli-likc leaves having four angles, which come out in duflxrs from each joint. The (lowers ~~pro~~ in fjneadng ambell at the extremity of tin branches, whicli art fnull and of an herbaceous colour, and arc fuccceded by obtung channelled ~~•••••~~.

This lorisccommonly propagated by cuttings, which readily take root, if rlyty arc jointed in April in pots filled with light ruth, and plunged into a moderate hot-bed, and when they have taken root, dicy (lion!.) K inured to the open air by drgrees, and after they have drained strength, may be planted eadi into l feparatt pot filled with light loamy earth, placing them in die fh.uk, till they have taken freffi root, when they may be placed with other exotic plus in a fhdtcred filiation, where they may • main till tin; autumn, when they muft be removed into the greerj-houft, and pbeed with. Tuch hardy plants as require a large ihire of air in niild weather, and only require a protection from froft.

If ibis plant Ls propagated by feeds, they fhould be fbwn in the autumn, loon after they are ripe, in pis filled with light earth, which muft be fhdtcred under j. r. rnic in winter, and in the faring removed to a «ery gentle hotbed, which will tdon bring up die plants i thefc muft be inured to bear the open air by degrees, and then treated in ihe fame manner as ihujc ~~raised from~~ rotting*. This plant flowers in July, and the lints ripen in Siyteniber.

This genus of plants is ranged in the first fection of
Luutrus's i •city first clafs, intitled Sy: cnefia poly-
gamij iequalu ; thefi bive at] henOTphrodiw flowers
which l ire fertile.

The SPICK are,
1. CACALIA (jflplna) foliis rcnifiirmibus acutis dentku-
latis calycibus tubulosis, Gouan, Measp. 239. Ca-
ch a with lobed feget leaves ... indau-
id, and generally flow fevers in each capsulement, CV
cilia foliis crassis herbis. C. B. P. 197.

2. CACALIA (Glauc) foliis cuneatis rhomboides
C.B. P. 197. Cacalia with smooth leaves, having
pinks. Cacalia glabra L. io. Cuf, HU
p. 115.

3. CACALIA (Saxatilis) caule herbaceo foliis hastato-
littatis denticubi; petiolis foris dilatatis. Hort.
Uplid. 224. Cacalia with an herbaceous stalk, four-
toothed indented leaves, and the upper ribs of the first stalk
spreading. Cacalia Americana proceris, folio triangu-
ari ptr baffn auricub.'', Borbas alba. Edle prie.
4. CACALIA

4. CACALIA (*Atriploidfolia*) caule herbaceo, foliis fubcordatis dentato-finuatis, calycibus quinquefloris. Lin. Sp. Plant. 835. *Cacalia with an herbaceous stalk, heart-shaped finuated leaves, and five florets in each empalement*, Nardus Americana procerior, foliis caefiis. Pluk. Aim. 251.
5. CACALIA (*Ficoides*) caule fruticofo, foliis compreflis carnolis. Lin. Sp. Plant. 834. *Cacalia with a jhrubby stalk, and flefhy comprefed leaves*. Senecio Africanus arborefcens, ficoidis folio & facie. Com.; Rar. Plant. 40.
6. CACALIA (*Kleinia*) caule fruticofo compofito, foliis lanceolatis planis, petiolorum cicatricibus obfoletis. Lin. Sp. Plant. 834. *Cacalia with a compound jhrubby stalk, plain fpear-shaped leaves* and the foot-ftalks leaving fears*. *Cacalianthemum folio nerii glauco*. Hort. Elth. 61. tab. 54.
7. CACALIA (*JPapillaris*) caule fruticofo obvollato fpinis petiolaribus truncatis. Lin. Sp. Plant. 834. *Cacalia with a Jhrubby stalk, guarded on every fide with broken rough foot-ftalks*. *Cacalianthemum caudice papillari*. Hort. Elth. 63. tab. 55.
8. CACALIA (*Ante-euphorbium*) caule fruticofo, foliis ovato-oblongis, petiolis bail linea triplici dedu&is. Lin. Sp. Plant. 834. *Cacalia with a Jhrubby stalk* oblong oval leaves, and three lines conneSed to the bafe of the foot-ftalk*. *Kleinia foliis carnolis planis ovato-oblongis*. Hort. Cliff. 395.
9. CACALIA (*Sonchifolia*) caule herbaceo, foliis lyratis amplexicaulibus dentatis. Lin. Sp. 1169. *Cacalia with an herbaceous stalk, and lyre-shaped indented leaves embracing the stalk*.
10. CACALIA (*Lntea*) caule herbaceo, foliis quinquepartitis acutis fubtus glaucis, floribus terminalibus pedunculis longiffimis. *Cacalia with an herbaceous stalk, leaves divided into five acute parts, glaucous on their under fide, and flowers with long foot-ftalks terminating the ftalks*.
The firft fort grows naturally in Auftria, and the Helvetia mountains, but is frequently preferred in curious gardens for the fake of variety. This hath a flefhy root which fpreads in the ground, from which fpring up many leaves, (landing on fingle foot-ftalks, fhaped like thofe of Ground Ivy, but of a thicker texture, of a flining green on their upper fide, but white on their under; between thefe arife the foot-ftalk, which is round, branching toward the top, and grows a foot and a half high; under each divifion of the ftalk is placed a fingle leaf, of the fame fhape with thofe below, but much fmaller; the branches are terminated by purplifh flowers, growing in a fort of umbel. Thefe are fucceeded by oblong feeds, crowned with down.
The fecond fort hath the appearance of the firft, but the leaves are almoft heart-shaped, pointed, and fharply fawed on their edges, and on both fides very green*, the ftalks rife higher; the leaves upon the ftalks have much longer foot-ftalks than thofe of the firft. The flowers of this are of a deeper purple colour. This grows naturally on the Alps. They flower toward the end of May, or the beginning of June.
The third fort grows naturally in North America. This hath a perennial creeping root, which fends out many ftalks, garnifhed with triangular fpear-shaped leaves, fharply fawed on their edges, of a pale green on their under fide, but a deep flining green above, placed alternately. The ftalks rife to the height of feven or eight feet, and are terminated by umbels of white flowers, which are fucceeded by oblong feeds crowned with down. It flowers in Auguft, and the feeds ripen* in October. This plant multiplies greatly by its fpreading roots, and alfo by the feeds, which are fpread to a great diftance by the wind; the down which adheres to them being greatly affifting to their conveyance. The roots of this plant, which have been caft out of the Chelfea garden, have been carried by the tides to a great diftance, where they have lodged on the banks of the river, and fattened themfelves to the ground, and have increafed fo much, as that in a few years, it may appear as a native of this country. The ftalks decay in autumn, and new ones arife in the fpring.

The fourth fort is a native of America, but has been many years in fome curious gardens. This hath a perennial root, and an annual ftalk. The root is compofed of many flefhy fpreading tubers, fending out feveral ftrong ftalks in the fpring, which rife four or five feet high, garnifhed with roundifh heart-shaped leaves, greatly indented on their edges, of a fea-green on their under fide, but darker above, placed alternately the length of the ftalks, which are terminated by umbels of yellowifh herbaceous flowers, appearing in July and Auguft, and are fucceeded by feeds like thofe of the former fort, which ripen in October.

The firft and fecond forts are propagated by parting their roots, for they feldom produce good feeds in England. The beft time to tranfplant and part their roots is in autumn. They require a loamy fojj and a fhady fituation.

The third and fourth forts propagate in great plenty, both by their fpreading roots, and alfo their feeds. The roots fhould be tranfplanted in autumn, and require a moift foil and an open fituation. If the feeds are permitted to fcatter, the plants will come up in the fpring without any care.

The fifth fort grows naturally at the Cape of Good Hope. This rifes with ftrong round ftalks to the height of feven or eight feet, which are woody at bottom, but foft and fucculent upward, fending out many irregular branches, garnifhed more than half their length with thick, taper, fucculent leaves, a little comprefed on two fides, ending in points, covered with a whitifh glaucous farina, which comes off when handled. Thefe, when broken, emit a ftrong odour of turpentine, and are full of a vifcous juice; at the extremity of the branches the flowers are produced in fmall umbels; they are white, tubulous, and cut into five parts at the top. The ftigma which crowns the ftyle is of a dark purple colour, and ftands eredt above the tube. The ftamina are much fhorter, and furround the oblong germen, which is fituated in the center of the tube, and is crowned by long, white, hairy down. The germen afterward becomes an oblong feed, with the fame down adhering to it; but thefe do not ripen in England. Some of the noblemen in France have the leaves of this plant pickled*, in doing of which, they have a contrivance to preferve the white farina with which they are covered, and thereby render them very beautiful.

This fort is eafily propagated by cuttings during the fummer months: thefe (hould be cut from the plants and laid to dry a fortnight, that the wound may be healed over before they are planted. Moll people plunge the pots, in which thefe are planted, into a moderate hot-bed, to forward their putting out roots, but if they are planted in June or July, they will root as well in the open air. I have frequently had the branches broken off by accident, and fallen on the ground, which have put out roots without any care. Thefe branches may be kept fix months put of the ground, and will take root if planted. This fhould have a light fandy earth, and in winter be placed in an airy glafs-cafe, where they may enjoy the fun and air in mild weather, but mult be protected from froft. During the winter feafon, the plants mult have but little water*, and in fummer, when they are placed in the open air, it fhould not be given them too often, nor in great quantity, but treated like the *Ficoides*, and other fucculent plants from the fame country. It flowers ufually in autumn, but is not conftant to any feafon.

The fixth fort grows naturally in the Canary Iflands, but has been long an inhabitant in the Englifh gardens. This rifes with a thick flefhy ftem, divided at certain diftances, as it were, in fo many joints; each of thefe divifions fwells much larger in the middle than they do at each end; the ftalks divide into many irregular branches of the fame form, which, toward their extremities, are garnifhed with long, narrow, fpear-shaped leaves, of a glaucous colour, landing all round the ftalks without order. As thefe fall

but they leave a scar at the place, which always remains on the branches. The flowers are produced in large clusters, at the extremity of the branches, which are tubulous, and of a faint Carnation colour. They appear in August and September, but continue great part of October, and are not succeeded by seeds in this country. There have been stones and fossils dug up at a great depth in some parts of England, which have very perfect impressions of this plant upon them; from whence Dr. Woodward has supposed, the plants were lodged there at the universal deluge, and finding the impressions of many other plants and animals, which are natives of those islands, he concludes that the waters flowed hither from the south-west.

This plant has been called Cabbage-tree by the gardeners, I suppose from the resemblance which the stalks of it have to that of the Cabbage: others have titled it Carnation-tree, from the shape of the leaves, and colour of the flowers.

It is propagated by cuttings, in the same manner as the former sort, and the plants require the same culture; but must have a dry warm glass-case in winter, and very little water, being very subject to rot with wet. In summer they must be placed in the open air, in a warm sheltered situation, and in very dry weather refreshed moderately with water. With this management the plants will flower annually, and grow to the height of eight or ten feet.

The seventh sort resembles the sixth in its form and manner of growth, but the leaves are narrower and more succulent. These do not fall off entire like the other, but break off at the beginning of the foot-stalk, which are very strong and thick; and always continue, so that the main (stalk of the plant, and the lower part of the branches, which are destitute of leaves, are set round on every side with these truncated foot-stalks. This sort hath not as yet produced any flowers in England. It is propagated in the same manner as the two former sorts, from cuttings, and the plants must be treated as hath been directed for the fifth sort, but require to be kept drier, both in winter and summer, therefore, in very wet seasons, the plants should be flickered from hard rains, which often cause them to rot, when they are exposed thereto, but they require the open air in summer. This sort grows naturally at the Cape of Good Hope. The eighth sort has been long preserved in the English gardens, and was generally titled *Ante-euphorbium*, supposing it to have a contrary quality to the *Euphorbium*. This rises with many succulent stalks from the root, as large as a man's finger, which branches out upward, into many irregular stalks of the same form, but smaller, garnished with flat, oblong, succulent leaves, placed alternately round the branches; under each foot-stalk there are three lines or ribs, which run longitudinally through the branches joined together. This sort very rarely flowers in Europe, but is propagated by cuttings in the same manner as the fifth, and is equally hardy. It must have very little wet, especially in winter, and requires a dry, sandy, poor soil.

The ninth sort grows naturally in Ceylon, China, and also in the Spanish West-Indies, from whence I received the seeds. This sort seldom continues longer than to ripen its seeds. The stalk rises near two feet high, branching a little toward the top, the leaves are cut on their sides, and sinuated somewhat like those of Mustard, fitting close to the stalks, which are terminated by flowers formed almost in an umbel; these are in some plants yellow, and in others purple; they are small, and are succeeded by oblong oval seeds, having a feathery down. It flowers in July, and the seeds ripen in September, soon after which the plant decays.

This is propagated by seeds, which, if sown in the autumn soon after they are ripe in a pot, and plunged into the tan-bed in the stove, will more certainly succeed than those sown in the spring; but where there is not such conveniency, the seeds should be

sown on a hot-bed in the spring, and when the plants are fit to remove, they should be planted on another hot-bed to bring them forward, shading them till they have taken new root, after which air should be daily admitted to them in proportion to the warmth of the season. When the plants have acquired strength, they should be planted in pots, and either plunged into a moderate hot-bed under a deep frame, or placed in a glass-case, where they will flower and perfect their feeds.

The tenth sort grows naturally at St. Helena, from whence I received the plants: the roots of this sort spread and increase under the surface, so is easily propagated by parting the roots; the leaves arise immediately from the root, having very short foot-stalks; these are cut into five or six long acute segments almost to the midrib, the segments are also acutely cut on their sides in two or three places: the under side of the leaves are glaucous, their upper side of a dark green. The flower-stalk arises between the leaves immediately from the roots; this is naked, about eight inches high, terminated by six or eight yellow compound flowers standing on long foot-stalks, almost umbriliform; the flowers are succeeded by oblong seeds, which rarely ripen in England.

As this plant increases so fast by its root, there is little want of the seeds; therefore the roots may be parted either the beginning of September, or the latter end of March, and should be planted in pots filled with light earth, and plunged into the tan-bed in the stove, where it should be constantly kept, being too tender to thrive elsewhere in this climate.

C A C A O. Tourn. Inft. R. H. 660. *Theobroma*. Lin. Gen. 806. The Chocolate-nut.

The CHARACTERS are,

The empalement is composed of five spear-shaped leaves which spread open. The flower hath five petals* which are irregularly indented* and spread open* it hath five erect stamina* which are as long as the petals* terminated by pointed summits. In the center is placed the ovary* supporting a single style* the length of the stamina* crowned by an erect stigma. The germens afterward becomes an oblong pod, ending in a point; which is woody* warted* and divided into five cells* which are filled with oval* compressed, fleshy seeds.*

This genus of plants was constituted by father Plumier, who communicated the characters, which he had drawn in America, to Dr. Tournefort, who has inserted it in the Appendix to his Institutions. Dr. Linnaeus has joined this to the *Guazuma* of Plumier, under the title of *Theobroma*; but as the fruit of these plants are very different from each other, I shall keep them under different genera.

We have but one SPECIES of this plant, which is, C A C A O. Cluf. Exot. *The Chocolate-nut-tree*.

This tree is a native of America, and is found in great plenty in several places between the tropics, but particularly at Caracca and Carthagen, on the river Amazons, in the isthmus of Darien, at Honduras, Guatemala, and Nicaragua. At all these places, it grows naturally without culture; but it is cultivated in many of the islands which are possessed by the French and Spaniards, and was formerly planted in some of the islands which are in the possession of the English; but it has been neglected for many years past, so that at present it is so scarce in those places, that the English are supplied with it by the French and Spaniards, who make the inhabitants pay then a good price for it; and as there is a great quantity of it consumed in England, consequently it must make an alteration in the balance of trade greatly to the prejudice of the English; which might be easily remedied, if the planters in our colonies might be encouraged; but the least industrious; since, as it formerly grew on those islands, so as to produce not only a sufficient quantity for their own consumption, but to supply Europe with great quantities, there can be no objection to the planting it in those islands again, especially in those situations where the sugar canes do not thrive to advantage.

I shall therefore subjoin the best account of this plant, and the culture which it requires in those countries, with the profits which have arisen from it to those who have planted some of these trees of late years, by way of experiment, in order to excite others to follow their example; and shall afterward give directions for cultivating it in England, by way of curiosity.

In making a plantation of Chocolate-trees, you must first be very careful in the choice of the situation, and the soil, otherwise there will be small hopes of success. As to the situation, it should be in a place where the trees may be protected from strong winds, to which if they are exposed, they will soon be destroyed: so that in such places where torrents of water have washed away the earth so as to leave broad and deep furrows (which the inhabitants of those islands call gullies,) these trees will thrive exceedingly: and as these are very frequently to be found in those islands, and many of them are of large extent, and not much cultivated, it may be a great improvement to some estates, which, at present, are of small value. The soil in these gullies is generally rich and moist, which is what these trees require, so that they will make great progress in these places, as hath been experienced by those persons, who have lately made trials of the plants in these situations; but where there are not a sufficient number of these gullies, choice should be made of a situation which is well frequented by large trees; or, if there are not trees already grown there should be three or four rows planted round the spot which is designed for the Chocolate-trees, of such sorts which are of quickest growth, and within these rows there should be some Plantain-trees, planted at proper distances, which being very quick of growth, and the leaves very large, will afford a kindly shelter to the young Chocolate-trees placed between them.

The Chocolate-trees which are cultivated, seldom grow to more than fourteen or fifteen feet in height, nor do they spread their branches very wide; so that if the Plantain-trees are placed in rows, about twenty four feet under, there will be room enough for two rows of Chocolate-trees between each row of Plantains, and if they are placed at ten feet distance in the rows, it will be sufficient room for them. Those trees which are found wild in uncultivated places, are generally of much larger growth, which may be occasioned by the other trees, amongst which these are found growing; for, being protected from the winds by those, they are not so much in danger therefrom, as those which are cultivated: and the other trees closely surrounding them, will naturally draw them up to a greater height: however, that is not a desirable quality in these trees; for the lower they are, the better the fruit may be gathered without hurting the trees, and the less they are exposed to the injuries of the weather; so that the inhabitants never desire to have their trees above twelve or fourteen feet high.

The soil upon which these trees thrive to most advantage, is a moist, rich, deep earth; for they generally send forth one tap root, which runs very deep into the ground, so that wherever they meet with a rocky bottom near the surface, they seldom thrive, nor are they of long continuance; but in a rich, deep, moist soil, they will produce fruit in pretty good plenty the third year from seed, and will continue fruitful for several years after.

Before the plantation is begun, the ground should be well prepared by digging it deep, and clearing it from the roots of the trees, and noxious plants, which, if suffered to remain in the ground, will shoot up again after the first rain, and greatly obstruct the growth of the plants; so that it will be almost impossible to clear the ground from those roots, after the Chocolate plants are come up, without greatly injuring them.

When the ground is thus prepared, the rows should be marked out by a line, where the nuts are to be

planted, so as that they may be placed in a quincunx order, at equal distance every way, or at least that the Plantain-trees between them may form a quincunx, with the two rows of Chocolate-trees, which are placed between each rows of them.

In making a plantation of Chocolate-nut-trees, the nuts must be planted where the trees are to remain; for if the plants are transplanted, they seldom live; and those which survive it, will never make thriving trees; for, as I before observed, these trees have a tender tap root, which, if broke, or any way injured, the tree commonly decays.

The nuts should always be planted in a rainy season, or at least when it is cloudy weather, and some hopes of rain falling soon after. As the fruit ripens at two different seasons, viz. at Midsummer and at Christmas, the plantation may be made at either of those; but the chief care must be to choose such nuts as are perfectly ripe and sound, otherwise the whole trouble and expence will be lost. The manner of planting the nuts is, to make three holes in the ground, within two or three inches of each other, at the place where every tree is to stand, and into each of these holes should be one sound nut planted about two inches deep, covering them gently with earth. The reason for putting in three nuts at every place is, because they seldom all succeed; or, if most of them grow, the plants will not be all equally vigorous; so that when the plants have had one year's growth, it is very easy to draw up all the weak unpromising plants, and leave the most vigorous; but in doing this, great care should be had to the remaining plants, so as not to injure or disturb their roots in drawing the other out.

It is very proper to observe, that the Chocolate-nuts will not retain their growing faculty long after they are taken from the trees, so that there is no possibility of transporting them to any great distance for planting; nor should they be kept long out of the ground in the natural places of their growth. There are some authors who have written the history of this tree, and distinguished three different sorts of the nuts, from the colour of their skins, one of which is of a whitish green colour, one of a deep red, and the third of a red and yellow colour; but these are not specifically different, but all arise from seeds of the same tree, as is the case of our Filberts, which differ in the colour of their skins, but are of the same colour within, and have the same taste. There are others, who would distinguish these nuts by their size and form, some being large and thick, others almost as flat as Beans; but these differences, I have been credibly informed, arise from some accident, as those trees which are young and vigorous, and grow upon a deep rich soil, will always produce larger and better nourished fruit, than those which stand on a shallow dry ground, and are unthriving trees: as will also the age of a tree make a great alteration in the size of the fruit; for old trees are generally observed to produce smaller and flatter nuts than those which are young, or than the same trees did bear while they were vigorous.

When the Chocolate-trees first appear above ground, they are very tender, and subject to great injuries from the strong winds, the scorching sun, or great droughts, for which reason the planters are obliged to guard against all these enemies, first, by making choice of a sheltered situation, or at least by planting trees to form a shelter; and, if possible, to have the plantation near a river, for the convenience of watering the plants the first season, until they have made strong roots, and are capable of drawing their nourishment from some depth in the earth, where they meet with moisture. But in order to shelter the plants from the scorching rays of the sun, they generally plant two rows of Cassada between each row of Chocolate-trees, which will grow about seven or eight feet high, and screen the young plants from the violence of the sun the first season; after which time, they will be in less danger of injury therefrom; and

and the following season, when the Caffada is taken up for use, the ground (should be worked between the young plants, being very careful not to injure their roots by this operation. This method of planting the Caffada between the young Chocolate-trees, is of great advantage to the planter, for when the roots of the Caffada are taken up for use, it will defray the expence of keeping the ground clean from weeds, without which the young plants will come to nothing. The Plantains alib, which will be fit to cut in about twelve months after planting, will defray the whole expence of preparing the ground, so that the produce of the Chocolate-trees will be neat profit, for as the Plantains produce fruit and decay, they will be succeeded by suckers, which will produce fruit in eight months after; whereby there will be a continual supply of food for the negroes, which will more than pay for keeping the ground wrought, and clear from weeds, until the Chocolate-trees begin to produce fruit, which is generally the third year after planting.

The planters usually set the Plantain-trees two or three months before the Chocolate-nuts are ripe, that they may be large enough to afford shelter to the young plants when they come up, and the Caffada is always planted a month or six weeks before the Chocolate-nuts, for the same reason. Some people plant Potatoes, others Cucumbers and Melons, or Water Melons, between the rows of Chocolate plants, which, they say, will prevent the weeds from rising to injure the young plants, for as all these trail on the ground, they occupy the whole surface, and prevent the weeds from growing: but where this is practised, it should be done with great caution, lest, by being over-covetous, you injure the young Chocolate-nuts so much, that they may never recover it; therefore great care should be taken to reduce the growth of these plants, whenever they approach the Chocolate-trees, otherwise they will soon greatly injure, if not totally destroy them.

In about seven or eight days after the Chocolate-nuts are planted, the young plants will begin to appear above ground, when they should be carefully looked over, to see if any of them are attacked by insects, in which case, if the insects are not timely destroyed, they will soon devour all the young plants; or if there should be any weeds produced near the plants, they should be carefully cut down with a hoe; in doing which, great care should be taken that neither the tender shoot, nor the rind of the bark are injured. About twenty days after the plants have appeared, they will be five or six inches high, and have four or six leaves, according to the strength of the plants. These leaves are always produced by pairs, opposite to each other, as are also the branches; so that they make very regular handfomc heads, if they are not injured by winds. In ten or twelve months they will be two feet and a half high, and have fourteen or sixteen leaves. By this time the Caffada, which was planted between the rows of Chocolate plants, will have large roots fit for use, therefore should be taken up; and the ground being then wrought over again, will greatly encourage the young plants.

In two years time the plants will have grown to the height of three feet and a half, or sometimes four feet, many of which will begin to flower; but the careful planters always pull off all these blossoms; for if they are permitted to remain to produce fruit, they will so much weaken the trees, that they seldom recover their strength again, so as to become vigorous. When these plants are two years and a half old, they will produce flowers again, some of which are often left to bear fruit; but the most curious planters pull off all these, and never leave any to produce fruit until the third year; and then but a few, in proportion to the strength of the trees; by which method, their trees always produce larger and better nourished fruit, than those which are suffered to bear a larger quantity, and will continue much longer in vigour. The fourth year they suffer their trees to bear

a moderate crop, but they generally pull off some flowers from those trees which are weak, that they may recover strength before they are too old.

From the time when the flowers fall off, to the maturity of the fruit, is about four months. It is easy to know when the fruit is ripe by the colour of the pods, which become yellow on the side next the sun. In gathering the fruit, they generally place a negro to each row of trees; who, being furnished with a basket, goes from tree to tree, and cuts off all those which are ripe, leaving the others for a longer time to ripen. When the basket is full, he carries the fruit, and lays it in a heap at one end of the plantation; where, after they have gathered the whole plantation, they cut the pods lengthways, and take out all the nuts, being careful to divert them of the pulp which closely adheres to them; and then they carry them to the house, where they lay them in large casks, or other vessels of wood, raised above ground, and cover them with leaves of the Indian Reed and mats, upon which they lay some boards, putting some stones thereon to keep them down close, in order to press the nuts. In these vessels the nuts are kept four or five days; during which time, they must be stirred and turned every morning; otherwise they will be in danger of perishing from the great fermentation they are usually in. In this time they change from being white to a dark red or brown colour. Without this fermentation, they say the nuts will not keep; but will sprout, if they are in a damp place, or shrivel and dry too much, if they are exposed to heat.

After the nuts have been thus fermented, they should be taken out of the vessels and spread on coarse cloths, where they may be exposed to the sun and wind; but at night, or in rainy weather, they must be taken under shelter, otherwise the damp will spoil them. If the weather proves fair, three days time will be long enough to dry them, provided they are carefully turned from time to time, that they may dry equally on every side. When they are perfectly dry, they may be put up in boxes or sacks, and preserved in a dry place until they are shipped off, or otherwise disposed of. The freer these nuts are, the more oil is contained in them; so that the older they are, the less they are esteemed.

These trees do not produce their fruit on the young branches, or at their extremities, as most other trees do; but from the trunk, and the larger branches, come out the buds for flowers and fruit. While the trees are young, they do not produce their fruit in great plenty; for before the trees are eight years old, they reckon it a good crop to have twenty-eight or thirty pods on each tree at one gathering, especially that at Midsummer; which is always a much worse crop than the Christmas season, which is occasioned by the much greater drought of the spring; for the autumns being the rainy seasons, the Chocolate-trees produce a much greater quantity of fruit. When the trees are full grown and vigorous, they will sometimes produce two hundred, or two hundred and forty pods at one season; which will make ten or twelve pounds of Chocolate, when dried; so that it is a very profitable commodity, and can be managed with very little charge, when compared with sugar. I have been credibly informed by a person of great worth and integrity, who resided some years in America, that he has seen as much Chocolate gathered from one tree in a year, as hath been worth thirty (hillings sterling on the spot: so that the trouble of gathering and preparing for the market, being much less than for many other commodities which are manufactured in the British colonies, it is surprising (should be neglected) especially as it yields so large a share of sustenance to the wealthier inhabitants of those colonies, that they cannot live comfortably without it, and purchase it from the French and Spaniards at a considerable price; which in time must greatly impoverish the colonies.

The Chotohtc-trees, if planted on a g«kl fell and properly taken care of, wilt continue vigorous and fruitful twenty-five or thirty year; thref,, the charge of cultivating a plantation of these trees, muff be muchlcs than EW of Sugar, for although the ground between the rows of | lants will require to be often hoed ami wrought, yet the first working of s ground totnakc a new plantation of Sugar, Indigo, Caflada, &c. is a larger expenrc dun the after-work-

Befides, Sugar-cura require as nan a labour in their cultivation, as any plant whatever; and fince the infects which defray the Sugjr-cancs, have fpreail ft) mush in tin. British col; iies, nothing is a more uncertain crop than Sugar; for which reason, I think it would be greatly worth those planters care, who arc poUefiid of proper lands for the Chocolate

—%oi to make fame fmall trials at leift, to be con- red of the truth of this fait
 The leaves of these trees being large, make a gi- ar litter upon the ground when they fall) but cRL „ (injurious, but rather of iervice to the rreej; for the surface of the ground being covered with them, they prefervc die moiithire in the ground, and prevent rvjpoi:itngi which is of pTcat life to tiee young der roots, which are juft under the furtac when the leaves are rotten, they may be buried in digging the ground, and it will revc as good n. Some planters lei the pods, in wiuch tie Ch i olare is iiduled, lie and rot in a heap (.liter they have ten the nuti out) which they atfo fprac on the ground intcad of dung. Either of thete mai- res are ve' good, provided they are well rotted before they arc Uud on die ground j and great care mould be had, thai no vermin lhouid be carried on the pbn- sion with the dung.

Befides the ordinary care of digging, hoeing, and manuring the plantation; of Chocolate-trees, tSerc is alJb another thing requifite in order to their doini> well* which is, to prune the decayed brarii: ami to take iway fmall ill placed branches, v., they are produced- But you shoud be cautious how this work h performed; for there (koullil h vigorous branches (horncd, nor any large urrpUttions made on thec trees i becaufe tie'u'ly aboui' with afoj, glutinous, milky juice, which will flow out for many days whencm [hey are wounded, which gmuly weakens the trees. However, fuch branche! whole extreme part* arc decayed, lhouid be cut off, tupre- vent; lie infe&ion from proceeding fartheri and flich branches as are mucii decayed, lhouid AK i. cloie to the Item of the tree; but this flhould be performed in dry weather, loon after the crop of fruit is gathered.

Somt jpeople rWV perhaps imagine, that what I have directed, is a tedious laborious work, and not fo be performed by a lew llavei: but this is a great niiftake, iijj! I have Ixtn credibly infbnjed, that five or (« neg tea will cultivate a plantatioti of ten thoutid of thefe tree*, piw i and they are properly instructed, which it a linall numbeij when comp-ired to the quantity neccffary to cultivate >i S r plantations of the like extent of ground. And when the profits of both are compared, there will be a great difference: for, lupposmf we let die ; rice of live burlings per annum, for the produce of e idi tret, when grown, (which I am of opinion is very moderate, confidering what has r>en related,) then a plantation of ten thousand tree) will produce twenty-five hundred pounds a year; which, managed by fix or feven nt-groes, without the exjience of farnac< . &c. is a much greater profit iji-i", I think, can be drawn from of diey ; roduftion.

In order to cultivate this plant in Europe, by w»y of curiolity, it will be neccffary to have the nuti planted into boxes of earth [in the countries where they grow j loon after they are ripe j becaufe, if the nuti are lent over, they will loft their growing quality before they arrive. Thefe bones flhould be' placed in a Jbdy fitUMion, and must be frequently water-d, in order to forward the vegetation of die nuu. In

about a fortnight after the nuts are • planted, the piant* will begin to appear above ground; when they should be carefully watered n dry weat... and provided from the violent heat of the fun, which is very inju- rious to thefe plants, cfjwcially while tb your- they should alfo be kept very clear from weed, which, if suffered to grow in the boxes, will soon overbear the plants a deliroy ru
 When the plants are grown to the height of four or five inches, they should be dug up . l and pl^ed where they may be fceced from ftroy winds, fait water, and the violent heat of the Tun. ! n .; :ige they niult be freque- refreshed with ; :ot but it mult be • lii-m in gre<t quannde

These plant ... arc natrvej of the Wcft-Indiej, where [here aie niurc luru ilian are ierv enumerated:] u-r-for> u^ (kill were to examine thole iflands. Tiicie have been aljout four of the large kind known-t; to England, fome of which have been enameled with a prickk* brown cap, in it'irm uf one of the v-hi chare womt ... and others, which have becntklitue of theft^ caps, although du ... full as large as thoit wh ... had them; therofoe foau ... have fuppofed them to be diftinct fpec-ies ... fpecially ince they have been many years pro-ferred in the gardens, and no appearance of any caps as yet have been produced, but as thole have been rarely propagated by feeds, it is difficult to determine if they arc ... fennally different. Thole which have thole caps, produce their fruit in circles round the

Upper part of the cap *, whereas, the smaller forts produce their fruit from between the tubercles, round the middle of the plant; and in some figures of the larger forts of these plants, the fruit is represented as coming out near the crown of the plant; so that if a skilful botanist was to examine these plants in the places of their growth, there would probably be found a much greater variety of them than is at present known.

These strange plants commonly grow upon the steep sides of rocks in the warmest parts of America, where they seem to be thrust out of the apertures, having little or no earth to support them; their roots shooting down into the fissures of the rock to a considerable depth, so that it is troublesome to get the plants up, especially as they are so strongly armed with thorns as to render it very dangerous to handle them * and as these plants delight in those rocky places, they seldom live long when they are transplanted into better soil by the inhabitants of those islands.

The great forts were some years since brought over to England in much greater plenty than of late; but then the greatest part of them were destroyed, by the unskilfulness of those persons who had the care of them in the voyage; for, by giving them water, they generally caused them to rot before they were taken out of the ships; and some of those which have appeared to be found, have been so replete with moisture, as to rot soon after they have been placed in the stoves; therefore whoever proposes to bring these plants from abroad, should be very careful to take up their roots as entire as possible, and to plant them in tubs filled with stones and rubbish, mixing very little earth with it, and to plant three or four plants in each tub, in proportion to their sizes *, for if they are placed close together, it will save room *, and as they do not increase their growth during their passage, there need not be any room allowed them for that purpose. There should be several pretty large holes bored thro' the bottom of these tubs, to let the moisture pass off, and if these plants are planted in the tubs a month before they are put on board the ship, they will in that time have made new roots, which will be the most secure method to have them succeed * but, during their continuance in the country, they should have no water given them, and after they are put on board the ship, they must not have any moisture whatever, therefore it will be a good method to cover the * plants with tarpaulin, to keep off the spray of the sea in bad weather, and expose them at all times to the open air when the sea is calm. By observing these directions, the plants may be brought to England in good health, provided they are brought in summer.

Some of the large fort which have been brought to England, have been more than a yard in circumference, and two feet and a half high, including their caps *, but I have been informed by several persons who have resided in the West-Indies, that there are plants near twice as large.

The third fort was brought into England by the late Dr. William Huxtable, who procured the plants from Mexico; but as they were long in their passage, and had received wet, they were decayed before they arrived in England *, but from the remains of them which were left, they appeared to be the most singular of all the species yet known. This has two orders of thorns; one of which are straight, and set on at the joints in clusters, spreading out from the center each way like a star *, and in the middle of each cluster is produced one broad flat thorn near two inches in length, which stands erect, and is recurved at the point and is of a brownish red colour. These thorns are, by the inhabitants of Mexico, set in gold or silver, and made use of for picking their teeth, and the plant is by them called Vilhaga, i. e. tooth-pick.

The fort with spiral ribs, as also that with white spines, I received from Antigua, with the common fort *, but whether these are only accidental varieties, arising from the same seeds, or real different species,

I cannot take report me to determine; since, in this country, they are very rarely propagated by seeds * nor could I observe, in the several years that I have had these plants under my care, there was the least disposition in either of them to produce fruit * when, at the same time, the common large fort produced plenty of fruit out of their caps every year, from the seeds of which I have raised some young plants * but although some of these have grown to a considerable size, yet none of them have as yet produced caps, therefore no fruit can be yet expected from them.

The fifth fort produces quantities of fruit annually; and as the seeds grow very readily, it is now very common in those gardens where there are stoves * keep them; for the fruit is permitted to drop upon the earth of the pots, and that is not disturbed, there will plenty of plants come up without any farther trouble; and these seedling plants may be taken up as soon as they are of a proper size to remove, and planted six or seven of them into a small halfpenny pot, where they may stand one year; by which time they will be large enough to be each planted into a separate pot, and afterward they will make great progress, especially if they are plunged into a hot-bed of tanners bark in summer; for although this fort is much more hardy than the large kind, and may be preserved in a moderate stove, yet the plants will not make near the progress as those which are kept in a greater degree of heat. This fort will continue many years with proper care, and the plants will grow to be a foot high or more; but when they are so tall, the lower part of them is not so firmly, their girth being decayed, and the spines changed to a dark dirty colour, they appear as if dead, so that the upper part of these old plants only seem to have life; whereas the plants of the middling size appear healthy from top to bottom. The flowers of this fort appear in July and August, and are succeeded by the fruit quite round the plant, which are of a fine scarlet colour, and continue fresh upon the plants through the winter, which renders them very beautiful at that season. And in the spring, when the fruit shrivels and becomes dry, the seeds will be ripe, and may then be rubbed out, and sown upon the surface of the earth in small pots, which should be plunged into a hot-bed of tanners bark to bring up the plants.

The sixth fort is but little larger than the fifth, growing nearly in the same form * but this produces a great number of young plants from the sides, by which it is increased. This fort produces tufts of a soft white down upon the knobs, and also between them at every joint, which makes the whole plant appear as if it was covered with fine cotton. The flowers of this fort are produced from between the knobs round the sides of the plants, which are in shape and colour very much like those of the fifth fort, but larger. These flowers are not succeeded by any fruit, at least all those which I have under my care, have not produced any, although they have produced plenty of flowers for some years *, but from the same places where the flowers have appeared, there have been young plants thrust out the following season. These young plants I have taken off, and after laying them to dry for two or three days, I have planted them, and they have succeeded very well.

All the species of this genus are plants of a singular structure, but especially the larger kinds of them, which appear like a large fleshy green Melon, with deep ribs, set all over with strong sharp thorns *, and when the plants are cut through the middle, their inside is nothing but a soft, green, fleshy substance, very full of moisture. And I have been assured by persons of credit, who have lived in the West-Indies, that in times of great drought, the cattle repair to the barren rocks, which are covered with these plants, and after having ripped up the large plants with their horns, so as to tear off the outside skin with the thorns, they have greedily devoured all the fleshy moist parts of the plants, which has afforded them both meat and

and drink i but how any animal should ever attack plants which are so well defended by strong thorns, which are as hard and stiff as whalebone, or any other bony substance, is difficult to conceive; nor could any thing but distress; for moisture ever have tempted them to venture amongst these troublesome plants to seek for relief, since they must encounter with many difficulties, before they could find a method of dislodging the thorns.

The fruit of all the sorts of Melon-thistles, are frequently eaten by the inhabitants of the West-Indies, there is scarce any difference in the fruits of all the kinds I have yet seen, either in size, shape, colour, or taste. They are about three quarters of an inch in length, of a taper form, drawing to a point at the bottom toward the plant, but blunt at the top, where the empalement of the flower was situated. The taste is an agreeable acid, which, in a hot country, must tender the fruit more grateful.

All the sorts of these plants require a very good stove to preserve them through the winter in England, nor should they be exposed to the open air in summer, for although they may continue fair to outward appearance when they have been some time exposed abroad, yet they will imbibe moisture, which will cause them to rot soon after they are removed into the stove. And this is frequently the case of those plants which are brought from abroad, which have a fair healthy appearance many times at their first arrival, but soon after decay, and this will happen very suddenly. Scarce any appearance of disorder will be seen, till the whole plant is killed; which, in a few hours time, has often been the fate of those plants, when they have been placed in the stove.

If these plants are plunged into a hot-bed of tanners bark in summer, it will greatly forward them in their growth, but when this is practised, there should be scarce any water given to the plants, for the moisture which they will imbibe from the fermentation of the tan, will be sufficient for them, and more would cause them to rot. The best method to preserve all the large kinds is, in winter, to plate the pots, either upon the tops of the flues, or, at least, very near them, that they may have the warmest place of the stove, and during that season, never to give them any water; but when the season comes for leaving out the fire in the stove, to remove them into a bed of tanners bark, which will soon set them in a growing state, and recover their verdure. The soil in which these should be planted, must be of a sandy nature, and if mixed with some dry lime rubbish, it will be still better. In the bottom of the pots should be placed some stones, in order to drain off any moisture which may be in the earth; for as these plants naturally grow upon the hot dry burning rocks which have no earth, and, were it not for these plants, would be absolutely barren, we must imitate their natural soil as near as possible, making some allowance for the difference of climates.

The great sorts may be propagated by seeds, which must be sown and managed as hath been directed for the smaller sort; but as the plants which are raised from seeds in England, will be some years in arriving to any considerable size, it will be much the best way to procure some plants from the West-Indies, and if the plants arrive here in any of the summer months, so as that there may be time for them to get new roots before the cold comes on in autumn, the plants will more certainly succeed. When the plants come over, it will be proper to take them out of the earth as soon as possible, and lay them in the stove upon the shelves, to dry for a fortnight or three weeks, and when they are planted they should be plunged into a good warm bed of tanners bark, to promote their making new roots. In this bed they may remain till the beginning of October, when they must be removed into the stove, and created in the manner before directed.

The two small sorts propagate so fast in England, as to render it unnecessary to send for plants of these kinds from abroad, for whoever hath a mind to be,

plentifully stocked with them, may be soon supplied with the fifth sort from seeds, and the sixth from the young plants which are thrust out from the side of the old.

CIBESALPINA. Plum. Nov. Gen. 9. Brafiletto.

This plant was so named by father Plumier, who discovered it in America, in honour of Andreas Csesalpinus, an eminent botanist, and one of the first writers on a method of classing plants.

The CHARACTERS are,
// bath a quinquifid pitcher-shaped empalement, the under lobe being large. The flower bath five almost equal petals* of the butterfly kind. It bath ten declining stamina which are distinct, and terminated by roundish summits, and an oblong germen supporting a single style the length of the stamina, crowned by a blunt stigma. The empalement afterward becomes an oblong compressed pod, with one cell inclosing three or four compressed seeds.

This genus of plants is ranged in the first edition of Linnaeus's tenth class, intitled Decandria Monogynia, the flower having ten separate stamina and one style.

The SPECIES are,

1. GA: SALPINA (*Brafilienfis*) foliis duplicato-pinnatis, foliolis emarginatis, floribus decandris. *Cafalpinawith doubly winged leaves > whose small leaves are indented at the end and flowers with ten stamina. Pseudo-fantulum croceum.* Sloan. Hist. Jam. Vol. II. p. 184. *Saffron-coloured Bastard Sautiders, commonly called Brafiletto.*
2. CBSALPINA (*drifta*) foliis duplicato-pinnatis foliolis ovatis integerrimis floribus pentandris. *Cafalpina with doubly winged leaves? whose small leaves are oval and entire^ and flowers with five stamina.* Csesalpina polyphylla aculis horrida. Plum. Nov. Gen. 28.

The first sort is the tree which affords the Brafiletto wood, which is much used in dyeing. It grows naturally in the warmest parts of America, from whence the wood is imported for the dyers, and the demand for it has been so great, that there are no large trees left in any of the British colonies, the biggest scarce exceeding eight inches in diameter, and fifteen feet in height. It hath very tender branches, which are armed with recurved thorns. The leaves are winged, branching out into many divisions, each being garnished with small oval lobes which are indented at the top, and are placed opposite. The foot-stalks of the flowers come out from the side of the branches, and are terminated by a loose pyramidal spike of white flowers, which are shaped somewhat like those of the butterfly kind, having ten stamina which are much longer than the petals, and terminated by roundish yellow summits. The germen afterward becomes a long compressed pod with one cell, inclosing several oval flat seeds.

The second sort grows naturally in the same countries with the first, but is of larger size: it sends out many weak irregular branches, armed with short, strong, upright thorns. The leaves branch out in the same manner as the first, but the lobes (or small leaves) are oval and entire. The flowers are produced in long spikes like those of the former, but are variegated with red, these have each but five stamina, therefore, according to Linnaeus's system, should not be ranged in this class, but as in all the other characters they agree, I have continued them together.

Dr. Linnaeus has joined these two species together, in which he has been followed by Dr. Burman, but if either of them had seen the plants, they could not have committed this mistake. To this genus Linnaeus has added two other species, one of which is a Guilandina, and the other a Bauhinia: to the latter he has added the Synonyme of Colutea Verse & Veficaria, which is a plant totally different, being a genuine Colutea. I received this from the late Dr. Houftoun, who found it growing naturally at La Vera Cruz, in New Spain.

These plants are propagated by seeds, which should be sown in small pots filled with light rich earth early in the spring, and plunged into a hot-bed of tanners bark, observing to water the earth as often as it appears

pears dry, in order to promote the vegetation of the feeds; and if the nights should prove cold, the glasses of the hot-bed should be covered with mats, to keep the bed in a moderate warmth. In about six weeks after, the plants will begin to appear, when they must be carefully cleared from weeds, and frequently refreshed with water; and, in warm weather, the glasses of the hot-bed should be raised in the middle of the day, to admit fresh air to the plants, which will greatly strengthen them, otherwise they are apt to draw up weak. When the plants are about three inches high, they should be carefully taken out of the pots, and each transplanted into a separate small pot filled with fresh light earth, and plunged into the hot-bed again, observing to water them, and screen them from the heat of the sun until they have taken new root -, after which time, the glasses of the hot-bed should be raised every day, in proportion to the heat of the weather, to admit fresh air to the plants. In this hot-bed the plants may remain till autumn, when they should be removed into the stove, and plunged into the bark-bed, where they may have room to grow. These plants being tender, should always be kept in the bark-stove, and have a moderate share of heat in the winter, and being placed among other tender exotic plants of the same country, will afford an agreeable variety.

- CALABABA, Indian Maftich-tree. See CORNUS.
- CALAMINTHA. See MELISSA.
- CALCEOLUS, Ladies Slipper, See CYPRIPE-DIUM.

The CHARACTERS are,
It hath a uniform compound flower, composed of many equal hermaphrodite florets, included in a loose imbricated empalement -, the florets are tubulous, divided into five segments -, they have each five stamina with cylindrical summits, and an oblong germen, with a slender style the length of the corolla, crowned by two recurved stigma. The florets are succeeded by an oblong feed, crowned with a hairy down, having a chaffy substance between each feed.

This genus of plants is ranged in the first order of Linnaeus's nineteenth class, intitled Syngenesia Polygamia sequalis, the flowers being composed of hermaphrodite flowers.

- The SPECIES are,
1. CALEA (*Oppositifolida*) corymbus congestis, pedunculis longifloris, foliis lanceolatis, caule herbaceo. Amcen. Acad. 5. p. 404. *Calea with a clove corymbus, very long foot-stalks to the flowery spear-shaped leaves, and an herbaceous stalk.* Santolina Americana foliis oblongis integris, floribus albis. Houft. MSS.
 2. CALEA (*Amellus*) floribus subpaniculatis, calycibus brevibus, feminibus nudis, foliis ovato-lanceolatis petiolatis. Amcen. Acad. 5. p. 44. *Calea with flowers in panicles, short empalements, naked feeds, and oval spear-shaped leaves on foot-stalks.* Santolina scandens Americana Lauri foliis, floribus racemosis. Houft. MSS.

These plants grow naturally in Jamaica. The first hath an upright herbaceous stalk three feet high, garnished with entire spear-shaped leaves, placed opposite at the joints 5 the stalk is terminated by three foot-stalks, one in the middle, and one on each side, supporting a small corymbus of white flowers closely joined together.

The second sort hath ligneous branches, which spread over the neighbouring plants, and rise eight or ten feet high, garnished with thick spear-shaped leaves, placed opposite 5 from these stalks are put out many side branches, garnished with smaller leaves placed opposite, and terminated by panicles of yellow flowers, having short empalements: these are succeeded by naked feeds inclosed in the flower-cup.

These plants are both propagated by feeds, which should be sown upon a hot-bed early in the spring 5

when the plants come up, they should be tenderly treated while young, admitting fresh air to them daily in proportion to the warmth of the season, giving them water frequently, but sparingly; when they have obtained strength enough to be removed, those of the first sort should be transplanted into another hot-bed, allowing them four inches distance. The plants of the second sort should be put into small pots plunged into the tan-bed, observing to shade them until they have taken new root; after which they should be treated in the same manner as other tender exotic plants, watering them frequently in warm weather, and admitting fresh air to them daily. When the plants of the first sort have grown so strong as to meet, they should be carefully planted in pots, and removed either into the stove or glass-case, where they may remain to ripen feeds, after which they soon die. The plants of the second sort will live many years if they are preserved in the bark-stove, but they are too tender to thrive in the open air. in this country; however, they should have plenty of fresh air admitted to them in summer when the weather is warm.

CALENDULA. Lin. Gen. Plant. 885. Marigold.

The CHARACTERS are,
It hath a compound radiated flower, consisting of hermaphrodite and female florets, included in a common single empalement, the border or rays being composed of female florets, which are stretched out on one side like a tongue - these have no stamina, but an oblong three-cornered germen, supporting a slender style, crowned by two reflexed stigma. The hermaphrodite florets, which compose the disk, are tubulous and quinquefid, having five short slender stamina, terminated by cylindrical summits. The germen is situated under the petal, supporting a slender style, crowned by an obtuse bifid stigma. These florets are barren, but the female florets are each succeeded by one oblong incurved feed, with angular membranes.

This genus of plants is ranged in the fourth section of Linnæus's nineteenth class, intitled Syngenesia Polygamia neceflaria 5 in which are included all those plants which have hermaphrodite barren flowers in the disk, and fruitful female flowers in the border.

- The SPECIES are,
1. CALENDULA (*Arvensis*) feminibus cymbiformibus muricatis incurvatis. Flor. Suec. 711. *Marigold with rough boat-shaped feeds.* Caltha arvensis. C. B. P. 275.
 2. CALENDULA (*Sanffa*) feminibus urceolatis obovatis levis, calycibus submuricatis. Lin. Sp. 1304. *Marigold with smooth pitcher-shaped leaves, and a rough empalement.* Caltha media folio longo cinereo, flore pallido. Bobart. *Middle Marigold with a long Ash-coloured leaf, and a pale flower.*
 3. CALENDULA (*Officinalis*) feminibus cymbiformibus muricatis, incurvatis omnibus, Lin. Sp. 1304. *Marigold with boat-shaped, prickly, incurved feeds.* Caltha vulgaris. C. B. P. 275. *Common Marigold.*
 4. CALENDULA (*Pluvialis*) foliis lanceolatis finuato-denticulatis caule folioso, pedunculis filiformibus. Hort. Upfal. 274. *Marigold with spear-shaped indented leaves and slender foot-stalks.* Caltha Africana flore intus albo extus violaceo. Tourn. Inft. R. H. 499,
 5. CALENDULA (*Nudicaulis*) foliis lanceolatis finuato-denticulatis caule subnudo. Lin. Sp. Plant. 922. *Marigold with finuated, indented, spear-shaped leaves, and a naked stalk.* Caltha Africana flore intus albo, extus leviter violaceo, femine piano cordato. Boerh. Ind. alt. 1. p. 113.
 6. CALENDULA (*Hybrida*) foliis lanceolatis dentatis caule folioso, pedunculis superne incrassatis. Hort. Upfal. 274. *Marigold with indented spear-shaped leaves, and the tipper part of the foot-stalk swelling.* Cardipermum Africanum pubescens foliis incisus parvo flore. Vaill. Mem. Acad. Sc. 1724.
 7. CALENDULA (*Graminifolia*) foliis linearibus subintegerrimis caule subnudo. Lin. Sp. Plant. 922. *Marigold with narrow entire leaves, and a naked stalk.* Caltha Africana foliis Croci angustis, florum petalis externe purpurascens, interne albis, Boerh. Ind. alt. 1. p. 113.

§" CALENDULA (*Fruticofa*) foliis obovatis fubdentati. caule fruticofa. Amcen. Acad. '5. p. '25. *Marigold with obverfe, oval, indented leaves, and ajhrubby Jtalk.*

9. CALENDULA (*Decumbent*) foliis oppofitis pinnatifidis aperfis, iūbtus incanis, ramis decumbentis, pedunculariudis. *Marigold with rough pinnatifid leaves growing oppofite, which are white on their under Jide, trailing branches, and naked foot-ftalks.* *Caltha Americana foliis laciniatis flore luteo.* Houft. MSS.

10. CALENDULA (*Americana*) caule ere&o ramofo, foliis oblongis oppofitis hirtutis, floribus lateralibus. *Marigold with an upright branching ftalk, oblong hairy leaves growing oppofite, and flowery proceeding from the fides of the Jtalk.* *Caltha Americana eredta, & hirtuta, flore parvo ochroleuco.* Houft. MSS.

The firft fort grows naturally in the fourth of France, Spain, and Italy; it rifes with a flender branching ftalk, which fpreads near the ground, and is garnifhed with narrow, fpear-lhaped, hairy leaves, which half furround the ftalk at their bafe, the flowers are produced at the extremity of the branches upon long naked foot-ftalks. They are very fmall, and of a pale yellow colour \ the rays are very narrow, as are alfo the leaves of the empalement. The feeds are long, narrow, and on their outfide armed with prickles. The root is annual, and perifhes foon after the feeds are ripe. If the feeds of this plant are permitted to fcatter, there will be a frefh fupply of young plants: fo that from May, when the flowers firft appear, till the froft puts a flop to thefe, there will be a fuccellion of plants in flower. There are feveral botanifts who fuppofe the common Marigold, which is cultivated in gardens, to be only a variety of this, arifing from culture, but I have cultivated this in the garden more than forty years, without finding the leaft alteration in it, therefore cannot doubt of its being a diftindt fpecies.

The fecond fort I gathered in the garden at Leyden, where it had been feveral years cultivated without altering, the leaves of this fort are fsmooth, and much larger than thofe of the former, but not fo large as thofe of the common Marigold; the flowers are alfo of a middle fize between them, and are of a veiy pale yellow colour. This is alfo an annual plant. If the feeds are permitted to fcatter, there will be a conftant fupply of young plants come up.

The third fort is the common Marigold, which is cultivated for ufe in the gardens; this is fo well known, as to require no defcription. Of this there are the following varieties; the common fingle, the double flowering, the largeft very double flower; the double Lemon-coloured flower; the greater and fmallr chiding Marigold.

Thefe varieties are fuppofed to have been originally obtained from the feeds of the common Marigold, but moft of thefe differences continue, if the feeds are properly favec\ nor have I ever obferved the common fort approaching to either of thefe, where they have been long cultivated in the greateft plenty, but as the two chiding Marigolds, and the largeft double, are fubject to degenerate, where care is not taken in faving their feeds, I conclude they are not diftindt fpecies. The beft way to preferve thefe Varieties, is to pull up all thofe plants, whofe flowers are lefs double, as foon as they appear, that they may not impregnate the others with their farina, and fave the feeds from the largeft and moft double flowers, and the chiding fort fhould be fown by itfelf in a feparate part of the garden, and the feeds laved from the large center flowers only, not from the fmall ones which come from the empalement of the other, for the feeds of thefe are apt to change.

The feeds of thefe may be fown in March or April, where the plants are to remain, and will require no other culture but to keep them clean from weeds, and to thin the plants where they are too clofe, leaving them ten inches a/under, that their branches may have room to fpread. Thefe plants will begin to flower in June, and continue in flower until the froft kills them. The feeds ripen in Auguft and Septem-

ber, which, if permitted to fcatter, will furnifh a fupply of young plants in the fpring; but as thefe will be a mixture of bad and good, the beft method is to fave the beft feeds, and fow each of the varieties diftina, which is the fure way to have them in perfe&ion. The flowers of the common Marigold are ufed in the kitchen.

The fourth fort grows naturally at the Cape of Good Hope. This plant is annual, and perifhes foon after the feeds are perfected.

The lower leaves are oblong, fpear-ftiaped, and deeply indented on their edges; they are flefhy, and of a pale green colour. The ftalks are produced on every fide the root, which decline toward the ground, and are from fix to eight inches long, garnifhed with leaves from the bottom, to within two inches of the top. The leaves on the ftalks are much narrower, and more indented than thofe at the root. The upper part of the ftalk is very (tender, upon which refts one flower, fhaped like thofe of the common Marigold, having a purple bottom; and the rays (or border) of the flower are of a Violet-colour on their outfide, and of a pure white within; thefe open when the fun ihines, but ihut up in the evening, and remain fo in cloudy weather. When the flower decays, the pedicle (or foot-ftalk) becomes Weak, and the head hangs down, during the formation and growth of the feeds; but when they are fully ripe, the foot-ftalk raifes itfelf again, and the heads of the feeds ftand upright.

The fifth fort is a native of the Cape of Good Hope. This is alfo an annual plant, and has much the appearance of the former, but the leaves are more deeply indented on their edges; the ftalks grow about the fame length as the former; the flower is a little fmallr, and the outfide of the rays are of a fainter purple colour. The feeds of this are flat and heart-lhaped, but thofe of the former are long and narrow.

Hie fixth fort was brought from the fame country with the two former, and is alfo an annual plant; the leaves of this are much longer than thofe of either of the former forts, and broader at the end, they are regularly indented near the root, but thofe on the ftalks have but few and (hallow indentures. The ftalks of this fort are much longer and thicker than thofe of the former; and at the top, juft below the flower, fwel larger than at the bottom; the flower is fmallr than thofe of the other forts, but is of the fame colour. Thefe plants flower in June, July, and Auguft, and their feeds ripen about fix weeks after, fo that they muft be gathered 3t different times as they come to maturity.

The feeds of thefe plants fhould be fown in the fpring in the borders of the garden where the plants are defigned to remain, for they do not bear tranf planting well, therefore they may be treated in the fame manner, and fown at the fame time, with Candy Tuft, Venus Looking Glafs, and other hardy annual plants, putting four or five feeds in each patch* if they all grow, there fhould not be more than two plants left in each patch: after this, they require no farther care but to keep them clean from weeds. If the feeds of thefe plants are permitted to fcatter, the plants will come up the following fpring without care, and thefe will flower earlier than thofe which are fown in the fpring.

The feventh fort is alfo a native of the fame country. This is a perennial plant, which divides near the root into feveral tufted heads, which are clofely covered with long graffy leaves coming out on every fide without order, fome of thefe have one or two indentures on their edges, but the moft part are entire. From between the leaves arife naked foot-ftalks about nine inches long, fuftaining one flower at the top, which is about the fize of the common Marigold, having a purple bottom; the rays are alfo purple without, but of a pure white within. Thefe expand when the fun ihines, but always clofe in the evening, and in cloudy weather. The general feafon of their beauty

beauty is in April and May, when they have the greatest number of flowers upon them; but there is commonly a succession of flowers late in the autumn, though not in so great plenty. This sort doth not often produce good seeds in Europe, but it is easily propagated by slips taken off from the heads, in the same manner as is practised for Thrift. They may be planted any time in summer, in pots filled with light fresh earth, which may be plunged into a very moderate hot-bed, to forward their putting out roots; or otherwise the pots may be sunk in the ground up to their rims, and covered with a Melon-glass, which, in the middle of summer, will answer full as well, but in the spring or autumn* the former method is to be preferred: when these are planted, the glasses must be shaded in the heat of the day, and the slips must be frequently refreshed with water, but it must not be given them too liberally, for much wet will rot them: after they have got strong roots, they should be each planted into separate small pots, filled with fresh light earth, and placed in a shady situation, till they have taken fresh root, when they may be placed in the open air, in a sheltered situation, where they may remain till autumn, and then should be placed in a dry, airy, glass-case, for the winter season, or under a common hot-bed frame; for these plants do not thrive in artificial heat, they only require protection from frost and wet, and should enjoy the air at all times when the weather is mild. The seeds of this sort are heart-shaped, like those of the fifth* I have sometimes had one or two heads of them ripen in a season, but this is very rare, and if the seeds are not sown in autumn, they seldom grow.

The eighth sort has been of late years introduced into the Dutch gardens from the Cape of Good Hope. This was sent me by Dr. Van Royen, professor of botany at Leyden, some years past. It hath a slender, shrubby, perennial stalk, which rises to the height of seven or eight feet, but requires support; this sends out a great number of weak branches, from the bottom to the top, which hang downward, unless they are supported; they are garnished with oval leaves, having short flat foot-stalks, most of these are slightly indented toward the top, and many of them are entire, they are of a shining green colour on their upper side, but paler underneath; the flowers come out at the end of the branches, on short naked foot-stalks, and are in size and colour like those of the sixth sort; these are sometimes succeeded by flat heart shaped seeds. The flowers appear during the summer months.

This is easily propagated by cuttings, which may be planted any time in summer in a shady border, or otherwise shaded with mats in the heat of the day: in five or six weeks, these will have taken root, when they should be carefully taken up, and each put into a separate pot, filled with light sandy earth, but not dunged, and placed in the shade till they have taken fresh root, then they may be placed with other hardy exotic plants in a sheltered situation where they may remain till the frost begins, when they must be removed into the green-house, placing them near the windows that they may enjoy the free air, for this plant only requires protection from frost. The earth in which these are planted, should be light, but very poor, for in rich earth they grow too luxuriant, and seldom flower.

The ninth sort was sent me from La Vera Cruz, in New Spain, by the late Dr. Houffout, where he found it growing naturally in great plenty. This sends but many herbaceous stalks from the root, which are hairy, and trail upon the ground. The leaves are placed by pairs opposite; these are long, narrow, and indented on their edges in two or three places opposite to each other, so as to appear like three, five, or seven lobes: they are rough, and of a deep green on their upper side, but hoary on their under, covered with slender hairs. From the divisions of the branches and the wings of the leaves, come out long naked foot-stalks, terminated by single yellow

flowers, about the size of those of the Field Daify; which are succeeded by long, flat, rough seeds. It grows naturally in poor sandy ground, and flowers in the spring. This plant is annual; the seeds must be sown in the spring upon a hot-bed, and when the plants are fit to remove, they should be planted in pots filled with light sandy earth, and plunged into a hot-bed of tanners bark* observing to shade them until they have taken new root, then they must have air admitted to them every day, in proportion to the warmth of the season, and treated in the same manner as other tender plants from the same countries. With this management, the plants will flower by August, and the seeds ripen in October.

The tenth sort rises with an upright stalk about eight inches high, sending out slender stiff branches on every side, those near the ground being much longer than the upper; these are garnished with oblong hairy leaves without foot-stalks, placed opposite. From the wings of the stalk, arises the foot-stalk of the flower, having two small leaves placed opposite, just below the flower, which hath a single empalement, like the other species. The flowers are of a yellowish white colour. This sort was sent me with the former from La Vera Cruz, by the same gentleman. It is an annual plant, and requires the same treatment as the former sort.

CALLA's SNOOT. See ANTIRRHINUM.

CALLA. Lin. Gen. Plant. 917. Wake Robin, or Ethiopian Arum.

The CHARACTER; A,

It hath a large open spathe of one leaf, which is oval and heart-shaped, ending in a pointy it is coloured and permanent) and a single upright spadix, to which the flowers and fruit adhere. This hath male and female flowers, intermixed toward the upper part of the club. (for spadix.) The male flowers consist of many very short stamina, terminated by small yellowish summits; the female flowers have a empalemed style, resting upon an obtuse germen, crowned by 6 pointed stigma. These flowers* at their first appearance, have a short green empalement which soon falls off, leaving the style naked. The germen afterward becomes a globular pulpy fruit, compressed on two sides, which hath two or three obtuse seeds.

This genus of plants is ranged in the seventh section of Linnaeus's twentieth class, entitled Gynandria Polyandria. This class includes those plants whose male and female flowers are intermixed; and this section, those whose male parts have many stamens.

The SPECIES are,

1. CALLA (*Ethiopica*) foliis sagittato-cordatis, spathe cucullata, spadice superne maculo. Hort. Cliff. 436. Calla with arrow-beaded heart-shaped leaves, a hooded spathe or sheath, and male flowers situated on the upper part of the spadix. Arum Africanum flore albo odorato. Par. Bat. Prod.
2. CALLA (*Palustris*) foliis cordatis, spathe plana, spadice undique hermaphrodito. Hort. Cliff. 436. Calla with heart-shaped leaves, a plain sheath, and every part of the foot-stalk both hermaphrodite flowers. Dracunculus aquatilis. Dod. Pempt. 330.
3. CALLA (*Orientalis*) foliis ovatis. Gron. Orient. 282. Calla with oval leaves. Arum minus Orientate, rotundioribus foliis. Mor. Hist. 3. p. 544.

This plant hath thick, fleshy, tuberous roots, which are covered with a thin brown skin, and strike down many strong fleshy fibres into the ground. The leaves arise in clusters, having foot-stalks more than a foot long, which are green and succulent. The leaves are shaped like the point of an arrow, they are eight or nine inches in length, and of a shining green, ending in a sharp point, which turns backward; between the leaves arise the foot-stalk of the flower, which is thick, smooth, of the same colour as the leaves, and rises above them, and is terminated by a single flower, shaped like those of the Arum; the hood or spathe being twisted at the bottom, spreads open at the top, and is of a pure white colour. In the center of this is situated the spadix or club, which is of an herbaceous yellow colour, upon which the small herbaceous

Weous flowers are placed, and fo clofely joined, as that the male and female parts' are very difficult to diftinguifh, without the affiftance of glaffes. When thefe fade, part of thofe which are fituated at the top of the club, are fucceeded by roundifh flefhy berries compreffed on two fides, each containing two or three feeds.

This plant grows naturalljr at the Cape of Good Hope, but has been long an inhabitant in the Englifh gardens. It propagates very faft by offsets, which fhould be taken off the latter end of Auguft, at which time the old leaves decay; but this plant is never deftitute of leaves, for before the old ones decay, there are young leaves produced, which advance in height all the winter *, but at this feafon the roots are in their moft inactive ftate. Thefe roots have generally a great number of offsets about them, fo that unlefs there is a want of them, the largeft only fhould be chofen; which fhould be feperated from all the fmaller, and each planted in a feperate pot, filled with kitchen-garden earth, and placed with other hardy exotic plants in the open air till autumn, when they muft be removed into fhelter for the winter feafon, during which time, they muft not have too much wet, for that will rot the roots. This plant is fo hardy as to live in the open air in mild winters, without any cover, if they are planted in warm borders, and have a dry foil; but with a little fhelter in hard froft, they may be preferred in the full ground very well. It flowers in May, and the feeds ripen in Auguft *, but as the roots increafe fo plentifully, few perfons care to fow the feeds, becaufe the young plants will not flower in lefs than three years. The flowers of this plant have but little fweetnefs, altho* by Herman's title, it fhould have a very agreeable odour; but unlefs a perfon places it near him, it cannot be perceived. I have frequently received the feeds of this from the Cape of Good Hope, but have always found they produced the fame fort.

The fecond fort grows naturally in moift or marfhy grounds in many parts of Europe, fo is rarely admitted into gardens.

The third fort grows naturally on the mountains near Aleppo. This hath a thick tuberous root, from which fpring up feveral oval leaves, Handing on pretty long foot-ftalks -, the fpadix of the flower rifes between the leaves, about fix or eight inches high, fupporting one white flower at the top.

The roots of this fort fhould be planted in pots filled with light earth, and in fummer they may be placed with other exotic plants in the open air; but in winter they fhould be placed under a common hot-bed frame, to fcreen them from froft, to which if they are exgofed the roots will be deftroyed; there is little beauty in this plant, fo it is only preferred in botanic gardens for variety.

CALLACARPA. See JOHNSONIA.

CALTHA. Lin. Gen. Plant. 623. *Marfh. Marigold.*

The CHARACTERS are,

The flower bath no empalement, but is compofed of five large, oval, concave petals which fpread open. It hath a great number of flender ftamina, which are fhorter than the petals, terminated by obtufe ereft fummits: in the center there are feveral oblong compreffed germen fituated, which have no Jyles, but are crowned by fingle ftigma. We germen afterward become fo many Jhort pointed cap-Jules, containing many roundifh feeds.*

This genus of plants is ranged in the feventh feftion of Linnaeus's thirteenth clafs, intitled Polyandria Polygynia, the flowers of this clafs having many ftamina, and of this feftion feveral germen.

The SPECIES are,

1. CALTHA (M^?r) foliis orbiculatiscrenatis, fioremajore. *Marfh. Marigold with round crenated leaves, and a larger flower.* Populago flor majore. Tourn. Inft. 273.
2. CALTHA (Minor) foliis orbiculato-cordatiscrenatis flore minore. *Marfh. Marigold with round beart-Jhaped leaves which are crenated, and a fmaller flower.*

Thefe two forts are fuppofed to be the fame, but I have never obferved either of them to vary, either in

their natural places of growth, or when they are removed into a garden. They both grow upon moift boggy land, in many parts of England, but the firft is the moft common *, of this there is a variety with very double flowers, which for its beauty is preferred in many gardens. This is propagated by parting the roots in autumn, and fhould be planted in a moift foil and a fhady fituation; and as there are often fuch places in gardens, where few other plants will thrive, fo thefe may be allowed to have room, and during their feafon of flowering, will afford an agreeable variety. This fort with double flowers, doth not appear fo early in the fpring as the fingle, but continues much longer in beauty. It flowers in May, and if the feafon is not very warm, will continue till the middle of June.

CALYCANTHUS. See BASTERIA.

CALYX [with botanifts, fignifies the cup of a flower before it opens: this is ftyled the empalement of the flower; in fome plants this continues, and becomes afterward a cover to the feeds of herbs, and fruit of trees.] *Lat.* -The cup inclofing or containing the flower.

CAMARA.. See LANTANA.

CAMERARIA. Plum. Nov. Gen. 18. tab. 29. Lin. Gen. Plant. 264.

This plant was fo named by father Plumier, in honour of Joachim Camerarius, a phyfician and botanift of Nuremberg; who publifhed an edition of. Matthiolus, in Latin and High Dutch, with new figures of the plants, and many obfervations.

The CHARACTERS are,

The flower bath a Jhort permanent empalement of one leaf, cut into five acute fegments at the top: the flower is of one leaf, falver-Jhaped, having a long cylindrical tube at bottom, which is enlarged above, and divided at the top into five acute fegments. It bath five Jhort inflexed ftamina, which are terminated by obtufe membranaceous fummits. In the bottom of the tube are fituated two roundifh germen, having one common Jyle, which is cylindrical and the length of the ftamina, crowned by two ftigma \ the under one is orbicular and flat, the other is concave. The germen afterward becomes two long, taper, kafy cap-Jules, filled with oblong cylindrical feeds.*

This genus of plants is ranged in the firft feftion of Linnaeus's fifth clafs, intitled Pentandria Monogynia* the flowers of this clafs having five ftamina, and thofe in this feftion but one ftyle.

The SPECIES are,

1. CAMERARIA (*Latifolia*) foliis ovatis, utrinque acutis tranfverfe fratis. Hort. Cliff. 76. Lin. Sp. Plant. 210. *Cameraria with roundifh leaves ending in points tranfverfly ribbed.* Cameraria lato Myrti folio. Plum. Nov. Gen. 18.
2. CAMERARIA (*Angustifolia*) foliis linearibus. Lin. Sp. Plant. 210. *Cameraria with long narrow leaves.* Cameraria angufto linariae folio. Plum. Nov. Gen. 18. The firft fort was fent me from the Havanna by the late Dr. Houftoun, where he found it growing naturally in great plenty. This rifes with a fhubby ftalk to the height of ten or twelve feet, dividing into feveral branches, garnifhed with roundifh pointed leaves placed oppofite, having many fmooth tranfverfe veins running from the midrib to the borders. The flowers are produced at the end of the branches in loofe clufters, which have long tubes enlarging gradually upward, and at the top are cut into five fegments, hroad at their bafe, but end in fliarp points: the flower is of a yellowifh white colour. After the flowers are fallen, the germen become two leafy capJules joined at their bafe, and have two fwelling protuberances on each fide at the bottom, the middle being extended confiderably longer; thefe have one cell, filled with cylindrical feeds. It flowers in Auguft, but never produces any feeds in England.

The fecond fort hath an irregular fhubby ftalk, which rifes about eight feet high, fending out irregular branches, garnifhed with very narrow thin leaves, placed oppofite -% thefe have two ribs running longitudinally

• tudinally through each. The flowers *ixt* produced fcattringly at the end of the branches, which are fhaped like thofe of the former fort, but fmaller. Both thefe plants abound with an acrid milky juice like the Spurge. The fecond fort grows naturally in Jamaica.

Thefe plants are propagated by feeds, which muft be procured from the places of their growth, for they do not perfect their feeds in England* They may alfo be propagated by cuttings planted in a hot-bed during the fummer months: they muft have a bark-ftove, for they, are very tender plants; but in warm weather muft have plenty of air.

C A M O C L A D I A, the Maiden Plumb.

The CHARACTERS are,

It hath a tripartite coloured emp dement of one leaf spreading open -, the flower hath three plain, oval, spreading petals, and three awl-Jhaped ftamina fhorter than the corolla, terminated by roundijh incumbent fummits, and an ovalgermen, but no flyk, crowned by an obtufe ftigma; the empalement afterward becomes an oblong Plumb, having three pun ffures at the top, inclofng a nut of the fame formm

This plant is ranged in the firft order of Linnaeus's third clafs, intitled Triandria Monogynia, the flower having three ftamina and one fyle.

The SPECIES are,

1. CAMOCLADIA (*Integrifolia*) foliis integris. Jacq. Amer. 12* *Camocladia with entire lobes. Prunus race-mofa, caudice non ramofa, alato fraacini folio non crenato, fructu rubro fubduki. Sloan. Cat. 184. The Maiden Plumb:'*

2. CAMOCLADIA (*Dentata*) foliis fpinofo-dentatis. Jacq* Amen 12. *Camocladia with prickly indented leaves.*

The firft fort grows naturally in Jamaica, and alfo in many other of the iflands in the Weft Indies; this rifes with an upright ftem near twenty feet high, garnifhed with long winged leaves, whofe pinnae are entire; at the top there are a few branches fent out about a foot long, which fuftain the flowers and fruit.

The fecond fort grows naturally at the Havanna, where it rifes about the fame height with the former; but as the flowers and fruit of this are unknown to the author, he can give no farther account of them.

Thefe plants are propagated by feeds, when they can be obtained from the places of their growth, which fhould be fown in pots and plunged into a hot-bed; the plants, when fit to remove, fhould be each planted in a fmall pot, and plunged into a tan-bed, and in the autumn fhould be plunged into the bark-bed in the ftove, and treated as other tender plants.

C A M P A N I F O R M flowers [of campana, a bell; and forma, *Lat.* fhape,] fuch flowers as in fhape refemble a bell.

C A M P A N U L A. Tourn. Inft. R. H. 108. tab. 38. Lin. Gen. Plant. 201. [fignifies a little bell, as tho' parva campana, *Lat.* fo called, becaufe the flowers refemble a little bell.]

The CHARACTERS are,

The empalement is divided into five acute parts, is upright, fpreading, and refts upon thegermen. The flower is of one leaf, fhaped like a bell, fpreading at the bafe where there are holes. In the bottom is fituated the five cornered neEtarium, which is joined to the top of the receptacle. It hath five jbandrt ftamina, which are infer ted in the top of the valves of the nettarium, terminated by long comprreffed fummits: below the receptacle is fituated the angular germen, fupporting a fyle which is longer than the ftamina, crowned by a thick, oblong, tripartite ftigma. the empalement afterward becotnes a roundijh angular capfule, which in fomefwecw have three, and in others five cells, each having a hole toward the top, through which (be feeds)are-fcattered when ripe.

This genus of plants is ranged in the firft fection of Linnaeus's fifth clafs, intitled Pentandria Monogynia; the flowers of this clafs have five ftamina, and in this fection but one fyle.

The SPUCIES are,

- r. CAMPANULA (*Pyramidalis*) foliis ovatis glabris fubferratis, caule erecto paniculato, ramulis brevibus Lin. Sp. 233. *Bell-flower with ovalfmooth leavesfawed below, an upright paniculated ftalk, andffort branches** Campanula pyramidata altiffima. Tourn. Inft: 109; *Talleft pyramidal Bell-flower.*

Inft. in .

There are feveral other fpecies of this genus, fome of which grow naturally in England, and others in the northern parts of Europe, which have but little beauty, therefore are feldom cultivated in gardens, fo I fhall not enumerate them here. There are alfo feveral varieties of fome of the forts here mentioned, which I fhall take notice of in their proper place, but as they are not diftindt fpecies, they are omitted in the above lift.

The firft fort hath thick tuberous roots which are milky, this fends out three or four ftrong, fmooth, upright ftalks, which rife near four feet high, and are garnifhed with fmooth oblong leaves, whofe edges are a little indented. The lower leaves are much broader than thofe which adorn the ftalks. The flowers are produced from the fide of the ftalks, and are regularly fet on for more than half their length, forming a fort of pyramid; thefe are large, open, and fhaped like a bell. The moft common colour of the flowers is a light blue; but there have been fome with white flowers, which "make a variety when intermixed with the blue, but the latter is moft efteemed.

This plant is cultivated to adorn halls, and to place before die chimnies in the fummer, when it is in flower, for which purpofe there is no plant more proper, for when the roots are ftrong, they will fend out four or five ftalks, which will rife as many feet high, and are garnifhed with flowers great part of their length. Thefe upright ftalks fend out fome fhort fide branches, which are alfo adorned with flowers, fo that by fpreading the upright ftalks to a flat frame compofed of flender laths (as is ufually praftifed) the whole plant is formed into the fhape of a fan, and will fpread near the width of a common fire-place. When the flowers begin to open, the pots are removed into the rooms, where, being (haded from the fun, and kept from the rain, the flowers will continue long in beauty, and if the pots are every night removed into a more airy fituation, but not expofed to heavy rains, the flowers will be fairer, and continue much longer in beauty.

Thofe plants which are thus treated, are feldom fit for the purpofe the following feafon, therefore a fupply of young plants fhould be annually raifed. The common method of propagating this plant, is by dividing the roots. The bell time for doing this is in September, that the offets may have time to get ftrong roots before winter.

This method of propagating by the offets is the

quickeft, therefore generally praftifed, but the plants which are raifed from feeds, are always ftronger, the ftalks will rife higher, and produce a greater number of flowers, therefore I recommend it to the practice of the curious; but in order to obtain good feeds, there fhould be fome ftrong plants placed, in a warm fituation, near a pale, or wall, in autumn, and, if the following winter fhould prove fevere, they fhould be covered either with hand-glaffes or mats, to prevent their being injured by the froft; and, in the fummer, when the flowers are fully open, if the feafon fhould prove very wet, the flowers muft be fcreened from great rains, otherwife there will be no good feeds produced: the not obferving this, has occasioned many to believe that the plants do not bear feeds in England, which is a great miftake, for I have raifed great numbers of the plants from feeds of my own laying, but I have always found that the plants which have been long propagated by offsets, feldom produce feeds, which is the fame with many other plants which are propagated by flips, or cuttings* which in a few years become barren.

When the feeds are obtained, they muft be fown in autumn in pots, or boxes, filled with light undunged earth, and placed in the open air till the froft or hard rains come on, when they fhould be placed under a hot-bed frame, where they may be fheltered from both, but in mild weather the glaffes fhould be drawn off every day, that they may enjoy the free air; with ijs management the plants will come up early in the fpring, and then they muft be removed out of the frame, placing them firft in a warm fituation, but when the feafon becomes warm, they fhould be removed where they may have the morning fun only. During the following fummer they muft be kept clean from weeds, and in very dry weather, now and then refrefhed with water, which muft be given with great caution, for the roots are very fubjeft to rot with too much moifture. In September the leaves of the plants will begin to decay, at which time they fhould be tranfplanted, therefore there muft be one or two beds prepared, in proportion to the number of plants. Thefe beds muft be in a warm fituation, and the earth light, fandy, and without any mixture of dung, which laft is an enemy to this plant. If the fituation of the place is low, or the natural foil moift, the beds muft be raifed five or fix inches above the furface of the ground, and the natural foil removed a foot and a half deep, putting lime rubbifh eight or nine inches thick in the bottom of the trench, to drain off the moifture. When the beds are prepared, the plants muft be taken out of the pots, or cafes, very carefully, fo as not to break or bruife their roots, for they are very tender, and, on being broken, the milky juice will flow out plentifully, which will greatly weaken them. Thefe fhould be planted at about four inches diftance each way, with the head or crown of the root half an inch below the furface; if there happens a gentle fhower of rain foon after they are planted, it will be of great fervice to the plants; but as the feafon fometimes proves very dry at this time of the year, in that cafe, it will be proper to give them a gentle watering three or four days after they are planted) and to cover the beds with mats every day, to prevent the fun from drying the earth; but thefe muft be taken off in the evening, that the dew may fall on the ground. Towards the end of October the beds fhould be covered over with fome old tanners bark to keep out the froft, and where there is not conveniency of covering them with frames, they fhould be arched over with hoops, that in fevere frofts they may be covered with mats; for thefe plants, when young, are often deftroyed in winter, where this care is wanting. In the fpring the coverings muft be removed, and the following fummer the plants muft be kept clean from weeds; and, if the feafon fhould prove very dry, they muft now and then be refrefhed with water. The following autumn the furface of the ground fhould be ftirred between the plants, and

some fresh earth spread over the beds, and in the winter covered as before. In these beds the plants may remain two years, during which time they must be treated in the manner before directed; by which time the roots will be strong enough to flower: in September they should be carefully taken up, and some of the most promising planted in pots; the others may be planted into warm borders, or in a fresh bed, at a greater distance than before, to allow them room to grow. These plants which are potted should be sheltered in winter from great rains and hard frosts, otherwise they will be in danger of rotting, or at least be so weakened, as not to flower with any strength the following summer* and those which are planted in the full ground, should have some old tanners bark laid round them, to prevent the frost from entering deep to the roots*, with this management these plants may be brought to the utmost perfection, and a constant succession of good roots raised, which will be much preferable to those which are propagated by offsets. I have been informed that there is a double flower of this kind, but as I have not seen any, I can give no farther account of it. This sort is by some called Steeple Bell-flower.

The second sort grows naturally in the northern parts of Europe, but has been long cultivated in the English gardens*, of this there are the following varieties, viz. the single, blue, and white flower, which have been long here; and the double flower of both colours, which has not been more than twenty-eight years in England, but has been propagated in such plenty, as to have almost banished those with single flowers from the gardens. All these varieties are easily propagated by parting their roots in autumn, every head which is then flipped off will take root*, they are extreme hardy, so will thrive in any soil or situation, therefore are very proper furniture for the common borders of the flower-garden.

This hath a root composed of many fibres, and sends up an angular, or channelled stiff stalk, about two feet and a half high, garnished with oblong, oval, stiff leaves near the root, which are placed without order y but those on the stalks are longer and narrower, having their edges (lightly indented, and are of a shining green. The flowers are produced towards the upper part of the stalk upon short foot-stalks. These are shaped like those of the former sort, but are smaller, and more expanded. This flowers in June and July, and in cool seasons there will be some continue great part of August.

The third sort is a biennial plant, which perishes soon after it hath ripened seeds. It grows naturally in the woods of Italy and Austria, but is cultivated in the English gardens for the beauty of its flowers. Of this sort there are the following varieties; the blue, the purple, the white, the striped, and the double flowering, but the last two are not very common in England.

This hath oblong, rough, hairy leaves, which are serrated on their edges, coming out without order from the root; from the center of these a stiff, hairy, furrowed stalk, arises about two feet high, sending out several lateral branches, from the bottom upward, garnished with long, narrow, hairy leaves, fawed on their edges, and are placed alternately*, from the setting on of these leaves, come out the foot-stalks of the flower, those which are on the lower part of the stalk and branches being four or five inches long, diminishing gradually in their length upward, and thereby form a sort of pyramid. The flowers of this kind are very large, so make a fine appearance*, they come out the beginning of June, and, if the season is not very hot, will continue a month in beauty. The seeds ripen in September, and the plants decay soon after.

It is propagated by seeds, which must be sown in the spring in an open bed of common earth, and when the plants are fit to remove, they should be transplanted into the flower-nursery, in beds six inches asunder, and to water them frequently till they

have taken new root j after which they will require no other culture, but to keep them clean from weeds till the following autumn* when they should be transplanted into the borders of the flower-garden. As these plants decay the second year, there should be annually young ones raised to succeed them.

The fourth sort hath a perennial root, which sends up several stiff hairy stalks, having two ribs or angles. These put out a few short side branches, garnished with oblong, pointed, hairy leaves, deeply fawed on their edges. Toward the upper part of the stalks the flowers come out alternately, upon short trifid foot-stalks, having hairy empalements. The flowers are of the shape of the former, but shorter, spread more at the brim, and are pretty deeply cut into many acute segments. This flowers in June, and the seeds ripen in autumn.

The varieties of this are, the deep and pale blue -, the white with single flowers, and the same colours with double flowers. The double sorts are propagated by parting their roots in autumn, which should be annually performed, otherwise the flowers are apt to degenerate to single*, to prevent which, the roots should be every autumn transplanted and parted. The soil should not be too light or rich, in which they are planted, for in either of these they will degenerate; but in a strong fresh loam their flowers will be in the greatest perfection. These plants are extreme hardy, so may be planted in any situation; those* with single flowers do not merit a place in gardens.

The fifth sort grows naturally in the northern parts of England: this hath a perennial root, composed of many fleshy fibres, which abound with a milky juice, from which arise several strong, round, single stalks, which never put out branches, but are garnished with oval spear-shaped leaves, (lightly indented on their edges, which are placed alternately. Toward the upper part of the stalk the flowers come out singly upon short foot-stalks; these spread open at the brim, where they are deeply cut into five acute segments. After the flowers are past, the empalement becomes a five-cornered seed-vessel, which turns downward till the seeds are ripe, when it rises upward again.

The varieties of this are, the blue, purple, and white flowering. This sort is easily propagated by seeds, which it furnishes in great plenty, and, if suffered to scatter, the plants will come up in as great plenty the following spring; when they may be transplanted into the nursery till autumn, at which time they should be transplanted where they are designed to remain. As this sort delights in shade, the plants may be planted under trees, or in shady borders where few better things will thrive, they will afford an agreeable variety when they are in flower. It flowers in June and July, and the seeds ripen in autumn.

The sixth sort hath roundish fleshy roots which are eatable, and are much cultivated in France for fallads, and some years past it was cultivated in the English gardens for the same purpose, but is now generally neglected. It grows naturally in several parts of England, but the roots never grow to half the size of those which are cultivated. This is propagated by seeds, which should be sown in a shady border the latter end of May, and when the plants are about an inch high, the ground should be hoed, as is practised for Onions, to cut up the weeds, and thin the plants to the distance of three or four inches and when the weeds come up again, they must be hoed over to destroy them: this, if well performed in dry weather, will make the ground clean for a considerable time, so that, being three times repeated, it will keep the plants clean till winter, which is the season for eating the roots, when they may be taken up for life as they are wanted: These will continue good till April, at which time they will send out their stalks, when they will become hard and unfit for use, as do also those roots which have flowered; so that the young roots only are such which are fit for the table, therefore when the seeds are sown too early, the plants frequently run up to flower the same year, which spoils their roots.

If his fort fends out upright ftalks about twd feet high, which are garnifhed with oblong fpear-fhaped leaves, placed alternately. Towards the upper part of the ftalk the inall BeU-flowers are produced, Handing upright clofe to the ftalk ; fome of thefe flowers are blue, and others white -, they come out in June and July, and the feeds ripen in autumn.

The feventh fort grows naturally upon chalky pafures in many parts of England, where the ftalks do not rife many times a foot high, and in other places it grows to double that height, which has occafioned their being taken for two diftindt plants. This hath a perennial root, which fends up feveral round hairy ftalks, which often rife upward of two feet high *, the bottom leaves are broad, and ftand upon long foot-ftalks, and are (lightly fawed on their edges. Thofe which are upon the ftalks are long, narrow, have no thot-ftalks, and are placed alternately at confiderable diftances* From the wings of the leaves, towards the upper part of the ftalk, come out long naked foot-ftalks, fupporting two or three bell-ihaped flowers, clofely joined together in a head, and the main ftalk is terminated by a large clutter of the fame flowers, which are fucceeded by roundilh capfules filled with fmall feeds. This plant is eafily propagated either by feeds, or parting their roots, and will thrive in any foil or fituation. It flowers in July, and the feeds ripen in autumn.

The eighth fort is an annual plant, which rifes with (lender ftalks a foot high, branching out, garnifhed with oblong leaves, a little curled on their edges 5 from the wings of the leaves come out the flowers, fitting clofe to the ftalks, which are of a beautiful purple, inclining to a Violet-colour, divided into five fegments, which refemble fo many leaves, and in the evening contract and fold into a pentagonal figure ; from whence it is by fome titled Viola Pentagonia, or five-cornered Violet. The empalement which encompaffes the flower, is compofed of five, long, narrow, green leaves, which fpread open, and are much longer than the petals of the flower 5 thefe remain on the top of the prifmatic feed-veffel, which is filled with fmall angular feeds. If this plant is fown in autumn, it will grow much taller, and flower a month earlier than when the feeds are fown in the fpring* The autumnal plants will flower in May, and the fpring plants in June and July. There is a variety of this with white flowers, and another with pale purple,

The ninth fort is the common Venus Looking-glafs, which hath been long cultivated in the Englifh gardens. This fort feldom rifes more than fix inches high, with a ftalk branching from the bottom upward, garnifhed with oval leaves, fitting clofe to the ftalks, From the bafe of which the branches are produced, which are terminated by flowers very like thofe of the former fort.

The tenth fort grows naturally in the fouth of France and Italy. This is alfo a low annual plant, which feldom rifes fix inches high, but divides into many branches, garnifhed with fhort oval leaves, fitting clofe, which are deeply indented on both fides. The flowers are produced at the ends of the branches, which are fhaped like thofe of the other fort laft mentioned, but they are fmall, their colours lefs beautiful, and the leaves' of the empalement are broader.

The eleventh fort grows naturally in Thrace, but hath been long in the Englifh gardens. This is alfo a low annual plant, which rifes little more than fix inches high; the ftalks divide by pairs, and frequently there arifes a branch from the middle of the divisions *, the lower leaves are oblong and obtufe, but thofe which come out toward the end of die branches are much narrower, and pointed. The flowers come out fingle at the end of the branches, having a long five-leaved empalement, and are larger than thofe of the three laft forts, of a fine blue colour; the feeds are like thofe of the eighth fort.

The twelfth fort is an annual plant, which, in good ground, will rife a foot and a half high, but in poor

land, or it where it grows wild among corri, feartely rifes to the height of fix inches. The ftalk is fingle, rarely putting out any branches, unlefs near the root, from whence there are fometimes one or two fhort lateral branches produced. The leaves are roundilh* and embrace the ftalk at their bafe; their edges are fharply fawed, and from their bafe comes out a clofe tuft of flowers, furrounded by the leaf, as in an empalement. The flowers are five-cornered, fhaped like thofe of the Venus Looking-glafs, but are much fmaller -, thefe are produced the whole length of the ftalk. The feeds are inclofed in fhort capfules, which are fhaped like thofe of the former forts. It grows in Italy, and alfo in Virginia. If the feeds of this fort are permitted to fcatter, the plants will come up without care; or the feeds may be fown in the fpring, in the fame manner as thofe of the laft forts, and treated in the fame way.

The thirteenth fort is a native of America, but has been long cultivated in the gardens of the curious, both in England and Holland. This hath many rigid oblong leaves coming out from the root on every fide, which form a fort of head like thofe of Houfe-leek, crenated, having a ftrong rib running on their border longitudinally. From the center of the plant proceeds the ftalk, which rifes about a foot high, and is thinly garnifhed with very narrow ftiff leaves, of a fhining green. From the wings of the leaves come out the foot-ftalks of the flower, which are from two to four inches long, each being terminated by one fpreading bell-fhaped flower, whofe empalement is fhort, and cut into five acute fegments. The fyle of this is longer than the petal, and is crowned by a bifid ftigma. There is a white and a blue flower of this fort in the gardens, but in Holland they have it with a double flower. This fort doth not produce feeds in England, fo is only propagated by offsets; thefe may be taken off from the old plants in Auguft, that they may get good root before the cold weather begins: they muft be planted in fmall pots filled with frefh, light, loamy earth, and placed in the fhade until they have taken root; then they may be placed with other hardy exotic plants, and in autumn they muft be removed into fhelter, for in fevere winters thefe plants are often deftroyed which are expofed *, though in mild winters they will live in the open air. It flowers in July and Auguft.

The fourteenth fort is a native of the Canary Iflands, from whence it was introduced to the gardens in Europe, where it hath been many years cultivated *, and of late years great numbers of the plants have been raifed from feeds which were brought from thence, but the flowers of thefe new-raifed plants are not fo well coloured as thofe of the old ones.

This hath a thick flefhy root, which is of an irregular form, fometimes running downward like a Parfnep, at other times dividing into feveral knobs near the top, and when any part of the root is broken, there iffues out a milky juice at the wound. There are many ftrong flefhy fibres fent out, which ftrike deep into the ground, and from thefe a numerous quantity of fmall ones. From the head, or crown of the root, arife one, two, three, or more ftalks, in proportion to the fize of the root; but that in the center is generally larger, and rifes higher than the others. Thefe ftalks are very tender, round, and of a pale green; their joints are far diftant from each other, and when the roots are ftrong, the ftalks will rife ten feet high, fending out feveral fmaller fide branches. At each joint they are garnifhed with two, three, or four fpear-fhaped leaves, with a fharp pointed beard on each fide. Thefe are of a fea-green, and, when they firft come out, are covered (lightly with an Afh-coloured pounce. From the joints of the ftalk the flowers are produced, which are of the perfeft bell-fhape, and hang downward; they are of a flame colour, marked with ftripes of a brownifkred; the flower is divided into five parts, at the bottom of each is fituated a nectarium, covered with a white tranfparent fkin, much refembling thofe of the Crown Imperial, but

C A M

are fmiSer; upon each of these is fimatit men, which lifia almoft the length of the petal, a: i i is ter-
 m... I by oblong firamiu. In the center of the flower is fiuated the Uric, which is longer than the ftiminj, and is crowned by a crtdf ftigma. The flow... The flow... JL:TI in the beginning of Ociobtf, and there is often a fuccetlion of them till March. '1 I... <y to the root in June, and new ones Ipring up in Auguft

It is propagated by parting their roots, which must be "done v. i fir if the roots are broken or wounded] the milky juice will flow out plentifully, ib that it... hhiisl before the wound* an-
 lkiiiiifj ovct, it octafions their rotting-, therefore whenever <ny of them are broken, they fhould be laid in the ^reohqafe i few days to heal. Theft roots muft tint be too often parted, pfpccially if they are expected to flower well: for by frequent parting the r j(its Mi v. enkffcd, The beft rime for tranl'pJant-
 tna anil parting their roots, is in July, loon after the Ihiks are decayed. The earth in which thefe fhould be planted, iliouliJ not be rich, for thail will caufe them to be luxuriant in branches, and but thiiij par-
 nilimJ with flowers. The foil in whit h they have fucceded beft, is a light fondy loam, mixed with a fourth partof fended lirr-w-rubbiij; when the roots are Uric planted, the pots fhould be placed in the lhades and, uniefs the fafon is very dry, fhoul r.tii be watered, for during the time they are inactive, wet is very ufprioth to them. About the middle of Augufc tin- roots will begin to put out fibres, at which time-, if the ppts 3tv placed under a hot-bed frame,

- The first fort grows naturally in both Indies: the inhabitants of the British islands in America, call all the species without distinction Indian Shot, from the roundness and hardness of the feeds.
- This plant hath a thick, fleshy, tuberous root, which divides into many irregular knobs, spreading wide near the surface of the ground, sending out many large oval leaves without any order; these, at their first appearance, are twilled like a horn, but afterwards expand and are near a foot long, and five inches broad in the middle, lessening gradually to both ends, and terminating in points. They have many large transverse veins running from the midrib to the sides, which are prominent on their under side; and between each of these run two smaller, parallel, pointed veins, which are peculiar to this species. The stalks are herbaceous, rising four feet high, encompassed by the broad leafy foot-stalks of the leaves; these are compressed on two sides; at the upper part of the stalk the flowers are produced in loose spikes, each being at first covered by a leafy hood, which afterward stands below the flower, and turns to a brown colour. Each flower hath one petal, which is cut almost to the bottom into six slender segments, the three upper being broadest, these are of a pale red colour. The flower is encompassed by a three-leaved empalement, which fits upon a small, roundish, rough germen, which, after the flower is fallen, swells to a large fruit or capsule oblong and rough, having three longitudinal furrows, and is crowned by the three-leaved empalement of the flower which remains. When the fruit is ripe, the capsule opens lengthways into three cells, which are filled with round, hard, black, shining seeds. The principal season of these plants flowering, is in June, July, and August.
- As this fort is a native of the warmest parts of America, it requires to be placed in a moderate stove in winter, otherwise the roots will decay. I have frequently tried to keep these roots through the winter in a green-house, but could not succeed; for although some have escaped, yet they were so much weakened by the cold, as not to recover their strength the following summer, so as to flower in any tolerable degree of perfection; so that I have since constantly kept them in winter in a moderate stove, where they always flower in their season, at which time they make a fine appearance, and in the summer, place them abroad in a sheltered situation with other tender exotic plants, where they flower again, and produce ripe feeds annually.

The second fort grows naturally in Carolina, and some of the other northern provinces of America. The leaves of this fort are longer than those of the former, and terminate in sharper points. The stalks grow taller, and the segments of the flower are much narrower; the colour is a pale red, so it makes no great appearance. The feeds are like those of the former fort. If the roots of this fort are planted in warm borders and a dry soil, they will live through the winter in the open air. I have plants of this fort in the Chelsea garden, which have survived twelve winters in a fourth-west border without cover, and flower well every year, but do not produce feeds.

The third fort hath larger leaves than either of the former, the stalks rise much taller. I have received the feeds of this from America, and from the Brazils, by the title of Wild Plantain. The flower-stalks of this fort rise more than six feet high. The leaves are very large, and those near the root have long foot-stalks. The flowers are produced in larger spikes than those of the former sort, and are of a

much brighter scarlet. The feed-veffels are longer, and the feeds larger than those; and these differences are permanent from feeds, so that I make no doubt of its being a distinct species.

The fourth fort is let common in America than either of the former. I received the feeds of this from India, but have had two varieties arise from the feeds, one with a plain yellow, and the other a spotted, flower, which I find are apt to change from one to the other, when propagated by feeds. This fort hath shorter and rounder leaves than either of the former forts. The stalks seldom rise higher than three feet, and the spikes of flowers are like those of the first species, excepting the colour of the flowers.

The feeds of the fifth fort I received from Carthage in New Spain, in the year 1733, which produced very strong plants the first year, some of which flowered the same autumn. The roots of this are much larger than either of the former forts, and strike down strong fleshy fibres deep in the ground. The stalks rise seven or eight feet high. The leaves are near two feet long, narrow, smooth, and of a sea-green colour. The flowers are produced in short thick spikes at the extremity, which are large, and of a pale yellow colour, the segments of the petal are broad, but their shape like those of the other forts. The feed-veffels are larger, and much longer than those of the other forts, but contain fewer feeds, which are very large. The young plants which are raised from feeds of this fort, do more certainly flower than the old roots, or the offsets taken from them; for the roots send out many offsets, which will spread to a considerable distance where they have room, but seldom produce flowers; so that it is the best way to raise a succession of plants from feeds, and to throw out the old ones after they have perfected their feeds.

All the forts are propagated by feeds, which should be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted into separate small pots, filled with rich kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, observing to shade them till they have taken root, after which, they should have a large share of free air admitted to them every day in warm weather, and be frequently refreshed with water. As these plants will make great progress in their growth, they must be shifted into larger pots filled with the same sort of earth, and part of them plunged into the hot-bed again; and the others may be placed abroad in June, with other exotic plants, in a warm situation. Those which are placed in the hot-bed, will be strong enough to flower well in the stove the following winter; but those in the open air, will not flower before the following summer. These may remain abroad till the beginning of October, when they must be removed into the stove, and treated in the same manner as the old plants; and in May, if a gentle hot-bed is made, and covered a foot thick with rich earth, and the plants turned out of the pots, planting them with their balls of earth upon the hot-bed, covering each with a bell-glass, which may be raised on one side every day to admit air to the plants; and as these advance, they must be gradually inured to bear the open air. With this management the plants will grow much taller, and flower stronger than those which are kept in pots, and from these good feeds may be expected in autumn. These plants will continue many years with proper management; but as young plants always flower better than the old roots, it is scarce worth while to continue them after they have borne good feeds.

The second fort, which is much hardier than either of the other, should have a different treatment. The young plants of this must be earlier inured to the open air, where they may remain till the frost begins; then they must be placed in the green-house, and should have but little wet in winter; and the beginning of May, these should be turned out of the pots, and planted in a warm fourth border, in a dry soil, where they will thrive and produce flowers annually;

but

but as there is little beauty in this fort, a few plants for variety will be as many as most persons will choose to keep. There is a variety of this with variegated-leaves, which is preserved in some gardens, and is propagated by parting the roots -, but this hath little beauty, so is scarce worth cultivating.

CANELL A. See WINTBRANA.

CANNABIN A. See DATISCA.

CANNABIS [K*W&K, Gr.] Lin. Gen. Plant 988. Hemp.

The CHARACTERS are,

It is male and female in different plants. The male flowers have a five-leaved empalement which is concave, but have no petals \ they have five Jhort hairy ftamina > terminated by oblong fquare fummits. The female flowers have permanent empalements of one leaf which are oblong and pointed. They have no petals, but a small germen, supporting two long ftyks, crowned by acute fligma \ the small germen afterward becomes a globular depreffed feed, inch fed in the empalement.

This genus of plants is ranged in the fifth fection of Linnaeus's twenty-fecond clafs, intituled Dioecia Pentandria, the male and female flowers being in feperate plants, and the male having five ftamina.

We have but one SPECIES of this plant, which is, CANNABIS. Lin. Sp. Plant. 1027. Hemp. Cannabis fativa. C. B. P. 320. *Manured Hemp.* Most of the old writers have applied the latter title to the female Hemp, and the male they have titled Cannabis erratica, or Wild Hemp; but as both arise from the same feeds, so they should not be made different plants. This plant is propagated in the rich fenny parts of Lincolnshire, in great quantities, for its bark, which is usefull for cordage, cloth, &c. and the feeds afford an oil, which is used in medicine.

Hemp is always sown on a deep, moist, rich foil, such as is found in Holland,, in Lincolnshire, and the fens in the ifle of Ely; where it is cultivated to great advantage* as it might in many other parts of England, where there is the like foil; but it will not thrive on clay, or stiff cold land: it is esteemed very good to destroy weeds, which is no other way effected, but by robbing them of their nourishment; for it will greatly impoverish the land, so that this crop mull

which Hemp is designed to be sown, **is ploughed, and made very fine by harrowing**, *out the middle of April is a good season for sowing the feed: three bushels is the usual allowance for an acre, but two is fully sufficient. In the choice of the feed, the heaviest and brightest coloured should be preferred *, and particular care should be had to the kernel of the feed, so that some of them should be cracked to see if they have the germ or future plant perfect; for in some places the male plants are drawn out too soon from the female, i. e. before they have impregnated the female plants with the farina: in which case, though the feeds produced by these female plants nixy-seem fair to the eye, yet they will not grow, as is well known by the inhabitants of Bickar, Swinehead, and Dunnington, three parishes in the fens of Lincolnshire, where Hemp is cultivated in great abundance, who have dearly bought their experience.

When the plants are come up, they should be hoed out in the same manner as is practised for Turneps, leaving the plants a foot or sixteen inches apart; observe also to cut down all the weeds, which, if well performed, and in dry weather, will destroy them. This crop will require a second hoeing about a month or six weeks after the first, in order to destroy the weeds. If this be well performed, it will require no farther care; for the Hemp will soon after cover the ground, and prevent the growth of weeds, the first season for pulling the Hemp, is usually about the middle of August, when they begin to pull what they call the Fimble Hemp, which is the male plants; but it would be much the better method to deter this a fortnight or three weeks longer, until these male plants have fully shed their duft, without which, the

feeds will prove abortive, produce nothing if sown the next year, nor will those concerned in the oil-mills give any thing for them, there being only empty hulks, without any kernels to produce the oil. These male plants begin to decay soon after they have shed their farina.

The second pulling is a little after Michaelmas, when, the feeds are ripe: this is usually called Karle Hemp, it is the female plants which were left at the time when the male were pulled. This Karle Hemp is bound in bundles of a yard compass, according to statute measure, which are laid in the sun for a few days to dry; and then it is stacked up, or hooped to keep it dry, till the feed can be threshed out. An acre of Hemp on a rich foil, will produce near three quarters of feed, which, together with the unwrought! Hemp, is worth from six to eight pounds.

Of late years the inhabitants of the British colonies in North America, have cultivated this useful plant, and a bounty was granted by parliament for the Hemp, which was imported from thence -, but whether the inhabitants of those colonies grew tired of cultivating it, or the bounty was not regularly paid, I cannot say 5 but whatever has been the cause, the quantity imported has by no means answered the expectation of the public, which is greatly to be lamented; because, as this commodity is essential to the marine, which should be the principal object of this kingdom, the being furnished with it from our own plantations, will not only save the ready money paid for it, but secure to the country an ample supply at all times, without being obliged to our neighbours for it.

CANNACORUS. See CANNA.

CAPERS. See CAPPARIS.

CAPILLAMENTS [*Capillamenta, Lat.*] the firings or threads about the roots of plants.

CAPILLARY plants, [of *Capillaris, Lat.* of, or like hair,] are such plants as have no main stem, but the leaves arise from the root upon pedicles, and produce their feeds on the back of their leaves, as the Fern, Maiden Hair, &c.

CAPITULUM -, i. e. a little head; the head or top of any flowering plant.

CAPNOIDES. See UMARIA.

CAPNORCHIS. See UMARIA.

CAPPARIS. Lin. Gen. Plant. 567. The Caper Brieh.

The CHARACTERS are,

The empalement is composed of three oval concave leaves \ the flower hath four large roundish petals which are indented at the top, and spread open \ it hath a great number of slender ftamina, which are as long as the petals* terminated by single fummits. In the midst of these arise a single style longer than the ftamina, with an oval germen, crowned by a Jhort obtuse stigma. The germen afterward becomes a fleshy turbinated capsule, with one cell, filled with kidney-shaped feeds.*

This genus of plants is ranged in the first fection of Linnseus's thirteenth clafs, intituled Polyandria Monogynia, the flower having many ftamina and but one style.

The SPECIES are,

1. CAPPARIS (*Spinosa*) pedunculis foliariis unifloris, stipulis spinosis foliis annuis, capsulis ovalibus. Lin. Sp. 720. *Caper with one flower on each foot-stalk, prickly stipula, annual leaves, and oval fruit.* Capparispinosa, fructu minore, folio rotundo. C. B. P. 480.
2. CAPPARIS (*Baducca*) pedunculis subfoliariis, foliis perffitentibus ovato-oblongis nudis determinate confertis. Lin. The tirt Li the common Caper, whoc full grown Bower-bud is ljicUed, and brought to England annually from Italy, and the Mediterranean. This is a low lbrub, which generally grows out of die Joints or old walls, die itlures of rucks, and amonglt rub-bifh, in moft of the warm iirts of Kuropc : the ftalks art- ligneous, and covered vidi awliiee bark, which fendi out many lateral deader bpmcbej •, under each of thi-le arc plated two thort crooketl (pines, between which and thic branches come out the foot-IULK of the lava, wtkh ate Cngtc, lhort, anil fuftain a round> fmoodi, entire leaf; at the internediate joints between the bi-ancies, come out the flowers upon long foot-flails; before thefc expand, ihc bud, with the c; ipnlement, is gadiered for picklinff; but dioc wh h .ircleft expand in form of a fingleKofe, having five lar^e, white, roundifh, concave pptalsj in the middle is placed a great innbcr of kmg flamina, iurrounding a Ryle, which rifes above them, and is crowned with an oval gerroen, v.liidi afterward becomes a capsule, filled with kidney-flap. • I kqds.

This fort is cultivated upon old walls about nlon, and is feveral parts of it. • Mr. Raj ubferved it growing naturally on the walls ;jid ruitu at Home, Sicily, and France

The wand tort hath a tree-like fctm • jwlding into branches, which are fmooih, hiving no fpines on them; the leaves arc oblong, oval, anafmooth, •• huch continue (I ough the year. Prom die: wings of the leaves come out the foot-ftalks. I of the flower*, which are produced iir. . . ; thic ; jwers are i: . . die buds.

The plants of the fifth fort are with difficult I pre-ferred in England, for they delight to grow Jii ere-vices or rocks, and the joints of old walls or ruins, and always therrc fall in an horizontal pofition; fo that when they are planted under a gale, or the full ground, they rarely thrive, though they may be kept alive for fome years. They are propagated by feeds in the warm parts of Europe, but it is very difficult to get them to grow in England. I have feveral

had three plantteomeup in an old wall, irilich being young and tender, wets defroyed in the ytur 174. but in the >••••• rufcd a good numb.; of plants from feeds, which were down the year before. There ii an old plant giw'ing out of a . v, all in the garden ai Cambdtu-Houfc, rcn Kentfngron, which fia- filkti tire cold for many yt-iiR, and suimilj- produce* many flowers, but the young flojots of it arc frequently killed to the (lump every winter.

The n>ois of this plant arc annually brought from Italy, by th (ome of whit!) luvc been planted iit wali, where they have lived a few •••••, but hve not cotuinuixl long. l'hc thirJ fort 1 received from Cardiagena in New Spain, near whic b place it grows naturally. This rrics with a woody Item to the height of twelve or fourteen iV •, lenden- on: many hireial brai covered with a rufct birk, girmiftid •••••, clofing oval U'avcj, ftanding upon long foot-ilalks; the flowers arc produced fium the fmic of the bnus. Jingle, Ibiuung upon long foot-ftalki, which arc tike thole of the hit fort.

The fourth fort was fent me from Carthigena by Ac iire Mr. Robert Milljr, furgeoa. THi grow with a Ilrong upright trunk near CWQy feet high, fending out many laicrjl branches, gamified with a very white bark, and cjtcfy gamiflu s of a rJieeker con(ift n«« thnn tWe 1 of the common Laurelj of fplcmdM green, luing feveral traoferve nerves from she midrib to the border, which art prominent on their under Jide; the Howers conic out from the lideof the branches, luich arc large, and thic (iimmits of the (amina are purph-. The fifth • t me from the fine county.

Thb rife with a trunk about twentr feet high, fending out many long (lender brandus, which are to-veced with .l brown (jyrk, and garniied \jch kavts like tirole of the Bay-tree, I and deeply ribbed on tht-ir under fide, (landing upon pretty lung foot-ftalks opiMifin: re produced »juaa long brandiinp foot-ftalcs, which [erminate d>c branches, each iiiiHaininy tv/o or tl: JULII are large, white, and are fticceeded by potU two or three mehes long, the ducknela of » nun'i luicd finger, vifich are filled «iili brj Tnd^: thL-k' potK have -i thick Red

The sixth loit was tent me from Tolu it An This nSa with n ihubby Hall; to the height of eight or ten feet, lending out iron* ligneous brj; covered with a rufhish brown bark, gamified with oblong, fpear-ftaped, flit leaves, having punctures on the >i from the of the leaves are the foot-ftalks of the flowers, which are long, femlar, and coi ; which fuibi a fmall white flowt-f. which is fucceeded by an oval pod, containing iniwy fmallkkli.

Thefcventh fort rifes with a (irubby ftem to die height: of twelve or fourteen feet, fending out many (Iron: lateral branches, covered with a dark brown bark, gamimwl with fpear-fjiapts! pointed leaves, placed alternately, having very fhort foot-ftalks; die leaves are of a thicker confidence than thofe of the Bay-tree; at the foot-ftalk of each leaf comes out a fingle flovnrc, alir. h of thu lirir whidi are fmiill, i ikz Canmits of thic flowers are of a purplifh colour, but th lamina are white. This fort was from Tolu.

The eighth fort riles with a fhubby Ealk to thc height of u-u or : feet, lending out flender branches, which are covered with a With the joints of thic branches are far diftant at each I come out feveral leaves in clufters, without ur: ftanding upon pretty long foot-ftalks; they are fix inches long, and three broad in the middle, and as thick as thofe of the Laurel; of a flining green, femlar on their upper fide, but have many tranfverfe ribs on their under fide, which are prominent. I received this fort from Tolu, with the ferroz.

The ninth sort grows naturally in most of the islands in the West Indies; it hath a strong woody stem, twenty-five or thirty feet high, dividing into many branches, covered with an Ash-coloured bark, and garnished with oblong oval leaves, downy on their under side, but smooth on their upper, placed without order, the flowers are produced in loose panicles at the extremity of the branches; these consist of four pretty large concave petals, of a purple colour, including eight long purple stamens, with a very long style crowned by an obtuse stigma; the germen afterward turns to an oblong fleshy pod, containing four or five seeds.

The tenth sort hath slender (hrubby stalks, which rise seven or eight feet high, sending out many ligneous branches, garnished with very long, nervous, (pear-flaped leaves. The flowers come out at the end of the branches, three (landing upon each foot-stalk; these are small, white, and are succeeded by oval fruit.

These last nine sorts are natives of warm countries, so will not live through the winter in England, without the assistance of a stove. They are propagated by seeds; which must be procured from the countries where they grow naturally, for they do not produce any in England; these must be sown in (mail pots, filled with light sandy earth, and plunged into a hot-bed of tanners bark; which (should be now and then refreshed with water, but by no means (should have it given in too great plenty: these seeds frequently remain in the ground a year before they vegetate, therefore the pots in which they are sown (should be protected w/ winter; and the spring following must be plunged into a fresh hot-bed of tanners bark, which will bring up the plants if the seeds were good; when the plants appear they must have but little wet, and a good (share of air in warm weather; but when they are large enough to remove, they must be each transplanted into a (separate small pot, filled with the same earth, and then plunged into the hot-bed again, observing to shade them until they have taken fresh root; after, which they (should have fresh air admitted to them every day, in proportion to the warmth of the season. In the autumn they must be removed into the stove, and plunged into the bark-bed, where (they must constantly remain, and will require the same treatment as other tender exotic plants from the same countries; with this difference only, that they require but little water, especially during the winter, for the roots of these plants are very subject to rot with wet.

If the seeds are brought over in their capsules, they will keep much better than without them; but these should be secured from insects, by wrapping them in Tobacco leaves which are well dried; without this precaution, the seeds will be destroyed before they arrive.

CAPER [BEAN.] See ZYGOPHYLLUM.

CAPRARIA. Lin. Gen. Plant. 686. Sweet Weed.

The CHARACTERS are,

// hath a permanent empalement of one leaf, cut into five oblong narrow segments, which are ereff and stand under the flower is bell-shaped, of one leaf, divided at the top into five equal parts, the two upper standing ereff, it hath four stamens, which are inserted in the base of the petal, and but little more than half so long, two of the under being shorter than the other, and terminated by heart-shaped stamens; it hath a conical germen supporting a slender style, longer than the stamens, crowned by a bivalve heart-flaped stigma. The germen afterward becomes an oblong conical capsule, compressed at the point, having two cells, divided by a partition filled with round seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flower having two long and two short stamens, and the seeds being included in a capsule.

We have but one SPECIES of this genus, viz.

CAPRARIA (*Biflora*) foliis alternis floribus geminis. Jacq.

tab. 15. *Capraria with alternate leaves, and foot-stalks with two flowers.* Capraria Curaçavica. Par. Bat* 110. This plant grows naturally in the warm parts of America, where it is often a troublesome weed in the plantations; it rises with an angular green (talk about a foot and a half high, sending out branches at every joint, which sometimes come out by pairs opposite, but generally there are three at a joint standing round the italic; the leaves are also placed round the branches by threes; these stand upon short foot-stalks, are oval, hairy, and a little indented on their edges. The flowers are produced at the wings of the leaves, coming out on each side the (talk, each foot-stalk sustaining two flowers; they are white, and succeeded by conical capsules compressed at the top, opening in two parts, and filled with small seeds.

This plant is preserved in botanic gardens for the sake of variety; but as it hath no great beauty, so is seldom admitted into other gardens.

It is propagated by seeds, which must be sown upon a hot-bed in the spring of the year, and the plants must be brought forward by planting them upon a second hot-bed; and about the middle or latter end of June they may be transplanted either into pots of rich earth, or a warm border, and may then be exposed to the open air, where they will perfect their seeds in autumn.

CAPREOLATE plants [of capreolus, Lat. the tendril of a Vine,] such plants as twist and climb upon others, by means of tendrils.

CAPRIFOLIUM. See PERICLYMEKUM.

CAPSICUM. Lin. Gen. Plant. 225. [takes its name of capsa, Lat. a cheft; because the seeds of this plant are included, as it were, in a little cheft; or esse of ~~the~~, to bite, because it is a burning pungent plant.] Guinea Pepper; in French, *Poivre d'Inde ou de Guinée*.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, divided into five parts, which are ereff. It hath but one petal, which is wheel-shaped, having a very short tube, spread open above, and divided into five parts; it hath five small stamens, terminated by oblong stamens, which are "connected. It hath an oval germen, supporting a slender style, longer than the stamens, and crowned by an obtuse stigma. The germen afterward becomes a soft fruit, or capsule, of an indeterminate figure, having two or more cells, divided by intermediate partitions, to which adhere many compressed kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamens and but one style.

The SPECIES are,

1. CAPSICUM (*Annuum*) caule herbaceo, fructu oblongo propendente. Capsicum with an herbaceous stalk, and an oblong fruit hanging downward. Capsicum filiquis longis propendentibus. Tourn. Inf. 152.
2. CAPSICUM (*Cordiforme*) caule herbaceo, fructu cordiformi. Capsicum with an herbaceous stalk, and an heart-shaped fruit. This is the Capsicum filiqua propendente oblonga & cordiformi. Tourn. Inf. 152.
3. CAPSICUM (*tetragonum*) caule herbaceo, fructu maximo anguloso obtuso. Capsicum with an herbaceous stalk, and a large angular obtuse fruit. Capsicum fructu longo, ventre tumido, per se tetragono. Tourn. Inf. 153- Bell Pepper.
4. CAPSICUM (*Angulosum*) caule herbaceo, fructu cordiformi anguloso. Capsicum with an herbaceous stalk, and an angular heart-shaped fruit. Capsicum filiquis fure & cordiformibus angulatis. Tourn. Inf. R. H.
5. CAPSICUM (*Cerastiforme*) caule herbaceo, fructu rotundoglabro. Capsicum with an herbaceous stalk, and a round smooth fruit. Capsicum filiquis fure & Cerastiformi. Tourn. Inf. 153.
6. CAPSICUM (*Oliviforme*) caule herbaceo, fructu ovato. Capsicum with an herbaceous stalk, and an oval-shaped fruit. Capsicum filiqua olivae forma. Tourn. Inf.

do make a pretty appearance in the latter part of (imincr, when they ate properly dipolct) in ih borders of the llower-garden; or if they are planted in pot-; for the decoration of courts, &c. titrijlg ill-termixed with other annual plants, which arc in beauty at the fame feafon, they will make an agreeable variety; especially, if as many of the difcrent lhapcd &UU3, or both the red and yellow colours as can be procured, are p:

The four bit forts hive perennial lhnibby (talks, which rife four or five feet high; theft an not lb bardy as the other, therefore wicn the plants have been brought forward in the hot-bed, as was difrected for the common forts, they (hould be cadi planted in a pot filled with rich earth, and plunged into a very moderate hot-bed, under a deep frame, where they may have room to advance *, anil in wann weatlcr, they (hould have a Urge iharc of air admitted to them, but muft be covered with glaffes every night, or in coUl weather, and frequently watered. With this management, they will produce plenty of fruit in autumn, which ripin in winter-, but they rciufV be removed into the (toe, on thefirft approach of trofl, and placii where they may have a temperate warmth, in which they will thrive better than in a greater heat-, and the fruit will continue in beauty molt part of winter, making a pretty appearance in the (love during that feafon.

The feeds of the lev-nth (ore I received from Egypt: the lIMVCS of t^ much narrower than thote of any other &•• . * feen; the pods always grow creel, iiced in grew plenty, fb that the plip* ^ood appearance forthreemonths in <•• jnd they may be prefervcJ two or three >ut is the young plants arc die mod fi i <<// ptrfons prierve the old longer, tian till they .have perfected their fruit, when they begin to lofe their beauty. I have cultivated this fon feveral years, and have never found it vary, ^o conclude it is a iliftinct fpeciej.

The eighth fort I received from Antigun, bytnetnk of Hen Proper. This rife-, with a (nrubby folk *Jm< cr high, fending out many branches lev-JTI^1 f: the fruit is about half an inch long, ,rm of an obrufe cone, and of a bright rref. This ripens its fruit in winter, aakes a pretty appearnci-

i nth fortgrows about the fame height a; Ac egli-.i, but differs from it in the fhajie and fae of die fruit: thofe of this fon being about the bigntli of a Barberry, and nearly of the Tame fhape. This I have long cultivated, and have not oblcrved a to alter.

The tenth fon is commonly known by the tHr of llnl Pepper in America. This rife with a flvabby flak four or five feet high: the leaves arc broad, and rounder at the ends than thofe of the other fora, and of a itdd green: the fruit (pww d'vifions of the branches. Handing erect i thefe arc fmall, oval, and of a bright red; ihry arc much m^re Jharp and biting than thofe of the other forts. From die fruit of this fon k made tire Cayan butter, or what the inhabitants of America call Pepper-pora, which they efteem as the beft of all the fpices. Tie Winning is a receipt for making a Pepper-pot: take of the ripe, pods of thb fort of Capiicum, and dry them well in the fun, then put them into an earthen or (tone pot, mining flour between every ftrau or pods, and put them into an oven after the biking of brtttd, thiat they may be thoroughly dried-, after which, they mult be well deanfed from the flour, ufid or ihe (talks remain to the pods, they ihould be laken ofT, and the pods beaten, or ground to fine powder t to every ounce of thi>i " ^ a pound of Wheat dour, and u much leaven di is fuffeiem for tlte quantity irendf U (alter this has been properly mixed and wrought, it fhodd be made into small cakes, and bked in the fame mail: moo cakci of the fame l in them into ftruil parts, and tckr them again, that they m*y be as dry and hard is

The firft fort grows naturally in the meadows in many parts of England; it is called Cuckow Flower, and Lidit-s Smock. Of diis there are four varieties, ^z, the fingle purple with white flowers, which are fluently intermixed in the meadows, and the double flower of both colours. The fintrle forts are feldom admitted into carders; but as the tirft fort (lands in tlw lift of medkiiKil plants, I have enumerated ic. The young leaves of thli plant have been gathered in the fpring, by fomic pertuns, and put into fallsds inftead of Creis: it ii tippedcd 10 be an anttfeorbucic. The two varieties wiith double Bowers were accidentally foimd growing in the meadows, and were tranfplanEcd into gardens, where they have been prt> pagated. Thfc deserve a pbec m lludy floift borders of the fiowtr^girden, where they will thrive, and make a pretty appearance during their continuance in flower: they si* propagated by parting their roots; the beft time for diis 13 in autumn, when thry (hould be tranfulamed annually. They dtli^it in a foft loamy foil, not too itiff, and muft have a [tudy ficu-ftion. This flowers in MiV) and in cool leatbns will continue part of 1

I Tiic feventh, eighth, and tenth fam, grow naturally on the Alps, and otlic: mountainouj placn. I received thde from Verona, in the neighbourhood of winch place *thej* grow naturally. Thtie are low per-ennial plants, which may be propagaied by parting iheir roots in the auninut, ana require a llrang foil and (haiiy iituation: they may alfo be pnipaeitctt by *ittra*, which (haul be Town in ; he autumn, on a thady border, • here they will come up foan after, •ra) are Dever hurt by froft, Hi n;|| flower the folj-awing feafun. Thcle vstii'ties are prrlerved in fome gardens, but having link beauty, are ieldom admitted into the flowCT-jri

» The ninth fort ii alt-naturally in /ex be propagstol oy : I befown in an open ituation, .I will require no other care: liut ro kerp the plants clear from weeds. It flowers in June, and the feeds ripen in July.

The sixth fort grows naturally I by the sides of rivers and ditches in molt parts tif F.ngland, to is not admitted into gardens. l'herc has been a. variety of this found with double flowers, but it is not I yet much known. Tliis Bowers the latter end of April, and in May.

The other forts are low annual plants, which grow naturally in fveral pans of England, fo art (tidom admitted into gardens. Thefe have the title of Int-pwcm Creis, irom the elafiii -y of their pods, which, if touched when they are ripe, fpring open, a; I caft out their feeds with violence, to a confidcrable dip rancee. Thefe forts when young, are, by the country people, eaten in faUads, and have the flavour of the common Crefs, but milder.

Thcfe plant*, whenontc admitted into a garden, propagare in plenty; tor they produce great quantity of feeds, which, if permitted tu Cicler, there will IK a fuuply of plants, which only require to be thinned and kept clean from weeds, and will thrive beft in tie ftiaile.

rise to the height of eight or ten feet, but in England they seldom are much above half in height; in they lend out many of their branches, which spread in a considerable distance every way, and if cut or pruned, will furnish themselves to the places which are cut, and so they multiply themselves, and thereby spread over them.

They are annual, and perish soon after they have perfected their seeds, and being natives of warm countries, they will not thrive in England in the open air. They are propagated by seeds, which should be sown upon a hot-bed in the spring, and when the plants are two inches high, they should be each transplanted into a pot filled with light sandy earth, not too rich, then put them into a very moderate hot-bed, where they must be carefully shaded until they have taken firm root, after which they must have a large share of air admitted to them, to prevent their becoming drawn up tall and weak, and when their roots have filled the pots, they should be carefully shaken out, preserving all the earth to their roots (for if that should fall off, the plants will not thrive it) then put them into pots a little larger, filling them up with the same light earth, and place them either under a deep frame, or behind the plants in the flower, where they may be screened from the sun till they are well settled in the pots, after which they may be removed into a glass-case, where they may have a little more of air admitted from the bottom, if it is not too hot; in warm weather they will require a little more of air; with this management they will flower in July, and their seeds will ripen in autumn.

CARDUUS Lin. Sem Phnt. 83*. Thistle, in French. *Chardon*.

CHARACTERS. It has a compound flower made up of many hermaphrodite flowers, which are fruitful; the flowers are in a common hairy involucre, which is furnished with many sharp teeth, and is hairy; the flowers are yellow, being of one hue, having a funnel-like, with an oval base, and the base narrow towards the end; the flowers have four flat hairy leaves, terminated by cylindrical hair, which are inserted into the stem; the leaves are green, and are supported by a single rib, which is hairy and hairy. The flowers are of a white color, and are of a roundish shape. The flowers are of a white color, and are of a roundish shape. The flowers are of a white color, and are of a roundish shape.

This genus of plants is ranged in the first section of Linnæus's natural class, marked Synonymia Polygonia equalis; the flowers of this class have their segments connected into a cylindrical tube, but the stamens are separate, and the fruit is a flattened oval body, which is covered with a fine downy hair.

1. CARDUUS (*Polygonia*) foliis lanceolatis serratis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.
2. CARDUUS (*Erigeron*) foliis lanceolatis serratis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.
3. CARDUUS (*Aster*) foliis lanceolatis serratis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.
4. CARDUUS (*Aster*) foliis amplexicaulis lobatis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.

5. CARDUUS (*Aster*) foliis lanceolatis serratis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.

6. CALYPSO (*Carduus*) foliis lanceolatis serratis, spinis rufis latissimis. Hort. Cliff. 222. This is the most common sort, which is called in the fields, and is also called in the fields, and is also called in the fields.

The first sort grows naturally in Sicily. It is an annual plant, which rises with a channelled stem about a foot and a half high, sending out several side branches toward the top, furnished with long narrow leaves like those of the Austrian Primrose, which are of a deep green above, but white on their under side, placed alternately, just below the root stalk of the leaf come out several unequal yellow flowers, the end of the branches the flowers are produced, there are very thickly enveloped, under which are placed two long leaves, the flowers are purple, and shaped like those of the common Thistle, but are smaller; these are succeeded by oblong smooth seeds, which have a long woolly down lying on their top. This first flowers in July and August, and the seeds ripen in September. It is propagated by seeds, which should be sown on a bed of light earth in the spring, where the plants are to remain, for they do not bear transplanting, unless it is performed when they are very young; for they send long slender roots deep into the ground, which, if broken, the plant seldom survives it. The second sort grows naturally in the lowland countries of England. This is a perennial plant, which sends out many long leaves, which are of a deep green above, but white on their under side, placed alternately, just below the root stalk of the leaf come out several unequal yellow flowers, the end of the branches the flowers are produced, there are very thickly enveloped, under which are placed two long leaves, the flowers are purple, and shaped like those of the common Thistle, but are smaller; these are succeeded by oblong smooth seeds, which have a long woolly down lying on their top. This second flowers in July and August, and the seeds ripen in September. It is propagated by seeds, which should be sown on a bed of light earth in the spring, where the plants are to remain, for they do not bear transplanting, unless it is performed when they are very young; for they send long slender roots deep into the ground, which, if broken, the plant seldom survives it.

The third sort grows naturally in the lowland countries of England. This is a perennial plant, which sends out many long leaves, which are of a deep green above, but white on their under side, placed alternately, just below the root stalk of the leaf come out several unequal yellow flowers, the end of the branches the flowers are produced, there are very thickly enveloped, under which are placed two long leaves, the flowers are purple, and shaped like those of the common Thistle, but are smaller; these are succeeded by oblong smooth seeds, which have a long woolly down lying on their top. This third flowers in July and August, and the seeds ripen in September. It is propagated by seeds, which should be sown on a bed of light earth in the spring, where the plants are to remain, for they do not bear transplanting, unless it is performed when they are very young; for they send long slender roots deep into the ground, which, if broken, the plant seldom survives it.

The fourth sort grows naturally in Spain and Portugal. This rises six feet high; the leaves are long, narrow, and the edges are set thick with small hairs; at every indurment of the leaves there comes out two long yellowish spines, at the end of the branches the flowers are produced from the side of the stalk, which have woolly oval envelopes, chiefly armed with slender spines. The flowers are yellow, but make no great appearance, as they advance very little above the envelopes. It flowers in July and August, and the seeds ripen in autumn. This plant may be propagated by seeds in the same manner as the first.

malfhet u the former fort. It is called Fifth Thistle, from the resemblance which the (pines hive to the bones of filli.

The fourth lbrt grows very common on the side of banks, and in walk land in many part! of England, and Uby fame peribru blanchend anddrefTed as a curious dihi. This is a biennial plant, which ftiould belbvra very thin, and wlien the plants arc come up la as tobe. well diftinguiihtil, the ground flould be hoed, to cut down all die young weedis, and the plants left about a foot ...; fiilt diftance; and the following Imiimcr the ground llioulii be kept clean from weeds. to the auiumn the I avesof the plants flould be tied up, and tiie earth ilrawn up dofe to blanth them; »taa thry are properly whitened, they will be fit for tife. This it a biennial plant, which perUhes Toon •fter the lecdi are ripe.

The filth fort is a bwnniil plant, which is by fom- culcrated for medicinal uie. and has been fitpofed a remedy for feme fort of inadnefe. Thiis may be propagated by feeds in the fame manner as the fecond lorr. It ... natura!lv in (1* northern pans of England, and flowers in June.

The fixth fort is fippofcil to be the trueFifthThiltle of Theophrallus. This is a bicnniil plant, which ri&i with an uprihr IULK fix feet high, gamilhd with long (pear-hfped leaves, armed with triple [pines at every indenture on thicr edges; al the top ofihcFbA the flowers come out in duffers, which are of a purple cokrnr, and are fuccedeii by Imooth, oval, thck feed ... naturally in Sicily an;! the t.evant. It is pi- paged by feeds a> die fccoiid fort, wWkh (houli be lown on a warmhorder, o;hir- wile the plants will not live through the winter. li Sowtrjin lunc. and ihc feeds ripen in autumn.

C A R

be sown upon a bed of soil in any situation. I will require no other culture, but to keep them clear from weeds, and I thin the plants where they are crowded, this being a method that is kept in some parts, but it hampers the beauty. There is a variety of this, which grows much taller, the heads are larger, and the leaves are placed closer upon the stalks. This was found by Dr. Tournefort in the Levant.

The third fort was discovered by Toumefort in the island of Crete, from whence he sent it to the royal garden in Paris. This differs from the former, in having a smooth stalk; the leaves are very thick, deeply marked, smooth, and are armed with very strong spines; the heads of flowers are of a blue color, and the plant grows four feet high. This is a perennial plant, which may be blown and treated in the same way as the former, and Bowers about the same time.

The fourth fort has a perennial root, but an annual stalk. This grows sparingly in Spain, and may first be brought to England from Tangier; the seeds of this are never perfected in England, so it is propagated by cutting of the roots. The best time for planting is about the beginning of March; they should have a dry soil and a warm situation, otherwise they are liable to be destroyed in winter.

The fifth fort is five feet high, the stalks are thick and putting out any branches, garnished with narrow leafed leaves, which cover the whole length of the stalk. The leaves are thick and pointed, each is a simple ending in a spine. Each leaf is marked with a large fealy head of blue flowers, and is the same as the other species.

The sixth fort grows naturally in the South of France, Spain, and Italy. This has a perennial root and an annual stalk. It rises about four feet high; it is channelled, has in the leaf a narrow channel, ending in several sharp spines; the edges are rounded, each is a simple ending in a spine. Each leaf is marked with a large fealy head of blue flowers, and is the same as the other species.

It is difficult to propagate in England, for the seeds are put in water, which do not come to perfection; here, unless the leaf part be warm and dry. This plant is very common in the Levant.

The sixth fort is famous, to be the same as the fifth, which is a great mistake, for they are extremely different. This rises with a purple colour, hairy and channelled, closely garnished with broad spear-shaped leaves, which are finely lined on their edges, and covered with a fine lacy down. The stalk is marked with a large fealy head of blue flowers, having a fealy empalement, composed of two orders of leaves, the outer being broad, long, and armed with sharp spines; the inner are smaller, and terminate with sharp thorn. It lowers in June and July, and the seeds ripen in August. This fort may be propagated by pricking of their roots, which should be performed in autumn, when the leaves decay. It should have a light dry soil, in which it will endure the cold of our winters, and continue for many years. It may also be propagated by cuttings, which ripen well in dry seasons, but in the autumn the seeds are generally short; this requires as much care as to keep it clear from weeds. It grows naturally in Spain, France and Italy, on arable land.

The seventh fort I received from Andalusia, where it grows naturally in great plenty. This rises with a thick perennial stalk to the height of eight or ten feet, dividing into many branches, garnished with very long sword-shaped leaves, which are marked with sharp spines on their edges, which end in a

wide their surface. The branches are terminated by large, fealy, pointed heads of yellow flowers, which come out in July, but are overruled by winter, (so can only be propagated by cutting).

The eighth fort is a plant which is filled with light airy roots, and is called in our country, being very much valued for its medicinal qualities, which are removed into the open air, when they have lost their strength, they are planted in a warm dry place in the cold of our ordinary winters, but in severe frosts they are frequently destroyed.

The seeds of this fort were first sent me from Spain, where it grows naturally. It has a perennial root but an annual stalk; it is light, and never produces any branches, but is a simple ending in a spine. The leaves are narrow, of a pale greyish green, closely lined on their edges with short thick spines. The flowers are of a purple color, and are borne in a simple ending in a spine. This species is common in the Levant, and is very much valued for its medicinal qualities, which are removed into the open air, when they have lost their strength, they are planted in a warm dry place in the cold of our ordinary winters, but in severe frosts they are frequently destroyed.

The ninth fort is five feet high, the stalks are thick and putting out any branches, garnished with narrow leafed leaves, which cover the whole length of the stalk. The leaves are thick and pointed, each is a simple ending in a spine. Each leaf is marked with a large fealy head of blue flowers, and is the same as the other species.

The tenth fort is five feet high, the stalks are thick and putting out any branches, garnished with narrow leafed leaves, which cover the whole length of the stalk. The leaves are thick and pointed, each is a simple ending in a spine. Each leaf is marked with a large fealy head of blue flowers, and is the same as the other species.

This gem of plants is ranged in the second section of Linnaeus's fourth class, and is called Penuria Uygynia, the flowers being simple, and the leaves being simple.

The Swedes call it Capsella, and the Latins call it Capsella bursa-pastoris; it is a perennial plant, and is very common in the Levant.

The Carvi I received from Andalusia, where it grows naturally in great plenty. This rises with a thick perennial stalk to the height of eight or ten feet, dividing into many branches, garnished with very long sword-shaped leaves, which are marked with sharp spines on their edges, which end in a

The Carvi fort is the common Camempana, whole feeds are peculiarly unfit, no: only in medicine, but in the kitchen, &c. This grows naturally in the richest meadows in Lincolnshire and Yorkshire, and is sometimes round crowbeet in the pictures near London. It is cultivated for its medicinal qualities, and is a biennial plant, which rises from seeds one year, flowers the next, and produces seed after the seeds are ripe. It has a large root like a parsnip, but much smaller, which runs deep into the ground, and is a strong aromatic, lending out small fibres, which are white and soft.

C A R

folid, channelled stalks, about two feet high* garnished with winged leaves, having long naked foot-stalks, and many small wings placed opposite on the midrib, which are composed of many narrow, little, plain leaves, ending in fevetal points. The stalks divide upward into several smaller branches, each of which is terminated by an umbel, composed of six or eight small separate umbels or rays, which divide into several small foot-stalks, each sustaining a single white flower, with five heart-shaped petals; the flowers of these small umbels are closely joined together. After the flowers are decayed, the germen becomes an oblong channelled fruit, composed of two oblong channelled feeds, plain on one side, but convex on the other. It flowers in June, and the feeds ripen in autumn.

The best season for sowing the feeds of this plant is in autumn, soon after they are ripe, when they will more certainly grow, than those sown in the spring, and the plants which rise in the autumn, generally flower the following season, so that a summer's growth is hereby saved. When the plants come up, the ground should be hoed to destroy the weeds; and where the plants are too close, they must be thinned in the same manner as is practised for Carrots, leaving them three or four inches apart. In the following spring they will require to be twice more hoed, which will keep the ground clean till the feeds are ripe; then the stalks must be pulled up, and tied in bundles, setting them upright to dry, when the feeds may be threshed out for use.

The second sort grows naturally in Spain: the feeds of this were sent me from the royal garden at Paris. This plant rises with a stronger stalk than the former, which seldom grows more than a foot and a half high, but is closely garnished with fine narrow leaves like those of Dill; the stalks divide upward into many branches, each being terminated by loose umbels of white flowers, which are succeeded by large broad feeds, having the same aromatic flavour as the common sort. This is a biennial plant, and may be treated in the same manner as the former.

CARYOPHYLLATA. See GEUM.

CARTOPHYLLUS. Lin. Gen. 594. Caryophyllus aromaticus. Tourn. Inf. R. H. 661. tab. 432.

^The Clove-tree, or Allspice.

The CHARACTERS are,

It hath a double empalement, that of the flower is of one leaf, cut into four obtuse parts, upon which the germen is situated \ the fruit hath another empalment, which is finally and slightly divided into four parts, which are perwanent. The flower hath four blunt petals, which are situated opposite to the incisures of the empalment. It hath many stamina, which rise from the sides of the empalement, terminated by roundish summits. The germen is situated under the flower, and is crowned by the small empalement, supporting a single upright style, crowned by an obtuse stigma. The germen afterward becomes a soft berry with two cells, each containing a single kidney-shaped feed.

This genus of plants is ranged in the first section of Linnaeus's thirteenth class, intitled Polyandria Monogynia, the flower having many stamina and but one style.

The SPECIES are,

1. CARYOPHYLLUS (*Aromaticus*) foliis ovato-lanceolatis oppositis, floribus terminalibus, staminibus. corollâ longioribus. *The Clove-tree with oval spear-shaped leaves growing opposite, and flowers terminating the stalks, whose stamina are longer than the petals.* Caryophyllus aromaticus fructu oblongo. C. B. P. 410. *Aromatic Clove with an oblong fruit.*
2. CARYOPHYLLUS (*Pimento*) foliis lanceolatis oppositis, floribus racemosis terminalibus, & axillaribus. *Clove-tree with spear-shaped leaves growing opposite, and flowers growing in bunches at the ends of the branches, and wings of the leaves.* Myrtus arborea aromatica foliis laurinis. Sloan. Cat. 161. *The Pimento, or Allspice.*
3. CARYOPHYLLUS (*Fruticosus*) foliis lanceolatis oppo-

G A R

tis, floribus geminatis alaribus. Brown. Hift. Jam; 248. *Clove-tree with spear-shaped leaves placed opposite, and flowers growing by pairs from the sides of the stalks.*

4. CARYOPHYLLUS (*Cotihifolia*) foliis ovatis obtusis oppositis, floribus sparsis alaribus. *Clove-tree with oval blunt leaves placed opposite, and flowers growing thinly from the sides of the branches.* Myrtus cotini folio. Plum. Cat. 19. *Myrtle with a leaf of Venice Sumach.*

5. CARYOPHYLLUS (*Racemosus*) foliis oblongo-ovatis, emarginatis, rigidis, glabris, floribus racemosis terminalibus. *Clove-tree with oblong oval leaves, which are stiff, smooth, and indented at the edges, and flowers growing in branches terminating the stalk.*

The first sort grows naturally in the Moluccas, and the hottest parts of the world, where it rises to the height of a common Apple-tree 5 but the trunk generally divides at about four or five feet from the ground into three or four large limbs, which grow erect, and are covered with a thin smooth bark, which adheres closely to the wood. These limbs divide into many small branches, which form a sort of conical figure; the leaves are like those of the Bay-tree, and are placed opposite on the branches. The flowers are produced in loose bunches at the end of the branches, which are small, white, and have a great number of stamina, which are much longer than the petals. The flowers are succeeded by oval berries, which are crowned with the empalement, divided into four parts, which spread flat on the top of the fruit, in which form they are brought to Europe for it is the young fruit beaten from the trees before they are half grown, which are the Cloves used all over Europe.

I have not heard of any plants of this kind being in the gardens, either in England or Holland, but I chofe to mention it here, to introduce the other.

The second sort grows naturally in Jamaica, but particularly on the north side of that island, where it is found in great plenty, and is a considerable branch of their trade, the unripe fruit dried, being the Allspice so well known in Europe. It is now cultivated with care in many of the plantations, for the trees will thrive upon (hallow rocky land, which is unfit for the Sugar-cane; so that a great advantage is offered to the planters from those lands, which would otherwise be of small account to them.

This tree grows to the height of thirty feet or more, with a straight trunk, covered with a smooth brown bark, dividing upward into many branches which come out opposite, garnished with oblong leaves, resembling those of the Bay-tree in form, colour, and texture, but are longer, and are placed by pairs: when these are bruised or broken, they have a very fine aromatic odour like that of the fruit. The branches grow very regular, so that the trees make a fine appearance, and as they retain their leaves through the year, the trees are worthy of being propagated for ornament and shade about the habitations of the planters. The flowers are produced in large loose bunches from the side of the branches, towards their ends, each branch is also terminated by a larger bunch than the other 5 the flowers are small, and of an herbaceous colour, they are male and female upon distinct trees. I was favoured with fine samples of both, and also a particular account of the trees, by William Williams, Esq. of St. Anne's, on the north side of Jamaica, who has the greatest number of these trees on his plantation of any person in that island. The male flowers have very small petals, and a great number of stamina in each, which are of the same colour with the petals, terminated by oval bifid summits; the female flowers have no stamina, but an oval germen, situated below the flower, supporting a slender style, with a blunt stigma at the top. The germen afterward becomes a globular pulpy berry, including two kidney-shaped feeds. The usual season when these trees flower, is in June, July, and August.

When

When the fruit of these trees are designed for use, they are gathered, or beaten down from the trees a little before they arrive to their full size, and are separated from leaves, stalks, or any rubbish which may have accidentally mixed with them; then the fruit is exposed every day to the sun, spread on cloths for ten or twelve days to dry, but removed under cover every evening to screen it from the dews; when the fruit is perfectly dry, it is packed up for exportation. If the fruit is permitted to grow to maturity, the pulp, which surrounds the seeds, is so full of moisture, and is so glutinous, as to stick to the fingers of those who bruise them, therefore are unfit for those uses to which the dried fruit are applied.

It is called by some Jamaica Pepper, but the most general appellation is AU-spice, from its relish and flavour, partaking of many other spices, and is deservedly accounted one of the best and if it was as scarce and difficult to procure as those spices in the east, would be much more sought after and esteemed: our neighbours the Dutch, who have engrossed the spice trade to themselves, have also been artful enough to deceive us with this of our production, by purchasing the dried fruit of the AU-spice in England at a low price, and grinding it to a powder, then selling it to us at an advanced price for powder of Cloves. This I have been credibly informed of, by an eminent merchant, through whose hands great quantities of this commodity have passed.

The Dutch have also drawn an oil from the fruit of this tree, which they vend for oil of Cloves. I had a small phial of this oil sent me from Jamaica, which was shewn to some of the best judges of drugs in London, who tried many experiments with it, and declared they thought it as good oil of Cloves as they had seen.

As there is so great an affinity between this tree and the true Clove, it might be worthy of trial, if the fruit when first formed, or the flowers were beaten down from the trees, and dried in the same manner as the eastern Cloves might not answer the same purpose, or, at least, it would be a good succedaneum for that spice, and as it is the production of our own colonies, should have proper encouragement.

This tree is propagated by seeds, which in the natural course of its growth is conveyed, and sown by birds, to a great distance; and, it is very probable, the seeds passing through them, are rendered fitter for vegetation, than those which are immediately gathered from the tree; for I have received great quantities of the berries from the gentleman before-mentioned, which were perfectly ripe and fresh, great part of which I sowed in different ways, and communicated some of them to several other curious persons, who did the same, but none of them have yet succeeded, and upon informing my friend Mr. Williams of this, he told me that a friend of his, whose plantation was on the fourth side of Jamaica, desired him to save a large quantity of the ripe berries for him to sow on his plantation, which he accordingly did, but his friend forgot to tend for them till near two years after, during which time, they had lain in a large heap, and had fermented, and, on sowing those berries, the plants came up with the first rains in great abundance; so that it may be of great service to these seeds, either to pass through animal bodies, or to be fermented before they are sown.

The plants cannot be preserved in England unless they are placed in a stove during the winter season, but they will thrive in a moderate degree of warmth: they should be planted in a soft light soil, and in winter must have but little water. In the summer they should have a large share of air, and in July, if the season proves warm, they may be placed in the open air, in a warm sheltered situation, but upon the approach of cold nights, they must be removed into the stove again. The exposing of these plants to the open air for one month only, will be of great service to clean their leaves from insects or filth, which they are subject to contract, by remaining long in the

stove; but if the season should prove very wet or cold, it will not be safe to trust these plants longer abroad; therefore their leaves should be now and then washed with a sponge to clean them, which will not only render them more fitly, but also promote their growth. This tree is pretty difficult to propagate in England, where the seeds do not ripen; the only method in which this has been done, is by laying down the young branches, flitting them at a joint in the same manner as is practised in making layers of Carnations. If this is carefully performed, and the layers are regularly but gently watered, they will put out roots in one year; then they may be carefully separated from the old plants, and each planted in a small pot filled with light earth, and plunged into the tan-bed, either in the stove or under a frame, being careful to shade them until they have taken new root, after which they may be treated as the older plants*. This plant, being an Evergreen, makes a fine appearance in the stove at all seasons of the year; and their leaves having such an agreeable fragrance when rubbed, render them as worthy of a place in the stove, as any other tender exotic plant which is preserved for ornament.

The third sort grows naturally in Jamaica, from whence I received it some years past. This rises with a divided trunk to the height of eight or ten feet, sending out many branches, which are placed opposite, covered with a grey bark: the leaves come out opposite, which are shorter and rounder at their points than those of the last species, they are also smoother, and of a firmer texture. The flowers come out from the side of the branches between the leaves, upon slender footstalks, about an inch in length, two generally arising from the same point: these are succeeded by round berries, of a brighter colour than those of the former, having the empalement on their crowns. The leaves and fruit of this sort have no aromatic flavour, so are not of use, but the characters of the flower and fruit are the same as in the other sort.

This tree retains its leaves all the year, which being of a splendid green, make a very good appearance, when it is intermixed with other exotic plants in the stove, but the flowers being small, and growing thinly upon the branches, do not make any great figure, so it is only preserved for the beauty of its foliage. It is propagated by seeds, and requires the same treatment as the other sort.

The fourth sort was sent me by the late Mr. Robert Millar, surgeon, from Carthage in New Spain: this rises with many irregular stems about twelve or fourteen feet high, covered with an Ash-coloured bark, dividing into many branches upward: these are garnished with stiff oval leaves, placed opposite. The flowers are produced from the side of the branches, sometimes four, five, or six foot-stalks arise from the same point; at other times, they come out single, or perhaps by pairs: these are white, and of the same shape with those of the second sort, and are succeeded by berries which are rounder, and, for the most part, contain but one kidney-shaped seed.

This sort agrees with the second in its general characters, but not in the virtues, for it hath none of the aromatic flavour, with which that abounds; but as it retains its leaves through the year, may merit a place in the stove, better than many other plants which are preserved by the curious. This is propagated by seeds, in the same way as the second sort and the plants must be treated in the same manner as those.

The fifth sort was sent me from the island of Barbuda, where it rises to the height of twenty feet; the trunk and branches are covered with a smooth brown bark. The branches come out by pairs; they grow erect, and are garnished with very stiff, smooth, lucid leaves, which are placed opposite, and have very short foot-stalks. The leaves vary much in their form; some of them are oval, others oblong, and some are indented so deeply at their ends, as to

be almost heart-shaped. Their confidence is much thicker than thofe of the common Laurel, and their colour is a fplendent green, with one deep midrib running through their middle, and many fmall veins going from thence tranfverfly to their border. The flowers are produced in fmall loofe bunches at the extremity of the branches, which have feveral narrow leaves intermixed with the bunches. Thefe are fucceeded by berries of the fame fhape with thofe of the fecondfort, but larger.

This tree is propagated by feeds as the other fpecies, and deferves a place in the ftove, for the beauty of its evergreen leaves, which being of a thick confidence, and of a fliining green colour, make a fine appearance in the ftove at all feafons of the year; but this hath no aromatic flavour to recommend it, as hath the fecond fort, for which reafon it is feldom noticed. I take this to be the Bay-tree, mentioned by Hughes, in the Hiftory of Barbadoes, which he defcribes to have no flavour * for I have feen plants of this fort which were brought from Barbadoes, fo that I fuppofe it grows naturally there.

As the plants of thefe forts do not rife fo readily from feeds in England, the beft way to obtain them, is to get fome perfi of (kill in America, to take up a number of young plants, and plant them clofe in boxes of earth, letting them in the fhade till they have taken new root *, then remove them into an open fituation, where they may have time to eftablifh their roots before they are fhipped for England *, and in their paffage they muft be guarded from the fpray of the fea, and fait water, and fhould have very little water given them *, for moft of the plants which are fent to England, are killed in their paffage by having too much wet. If thefe direftions are obferved, the plants may be brought in good health to England, provided they come over any time in the fummer, that they may have time to get freffh root before the cold feafon begins and when once they are well eftablifhed in their roots here, they may be preferred many years in vigour *, but I have not feen many of the plants in flower here as yet.

CASSIA. See OsvRis.

CASSIA. Lin. Gen. Plant. 461. Caffia, or Wild Senna.

The CHARACTERS are,

The empdement is compofed of five concave coloured leaves, the flower hath five roundifh concave petals, which fpread open; it hath ten declining ftamina, three of the lower are long, the three upper are fhorter; the fummits of the three lower are large, arched, beaked, and feperated at their points \ the three upper ftamina have very fmall fummits; the four fide ftamina have no beaks, but fpread from the other. In the center is fituated a long taper germen, having a fhort ftyle, terminated by an obtufe Jigma. The germen afterward becomes a long pod, divided by tranfverfe partitions, each containing one or two roundifh feeds, faftend to the margin of the upper valve.

This genus of plants is ranged in die firft fe&ion of Linnaais's tenth clafs, intituled Decandria Monogynia, the flowers having ten ftamina and one ftyle.

The SPECIES are,

1. CASSIA (*Occidentalis*) foliis quinquejugis, ovato-lanceolatis, margine fcabris, exterioribus majoribus, glandulâ bafeos petiolorum. Lin. Sp. Plant. 337. Caffia with leaves compofed of five pair of oval fpear-fhaped lobes with rough borders, the upper lobes being the largeft and a fmall gland at the bafe of the foot ftalk. Senna occidentalis, odore opii virofo, orobi Fanjionici foliis mucronatis glabris. Hort. Amft. 1. p. 51. tab. 26.
2. CASSIA (*Frutefcens*) foliolis quinquejugatis ovatis glabris, exterioribus longioribus, caule fruticofa. Caffia with leaves compofed of free pair of fmooth oval lobes, the tipper being the longeft, and a fhubby ftalk. Senna fpuria Americana frutefcens, foliis mucronatis minoribus, filiquis teretibus, duplici feminum ordine foetus. Houft. MSS.
3. CASSIA (*Alata*) foliolis o&ojugatis, ovali-oblongis, interioribus minoribus, petiolis eglandulofis ftipulis

patulis. Hort. Cliff. 158. Caffia with eight pair of oblong oval lobes, the inner being the leaf, foot-ftalks without glands, and a fpreading ftipula. Caffia fylveftris fetida, filiquis alatis. Plum. Cat. 18. Wilifmking Caffia with winged pods.

4. CASSIA (*Villofa*) foliolis trijugatis, oblongo-ovatis fequalibus villofis, filiquis articulatis, caule ere&o arboreo. Caffia with three pair of oblong, oval, hairy leaves, which are equal, jointed pods, and an upright woody ftem. Senna fpuria arborea, villofa, foliis latis mucronatis, filiquis articulatis. Houft. MSS.
5. CASSIA (*Uniflora*) foftolis trijugatis, ovato-acuminatis, villofis, floribus folitariis axillaribus, filiquis erectis. Caffia with three pair of lobes in each leaf, which are oval, pointed, hairy, and fingle flowers proceeding from the fides of the ftalks, with upright pods. Senna fpuria herbacea orobi Pannonici foliis rotundioribus, flore parvo, filiquis ere&is. Houft. MSS.
6. CASSIA (*Marylandica*) foliis odtojugis ovato-oblongis, fequalibus, glandula bafeos petiolorum. Lin. Sp. 541. Caffia with fmall leaves compofed of eight pair of oblong, oval, equal lobes, having a gland at the bafe of the foot-ftalk. Caffia Marylandica pinnis foliorum ohlongis, calyce floris reflexo. Mart. Cent. 1. 21.
7. CASSIA (*Bicapfulari*) foliolis trijugatis obovatis glabris, interioribus rotundioribus minoribus, glandulâ interjeftâ glpbofâ. Hort. Cliff. 159. Caffia with three pair of oval fmooth leaves, the inner ones being rounder*, fmaller, and a globular gland placed between the leaves. Caffia hexaphylla* iilliquâ bicapfulari. Plum. Cat. 18.
8. CASSIA (*Fiftula*) foliis quinquejuga^s ovatis acuminatis, petiolis eglandulofis. Fior. Zè./l 149. Caffia with five pair of oval, pointed, fmooth lobes, and foot-ftalks having no glands. Caffia fiftula Alexandria. C. B. P. 405. The purging Caffia of Alexandria, or Pudding Pipe-tree.
9. CASSIA (*Bahamensis*) foliolis fejugatis, lanceolatis, glabris, interioribus minoribus, floribus terminatricibus. Caffia with fix pair of fmooth fpear-fhaped lobes, the inner ones being fmaller, and flowers terminating the ftalk. Caffia Bahamensis, pinnis foliorum mucronatis a^tis, calyce floris non reflexo. Martyn. Cent. 1. A
10. CASSIA (*Fruticofa*) foliolis bijugatis, ovato-lan-tis, glabris, floribus terminalibus, filiquis lo% retihus, caule fruticofa Caffia with two pair of fpear-fhaped, fmooth lobes, flowers terminating the long taper pods, and a fhubby ftalk. Caffia fr tetraphylla, filiquis eredtis. Houft. MSS.
11. CASSIA (*Javanica*) foliolis duodecemjugatis, oblongis, obtufis, glabris, glandula nulla. Lin. Sp. Plant. 379. Caffia with twelve pair of fmooth lobes, winch have no glands. Caffia fiftula Brafiliana. C. B. P. 403. Purging Caffia of Brafil, commonly called Horfe Caffia in America.
12. CASSIA (*Ligu/hina*) foliolis feptemjiugatis, oblongo-ovatis, floribus fpicatis axillaribus, filiquis recurvis. Caffia with feven pair of oblong oval lobes, and ftwifpikes of flowers proceeding from the fides of the ftalks, and recurved pods. Senna folio liguftri. Plum. Cat. 18? Senna with a Privet leaf.
13. CASSIA (*Emarginata*) foliolis trijugatis, obtufis, emarginatis, caulibus pilofis, floribus folitariis axillaribus petiolis longioribus. Caffia with three pair of obtufe leaves, indented at the top, hairy ftalks, flowers growing fingly from the fides of the ftalks upon a long foot-ftalk. Senna fpuria frutefcens, foliorum pinnis latioribus, caulibus pilofis, filiquis longiflimis pediculis infidentibus. Houft. MSS.
14. CASSIA (*Biflora*) foliolis quadrijugatis oblongo-ovatis, caulibus procumbentibus, floribus axillaribus pedunculis bifloris. Caffia with four pair of oval oblong leaves, trailing ftalks, and flowers proceeding from the fides of the ftalks, two growing upon each foot-ftalk* Senna fpuria minima, procumbens, foliorum pinnis fubrotundis, caule pubefcente. Houft. MSS.
15. CASSIA (*Arborefcens*) foliolis bijugatis oblongo-ovatis, fubtus villofis, floribus corymbofis, caule erecto arboreo. Caffia with two pair of oblong oval leaves, hairy, on their under fide, fowers growing in ruund bunche^ and an ere ft treelike ftèm. Senna fpuria

- tetraphylla arborea, filiquis compreffis, anguftis, longiffimis, pendulis. Houft. MSS.
26. CASSIA (*Flexuofa*) foliolis multijugatis linearibus, floribus folitariis axillaribus, pedunculis longiffimis. *Caffia with many pair of narrow leaves, Jingle flowers proceeding from the fides of the ftalks* and very long foot-ftalks.* Senna occidentalis, foliis herbae mimofae, filiqua fingulari, floribus pediculis longioribus infiftentibus. Sloan/Hift. Jam. 2. 51.
17. CASSIA (*Chamacrifia*) foliolis multijugatis linearibus, caulibus procumbentibus, frutescentibus, floribus maximis folitariis axillaribus, filiquis glabris. *Caffia with many fair of fmall leaves\ which are narrow\ Jhrubby trailing ftalks* large flowers growing Jingly from the fides of the ftalks* and fmooth pods.* Senna fpuria mimofae foliis, frutescens & procumbens, flore maximo, filiquis glabris. Houft. MSS.
18. CASSIA (*Pentagonia*) foliolis trijugatis ovatis, exterioribus majoribus glandula fubulata inter inferiora. Prod. Leyd. 46. *Caffia with three pair of fmall oval leaves* the upper being the largeft* and an awl-Jbaped glandule between the lower pair.* Senna fpuria pierumque hexaphylla filiqua pentagona alata. Houft. MSS.
19. CASSIA (*Racemofa*) foliolis quinquejugatis, lanceolatis rigidis floribus racemosis axillaribus, filiquis planis, caule fruticofo. *Caffia with five pair of fpear-shapedftiff leaves* flowers growing in bunches from the fides of theftalks flat pods, and a Jhrubby ftalk.*
20. CASSIA (*Procumbens*) foliolis bijugatis ovatis, caulibus procumbentibus, floribus folitariis axillaribus, filiquis hirtutisi *Caffia with two pair of fmall oval leaves* trailing ftalks* jingle flowers proceeding from the fides of the ftalk* and hairy pods.* Senna fpuria tetraphylla herbacea procumbens, filiquis hirtutis. Houft. MSS.
21. CASSIA (*Glandulofa*) foliolis multijugatis, glandula petioli pedicellata, ftipulis enfiformibus. Hort. Upfal. 101. *Caffia with many pair of leaves* and the gland on the foot-ftalk refembling an infeSt* and fword-jhaped ftipule.* Chamae chritta pavonis Americana, filiqua multiplici. Breyn. Cent. 64.

The firft fort grows naturally in moft of the iflands in the Weft Indies, where it is called Stinking Weed, from its unfavoury odour. This rifes with a channelled folk three or four^tet high, dividing into feveral brandies, garnifhed with winged leaves placed alternately *, each of thefe is compofed of five pair of lobes which are oval, fpear-shaped, fitting clofe to the midrib, having rough edges, the lower pair of lobes being the fmalleft, the others enlarge to the top, which are the biggeft; at the bafe of the foot-ftalk is produced a fmall protuberance, which is called a gland; this is differently fituated in the feveral fpecies of this genus. The flowers come out from the fides of the ftalks> two growing upon each foot-ftalk *, but the branches are terminated by loofe fpikes of flowers, which are compofed of five concave yellow petals, with ten declining ftamina* fituated round the germen and ftyle, which becomes a fword-lhaped flat pod, having a border on each fide, and is indented between each feed.

This is a biennial plant, which is propagated by feed in plenty, in the countries where it grows naturally *, but in England, the feeds muft be fown on a hot-bed in the fpring, and when the plants are fit to remove, they fhould be each planted in a feparate pot, filled with light earth, and plunged into a moderate hot-bed, where they fhould be fhaded till they have taken frelh root; after which they fhould have frelh air admitted to them every day, in proportion to the warmth of the feafon, and fhould be frequently watered. When the plants have fiffle&c P^ol^s with their roots, they fhould be fhifted iⁿ M^og^er; and if they are too tall to remain in the hot-bed, they muft be placed either in the ftove, or a glafs-cafe, where they may be defended from cold, but in warm weather have plenty of air. With this management the plants will flower in Auguft, and perfect their feeds in O&ober, but may be preferred through the winter in a ftove, where they will continue flowering a long time. In

warm fummrs the plants may be placed in the open air toward the latter end of June, where they will flower very well* but thefe will not perfect their feeds, unlefs they are removed into the ftove in autumn.

The fecond fort was fent me from Jamaica by the late Dr. Houftoun, who found it growing there naturally. This rifes with a fhrubby ftalk five or fix feet high, fending out many branches toward the top, garnifhed with winged leaves, compofed of five pair of fmall oval leaves, the upper ones being longeff. The flowers come out from the fide of the ftalks, and alfo terminate the branches in loofe fpikes, thefe are yellow, and fhaped like thofe of the former, but are fmaller; the pods are long, taper, and contain two rows of feeds.

This plant may be preferred three or four years in the ftove, and will annually flower and perfect the feeds. It is propagated by feeds, which fhould be fown on a hot-bed in the fpring *, and the plants muft be treated in the fame manner as the former fort, with only this difference, that thefe, when they are too tall to remain longer under the frames on the hot-bed, muft be removed into the ftove, where they will ofttn flower in autumn or winter, but they feldom perfect their feeds till the fecond year.

The third fort hath an herbaceous ftalk, which rifes five or fix feet high, garnifhed with long winged leaves, compofed of eight or ten pair of large oval lobes, each being more than three inches long, and one broad, rounded at the end, where they are lightly indented. The flowers are produced in loofe fpikes at the top of the ftalk, which are large, yellow, and of the fame fhape with thofe of the other fpecies; the pods are long, taper, and have four borders or wings running longitudinally 5 thefe contain a double row of angular feeds. The whole plant hath a ftrong foetid odour.

This fort feldom continues more than two years; it muft be raifed from feeds as the former forts, and placed in the tan-bed in the ftove, being very tender, and fhould have but little water in winter. The fecond year the plants will flower, but they very rarely produce feeds in England.

The-fourth fort was fent me from Campeachy by the late Dr. Houftoun, who found it growing there in great plenty. This rifes with a woody ftem to the height of fourteen or fifteen feet, fending out many lateral branches, garnifhed with winged leaves, compofed of three pair of oblong, oval, hairy lobes, of equal fize, the flowers come out in loofe bunches at the end of the branches, which are of a pale ftraw colour, and fmall, but fhaped like the others, the pods are long, narrow, and jointed, each feed being lodged in a fort of ifthmus * the feeds are oval and brown.

This may be propagated by feeds, which muft be fown upon a hot-bed, and the plants afterward treated as the former forts, placing them in a warm ftove, where they will continue feveral years producing their flowers in fummer, and in warm feafons the feeds will ripen.

The fifth fort is a low herbaceous plant, feldom rifing a foot high* the ftalk is fingle, and garnifhed with winged leaves, compofed of three pair of oval pointed lobes, which are hairy; the flowers come out fingle from the fide of the ftalks; they are of a pale yellow, and fmall; thefe are fucceeded by narrow taper pods two inches long, which grow upright. This plant is annual -, the feeds muft be fown on a hot-bed, and the plants treated as the fifth fort: they will flower in July, and ripen their feeds in autumn. This was fent me from Campeachy by the late Dr. Houftoun.

The fixth fort grows naturally in Maryland, from whence I received the feeds. It hath a perennial root* compofed of a great number of black fibres; this fends out feveral upright ftalks in the fpring, which rife four or five feet high, garnifhed with winged leaves, compofed of nine pair of oblong fmooth lobes, which are equal * toward the upper part of the ftalks

C A S

the flowws come out from the wings of the kaves, or three together i but the (talks are ttmnfcaud by lo^fc fpikj of pale yrllnw flowers, which are rarely fucced... : by pods inEngland. TheMks de-eav in autumn, and rile again in [lie lpnng. The roots of this fte continue many years, and will live abroai in a WBTIII border anil a dry foil. Tin feeds will COOK up in the full ground, if fown in April, end in auirfln djey may be planted into the borders where they are defigned tu remain.

The feventh fort is an annual pLmt, which rife a foot and a half high, with an erect herbactmu Italk, pttmiffitil with winged leivet, compofed of diree pair of oval lobes; the lowers come out Gn^ly from the wimp (if the Waves; tiete are final), yellow, u of tlic tune fhapt with thofe of the other fpeciu, and aKfucccednibytiiprrpoti?, having cell* containing two rows of feeds. It is propa^>ic<l by It-edfl, which null be finvn on a hen-bed, and manogvd as the other tender forts -, it •ill ainiinue two ur dttec years, if placed in a warm Rave.

The fourteenth brt fcnds out from the root two or three Bender It.dks, which trail on the ground, gar- ni (hod with wined k-nvei, luvtnq four piiir of fmall main... lli lobes, of a pale grctn; at the infertion of the foot: Lka arife thnie of the flower, whi... is jointed\ divitiitii, into two the rtrcr at the lop, ful&iu- ing two fmall yellow flowers. ... grows naturally tnjwniica, fromwhemx th. feeds were fent me. It is an annual plant, v | H B ^ s m11 n De < < < n early In the iplrln; on a... and treated like the other kind-:, but a; the bfiSttifi of this grow tm the ground, to the Janes may remain under a frame all tlic (umini, and will flower in July; when, if ilie feafon is warm, they muA hive have a lai... flare of air, otherwife the flowers will: fill off, without bcin; fucccedJed by pots-, but if richly n... the feeds will rpen... ^jlvlinn.

The fifteenth fort was fence me from La Vera Cruz, in New Spain, by the late Dr. Houftoun. This ritej with a strong upright trunk, to the height of twenty-five, or thirty feet, dividing into many branches, it is at 11 ura covered with an A (h-coloured bark, garnished with long foot-talks; each being composed of two pair of oblong oval lobes, four inches long, and near two broad, which are smooth, of a dark green on their upper side, but paler under! The Bowers are produced from the side of the ftjki, where they are few and featury, but the ends of the brandies have large round bunches of fkwors, which branch out from one center; they are deep yellow, inclining to an Orange colour. These are succeeded by compressed pods, near nine inches long, having a border on each side, and contain one row of oval, (mouth, complicated feeds.

This fort may be propagated by feeds, which should be sown on a hot-bed in the spring, and when the plants come up, they will require the same treatment as the (even in ibrt; with which maaagei the plants will thrive, and produce their flowers in a few-year!

The fix Kent h fort hath very flenkr miiing flails s, about two feet long, garnished with winged leaves, fitting close to the branches, composed of many narrow like tirole of the Sen Drive Plant* the flowers come out single from the side of the stalk, in a long lotie ilcndr foot-lh lks, which are small, of a bright yellow colour, shaped like those of the other species; they are succeeded by short Hat pods, containing two or three feeds. This grows naturally in Jamaica. It is a biennial plant, and requires the Unit (rc:itii) itai the fin

The seventeenth fort was lent me by the law Dr. Houiloun from La Vera Ctm, where he found it growing naturally. This ritej with several flirubby trailing Italics, which are two feet long, sending out many fine branches, clothed with winged leaves, com- posed of several pair of very narrow pinnae, (smaller than those of the fenitive Plant. The flowers are produced single from the side of the brandies, on very Hyl .oot-(talks -, they are Urge, of a deep Orange colour, and are succeeded by short, narrow, smooth pods. This plant differs much from the Chama x crifta pavonii major, of Breynius, in having a flirubby trailing IU!k; the leaves are much shorter, having but half the number of pinnae, which are also narrower and (shorter, the lower ones are larger.

This plant will continue two or three years, and produce flowers annually, but it must be treated in the same manner as the other ritej forts \ for it will not thrive unless it is 15 preferred in a warm stove, where it will flourish the second year. It flowers in July and August, and the feeds ripen in autumn.

The eighteenth fort ma (cut me) from Campechy, by the late Dr. Houiloun. This ritej with a flirubby flitidr (talk about two feet high, consisting of several bran- ches, which are finely garnished with winged leaves, composed of three pair of oval lobes, the upper being the largest; these stand upon long foot-stalks, from the side of which comes out the flowers, standing single on a short foot-stalk, of a pale yellow colour, and is succeeded by a bearing pod, near four inches long, having five longitudinal wings, ending in a point.

It is a biennial plant, which if hit in the spring, will flower the first summer, and sometimes the second year, but if the plants are placed in a warm stove, they will live through the winter, and the following summer will flower earlier, and good feeds may then be obtained. The nineteenth fort ritej with a flirubby stalk to the height of ten or twelve feet, dividing upward into many branches, garnished with winged leaves, composed of five pair of flat leaf-shaped lobes; the flowers come out from the side of the branches, on long branching foot-stalks, collected into large loose

clusters; these are of adccpOrarsgecoL. large, and flattened like those of the other species, and are succeeded by flat brown pods, about four inches long, containing one row of oval feeds. This fort was fence me from CirtJugenjt, by the late Mr. Robert Millm.

This fort is propagated by feeds in the same manner as the other species, and KCjuina n »»»rm (to preferve it, where it will thrive and produce flowers annually.

The twentieth fort was lent me from La Vera Cnre, by the late Dr. Hounoun. This has several trailing herbaceous (bilks, about two feet long, garnished with winged leaves, having long foot-stalks, which are placed at a considerable distance from each other; they have two pair of oval imtioil lubes. The flowers come out single from the side of the branches, which are large; How cakmr, and are succeeded by iliort, flit, hiir'pods, each containing one row of flat feeds.

This is an annual plant, which must be raised on a hot-bed early in the spring, and treated in the same manner as the other annual forts before-mentioned. It flowers in July, and the feeds ripen in autumn.

The twenty-first fort grows common in all the islands of the West-India. This ritej with a stout stalk about two feet high, sending out several branched upright stalks, garnished with winged leaves, composed of several pairs of narrow pinnae, like those of the fenitive /,UK. The flowers come out upon short foot-stalks from the side of the branches, each foot-stalk sustaining two or three yellow flowers, of the same form with the other species of this genus; these are succeeded by short flat pods, containing three or four flat feeds in each.

This is an annual plant, and requires the same treatment as the other forts of this grow- right, they will be too tall to stand in the summer; therefore when the plants are advanced to the height of two or three feet, they must be removed into the stove, or a phs cajir, where they may have room to grow, and be preserved from the cold, but in warm weather (without lube a good flux of air admitted to them; v-tili this managerif they will (lower in July, and perfect their feeds in autumn.

These plants are frequently preferred in the garden* of the natural curiosities, therefore I have enumerated them here, though several of them have not been recommended to me, but are chiefly kept for the sake of variety. The most beautiful are the fourth, die eighth, tenth, eleventh, fifteenth, and nineteenth forts; these will make a good appearance in the stove, especially when they are in flower; and as they retain their leaves all the year, they make an agreeable variety in the winter season, when intermixed with other plants from the same countries. All the species of this genus contract their leaves every evening as the sun declines, and open them again with the rising sun in the morning; which is also common to many other plants, some of which turn their upper surface outward, but all those of this genus turn their under surface outward, the upper being very closely folded together. These are what Linnæus calls sleeping plants. It must also be observed that most of these plants, whose under surface is turned outward, as they grow upon dry sandy land, where their roots do not find a supply of moisture, so that the lower surface of their leaves being generally covered with a short soft down, or hairs, obtain the property of being highly dried by the heat of the sun, and the lower part of their surface is cured outward, do not stand in need of the supply of Uting smooth, the moist Uirei* cast into, and not injured by them.

This is an annual plant, and requires the same treatment as the other forts of this grow- right, they will be too tall to stand in the summer; therefore when the plants are advanced to the height of two or three feet, they must be removed into the stove, or a phs cajir, where they may have room to grow, and be preserved from the cold, but in warm weather (without lube a good flux of air admitted to them; v-tili this managerif they will (lower in July, and perfect their feeds in autumn.

C A S

been in nfr time out of mind: we may alfo obferve, tha; the [jjace of is growth in the north, is the fame kinside as Paraf . . . ta Jbuth; (b I <bm beglr infer the account given of the Paraf . . . Tea by Monf. Freaief, who mi . . . called through great part of NrwSwniit, . . . order of th(. . . InSouthC.L . . . the plant is called Caffina, or South- fiea 1 . . . the inhabitants of that country do not make (ii or . . . of this Tea, « rhrfe-ol . . . and North Carolina; in the IJH of which, the white people hart it in as pew e&eam as the li . . . and make as conftant oft of it.

Monfieur Frwicr alfo firys, i . . . the Spaniards who live near the gold mines in Peru, arc obliged frequently to drink of the herb Pwamiay or Mate, to EDOfici their breads, without which, they at* liable to a tort of fu(location, from the (1 rong rxiations which arc continually coming from the min«. Ttie feme author alfo adds, that the inhabitants of Lima, during the day-time, make much ufc of the licrb Paraguay, which fome call St. ibriholoniew's Herb. who, they pretend, ctme into thof; provinces, where he made it who! dome . . . and benefits it wherca; before it wa^ venomous j this, he fays, is brought to Lima dry, arid aimed in powder. Infteavl of drinking the tinrwrc or infufinn apart, as we drink rra, they put the hrrb into a cup or bowl made of a c.tnba/h tipped with filver, which they cail mate i AKV add fugar, and pour the hot waier upoo JI, whilthly drink immediately, without giving it time to infufe, bctaulc it nimi black a* ink. To avoid following the herb, which fwims at tli . . . top, they make ufc of a Bhrer ppe, at the end whereof in a bowl full of little holes; fo dial the liquor fucked in ai the other end, is clear from thr herb. They drink round with the fame pipe, pouring hot witcf on the fame herb, at ir is drunk orF. Inftcad of ct pipe, which they call bombilla, fome part the herb with a liltv-r frJantor, called apartador, full of lirtle holes. Thr relufhtncy which . . . the French Live fhcVn m drink after all lbrts of people, in a country where many have the venereal difeafe, has occafioned H . . . inventing the vie of little glass pipes, which they began to ufe at Lima. This liquor, ht tiys, in his opinion, is better thj; tea; it has a flavour of the herb, whid) is agreeable enough: the people of the country are fo flic; to it, that even the ponrell drink it once a day, when they rife in the morning.

The trade for ih« herb, [he ! . . . is carried on at Sanra Fr, "whether it it brought up T . . . of Plate. There are two fora of it, throne called Yerba de J'alos; and the other, which ii finer, and of more virtue, Yerba de Camini; the lart a brought from the lands beSongng to the jrluits. The great confum . . . n of it a between La Paj and Cufco, where it is worth h;l, as much more as the other, which is fas from Pqtoii to La Paz. Trieru come yearly from Paraguay into Peru a! . . . i . . . land arrovas, twelve thoufand hundred weight of both lbrts, where- of at leaft one thini is of the Camini, without reck- oning twenty-live thoufand arrovas of that of Palo* . . . ill The; - rjay tar each parcel, containe foe or fcvm arrovas, (our royak fi . . . the duty called al- cavala r«cing a rate upon all goods fold) which, with the charge of carriage, b . . . ing above fix . . . idml leagues . . . covers the first parcel, which is about two ; . . . of eight i fo th;it ^t l'otoG il . . . comes to about five pieces of eight the arrova. The . . . charge is commonly by carts, which . . . airy an hundred and fifty arrovas Inset Saita . . . Fe to Juiuv, rhc bfr w . . . of the province of Pitcumanj and from tSencr to Pofull, v.hich is an hundred leagues farther . . . it is carried on mules.

What this curious author his obfervrd, on there being two fnm ct thii herb, i . . . very well agree with the two hll fbrs mentioned, fice; both of them are generally fupposed to come in their qualities, though one is much preferable to the c: . . . therefore I imagine the Yrba dc Camir? . . . is what we call Pai- gusy or South-Sea . . .; and Yerba (c P*1«t to be

Tilis plant grows najur.tlly in both Indies. I have
 received it rom Baroadoei, Jamaica, and the 5
 West Intl^a and that I j'rowa ali in tin- East Indies,
 a plant from its figure in the H. •rtus Malafa

It puts with taper succu. l. •• stalks, which dive le into
 many slender beculent branches; these come out (ve-
 jiiifr. lame joint, aft
 come out fide branches singly witliout order, and
 become very bulky; the flowers come one on the

side of the branch x-s fingiy, titling very clo/e tlierwo,
 via no empdment; it; U*c corolla is oval, white,
 ure of red, opening like a navel a;
 top, ii •ncn, lbrtna, Ihlc, anil
 oeftlrtnus glantls (0 ciojrjy, as not to be ti&covered
 *rll the iMrolla is cut 0; the flower is pa ft.
 •i men becomes n • oval, dark icedi,
 nth a ttiui

The plant is eajily pcojgated b' plantinir cuttinc^
 f're during the liunmer monrh; but .l3 tiirii: cuttings
 *" licculent, it will be •oper to •ul them off i
 •• lJrtort they nre pl*W ed, lying ilicm in the
 ftre, that the part cut may have time to he! OFer
 before they are planted. Their cuttings •ild he
 planted in small pots, which must be plunged into ii
 moderate hot bed, where, i : hey an: not over watercil,
 iii week; i then they may be
 feparare final po' filled
 with light sandy earth, and may be plunged again
 into the hotbed to forward their Lakuig new roue;
 after which they should be •moved into a dry ftovt,
 whether • I h oiii J cor. •' it, gi vin g in it ti rlc
 water in v in fummcr admitting » targe
 XT. for thk plant it ino
 tender to thrive in the open air in this climate.

 Canara, a city of Thrasy, •Mwre rhis n
 Chr'nut-tree, in French
 Character, or Mercur.

The **CHARACTERS ARE,**
 It hath milk and fleshy flowers on the stem tree, foun-
 dness at separate places, and at other times near each
 other. The milk flowers are fixed to a long fibre, form-
 ing a sort of whisk; these have not a stalk, but
 are fixed to the side of the stem; they have no petals, but
 include about ten or twelve highly furnished, terminated by
 white filaments. The fleshy flowers have all an empdment
 of one leaf, divided into four parts, being as pe-
 tals, but a green leaf to the empdment, supports three
 fleshy rounded, cylindrical flowers. The green leaf, which
 is found at the base of the empdment, becomes a
 rough fruit about twice the size, including UM cr

This genus of plants is ranged in the eighth section
 of Li *Methodus botanica*, entitled M i c e a F.

BK7T I

CAS

Cyandra, the plants of this section have male and fe-
 male flowers, and the male flowers have many fla-
 mina; but he has joined this genus to the Fagus,
 making these of one genus, so that he has entirely
 abolished the title. However, as the male flowers
 of the Chestnut are formed into long catkins, and
 those of the Beech are globular, they may with
 propriety be kept separate; and this I chioofe to do,
 that it may be more intelligible to common readers.

The **SPECIES ARE,**
 1. **CASTANEA (Setiva)** foliis lanceolatis acuminato-ser-
 ratis, subtus nudis, Cebant with spear-shaped leaves,
 which are sharply serrated, and naked on their under side.
 Castanea sativa. C. B. P. 418. The nutted Chestnut.
 2. **CASTANEA** foliis lanceolato-ovatis acumi-
 serratis, amictis filiformibus nodosis,
 i. spear-shaped leaves, which are covered with
 their under side, and a slender knotted
 hairs. C. B. P. 418. The hairy Chestnut.
 3. **CASTANEA** foliis oblongo-ovatis, serratis,
 fructu rotundo, so echinato, Chestnut with shining,
 very large, round, prickly fruit.
 amplis Castanea foliis, fructu echinato. Plum.
 en. 49.

The Chestnut is : :rrc wLe* ddtr, ^ ou care, as
 much a. anyot them es which are pu p a
 this country, either fry ubj or beauty, being one of

 the year after planting, in March, cut ... midown tot'
 ... eye next the furface of the ... be ground,
 which will caufe them to make one ftroag upright thioot,
 and may be afterwards trained into good ftair trees;
 but 11 ... fhould not be practifed, ' nrl'i the ...
 have abfolutely lat their leading thioot; Tor although
 the ficnu of tht ... fhould be very crooked (» b
 generally checdi with ilicju when ypung ... yet when
 Uity are tranfplanted out, and have room to grow,
 as they increafe in bulk, they will grow more up-
 right, and their items will tweome ltrait, *j I | ...
 frequently ublcrvcd where there have been great
 plantatjora made of them,
 But in doing of this, you muft ... becanfid not todilturb
 or break their too: ... which, perhaps might detroy
 them, TJ<r! ... trees require no other training th' ... anttea-
 own leaves, which fhould be fuffered to rot ... in i
 mau ... and in the fpring of the year, the ground
 fhould have a light digging, when thiee fhould be
 lizual between their roots, but not too clofe to the
 trees, whic ... iiiiight be iii;
 After having remained three or four years in the
 nurfety, the) ... Tor trjnlp. ... either in
 ru*s ... grow for ... timber, or in quarter
 detached plantations, but if you intend them for timber,
 it is by much the better method to low them in
 furrows (as is prafticed for Oaks, Sec.) ... let them
 remain unremoved; for thefe trees are apt to ... lu li-ve
 a downright tap-root, which, being hurt by tranf-
 planting, n other a check to their upright growth,
 and caufes them to fhoot out into lateral branches, as
 is the call with tiu Oak, Walnut, &c.
 Therefore, wh<irMr any of thefe trecM are planttd
 for ciEither, they fhould remain unremoved; but
 where the II uit of them is more faight other, then it
 is certainly the better w.-, to tranfplant them; for as
 F f f in ni-

ttafpianUDB is a check to the luxuriant growth of trees, ib it is a promoter of their fructification, as may be evinced by observing low ihvubby Oaks, Walnut*, tic. which generally luvra greater plenty of fruit, ihsn any of ihc larger and mure vigorovu tea-, and the fruit of luth i pa is tauch luperka in taste, though the seeds of vljoi->ui irew arc vailly preferable for i inEuions of timber; for it is a com- im i observation, that, by laving feeds from dwarf trees or pisms, from time to time, they may >c rendered much luvver in their growth than Is their DS- rural size -, but where the fruit is moll dcji-, then they "luulil be taken from fuch trees as produce the liirt^iti and Twee left nuts, which are commonly found upon such trees as fpcad the moil, ujd have hor- sants i roots ; for the weaker trees beinylefs capable LO fumilh a fupply of nuirifhmcni, and having a greater quantity of fruit upon them, to win: this mull be diltrib'ued, together with their roots; lying near the furface of the ground (by whicji means the juices ire better prepared by Inn, air, &c. befbre it enters vlinr vcltiii -L- deir juk < ir< bet- ter digefted !, and their fruits better matured, than mfc can poiTibly be, which grow upon [ttong vi- gorous trees, wllidi have long tap-roots running veral fcer deep into the earth, and conlcquently take in v,il quantities of crude unprejiarcd juite, which ji buoyed up 10 the extreme [aru of the tree; and ill fie ieldom hiiviti^many late rid brancht.-i, t' - light and prepare their juice, by perfpiring and tin- woy off : c crude part before it enters the fruits.

And this, 1 OJK Cy, I univerfally holds good in all forts of fruit trees, and is c:ini the occafion of tie good and bad qualities of die Eune lores of tVuits growing nli the fame foil.

What has been related about (^raiting this tree into L- Walnut, to proraote thal lie^ina, oi rentier ineir fruit l'airtrj or inoculatinr Cherries into the Cheiiut, for later fruit, is very whimftill and filly, fnee nci- tht.-:lii;Chdiuinor Wilnutivill receive its own kind any other way thin by jnocuhriag >r inarcUiuu, and it is the la i er only, by which the VWalnut can oe pro- psgitid ; nor was it ever known, that any two trees of i different genus would take upon ejuh other, > as ro produce either a good tree Oi fruit; cherefore we may juUuy explote ail thofe diferent "raftings of various t:ret upon each other, ib much talked of by tin- ancients ; at Irall we may fuppofte thioie creei are not !.lown by the liime names now, tlut the; are mnd i >nd by in itteir writings; fix 1 ban e matte many [rials upon diem, which, although pcdomcti with great care, and in diferent It-i:uns, yet fearCt!) line of them fucceded. But to return :

If HI defign a Ijr^o plantation of thefe trees for limber, after having two or three tim-t-i piovgli the ground, the better to clttroy the Ous of weeds, you fhould make your furrows about fix tea diltiict- froin each other, in which MAI ihuulil lay the nuts about ten inches apart, covering then) with earth about thro: inches deepj and, when they come up, \oii i mull carefully clear them (Wan wo : the dif- tance allowed betweca eiich row, is for t' : of the horle hoeing pltiugji, which will ilifpacdi a great deal of cilia work in a laort time, but it ihuuld be ;irr- (brmi with great eart, Ib js nouo injtn the younger plants; therefore the middle of the fpaci • only fhould be cleared with this iiftrntm, and a hand hoc mull be ufed to titan between the plants in the RW, and also on each lide, where it will be unlife for the plinth to be drawn: and in hand hoeing, there mull be great tare Wken, nrjt to cut the tender rind of the plants. If the following Iping the Spvxa are care- fully flirred with the plough, it will not on) make the ground rleenn, but alloloofen it, fo as that ike fun and noirtitrc may more eafily penetrate die fame, which will greatly promote the growth of die p- ants; and the oftener ihfc plough'ings are neared, the cleincr *Ut be tile § : and the greater will be the progrefs of die plana, which cinoot W.- I kept too clean while they are young. When thrfe li

maun i tht < orfcuti' years (if the nuts fuccceded in it) you will have many o: these trees to remove, which fhould be done at the I-sons before diltiched, leav- ing the trees about ih| feet diftance in the rows, at whicli tlitbiice they n ay remain for three or four years more, when you IIOIUJ renjii: every other tree to m. • room for the MOHuming, which will reduce the wholt plantjUiofl to fix • foare, Aich wil l u- chitance eno-ll gh for them to J remain in, until they are large enough for poles, wffin you ILLV cut down every • iher of tin to trees (making choice of the leafy promising,) within a foot of the ground, in order to make fuch foi poles, which, in eight or i.r. years time, will be frong enough Co lop for l'oope, hop poles, &c. for which purpofV they are prefer'd bk'to moft Othtr trees; fo that every tenth year, J er will be a freili crop, which wji pay the rent of the ground, and all othtr iDcumbent cli Jame itnK^ a tnU crop oi ^L. owing timber left upon the ground: but s^ (lit: 1 I've been in bulk, their diftance of twelve feet fquare will be too final; itieirfon: when they have grown to a fize for small boards, you :.n'ld tell cvrj other tree, which will reduce them to : • every four feet fquare, which is a proper diftance for them to remain for goods; this • will gin.* air co the under wood (which, by that time, wou'd be too r r. i • overthru by the difturb of the large trees) by Vliicli means that will be greatly en- couraged, and the small timber fell'd, will pay fuffi- ciiiitii intereR for tin. l' caulery as first had out to plant- ing, &c. with the pin i fual alio: in that all the re- maimng trca arc clew prutit, lor thi, under wood full out inumg, will jiny ilit rent i of the ground, and all othtr: capices | and what : fee there here will : lur a llii-i-iaing general ton. ti about fourcore years, J leave every one to judge.

TheChinctuajan, or Dwarf, Virguow Che&uc, is at prefent; very rare in Eoglaad: it is very CQinnm in the woods of America, where kfit! can grow ibwe twelve or fourtinfcet lii^li, • and produces great plenty of nuts, which ar^ l'ir the small part, fingle in CUh outer conr i Thia tree ij very I and will rt-Git the nuts at the --nttrrs in the open grounM, but ii v, cullly if it U pUnia ... of iteii; I've, if brought from ... ; i^ put up in land u fotm u tiey arc ... England uniatdiately, uthti wik t'ey lole UK. ing quality, which is tk rouon th'>tre < i> at'j to mance with us; foi not one ed in five < • I've Itn: ovci ever grew, wfiich w-s <iwin^ to tilt m of puttiivr diem up in ttis • iir;>er: inc. and, moft of the BU which i've been bluuigi: over, have been kiln-dried, to prelim them from fputting, which infallibly deftr the germs. When the nuts ar- rive, they fhould be put into the ground as a bonaj portable-, a) if the winter fhould prove feverc, it will be proper t'i cover the ground with leaves, tan, or rttfohaulm, to rircven! the froil from t'urtTitirig thiegrourwl, as to diltich the mits. The fort of Chefntii delights in imoift oil; but if th wet conti- nues long upon the ground in winter, it is apt to kill the trees. This will take by inarding it upon the commuii fort, but tin- trees fo mpagued : idan fucced well.

I hve ken i r pocinun, ind feme nu < of u i dwarf Chefnut, which were brought from South America, which differed fram ail the other forts, and \ have been nformtd, that the French have iulld plantj of this kind, from the nuts which were broughti from Canada; but ai 1 h*rc not been any clic pluit) rriifed in IMJIIIIII, I > an give no farther account of ii, than dm (brae of the late writ- have fupplid it niight Lt; the dwarf bunciiuir I had before men- tiOMd.

We have but one Species of this plant, viz.

CATERPILLAR. Lin. Sp. Plant. 109. The Lily Thorn. France ...

This shrub was discovered by Mr. ... near Naf-fau town, in the ... of Providence, where he saw two of them growing, which were all ... from them he gathered ... and brought them to England in 1736, from which nunv plants were raised in the English garden, ... which have since flourished here.

Branches with a branching stem, to the height of ten or twelve feet, which is covered with a pale ruffet bark; the branches come out alternately from the bottom to the top, which are furnished with ... resembling those of the Box-tree, coming out in clusters all round the branches; at certain distances; if the flowers come out single from the side of the branches, hanging downwards; they are ... and near six inches long, very narrow at their base, but widening upward toward the top, where it is divided into four parts which spread open, and are reflexed backward; the ... are of a dull yellow colour. After the flower decays, the garden twells ... oval flidly ben ... the size of a maddling Plum, hollow within, and filled with small ... seeds.

This shrub is propagated by seeds, which must be procured from the country where it naturally grows. If the seeds are brought over in fruit, the seeds will be better preserved; when they arrive in England, the seeds must be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark, and now and then moderately watered. If the seeds are good, the plants will appear in about six weeks after sowing; when, if the heat of the bed declines, the pots should be turned over to the bottom, and, if necessary, some fresh added to renew the heat, for these plants make but little progress the first year. When the pots are again plunged into the hot-bed, they must have fresh air admitted to them every day in proportion to the heat of the season, and frequently refreshed with water, in small quantities, for much wet will certainly kill them; if the winter should prove ... the plants should be covered with mats every evening. As the plants grow slowly, they will not require to be removed out of the hot-bed the first year. In the autumn the pots should be removed into a ... place, and plunged into the tan-bed. During the winter, the plants should

C E A

be watered with great caution, and in spring they should be carefully taken up, and each plant set in a separate small pot; till the light kindly ... artly, and j ... bed of ... being can't ill to shade them until they have taken fresh root; also to refresh them with water gently, as they may require it, and in spring, when the weather is warm, they should have good fire: admit to it; in autumn mull be removed into the iluv, where they should constantly remain, and not be treated afterwards in the same manner as the other ... plants.

This plant may be propagated by planting cuttings in small pots filled with light earth, during the month of July; the pots should be plunged into a moderate hot-bed of tanners bark, and the cuttings covered with small bell-glasses to it; if the weather is proper, the cuttings will put out roots in about two or three months, when they may be carefully separated, planting each into a small potted with light earth, and plunged into the hot-bed again, and afterwards mull be treated as the other plants.

Most of these plants which were raised from Mr. ... seeds, were killed by the ... in 1735; but (even years ago I received from ... seeds, which succeeded so well, as to ... innumerable plants to several curious persons in England.

CAULIFEROUS plants (see ...)

This is one of the umbelliferous plants with oblong seeds, which are a little flattened and prickly; the petals of the flower are unequal and heart-shaped. There are several species of this plant ... in the ... Locality ... I shall pass them over with only ... that it ... in autumn, soon after they are ripe ... kept till spring, they will produce ... They are much of use in ... and require to be sown every year. We have four or five species of them, which ...

The Character is,

It hath a ... of the leaf, ... the flower hath five ... petals which spread open, and are ... than the ... ; the ... and are ... of ... terminated in ... ; the ... of ... The ...

This genus of plants is ranged in the first section of Linnaeus's fifth class, ... Monogynia, the flower having five ... and two style.

The Species are,

- 1. CEANOTHUS (Africanus) Folia triseriata. !. in. Sp. Plant. 105. Cassia with leaves having three a rev. Eucalyptus Nova Belgii ... Hort. Amst. 1. 157. New Zealand ... 2. CEANOTHUS (Africanus) Folia ...

3. CEANOTHUS (*Arborefcens*) foliis ovatis fefilibus nervofus floribus alaribus. *Ceanothus with oval nervous leaves fet clofe to the branches* flowers proceeding from the wings of the leaves* commonly called Red-wood.*

The firft fort grows naturally in moft parts of North America, from whence great plenty of the feeds have been of late years brought to Europe, by the title of New Jerfey Thea, where I have been informed the inhabitantfuily the leaves of this fhrub to ufe as Thea. The people of Canada ufe the root in venereal cafes, I have received the feeds of this fort from New England, Penfylyania, Virginia, and Carolina; and the French mention it as a common fhруб in Canada, where they fay the cattle browse upon it, and keep it very low.

In England this fhруб feldom rifes more than three or four feet high, fending out branches on every fide from the ground upward. The branches are very tender, and as it is pretty late in the fpring before they begin to fhoot, they keep growing very late; therefore, unlefs the autumn proves dry and mild, the tender fhoots are often killed down very low by the early frofts; but, in favourable feafons, the extreme parts of the fhoots only are injured by the cold. Thefe branches are garnifhed with oval pointed leaves, having three longitudinal veins running from the foot-ftalk to the point, which diverge in the broad part of the leaves from each other: the leaves are placed oppofite, and are of a light green colour. At the extremity of each fhoot the flowers are produced in clofe thick fpikes, which are compofed of five fmall leaves, of a clear white. Thefe appear in July, and make a pretty appearance during their continuance; for, as every fhoot is terminated by one of thefe fpikes, the whole fhруб is covered over with flowers, the branches commonly growing very clofe to each other*, and when the autumn proves mild, thefe fhruvs often flower again in Oftober. After the flowers are paff, there fucceeds to each flower a tricarpular feed-veffel, flattened at the top, opening into three cells, each having a fingle feed. In warm feafons the feeds ripen in England. This fhруб is beft propagated by feeds, which fhould be fown in the autumn in fmall pots, laid plunged into an old hot-bed, ^{^v\^r*} they may remain during the winter, expofing them to the weather to the open air, but in froft they muft be protefted from cold. In March the pots fhould be plunged into a moderate hot-bed to bring up the plants, which fhould be inured to bear the open air by degrees; and as foon as they have obtained a little ftrength, they fhould be expofed in a fheltered fituation till autumn, when they muft be placed under a hot-bed frame, to free them from fevere froft in winter; but in mild weather they fhould be fully expofed to the open air, for while the plants are young, they will not endure the cold of the winter. In the following fpring, before the plants begin to fhoot, they fhould be tranfplanted; fome of them may be put into feparate pots, and the others into a nurfery-bed, in a warm fituation, where they may remain a year or two to get ftrength, after which time they may be removed to the places where they are defigned to remain. They fhould have a moderately dry foil and a fheltered fituation, where they will thrive and flower extremely well; but in ftiff cold land, they are always very late in the fpring before they come out, fo that their young fhoots are full of fap in the autumn, and the firft froft commonly kills their tops, which frequently caufes them to die great part of their length.

It may alfo be propagated by laying down the young branches, which, in a light foil, will put but roots in a year's time, but thefe layers fhould not be much watered*, for as the fhoots are tender, moifture will often occafion their rotting, when it is given in quantities, or top often repeated; therefore the beft method is to cover the furface of the ground in dry weather, all round the layers, either with mulch or rotten tan, which will preferve a fufficient moifture in the ground, provided the feafon is not extremely dry*

in which cafe they fhould have a little water once in eight or ten days, which will be fufficient.

The beft time for laying down thefe branches is in autumn, and if after this is performed, the furface of the ground is covered over with fome old tan, taken from a decayed hot-bed, it will prevent the froft from penetrating the ground, which will fecure them from injury; and the fame covering will prevent the winds from drying the ground in the fpring, and thereby promote their putting out roots. Thefe layers, when rooted, may be taken up the following fpring, and treated in the fame manner as thofe raifed from feeds.

The fecond fort grows naturally at the Cape of Good Hope, from whence it was originally brought to Holland, and has been many years preferved there; and fince has been communicated to moft of the curious gardens in Europe, where it has been long known by the title of Aiaternoides, &c. and by fome authors it is titled Ricinoides Africana arborefcens, &c. but Dr. Linnaeus, having examined the characters more exactly, has joined it to this genus.

This rifes to the height of ten or twelve feet, with a woody item, covered with a rough dark-coloured bark, and fends out many weak branches, which hang downward; thefe while young are green, but afterward change to a purplifh colour. They are garnifhed with oblong pointed leaves, of a lucid green, which are fmooth, and flightly fawed on their edges. The Bowers are fmall, of an herbaceous colour, coming out from the fide of the branches; thefe fometimes appear in July, but are not fucceeded by feeds in this country, nor do the plants often produce flowers; fo that they are preferred only for the beauty of their fhining evergreen leaves, which make a variety in the green-houfe during the winter feafon.

It may be propagated either by layers or cuttings; the latter being a very fure and expeditious method, is generally preferred. The cuttings fhould be planted in the fpring into pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, obferving to fhade them in the heat of the day, and now and then refrefh them with water. In about two months or lefs, they will have taken root, when they muft be gradually inured to the open air, placing them in a flickered fituation till they have obtained ftrength, when they may be feparated, and each planted in a fmall pot filled with light earth, placing them in the fhade till they have taken frefh root; then they may be removed, and intermixed with other exotic plants for the fummer feafon. In autumn they muft be houfed with Myrtles, and other more hardy exotic plants, and treated in the fame manner.

The third fort grows naturally in the Bahama Ilands, from whence the late Mr. Cateby brought the feeds to England. It alfo grows naturally in Barbadoes and fome other Ilands in the Weft Indies, from whence I have received the feeds. This, in the countries of its natural growth, rifes to the height of forty or fifty feet, with large trunks, which are by the inhabitants fawn into boards, and were at firft efteemed for the beauty of their colour; but being expofed to the air, their colour vanifhed and they became pale, fo have not fince been much regarded.

In Europe, where the plants have been properly treated, they have grown to the height of twenty feet; and if the ftoves in which they were placed had been lofty enough, would have grown much higher. The item is ftrong, woody, and is covered with a light brown bark, which, when young, has feveral furrows; the branches come out irregularly from every fide the item, garnifhed with pretty large oval leaves, of a light green colour, having feveral longitudinal veins inclining to white. The flowers are fmall, of an herbaceous white, fo make little appearance; they come out from the wings of the leaves, and, in their native foil, are fucceeded by roundifh fruit almoft the fize of fmall Peafe, opening in three cells; in each is inclofed one fhining black feed,

ally, ;li I have lud nppou
of comparing it with
fome which I have befii
brought to England. The co-
lor of the fruit, before it opens, is of a brown colour; the
fruit gwiv ert'et, upon foot-^h

it, the
it, the
water cover divides at the bottom into five equal parts,
and when these fall off, and the feeds are disperfed,
the foot-ftalk and the column remain fome months
after on the tree.

It is propagated by feeds, which may be easily pro-
cured from the Bahama Iflands, from whence moft
of the good feeds which have come to England were
brought; for moft of these which have been sent from
Jamaica, although brought in these parts, have not
increas'd; whereas, those from the Bahama Iflands,
have grown as well as if they were immediately taken
from the trees. The feeds should be sown in small
pots filled with light sandy earth, and plunged into a
hot-bed of tannin's bath, giving them a gentle wa-
tering once a week: if the trees get good, the plants
will appear in five or fix weeks; and when they are
two inches high, a sufficient number of small
pots should be filled with light earth, and plunged
into the hot-bed a day or two, that the earth may be
warmed before the plants are put into the pots; also the young
plants should be shaken out of the pots, and carefully
separated, so as not to tear their roots, and each plant
put in a single pot, being careful to shade them till
they have taken fresh root; t; airerlvficJi they mltifbe

The firll fort STOWS naturally in Virginii, and many odier pans of North America, wherc it riles to the height of eight or ten feet; but in England there are few of them much more than half that licight. It generally puts out kvo or three ftems from the root, which divide upward into 4"verj branches, covered with a brown bark, garnifhed vjth leaves pfa tiirtc inches long, and two broad, whii. ed flittr-narily on thc branches -, the finw come out in loofc fpikes at the end of the branches j thefe are wiLL- made up of five oval petals, with a ggrmeh in the center, attended by five (laminar when the Bowers fall off, the germen fwclth to & three-torncred capful, of a fearlet colour, let full of fmall protuberances ; this opens in three cells, each containing a hard oval ftea, covered with a thin reJ pulp. This fhrub flowers in July, but rarely produces good feeds in England.

[t a propagated here by layers, which will take root in one year, the young branches only are proper for this purpofe. To that when there K not any of thefe near the ground, the main iblks flould be drawn, down, r.nj fattened with pegs to prevent their riling, and the ytiung lfoots from them fhould be bid. JVc bed Qme fordoing thi\ is in autumn, when they begin to call their leaven, and by that time twelve-month they will be fufficiently rooted, when they ihould be cut from the old plant, and planted in 3. mirfery for two or three years to get ftrengrh; after which, they muft be removed to the places where they are to remain. This ilineb grows naturally in moift places, In will not thrive wclfin a dry foil. It is very Wdy, and bears the cold of our winters very well. It is alfo propgated by feeds, which lire frequently brought from America i but as thefe rarely am we here Lijic enough to fow before the faring, fo the plants never come up the firfl year; therefore the feeds may be lbwn either in poti, or in a bed of loamy earth, keeping th«n clean from weeds during the fummcr; r.nd thole in the pott JhouW be placed W the (bade till the Mtuinn, when the pou fhould be either plunged kt;o die ground in a worm fltuation, or placed

CEL

placed under a common frame, to prevent the frost from penetrating through the side of the pots; and if the surface of those which are plunged in the ground, and also the bed where the feeds are sown are lightly covered with some old tan from a decayed hot-bed, it will secure the feeds from being hurt by severe frosts. In the spring the plants will come up, which must be kept clean from weeds, and, if the season proves dry, they should have water now and then, which will greatly forward their growth. If the plants make good progress the first summer, they may be transplanted into a nursery in autumn, otherwise they should remain in the feed-bed till the second year, when they may be treated in the same manner as the layers.

The second sort sends out several ligneous stalks from the root, which are flexible, and twist themselves about whatever trees and shrubs grow near them, or when they are at a distance from such support, they twine about each other, and rise to the height of twelve or fourteen feet; but when they fall themselves about trees they will grow much taller, but wherever this happens, their branches girt the trees so closely, as in a few years will destroy them. These are garnished with leaves about three inches long, and near two broad, which are fawn on their edges, and placed alternately on the branches; they are of a lively green above, and paler on their under side, having several transverse nerves from the middle to the side. The flowers are produced in small bunches toward the end of the branches, which are of an herbaceous colour, composed of five roundish petals, these are succeeded by roundish three-cornered capsules, which are red when ripe, spread open in three cells, disclosing the seeds in the same manner as our common Spindle-tree. This flowers about the beginning of June, and the seeds ripen in autumn. The seeds of this sort generally ripen well in England, and the plants may be propagated from the seeds, or by layers, in the same manner as the former sort; it delights in a strong loamy soil, rather moist than dry, and will grow in woods among other trees and shrubs, where, when the fruit is ripe, they make a pretty appearance. It grows naturally all over North America, and is extremely hardy.

The third sort is a native of Ethiopia, from whence the seeds were first brought to the gardens in Holland, where the plants were propagated, and have been since communicated to most of the curious gardens in Europe. This rises with an irregular stalk about three or four feet high, sending out several side branches, covered with brown bark, garnished with leaves about two inches long, and more than half an inch broad, some of which are pointed, and others are obtuse, they are stiff, of a lucid green, and come out irregular from the branches; these continue green through the year. The flowers are produced from the sides of the branches in loose tufts, many of them arising from one point, (landing upon long footstalks, they are of an herbaceous white colour, composed of five petals, which spread open, and five spreading stamina, which surround a swelling germen, supporting a tapering style, crowned by an obtuse trifid stigma; the germen afterward becomes an oval fruit, of a fine red colour, which opens in three cells, containing one oblong hard seed, the other two cells being generally empty.

This plant is commonly propagated by cuttings in Europe, which is more expeditious than raising them from seeds, because the seeds rarely come up the first year. The cuttings may be planted any time in summer; but those which are planted early, will have more time to get strength before winter. They should be planted in small pots, which will contain four cuttings in each; the earth of a kitchen garden, which is well cultivated, is as good as any for this purpose. The pots should be then plunged into a moderate hot-bed, and shaded from the sun every day, and gently refreshed with water now and then; when they have taken root they must be gradually

CEL

raised to the open air, and then placed in a sheltered situation till they have obtained strength, when they should be separated, and planted each in a small pot filled with the same earth, then placed in the shade till they have taken fresh root, after which they may be placed with other exotic plants in a sheltered situation till autumn, when they must be housed with Myrtles, and other hardy green-house plants, and will require the same treatment.

This plant has been titled African Barberry by some ignorant persons, I suppose from the resemblance of its fruit to that of the Barberry.

The fourth sort grows naturally at the Cape of Good Hope, from whence I received the seeds. This rises with a slender ligneous stalk to the height of ten or twelve feet, covered with a light Ash-coloured bark, and full of joints, which are armed with long spines, upon which grow many small leaves, the branches are slender, and armed with the same spines at every joint, but the whole plant is so weak, as to require some support, without which they would fall to the ground. The leaves come out in clusters without any order, which are shaped somewhat like those of the narrow-leaved Box-tree, but are longer, and of a looser texture; the branches are angular, and when young their bark is whitish. As I have not seen the flowers of this shrub, I can give no farther description of it.

This rises very easily from seeds, and the plants make great progress; for I have raised them four feet high in two years from seeds, without any artificial heat; and some of the plants have lived thro' two winters against a fourth-east wall, but these have shed their leaves in winter, whereas those which were removed into the green-house have retained their verdure through the year.

It may be propagated by cuttings, which should be planted in the spring, and treated in the same manner as hath been directed for the former sort; or if the young shoots are laid, they will take root in one year, and may then be transplanted either into pots, or against a good supported wall, where I find they will endure our ordinary winters without any protection; and if they are covered in severe frosts, they may be brought, when old, to live abroad without protection. Those in pots will require a little shelter in winter, but should not be tenderly treated, for that will cause them to have weak branches, nor will the leaves have so much verdure, as when they are exposed to the open air in mild weather.

The fifth sort grows naturally in Jamaica, and also in some of the other islands in the West Indies, where it rises to the height of eighteen or twenty feet, sending out many side branches, garnished with leaves somewhat like those of the broad-leaved Myrtle, which are slightly fawn on their edges; the flowers come out from the side of the branches in long bunches; they are white, and composed of five petals, having five stamina placed opposite to them, and a germen in the center which is channelled; this afterward becomes a fruit, having five cells, each inclosing an oblong seed.

This plant is at present rare in England, for the seeds seldom grow the first year, therefore when the seeds arrive here, they should be sown in small pots filled with light earth, and plunged into a tan-bed, where they should remain till the following spring, when they should be plunged into a fresh hot-bed of tanners bark, and if the pots are duly watered, the plants will appear in about a month after; when they are fit to remove, they should be planted into separate small pots, and plunged again into the tan-bed, being careful to water and shade them till they have taken new root, after which they should be treated in the same manner as other tender plants from the same countries.

CELERY or SALARY. See APIUM.

CELLS of plants [of Cellae, *La?*] are those partitions or hollow places in the hulks or pods of plants, in which the seed is contained.

The firft fort here mentioned, grow3 naturaly in America, from whence I have frequently received the fe-ds. This riles with on upright ftalk about tw feet high, garnilhed with oval leaves ending in poim, of a pale colour; thofe on the lower part bein^ four or five indies long, and one md a hiif broad in die middJe, but they diminish graduaUy in their tije upward. Toward the upper part of tilt-ftalk, there an a tem fide branches fent out which ftand ereft -, each of which b terminated Ky n (tender fpike of anil the principal ftalk is irnmirred by one whic] is much Ur^er; this is rwo or three inchii long, ant about a* thick us a nun's middle ringer, the whole Ipikc being of 1 fdvery colour. But therc is a variety Of thii with Ocmlet pyratu'dal Qnkef, intermixed with rfd toward fire top, the feeds of vluch I received from Dr. Linnxui, bi am inclinable ro think it a different from that which was figured by Dr. Martyn in his Dreader of rare plants, wliich I have cultivated many years in th Chelica garden, and have nt-ver found it to vary The Ipikc of' this is much thicker than that of Lin : and of equal fizc tie whole length; whrrai

hit tiiimijhrs aim oft to a [soirt at the top, and th colour* of both are very different. Thto fort ii annual like the other Amaranths, wi riiquires the lkm culture.

The fecond fort ii well known by its common appelUdun of Cockfmm, ivhiirh wn piven > it from the rbfm of in crefted head of fio- rcs, resembling a CocWcomb 1 of this there arc many varieties, which differ in their form, magnitude, and colours; but a they viry Em feedi they m not iiumimi n

dillinfl fpecie?. I have rwded great varieties of thofe from feeds which came from China, and other countries, but have generally found them alter in a few years, notwithUndine great care hji been taken in the faving of their KMS: the princijul ccciiion of their headiare red, puqlic, yellow, and whit'-; but I have had tome, whole hrtkl* have been varicyai'd with two or three colour. I alfo railed lome from feed* which I rrcivt-ii from I'crfia, whofe luadu were divided like a plume of feathen, whkh wtce of a beautiful Karlet colour, but theli* in a frw yeatt deg^nerateit: thtfore I hllal ini. hide M the different varieties of Cocklcomb, under this general title.

The feeds of the third fort were fent me from JJ-rniks by the btt Dr. HoulltKin. Xtris KIOWS naturally in moft of the Sugar I (lands, li Ma with a weak ftalk near four feet high, gamiftictl with oblong pointed leaves which (Utui ojuxifite at earh joint. The ftowrre come out in loole ptniclu ironi the tije of the falks, and alfo at the end of the bnocrhs : there are divided inv a great number of very 0 tjiike5, which an: of a pale yellow, (hining with a glo& tike filk. The plums ot' thii penlhed in the autumn, without perfittng their I«rda.

The fourth fort I received from China t this hattt a rowl lblk, which rifes three or four li-rt high, gamifted with oval leaves which arc not eared at th.ii twfe j the ftalk is cefnirmted by feveral fpikes of flowers which are Tariouly formed, fome being L-reflui, others are plumed like feathers, of a brigiu Icarlet colour, fo make a good appearance; but die feeds of this when circuUy fared, are apt to degenerate.

The fifth fort is of humbler growth, the team arc oval, fpear-fliapcd, ending in very fcute points; the btanchei jmrfeed from the wings of the leaves, al-ift the length of the Stalk, and are terminated by lkndcr fpiitci of flowen of no great beauty, therefor* the plant » prcferved as a variety in the botanic MM

The fixth fort growl tawrally -1-, it rik-s wi-Ji a *rry white woolly fULK ft *nee lett hgh. gartiiftieti -with obmfe woolly leaves; from the upper part of the ftalk tere are two or three (ender fide brwi Jib ;he principal ftalk) arc terminated by mx iikes ot' flowers: th'd flowers arc fo cioley wrapped up in r heir woolly empalemcns, as to be icarce vifibie to die naked eye, fo they make no tpueirance; but the extreme whiwnctof the ftalk, leaves, and fyikes, make a pretty variety among other tender plants during their continuance.

I daai it rentier-, the feeds I hould be fiwn in the ipring upon • hot-bed, and the ptmu floitld be trented in the lame way ai b dimmed for rhe Cock-combs-, but when the plana we fully grown, thiry fhoulM be removed into an airy gtafs-cife, where they may be Jcixncd from col'd and wet, but have free air admitted to thwrn in warm weather, OT!; they will WK perfect their feeds in this country.

In order to nave Urge fine Amaranth*, great care ihould be taken in the choke of the fetch] for itthi-y 1 are not carefully coltocted, the whole expence and trouble of nifing them will be loft When you arc provided with good feed*, they muft be fawn on a hot-bed (which fhould have been prepared a trw days before, that the violent hrit may be abated) about th; beginning of March] and in about a founight's time ! if the bei' is in good temper) the plants will rile-, but as they arc temler when they firft aj-pe*r, they require greM tare tor a few dayi nil they get fhength j firft, in giving them » doe proportion of air, to prevent their drawing Up and next to ketp them from too greit moiftjre, fer n fmall (hare of moifture will cuile their

10 rot: in lowing the feeds there Jhouki be cats taken Bbt tB put tin-nt too c'ofe, for when the pbnti come up in cluftcn, they rreqently fpoilrath other for want of room to grow: in .1 :«rtinrlit of thi«

weeks time the plants will be fit to remove, when you must prepare another hot-bed, covered with good rich light earth, about four inches thick, which should be made a few days, that it may have a proper temperature of heat; then raise up the young plants with your finger, so as not to break off the tender roots, and prick them into the new hot-bed about four inches distance every way, giving them a gentle watering to settle the earth to their roots: but in doing this, be very cautious not to bear the young plants down to the ground by hasty watering, which rarely rise again, or at least so as to recover their former strength in a long time, but very often rot in the items, and die quite away.

After the plants are thus planted, they must be screened from the sun till they have taken fresh root, but as there is generally a great steam rising from the fermentation of the dung, which condenses to wet against the glasses, and this dropping upon the plants, very frequently destroys them; so the glasses should be frequently turned in the day-time, whenever the weather will permit; but if the weather happens to prove bad, that you cannot turn your glasses, it will be of great service to your plants, to wipe off all the moisture two or three times a day with a woollen cloth, to prevent its dropping upon the plants. When your plants are firmly rooted, and begin to grow, you must observe to give them air every day (more or less, as the weather is cold or hot) to prevent their drawing up too fast, which greatly weakens their stems.

In about a month or five weeks these plants will have grown so as to meet; therefore should have another hot-bed, which should be of a moderate temper, and covered with the same rich earth about six inches thick, in which they should be planted (observing to take them up with as much earth about their roots as possible) at seven or eight inches distance every way, giving them some water to settle the earth about their roots, but be very careful not to water them heavily, so as to bear down the plants, (as was before directed) and keep them (shaded in the heat of the day, until they have taken fresh root, and be sure to refresh them often (but gently) with water, and give them air in proportion to the heat of the weather, covering the glasses with mats every night, left the cold chill your beds, and stop the growth of the plants.

In the middle of May you must provide another hot-bed, which should be covered with a deep frame, that your plants may have room to grow: upon this hot-bed, you must set as many three-penny pots as can stand within the compass of the frame; these pots must be filled with good rich earth, and the cavities between each pot filled up with any common earth, to prevent the heat of the bed from evaporating, and filling the frame with noxious fumes; then, with a trowel, or some such instrument, take up your plants (from the former hot-bed) with as much earth as possible to the roots, and place each (single plant in the middle of one of the pots, filling the pot up with the earth before described, and settle it down to the root of the plant with your hands; water them gently, as before, and shade them in the heat of the day from the violence of the sun, by covering the glasses with mats; refresh them often with water, and give them a good quantity of air in the day-time.

In about three weeks more, these plants will have grown to a considerable size and strength, so that you must now raise the glasses very much in the day-time; and when the air is (oft and the sun is clouded, draw off the glasses, and expose them to the open air, and repeat this as often as the weather will permit; which will harden them by degrees, to be removed abroad into the places where they are to remain the whole year: but it is not advisable to set these plants out until a week in July, observing to do it when the air is perfectly soft, and if possible, in a gentle shower of rain.

Let them at first be set near the shelter of a hedge for two or three days, where they may be screened from the violence of the sun, and strong winds, to which they must be inured by degrees; these plants, when grown to a good stature, perform very freely, and must be every day refreshed with water, if the weather proves hot and dry; otherwise they will flout, and never produce their plumes as fine as they would do if taken care of.

This is the proper management, in order to have fine Amaranths; which, if rightly followed, and the kinds are good, in a favourable season, will produce wonderful large fine heads, and are the greatest ornament to a good garden for upwards of two months: by this method, I have had plants five or six feet high, with crests near a foot in breadth; and I am persuaded, if the kind is good, (and there is no want of dung, or conveniences) in a kindly season, they will grow much larger.

By the middle or latter end of September, the Amaranths will have perfected their feeds, so that you must make choice of the largest, most beautiful, and least branching plants of each kind for seed, which you should remove under shelter, (especially if the weather proves wet, or the nights frosty) that the feeds may be perfectly ripened; in the choice thereof, be sure never to take any feeds from side branches, nor from the neck of the plume, but such only as are produced in the middle thereof, which in many plants, perhaps, may be but a small quantity; but I do assure you, it is those only you can depend upon, to have your kinds good the succeeding year.

CEL SIA. Lin. Gen. Plant. 675. The name was given to this plant in honour of Dr. Olaus Celsius, professor of philosophy and theology in the university of Upsal, in Sweden, by Dr. Linnaeus. We have no English name for it.

The CHARACTERS are,

*// bath an obtuse permanent stemment, which is as long as the petal, divided at the top into five parts. The flower is of one leaf, with a very short tube, spread open above, and cut into five unequal parts; the two upper being small, and the under larger. It hath four hairy stamina, which incline toward the upper segments of the petal, two of which are longer than the petal, and two are of the same length, terminated by small roundish stamens. In the center is situated a roundish germen, supporting a slender style, crowned by an obtuse stigma. * The germen afterward becomes a roundish capsule compressed at the top, fitting upon the empurment, having two cells which are filled with small angular seeds.*

This genus of plants is ranged in the second edition of Linnaeus's fourteenth class, intitled Didymia Angiosperma, the flower having two long and two short stamina, and the seeds being included in a capsule.

There is but one SPECIES of this genus at present known, which is,

CELSIA (*Orientalis*) foliis duplicato-pinnatis. Hort. Cliff. 321. *Celsia with double winged leaves. Verbaicum orientale* Sophie folio. Tourn. Cor. 4*. *Eajlern Mullen with a FHweed leaf.*

This plant grows naturally in Armenia, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, where they succeeded, and have been since communicated to most parts of Europe. In its natural place of growth, this is an annual; but in England it will rarely ripen its seeds, unless the plants come up in the autumn and live through the winter.

It sends out many oblong leaves, which are finely divided almost to the mid-rib on both sides; these lie flat on the surface of the ground, and from the center arises a roundish herbaceous stalk near two feet high, garnished the whole length with leaves of the same shape, but diminishing in their size gradually to the top: these are placed alternately, and at the foot of each come out the flowers, more than half the length of the stalk, which are of an iron colour on their outside, but pale yellow within, spreading

ing open like thofe of the common Mullein, but are not fo regular *, the (hort tube being turned downward, and the lower fegments being larger than the upper, and the ftaminabeingunequal, have occafioned Linnaeus to remove: it to his ringent flowers. The feed-wiffel is round, compreffed, and hath two cells filled with fmall feeds. It flowers in June, and the feeds ripen in September: if the feeds of this plant are fown upon a warm dry border as foon as they are ripe, the plants will often come up and live through the winter, provided the foil is poor -, for in rich ground they are apt to grow rank, and then they are generally deftroyed by the early frofts, or will rot with much wet; but if the plants fhould not rife the fame autumn, there will be little hazard of their growing the following fpring. When the plants come up, they will require no other care but to keep them clean from weeds, and thin them if they are too clofe; for they do not bear removing well, fo fhould be fown where they are intended to remain.

I have fometimes, when the feafons have proved warm, had ripe feeds from plants fown in the fpring; but this cannot be depended on, therefore it is much better to fow the feeds in autumn.

CELTIS. Tourn. Inft. R. H. 612. tab. 383. Lin. Gen. Plant. 101a. The Lote or Nettle-tree, in French Micocoulier.

The CHARACTERS are,

It hath male and hermaphrodite flowers on the fame tree: the hermaphrodite flowers are fingle, and fituated above the male. The empalement of the hermaphrodite flower is divided into five parts, in which there are no petals, but five fhort ftamina terminated by thick quadrangular fummits, which have-four furrows. In the center is fituated an oval germen, fupporting two reflexed ftyles crowned by a fingle ftigma. The germen afterward becomes a round berry with one cell, inclafing a roundifh nut. The male flowers have their empalements divided into fix parts and have no germen or ftyle, but in other parts like the hermaphrodite.

This genus of plants is ranged in the firft fe&ion of Linnseus's twenty-third clafs, intided Polygamia Monoecia, from the fame tree having male and hermaphrodite flowers.

The SPECIES are,

- i. CELTIS (*Auftralis*) foliis lanceolatis atuminatis, ferratis, nervofis. *Nettle-tree with fpear-Jhaped pointed leaves, which are veined and fawed on their edges.* Celtis fru&u nigricante. Tourn. Inft. 612. *Lote-tree with a blackfruit.*
- i. CELTIS (*Occidental*) foliis obliquè-ovatis, ferratis, acuminatè. Lin. Sp. Plant. 1044. *Nettle-tree with oblique, oval, pointed leaves, which are fawed on their edges.* Celtis fru&u obfeurè purpurafcente. Inft. R. H. 612. *Lote-tree with a dark purple fruit.*
3. CELTIS (*Orientalis*) foliis ovato-cordatis, denticulatis, petiolis brevibus. *Nettle-tree with oval heart-Jhaped leaves, flightly indented, and fhort foot-ftalks.* Celtis orientalis minor, foliis minoribus & craffioribus, fructu flavo. Inft. Cor. 42. *Smaller Eaftern Lote-tree with fmailer, and thicker leaves, and a yellow fruit.*
4. CELTIS (*Americana*) foliis oblongo-ovatis, obtufis, nervofis, fupernè glabris, fubtus aureis. *Nettle-tree with oblong, obtufe, nervous leaves, which are fmooth on their upper furface, and of a gold colour beneath.* Celtis foliis citrii iùbtus aureo, fru&urubro. Plum. Cat. 18. *Lote-tree with Citron leaves, of a gold colour on their under-fide, and a red fruit.*

The firft fort grows naturally in the fouth of France, in Spain and Italy, where it is one of the largeft trees of thole countries: yet this is not fo plenty in England as the fecond, nor do I remember to have feen but two large trees of this fort in the Englifh gardens; one of which was formerly growing in the Bifhop of London's garden at Fulham, but was cut down fome years paft, * with many other curious exotic trees, which wqre there growing in great perfeftion: the other was in the garden of Dr. Uvedale at Enfield, which was there Handing a few years ago, when I paid a vifit to that place, which had frequently pro-

duced fruit, but was never propagated in this country 5 nor were there any young plants of this kind it the garden, till about fourteen years ago, when I procured a good quantity of the fruit from Italy, which I communicated to feveral of my friends.

This tree rifes with an upright ftem to the height of forty or fifty feet, fending out many (lender branches upward, which have a fmooth dark coloured bark, with fome fpts of gray; thefe are garnifhed with leaves placed alternately; which are near four inches long, and about two broad in the middle* ending in long fharp points, and deeply fawed on their edges, having feveral tranfverfe veins which are prominent on their under fide. The flowers come, out from the wings of the leaves all alding the branches 5 they have a male and an hermaphrodite flower generally at the fame place, the male flowers being fituated above the others: thefe have no petals but a green herbaceous empalement, fo make no figure 5 they come out in the fpring, at the fame time when the leaves make their firft appearance, and generally decay before the leaves have grown to half their magnitude. After the flowers are paft, the germen of the hermaphrodite flowers become a round berry about the fize of a large Pea, which, when ripe, is black.

The fecond fort grows naturally in North America; it delights in moift rich foil; in which it becomes a very large tree. This rifes with a ftrait ftem, which in young trees is fmooth, and of a dark colour, but as they advance, it becomes rougher and of a lighter green. The branches are much diffufed on every fide, and are garnifhed with oblique oval leaves, ending in points, fawed on their edges; they are placed alternately on the branches, with pretty long foot-ftalks. The flowers come out oppofite to the leaves, upon pretty long foot-ftalks *, the male flowers ftanding above the hermaphrodite as in the other fpecies -, after thefe decay, the hermaphrodite flowers are fucceeded by roundifh berries, which are fmaller than thofe of the firft fort, and when ripe, are of a dark purple colour. This tree flowers in May, and the feeds ripen in Oftober. Of this fort there are feveral pretty large trees in the Englifh gardens, fome of which produce great quantities of fruit annually, which in favourable feafons come to maturity, fo that from thefe feeds there have been plants raifed *, and there are few years, in which there is not fruit of this fort fent from America, whereby it is now become pretty common in the Englifh nurseries.

This tree is late in coming out in the fpring, but in recompenfe for that, it continues as long in beauty in the autumn, for it is the lateft in fading of any of the deciduous trees *, nor do the leaves alter their colour long before they fall, but continue in full verdure till within a few days of their dropping off; and, fo foon as they begin to fall, the trees will in a few days be quite deftitute of leaves, fo that the litter which their falling leaves occafion, may be fooner cleared away, than that of any other deciduous tree. There is little beauty in the flowers or fruit of this tree; but, as the branches are well clothed with leaves, which are of a fine green colour, the trees* when mixed with others in wilderneffes, make a pleafing variety during the fummer feafon. The wood of this tree being tough and pliable, is eftemed by coachmakers for the frames of their carriages.

The third fort was difcovered by Dr. Tournefort in Armenia, from whence he fent the fruit to the royal garden at Paris, where they fucceeded, and the trees, which were there raifed, have produced fruit for feveral years, fo that moft of the curious gardens in Europe have been furnifhed with it from thence. It rifes with a ftem about ten or twelve feet high, dividing into many branches, which fpread horizontally on every fide, having a fmooth greenifh bark, garnifhed with leaves about an inch and a half long, and near an inch broad, inclining to a heart-fhape,

but are blin... one of the cars of the bale being smaller and lower than the other, they are of a thicker texture than those of the common fort, and of a paler green, placed alternat on the branches, and have three ... The flowers ... E one from the first-blake of the leaves, in the same manner as the former, and ... re liittTcdeti by ova! yelkw berries, when fully ripe, turn 01 a da ... >ir. The wood ... this tree is very white.

Their trees are all propagated by seeds, which should be sown soon after they are ripe, when they can be procured at that season. For these frequently come up the following spring; whereas, those which are sown in the spring, will not come up till a twel remtmih after; therefore it is the best way to sow ;ticm in jxits or nibj, [fur they m>y bi* I fully respon cd, for thiofi: which are sown in the spring should be plant d in a shady situation in summer, and constantly kept clean from weeds; but in autumn they should be placed in a warm situation, plunging the pots into the ground; and if they are covered over with a ... tan from a decayed hot-bed, it will prevent the frost from penetrating the earth » inj ... And it" their pots are placed on a gentle hot-bed, in the tyri ... it will greatly forward the vegetation ... the seeds, whereby the plants will have more time to get through before I he Winter: but iviicn the plants appear above ground they must have a large share of air admitted to them; ... olWwif: they will draw up weak, and as soon as the weather is warm, they must be cjtjracti to the open air, and in summer they :utl be constantly itept clean from weeds; if the season proves dry, they will ttqake water two or three rimes' a week. In autumn it wiif be proper to remove the pots, ... md j'l' c tK m ... xdtmmc, t ... ter tiem in winter froi : ... where there ft r.M tiat convenicney, the pots should be plunged into the ground near plinis, when young.» ... full of top, and tender, the early tVufi in jtunimn fVequia

... covered with mats, or a litle (haw or PesTc-haulm) over them to protect them. In the following spring the [plants (hould be taken out of the first-pots, and planted in the full ground: this should be done about the middle or latter end of March, when the danger of the frost is over; therefore a bed or two should be prepared (according to the number of plants raised) in a sheltered situation, and, if possible, in a grassy leamy field. The ground must be well raked, and cleared from the roots of bad weeds, and when levelled, should be marked out in lines at one foot distance; then the plants should be carefully turned out of their pots, and watered, if necessary, to near their roots, and plant d in the lines at six inches asunder, pushing the earth down close to the roots. If the ground is very dry when they are planted, and there is no appearance of rain soon, it will be proper to water the beds. 10 fetde thit gfuund to the roots of the plants; and after this, if the surface of the ground is covered with some ...] ran or rain dng, it will fceep it u;>ic, and prevent the drying winds from penetrating to the roots of the plants.

The following summer, the necessary care must be to keep them constantly clean from weeds; but after the plants are pretty well established in the ground, they will not require any water, especially towards the latter end of summer, for that will occasion their late growth, whereby they will be in great danger of suffering by the autumn frosts; for the more any of these young trees are stopped in their growth by drought towards autumn, the firmer will be their texture, so better able to bear the cold.

The plants may remain in their nursery-beds two years, by which time they will have obtained sufficient strength to be transplanted where they are designed to remain for good, because their roots will have spread their roots wide every way; and if they stand long in the nursery, their roots will be cut in

ring, which HW. be a great prejudice M their future growth.

These Sorts are hardy enough to thrive in ihr open air in England, alter they tut become ibtrne; bite fur the two first win ten after they come Dp from their roots, they rtquire a litde prtM&ion, dj scially the ih:d fort, wiiL'i is ten Jf rer than either of the farmer. The young pliiits of this fort ... i-ufnrly Jntve varitgjcd craves, but timic art more ii: parent of child than the plain leaved,

The fourth sort was first discovered I ij father Plumier, in the French islands of America; and it was found growing in Jamaica, by Dr. Hansloot, who brought it to England. This tree with a fruit trtuk ten or twenty feet high, covered with a gray bark, divided into many branches upward, furnished with small leaves four inches long, and two and a half broad, rounded at their extremity, of a thick texture, very smooth on their upper surface, and on their under side are of a lard gold colour, placed alternately on the branches. The fruit is round and red, but the lionets I have not;

I hi? fccets if this fort; they come up the first year, but they may be raised in pots, and plunged into the tan-bed in the flower, where they should remain till the plants come up. These plants must be constantly kept in the bark-liver, and treated in the same manner as other tender exotics.

CENTAURIA R.E.A. Lin. Gen. Plant. Hist. Centaureum majw, Tom. 1. fol. 11. 449. tab. 270. Juss. Tournef. 443. Cyana. Tournef. 445. Greater Centaury, Knapp. ... Blue Borage, &c.

The CHARACTERS are, ft bt, ch a compound flower, white dyl: :t emspujtd </iwur/ ... trj ir TSJI of finxU ... infinded ... ttmf-

J fnumit; tit germn, is figured under the title, separating a female style, ornamented with an oblong stigma. The germen afterwards becomes a single seed, and is in the envelope. The female flower bears a slender tube, but expands above, where it is enlarged, and cut into five unequal parts, these are barren.

This genus of plants is ranged by the third edition of Linnaeus's sixteenth class, under the name of Centaury, the flowers of this section have their disk and middle composed of hermaphrodite florets, which are fringed, and thwr bonk'rt of i'enuie abortive florets.

22. **CENTAUREA** (*Spherocephala*) calycibus palmato-fpinofo, foliis ovato-lanceolatis petiolatis dentatis. Hort. Cliff. 422. *Centaury with a palmated prickly empalement, and oval, spear-shaped, indented leaves, having foot-stalks.* *Jacea spherocephala fpinosa Tingitana.* H. L. 332.
23. **CENTAUREA** (*Eriophora*) calycibus duplicato-fpinofo lanatis, foliis femidecurrentibus integris finuadque caule prolifero. Hort. Upfal. 272. *Centaury whose empalement is downy and doubly armed with spines, running leaves, some entire, others sinuated, and a childing stalk.*
24. **CENTAUREA** (*Benedicta*) calycibus duplicato-fpinofo lanatis involucratis, foliis femidecurrentibus denticulato-fpinofo. Lin. Sp. 1296. *Centaury whose empalement is downy and doubly armed with spines, running leaves with indentures, terminating in spines.* *Carduus Benedictus.* Camer. Epit. 562. *Benedict Thistle.*
- There are many other species of this genus, which are preserved in botanic gardens for the sake of variety; some of which grow naturally in England, and are often troublesome weeds in the fields, so do not deserve a place in gardens; therefore I chose not to trouble the reader with mentioning their titles, but have here selected those species which have some beauty to recommend them.
- The first sort grows naturally upon the Alps. This hath a perennial root, which strikes deep into the ground, sending out a great number of long, winged, smooth leaves, of a glaucous colour; the stalks rise near four feet high, and divide upward into many branches, garnished with small leaves of the same form as the lower, each of these stalks is terminated by a single head of yellow flowers, composed of many florets; those which occupy the disk are hermaphrodite, but those of the ray are female. This flowers in June and July, and, in dry seasons, will perfect their seeds in autumn. It may be propagated either by seeds, or by parting their roots in the autumn, being careful not to divide the roots too small. The seeds should be sown in the spring on a bed of light earth; and when the plants are fit to remove, they should be transplanted into a bed of fresh earth six inches asunder, in which place they should remain till autumn, when they should be planted where they are designed to remain.
- The second sort stands in the list of medicinal plants of the college, but is very rarely used; the root is reckoned

reckoned to be binding, and good for all kinds of fluxes, and of great use to heal wounds. This grows naturally on the mountains of Italy and Spain; it hath a strong perennial root like the former sort, from which come out a great number of long winged leaves, which spread wide on every side, of a lucid green, and fawed on their edges; the flower-stalks are slender, but very stiff and divide upward into many smaller foot-stalks; these, together with the other stalks, rise five or six feet high, having at each joint one small winged leaf of the same form with the other: each of these foot-stalks is terminated by a single head of purple flowers, which are considerably longer than the empalement. This sort flowers in July, and in very warm dry seasons will produce ripe seeds in England. It may be propagated by parting of the roots in the same manner as the former sort, and the plants must be treated in the same way, but should have more room to grow, therefore it is not proper for small gardens; but in large open borders, or to intermix in open quarters with other tall growing plants, this will make a variety.

The third sort was discovered by Dr. Tournefort in the Levant, who sent the seeds to the royal garden at Paris, and from thence it hath since been communicated to most of the curious gardens in Europe. This hath a perennial root, which strikes deep into the ground, from which forings up a great tuft of long entire leaves, shaped like those of Wood, growing upright, with many upright stalks, which grow near five feet high, garnished with leaves coming out single at each joint, of the same shape as the under, but are less, and have a border or wing running along the stalk. The upper part of the stalk divides into two or three smaller, each of which is terminated by a single head of yellow flowers, included in a silvery scaly empalement. This flowers in July, but rarely produces good seeds in England. It may be propagated by parting the roots in the same manner as the former, and the plants may be treated in the same way, being equally hardy; and as this doth not spread so much as the last, it may be allowed a place in smaller gardens.

The fourth sort grows naturally in Austria. This hath a perennial root as the former, from which come out many winged leaves, which are hoary, the segments narrow and entire, the stalks rise near three feet high, dividing into several branches, which have a single winged leaf at each joint, of the same shape with the other, at the end of each stalk is one head of purple flowers, included in an oblong scaly empalement, each scale being bordered with small hairs like an eye-brow. The flowers appear in June, and the seeds ripen in August. This is propagated by seeds, which may be sown in a bed of common earth, in a nursery; and when the plants come up they must be thinned, and kept clean from weeds, and the following autumn the plants may be transplanted where they are designed to remain; after which they will require no further care. Two or three of these plants may be allowed a place in gardens where there is room, for the sake of variety.

The fifth sort grows naturally in the south of France, and in Italy: I received the seeds of this from Verona. It hath a perennial root, which doth not divide and spread as the former, but grows single, sending out in the spring several entire spear-shaped leaves, and afterward a single stalk, more than a foot high, garnished at each joint with one divided hoary leaf; and at the top comes out a single, large, scaly head, shaped like a cone of the Pine-tree, very taper at the top, where it closely furrounds the florets, whose tops just peep out of the empalement: they are of a bright purple colour, and appear in June, but are not succeeded by seeds in England, so cannot be propagated unless the seeds are procured from abroad. These seeds may be sown, and the plants afterward treated in the same manner as the last.

The sixth sort is the common perennial Blue Bottle, which by some is titled Batchelors Button. This is

so well known as to need no description; the roots of this sort creep under ground to a great distance, whereby the plant propagates too fast, and often becomes troublesome in gardens. It flowers in May and June, and will grow in any soil and situation.

The seventh sort differs from the eighth, in having much longer and narrower leaves, which are not so white, the heads of flowers are also smaller; but whether this is only a variety from the other, I cannot determine, having never raised either from seeds; for these plants spread very much by their creeping roots, which renders them barren, as is frequently the case with many other creeping rooted plants, few of which produce seeds: however, this plant has always retained its difference from the year 1727, when I first brought it to England; and as it propagates so fast, it is now become almost as plenty in the gardens, as the common broad leaved sort. This is equally hardy, and may be planted in any soil or situation, where many other sorts will not thrive, and during its continuance in flower will make a variety in the garden.

The eighth sort is annual, so is only propagated by seeds. This has been many years propagated in the English gardens, under the title of Sultan Flower, or Sweet Sultan. It was brought from the Levant, where it grows naturally in arable land among the corn. This sends up a round channelled stalk near three feet high, which divides into many branches, garnished with jagged leaves, of a pale green, smooth, and stand close to the branches; from the side of the branches come out long naked foot-stalks, each sustaining a single head of flowers shaped like those of the other species, which have a very strong odour, so as to be offensive to many people, but to others is very grateful. The empalement of these is scaly* round, and without spines; the flowers are in some purple, and others white, and likewise a flesh colour between them hath come from the same seeds. There is also a variety of this with fringed flowers, and another with fringed flowers, commonly called Amberboi or Emberboi: but these have degenerated to the common sort in a few years, although I have saved the seeds with great care, so I suppose they are only varieties. These seeds are commonly sown upon a hot-bed in the spring, to bring the plants forward, and in May they are transplanted into the borders of the flower-garden; but if the seeds are sown in a warm border in autumn, they will live through the winter; and these plants may be removed in the spring into the flower-garden, which will be stronger, and come earlier to flower than those which are raised in the spring. The seeds may all be sown in the spring on a common warm border, where the plants will rise very well, but these will be later in flowering than either of the other. The autumnal plants will begin to flower the middle of June, and will continue flowering till September; and the spring plants will flower a month later, and continue till the frost fops them. Their seeds ripen in autumn.

The ninth sort has been supposed to be only a variety of the former, which is a great mistake; for although there is a great similitude in their appearance, yet they are specifically different, so never alter. I have cultivated this sort upward of forty years, and have never observed the least variation in it. This is much tenderer than the former, so the seeds must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be transplanted on a fresh hot-bed to bring them forward: when they have taken root in this bed, they must have air admitted to them every day, to prevent their drawing up weak, and refreshed with water sparingly, because they are very apt to rot with much wet. When the plants have obtained strength, they must be carefully taken up, and planted in separate pots filled with light earth, and some of them placed in the shade till they have taken root; then they may be placed with other annual plants in the pleasure-garden, where they will continue long in beauty. But as these plants which

itt j.: should be two or three plants kept in a moderate hot teaep frame, where they will come earlkr to flower, and being Brote&cd from wet and soil, they will ripen their leed every year, which a the in all method L to pfercm the fruit.
 This fort dirfvs from the COOM. In its IVM being laived o" ihtireti; the flowers are bluish, of abrigbtcakntr, and have a very agreeable fe-leftodour.

The eighteenth fort fitews naturaiij- in C<-ti-. This hath a [xmnnin] root l the lower Unvss are • and vrry woolly, dift on th i f c l k are fingle, wedge-fhaped, and indented; the ftalks are terminated by heads of yellow flowers, compofed of a many

florets as the other forts. This flowers in July, but rarely produces ripe feeds in this country, fo is propagated by flips as the fifth fort; and as the plants which are expofed to the open air in winter are frequently deftroyed, it will be proper to piace one of two of them under a common frame to preferve the fpecies.

The nineteenth fort grows naturally in Portugal: the ftalks of this are perennial; the leaves continue in verdure through the year, for which it is chiefly valued, for the flower has little more beauty than the common Knapweed. It flowers in June and July, and in warm feafons the feeds ripen in September. It is propagated by feeds, which, if fown in April in a bed of light earth, the plants will rife eafily. Thefe plants, in a dry foil and a fheltered fituation, will live in the open air in mild winters; but as they are frequently killed when the frofts are fevere, it will be proper to fhelter a plant or two under a common frame in winter to preferve the fpecies.

The twentieth fort grows naturally in Spain, and upon the Helvetian mountains. This rarely continues longer than two or three years: the lower leaves are doubly wing-pointed, thofe on the ftalks are fpear-flaped, Ringed, and indented; the ftalks rife three feet high, and are terminated by flowers like thofe of the common Knapweed, having filvery empalements. It flowers in July, and the feeds ripen in September. If thefe are fown in April on a bed of light earth, the plants will come up, and will live through the winter in the open air.

The twenty-firft fort grows naturally in the Campania of Rome. This is a biennial plant in England; thofe plants which arife from feeds in the fpring feldom flower till the following year, and when they perfeft their feeds they die. The ftalks of this fort rife three feet high; the lower leaves are wing-pointed, without fpines; thofe on the ftalks run along the ftalks like wings; the flowers are large, red, and their empalements are ftrongly armed with fpines. This flowers in July, and the feeds ripen in September. It may be propagated by feeds as the former.

The fecond fort grows naturally in Spain and Mauritania. This is an annual plant, which rarely ripens its feeds in England; the leaves of this are fpear-lhaped, indented, and woolly; the ftalk rifes two feet high, dividing upward into three or four branches, which are terminated by pretty large heads of flowers, whofe expalements are woolly, and ftrongly armed with fpines. This flowers in July, and in warm feafons the feeds ripen in September. It is propagated by feeds as the two former forts.

The twenty-third fort grows naturally in Portugal. The ftalk of this rifes two feet high, garnifhed with woolly leaves, fome of which are entire, others are finuated on their borders, the ftalks are terminated by woolly heads of flowers, ftrongly armed with double fpines on the empalement, which almoft inclofes the florets. It flowers in July, and in warm feafons the feeds ripen in September. It is propagated by feeds as the former.

The twenty-fourth fort is the Carduus Benedi&us, or Bleffed Thiftle, which is frequently ufed as an emetic. It grows naturally in Spain and the Levant; in England it is propagated in gardens for medicinal ufe. It is an annual plant, which perfities foon after the feeds are ripe. The fureft method of cultivating this plant, is to fow the feeds in autumn; and when the plants come up, to hoe the ground, to cut up the weeds, and thin the plants; and in the following fpring to hoe it a fecond time, leaving the plants a foot afunder, which will ripen their feeds in autumn, and foon after decay.

CENTAURIUM MINUS. See GENTIANA.
CENTINODIUM, Knot Grafs. See POL YGONUM.
CEPA, the Onion.

The botanical charafters of this genus are the fame with thofe of Allium, to which it is now joined by the late fyftem; but as this work is intended for the inftrufion of fuch as are not well acquainted with the

fcience of botany* or who may have no inclination to ftudy it, and yet may want information how to cultivate the plants which are ufeul in the kitchen, I have chofen to treat of thefe under their former appellation. Mr. Ray and Tournefort admit of the fiftular leaves and fwelling ftalks, as chara&ers to diftinguifh the plants of this genus from Porrum and Allium.

The VARIETIES of the common Onion are,
The Strafburgh. Cepa oblong. C. B. P. 71.
The Spanifh Onion. Cepa vulgaris, floribus & tiincis purpurafcentibus. C. B. P. 71.

The white Egyptian Onion. Cepa floribus & tunicis candidis. C. B. P. 71.

..All thefe vary from feeds, fo that there are feveral intermediate differences which are not worth enumerating.

Thefe three varieties are propagated by feeds, which fhould be fown at the latter end of February or the beginning of March, on good, rich, light ground, which fhould be well dug and levelled, and cleared from the roots of all bad weeds; then the feeds fhould be fown in a dry time, when the furface of the ground is not moift; and where they are intended for a winter crop, they muft not be fown too thick. The common allowance of feed is fix pounds to an acre of land; but the generality of gardeners fow more, becaufe many of them allow for a crop to draw out, which they call cullings; thefe are all fuch as want to be removed from others, fo are thinned out when young, and tied in bunches for the market; but thofe who have regard to their principal crop, never practice this; therefore fow no more feeds than is fufficient, which is the quantity before-mentioned, for when the plants come up too clofe, they draw each other weak; and when this happens, their roots never grow fo large as thofe which are thin: befides, there is a greater trouble in hoeing them; and when they are thinned for the market, the ground is trodden over, and the Onions which are to ftand have their leaves bruifed, whereby they are greatly injured; fo that where young Onions are wanted, it is a much better way to fow fome feperate beds for this purpofe, than to injure the future crop.

In about fix or feven weeks after fowing, the Onions will be up forward enough to hoe; at which time (choofing dry weather) you fhould, with a fmall hoe about two inches and a half broad, cut up lightly all the weeds from amongft the Onions; and alfo cut out the Onions where they grow too clofe in bunches, leaving them at this firft hoeing at leaft two inches apart. This, if well performed, and in a dry feafon, will preferve the ground clear of weeds at leaft a month or five weeks; when you muft hoe them over a fecond time, cutting up all the weeds as before, and alfo cut out the Onions to a larger diftance, leaving them this time three or four inches afunder. Thfs alfo, if well performed, will preferve the ground clean a month or fix weeks longer, when you muft hoe them over the third and laft time.

Now you muft carefully cut up all weeds, and fingle out the Onions to near fix inches fquare; by which means they will grow much larger, than if left too clofe. This time of hoeing, if the weather proves dry and it is well performed, will keep the ground clean until the Onions are fit to pull up; but if the weather fhould prove moift, and any of the weeds fhould take root again, you fhould, about a fortnight or three weeks after, go over the ground and draw out all the large weeds with your hands; for the Onions having now begun to bulb, they fhould not be difturbed with a hoe.

Toward the middle of Auguft your Onions will have arrived to their full growth, which may be known by their blades falling to the ground and fhrinking; you fhould therefore, before their necks or blades are withered off, draw them out of the ground, cropping off the extreme part of the blade, and lay them abroad upon a dry fpot of ground to dry, obferving to turn them over every other day at leaft, to prevent their

Striking fresh root into the ground; which they will suddenly do, especially in moist weather.

It about a fortnight's time your Onions will be dry enough to house, which must be performed in perfect dry weather *, in doing of this, you must carefully rub off all the earth from the roots, and be sure to mix no faulty ones amongst them, which will in a short time decay, and spoil all those that lie near them; nor should you lay them too thick in the house, which would occasion their sweating, and thereby rot them; nor should they be put in a lower room, or ground floor, but in a loft or garret; and the closer they are kept from the air, the better they will keep. You should, at least, once a month, look over them to see if any of them are decayed; which if you find, must be immediately taken away, otherwise they will infect all that lie near them.

But notwithstanding all the care you can possibly take in the drying and housing of your Onions, many of them will grow in the loft, especially in mild winters, which are generally moist; therefore those who would preserve them late in the season, should select a parcel of the firmest and most likely to keep from the others, and with a hot iron (lightly singe their beards, or roots, which will effectually prevent their sprouting; but in doing of this there must be great caution used not to scorch the pulp of the Onions, for that will cause them to perish soon after.

The best Onions for keeping are the Straßburgh kind, which is an oval-shaped bulb; but this seldom grows so large as the Spanish, which is flatter; the white lbrt is esteemed the sweetest *, but these varieties are not lasting; for if you have feeds of white Onions only, you will have a mixture of the red ones amongst them; nor will the Straßburgh Onion keep long to its kind, but will by degrees grow flatter, as do the large Portugal Onions, when planted in our climate, which in a year or two will be so far degenerated, as not to be known they were from that race.

But in order to have feeds, you must in the spring make choice of some of the firmest, largest, and best shaped Onions (in quantity proportionable to the feed you intend to have;) and having prepared a piece of good ground (which should be well dug, and laid out in beds about three feet wide,) in the beginning or middle of March you must plant your Onions in the following manner. Having traced a line about four inches within the side of the bed, you must, with a spade, throw out an opening about six inches deep, the length of the bed, into which you should place the Onions, with their roots downward, at about nine inches distance from each other; then with a rake draw the earth into the opening again to cover the bulbs; then proceed to remove the line again about a foot farther back, where you must make an opening as before, and so again till the whole is finished; so that you will have four rows in each bed, between which you must allow a space of two feet for an alley to go among them to clear them from weeds, &c. In a month's time their leaves will appear above ground, and many of the roots will produce three or four stalks each; you must therefore keep them diligently cleared from weeds, and about the beginning of June, when the heads of the flowers begin to appear upon the tops of the stalks, you must provide a parcel of flakes about four feet long, which should be driven into the ground, in the rows of Onions, at about six or eight feet apart; to which you should fasten some packthread, rope yarn, or small cord, which should be run on each side the Items of the Onions, a little below their heads, to support them from breaking down with the wind and rain; for when the feeds are formed, the heads will be heavy, and so are very often broken down by their own weight, where they are not well secured; and if the stalks are broken before the feeds have arrived to maturity, they will not be near so good, nor keep so long as those which are perfectly ripened. About the end of August the Onion feed will be ripe, which may be known by its changing brown,

and the Cells in which the feeds are contained openings so that if it be not cut in a short time, the feeds will fall to the ground: when you cut off the heads, they should be spread abroad upon coarse cloths in the sun, observing to keep it under shelter in the night, as also in wet weather; and when the heads are quite dry, you must beat out the feeds, which are very easily discharged from their cells *, then having cleared it from all the husk, &c. after having exposed it one day to the sun to dry, you must put it up in bags to preserve it for use.

The directions here given is for the general crop of winter Onions; but there are two other crops of this common sort of Onion, cultivated in the gardens about London to supply the market, one of which is commonly called Michaelmas Onions. These are sown in beds pretty close, the middle of August, and must be well weeded when they come up. In the spring of the year, after the winter Onions are over, they are tied up in bunches to supply the markets; but from the thinning of these they carry to market young green Onions in March, for fallads, &c.

And in the spring they sow more beds in the same manner, to draw up young for fallads, after the Michaelmas Onions are grown too large for that purpose; and where a supply of these are required, there may be three different sowings, at about three weeks distance from each other, which will be sufficient for the season.

There are also the following sorts of Onions cultivated in the kitchen-gardens.

The Shallot, or Echalottes, which is the *Cepa Acalonica*. Matth. 556.

The Ciboule, or *Cepa fiffilis*. Matth. Lugd. 1539.

The Gives, or *Cepa fe&ilil juncifolia perennis*, TVor, Hift. 2. 383.

The Welch Onion I suppose to be the same with the Ciboule, although they pass under different appellations; & I have several times received the Ciboule from abroad, which, when planted, prove to be what is generally known here by the title of Welch Onions. There is also a great affinity between the Echalottes and these, so that they are not well distinguished yet; for although they are generally cultivated in the gardens, yet they are not well known to the botanists,* some of whom have supposed a greater variety than is in nature; while others have joined them together, making but two species.

The Scallion, or Efcallion, is a sort of Onion which never forms any bulbs at the roots, and is chiefly used in the spring for green Onions, before the other sorts, sown in July, are big enough; but this sort of Onion, how much sooner in use formerly, is now so scarce as to be known to few people, and is rarely to be met with, except in curious botanic gardens: the gardeners near London substitute another sort for this, which are those Onions which decay and sprout in the house: these they plant in a bed early in the spring, which in a short time will grow large enough for use; when they draw them up, and after pulling off all the outer coat of the root, they tie them up in bunches, and sell them in the market for Scallions.

The true Scallion is easily propagated by parting the roots, either in spring or autumn; but the latter season is preferable, because of their being rendered more fit for use in the spring: these roots should be planted three or four in a hole, at about six inches distance every way, in beds or borders three feet wide, which in a short time will multiply exceedingly, and will grow upon almost any soil and in any situation; and their being so hardy as to resist the severest of our winters, and being green, and fit for use so early in the spring, renders them worthy of a place in all good kitchen-gardens.

The Cives are a very small sort of Onion/which never produce any bulbs, and seldom grow above six inches high in the blade, which is also very small and slender, and are in round bunches like the former;

* this

C E P

This was formerly in great request for fallads in the spring, as being milder than those Onions which had stood through the winter. These are propagated by parting their roots like the former, and are also very hardy, and will be fit for use early in the spring.

The Welch Onions are only propagated for spring use also; these never make any bulb, and are therefore only fit to be used green for fallads, &c. They are sown about the end of July, in beds of about three feet and a half wide, leaving alleys of two feet broad to go between the beds to clean them, and in a fortnight's time they will appear above ground, when they must be carefully cleared from weeds; towards the middle of October their blades will die away, so that the whole spot will seem to be naked, which hath led many people to dig up the ground again, supposing the crop totally lost; whereas, if they stand undisturbed, they will come up again very strong in January, and from that time grow very vigorously, resisting all weathers, and by March will be fit to draw for young Onions, and are, in the markets, more valued than any other sort at that season; for they are extremely green and fine, though they are much stronger than the common Onion in taste, approaching nearer to Garlick, which hath occasioned their being less esteemed for the table: but as no winter, however hard, will hurt them, it is proper to have a few of them to supply the table, in case the common sort should be destroyed by frosts.

The roots of these Onions, if planted out at six or eight inches distance, in March, will produce ripe seeds in autumn, but it will be in small quantities the first year; therefore the same roots should remain unremoved, which the second and third year will produce many stems, and afford a good supply of seeds; these roots will abide many years good, but should be transplanted and parted every second or third year, which will cause them to produce strong seeds.

C E P H A L A N T H U S. Lin. Gen. Plant. 105. *Platanoccephalus*; Vaill. Acad. R. Scien. 1722. Button Wood.

The CHARACTERS are,
// bath a number of small flowers, which are collected into a spherical head, these have no common empalement, but each particular flower bath a funnel-shaped empalement, divided into four parts at the top; the flower is funnel-shaped, of one petal, divided at the top into four parts, inclosing four stamina, which are inserted in the petal, and are shorter than the tube, being terminated by globular summits. The germen is situated under the flower supporting a style which is longer than the petal, and is crowned by a globular stigma; the germen afterward becomes a globular hairy capsule, inclosing one or two oblong angular seeds, these are joined to an axis, and form a round head.

This genus of plants is ranged in the first section of Linnaeus's fourth class, intitled Tetrandria; Monogynia, the flower having four stamina and but one style.

We have but one SPECIES of this plant, viz.

C E P H A L A N T H U S (*Occidentalis*) foliis oppositis ternisque. Flor. Virg. 15. *Button-tree with leaves growing opposite, and sometimes by threes. Scabiofa dendroides Americana ternis foliis caulem ambientibus, floribus ochroleucis.* Pluk. Aim. 336. tab. 77.

This shrub grows naturally in North America, from whence the seeds are annually sent to Europe, and of late years great numbers of the plants have been raised in the gardens of the curious; but there are no very large plants in the English gardens; the largest I have seen are in the curious gardens of his grace the Duke of Argyle, at Whitton, near Hounslow, where they thrive better than in almost any other place where they have been planted, so that in a moist soil they will do the best.

This seldom rises higher than six or seven feet in this country. The branches come out by pairs, opposite at each joint, the leaves also stand opposite, sometimes by pairs, and at other times there are three

C E R

arising at the same joint, standing round the branches these are near three inches long, and one and a quarter broad, having a strong vein running longitudinally through the middle, and some small transverse veins from that to the borders, they are of a light green, and their footstalks change to a reddish colour next the branches; the ends of the branches are terminated by loose spikes of spherical heads, about the size of a marble, each of which are composed of many small flowers, which are funnel-shaped, of a whitish yellow colour, fattened to an axis which stands in the middle, these appear in July, and, in warm seasons, are succeeded by seeds, which have sometimes ripened in England.

These plants are propagated chiefly by seeds (though there has been some raised from cuttings and layers) these should be sown in pots, for the greater convenience of removing them either into a shady situation, or where they may have shelter. If the seeds can be procured so early as to sow them before Christmas, the plants will come up the following summer; but if they are sown in the spring, they generally remain a year in the ground, therefore, in such case, the pots should be placed in the shade that summer, and in the autumn following removed under a common frame to shelter them from frost, and the spring following the plants will come up.

The first year, when the plants come up, it will be necessary to shade them in hot dry weather, while they are young, at which time they are often destroyed by being too much exposed, nor should the watering be neglected, for as these plants naturally grow on moist ground, so when they are not duly watered in dry weather, the young plants will languish and decay.

The next autumn, when the leaves begin to drop, the young plants may be transplanted into nursery-beds, which should be a little defended from the cold winds, and, if the soil is moist, they will succeed much better than in dry ground; but where it happens otherwise, it will be absolutely necessary to water them in dry weather, otherwise there will be great danger of the plants dying in the middle of summer, which has been the case in many gardens where these plants were raised.

In these nursery-beds the plants may remain a year or two (according to the progress they may have made, or the distance they were planted) then they may be taken up in October, and transplanted where they are to remain for good. Although I have mentioned but one season for transplanting them, yet this may also be performed in the spring, especially if the ground is moist into which they are removed, or that the plants are duly watered, if the spring should prove dry, otherwise there will be more hazard of their growing when removed at this season.

These plants make a pretty variety among other hardy trees and shrubs, being extreme hardy in respect to cold; but they delight in a moist light soil, where they will grow very fast, and their leaves will be larger than in dry land.

C E R A S T I U M. Lin. Gen. Plant. 518. *Moufe-ear, or Moufe-ear duckweed** in French, *Oreille de Souris*.

The CHARACTERS are,
It hath a permanent five-leaved empakment, which spreads opens the flower hath five obtuse bifid petals, which are as large as the empakment. It hath ten slender stamina shorter than the petals, terminated by roundish summits. In the center is situated an oval germen, from which arise five styles, which are hairy, erect, and crowned with obtuse stigma; the empakment afterward becomes an oval, cylindrical, or globular capsule with one cell, opening at the top, containing many roundish seeds.

This genus of plants is ranged in the fourth section of Linnaeus's tenth class, intitled Decandria; Pentagynia, the flower having ten stamina and five styles.

- The SPECIES are,
1. CERASTIUM (*Repens*) foliis lancolatis, peduculis ramosis, capfulis fubrotundis. Lin. Sp. Plant. 439. *Cerajium with spear-shaped leaves, branching foot-stalks, and roundish capfuls.* Myofotis incana repens. Tourn. Inft. R. H. 245. *Hoary creeping Moufe-ear, by some called Sea Pink.*
 2. CERASTIUM (*tomentofum*) foliis oblongis, tomentosis, pedunculis ramosis, capfulis globosis. Lin. Sp. Plant. 440. *Cerajium with oblong woolly leaves, branching foot-stalks, and globular capfuls.* Myofotis tomentosa, linariae folio angustiore. Tourn. Inft. R. H. 245. *Woolly Moufe-ear with a narrow Toad-flax leaf.*
 3. CERASTIUM (*Dicbotomum*) foliis lanceolatis, caule dichotomo ramofillimo, capfulis erectis. Prod. Leycl. 450. *Cerajium with spear-shaped leaves, a very branching stalk divided in forks, and upright capfuls.* Myofotis Hispanica legetum. Tourn. Inft. R. H. 54.5. *Spanijh Corn Moufe-ear, or Horned Chickweed.*
 4. CERASTIUM (*Pentandrum*) floribus pentandriis, petalis integris. Lin. Sp. Plant. 438. *Cerajium with flowers having five Stamina, and entire petals.*
 5. CERASTIUM (*Perfoliatum*) foliis connatis. Hort. Cliff. 173. *Cerajium whose leaves are joined.* Myofotis Orientalis perfoliata folio lychnidis. Tourn. Cor. 18. *Eastern perfoliated Moufe-ear with a Lychnis leaf.*

The first fort grows naturally in France and Italy, and was formerly cultivated in the English gardens under the title of Sea Pink, one of the uses made of it was to plant it as an edging to keep up the earth of borders; but this was before the Dwarf Box was brought to England, since which all those plants which were formerly applied for this purpose have been neglected. This plant was by no means fit for this use, because its creeping branches would spread into the walks where they put out roots into the gravel; so that unless they are frequently cut off, they cannot be kept within compass.

This sends out many weak stalks which trail upon the ground, and put out roots at their joints, whereby it propagates very fast; the leaves are placed by pairs opposite, which are about two inches long, and little more than half an inch broad, very hoary; those next the root are much smaller than the upper; the flowers come out from the side of the stalks upon slender foot-stalks, which branch out into several smaller, each supporting a white flower, composed of five petals, which are split at the top. The whole flower has the appearance of Chickweed flowers, but are larger, it flowers in May.

It propagates too fast by its creeping roots and trailing branches, when it is admitted into gardens, so may be planted in any soil or situation; and is very proper to be planted between (tones on the side of grottos, where it will spread, and thrive without care.

The seeds of the second fort I received from Istria, where it naturally grows; this is by Parkinson titled hoary narrow-leaved Pink. The leaves of this fort are narrower than those of the former, and are much whiter; the stalks grow more erect, and the seed-vessels are rounder, in which their chief difference consists. This is a trailing plant, and propagates by sending out roots at the joints, in the same manner as the former, and is equally hardy. It flowers in May and June, and the seeds ripen in August.

- The third fort is annual; this grows naturally on arable land in Spain, from whence the seeds were sent to England, where it is allowed a place in botanic gardens for the sake of variety, but hath not much beauty, this hath branching stalks, which grow about six inches high, dividing by pairs in forks, the flowers coming out in the middle of the divisions, which are fitted like those of Chickweed; the whole plant has a clammy moisture, which sticks to the fingers of those who handle it. This flowers in May, and the seeds ripen in July. If the seeds are sown in autumn, they will succeed better than in the spring; or if they are permitted to fall, the plants will rise without care.

The fourth fort is very like the third in its whole appearance, and differs from it, in having but five stamina in the flower, whereas the other hath ten. This was discovered by Mr. Loeffing, a pupil of Dr. Linnseus's, in Spain, from whence he sent the seeds to Upfal, part of which were sent me by the Doctor. The fifth fort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the royal garden at Paris, where they succeeded, and have been since communicated to most of the curious botanic gardens in Europe. This is an annual plant, which rises with an upright stalk a foot high, the lower leaves of this plant have much resemblance to those of the Lychnis, which is called Lobel's Catchfly, so that when the plants are young, it is not easy to distinguish them. The stalks are garnished with leaves of the same shape, but smaller, placed by pairs, and embrace the stalks at their base. The flowers come out at the top of the stalks, and alight from the wings of the leaves, on the upper part of the stalks, which are white, and shaped like those of Chickweed. They appear in May and June, and are succeeded by beaked capfuls, containing many roundish seeds.

If the seeds of this fort are sown in autumn, they will more certainly grow than those which are sown in the spring, or if the seeds are permitted to scatter, the plants will come up and live through the winter, and will require no other care but to keep them clean from weeds.

There are many other species of this genus than are here enumerated, which are weeds in many parts of England, so are never cultivated in gardens, therefore not worthy of notice here.

CERASUS [*ixtros*, Gr. so called according to Servius, from Cerasus, a city of Pontus, which Lucullus having destroyed, he carried the Cherry-tree from thence to Rome, and called it Cerasus, after the name of the city; but others will have it that the city took its name from the abundance of those trees which grew there.] The Cherry-tree.

The botanical characters of this genus, according to the system of Linnaeus, are the same with those of Prunus; therefore he has joined the Apricot Cherry, Laurel, and Bird Cherry together, making them only species of the same genus; but those who admit of the fruit, as a character to determine the genus, must separate the Cherry from the others, because they differ greatly in the shape of their stones; but there is a more essential difference in nature between them, which is, that the Cherry will not grow upon a Plumb-stock, by budding or grafting, nor will the Plumb take upon a Cherry-stock; and yet we know of no trees of the same genus which do not unite with each other, by budding or grafting.

However, as the joining so many genera into one, would occasion great confusion among gardeners, who cultivate these trees for sale, therefore if there were no other motive than that, it would be a sufficient excuse for not closely following that system in this work, which is designed for the instruction of those who have not made botany their study; so I (shall refer the reader to the article PRUNUS, under which the botanical characters will be inserted, and proceed to the species.

I (shall first enumerate the sorts which are specifically different from each other, and then mention the varieties of these fruits, which are cultivated in the English gardens; many of which seem to differ essentially from each other, that they may be allowed as specific differences; but as I have not had an opportunity of trying the various sorts from seeds, so see if they alter, so I chose to insert them only as varieties, till further observation may better settle their boundaries.

Two flrts with double flowers, one larger and fuller than the other, Thicfc arc propagated for ornament. The fecond fort -)ovc-menfined is the Blick Cherry, which is fuppofed to be a tiatire of England. This grws to be a large tree, fit for timber, and is frequently found growing a, fach in the woodi. From this, the only varietici *liitth I have ever known raised by •••etU, ire the Black Coraun, and the imall "WiWCherrr-, uf which there arr two or three-varieties, which differ in the 6w ind colour Oj their fruit.

Thcfe Wild Chfirw arc vrr>-proper w pUnr m p>rk?, becaufe thrr crow w a large iire, and make bwtiful tre>, and in* the fpring, when timjr are in flower, will be vrr,- ornamental. The twit of them will be TMd food for birds, as •': when the Axxare cut down, the wood i very ufcful for turners. Thcfe trees will thrive in poor la and better than moft other in TM fo there " in advantage in propagating them in their pl.ici. The French often plant them for avonics to their •••ies, upon fach land where they can K get any othtr trees 10 thrive. they alfo cultivate them in their Tuex- to cut i or hoops, and grtatty cilcem them for this purpofe.

The iices of this lart ire goncratly fown for raiQng flocks to graft or bud the other forts of Cherry a upes, being of quicker growth, and of longer duration than either of the other, fo are very juftly efteemed and preferred 10 ihem.

The wood of the fourth fort, is by the French peatly efteemed for making of c bins, becaufe it hath an agreeable odour. This, and the wood of the Bird Cherry, are often blended together, and put under the appellation of • Bob de S_ane Lacle; but the Bird Cherry is the true fort.

The fifth vrit w< brought tram Canada, where it grows natural U, to ih* garden* in France, where k

C E R

is cultivated as a flowering flirabfor ornament, The (tones of thti were lent me by Dr. Bernard de juUku* profcfbr of botany at Paris, which fuccceded ven ivcl) ij rlit: Ciiclfci garden; but by comparing thii- with a fyx-citnen of the old Chamxceraiiis, or CtraJus humilisof Cciitrd, and other old writers, I find it tn be the lbme planr, lor it alto agrees exafil; with their dL-feriptions of it.

This • a low firub, which Siidom grows more than three or four Ket high, tending out nuny horixontal brjneitrs, which rprtaui nrd dw ground on every tide-, and the lower brmdit-s arc very ibjctcl to lit in thK ground, where they ui!! put out roots, and (hi mulpny. The young branches have a wry fmooch bark, it'iclin'm^ ; toward rcd; the leaves are long, narrow, very Imoqtb, and entire, having tile ipp<-ar-ance of' lioftic llirci of Willow I vcs, of a light green i in their uper Bde, but of 3! • lilt or the green on tl. r under; the fl- -tri come out from the fide of the branches, two, three, ur four oririiig at the fame place, and part of the low lh of the young lhoatSi thec arr B and lilt fhwia of the civimom Chem-, but are foolcr, llonJing iip'jn long l, under foot-litlks. The fruit is like thafe of the Imall wild Cherry, [jut haii; a bitterifh favour. It flowers atout • at the fame time as the otter fora of Cherries, and the fruit ripen in July, the • fruit are good food for birds, and the French plant them among their otlier flirulie, to emice the birdi to harbour there.

It is: eafily propagated by laying down ilv: branchti early in the fpring, which will take root by tlw following autumn, uhrn they may b^ taken off; and cither phiitil in a nurfery v get flrengtk, or to the places where they art: dtligncd w rtmaint. It may alfo be propagated by laying tlw ftoicJ, in the fame mntn as other Cherries.

All the f. I. of Chenita i% h:di at ufually < cultivated in fruit-gardens, are propagated by budding or grafting the feveral kinds into flocks of the black or wild Red Cherries, which are frung ftocks, and of longer duration than •; of-the garden kinds. The ftimes of thcfe to 0 t-inds are fown in a bed of Hgfit &ndy <rrh in autumn (0: arc preferred in land till faring and thefc week.) WStocks arife they mull b. carefully wooded, and if in dry weatiter you n: :th them with •ittr, it will greatly promote their growth. Thcfe flocks lh: ilil fimAJn in the nurfery-lands till the fecond •••omt after fuwngi at which time you fhould prepare an open lymt of good freffi earth, which fhould be well watered but if the foil k tle, it will be the better. In the g-und, in October, you fhould plant out the young flocks At threc distance two fret in row, and about .1 foot afunder: the rows, being •••cilitil in taking them up irum iheir lied beds to loofen their roots wcl: with a fpade, to prevent their breaking, as Ub to prune their r. <u; JUUI if they are inclinab le to root Jown-wwdf, you fhould ihonen thit up-root to ciufe It to put out literal roots-, bur do not prune their tops, for this is what by no means they • ill endiirt.

The fecond year after planting out, if they take to growing well, they will ! IK fil IO bl. If they ;reir> tended for dwarts: but if (Key are for (b bards, they will not be tall enough until the fourth year. iirthey lould be budded ui _grafted near fix feet loin -hi ground, otherwise the graft will not advance much in IK light; fo that it will be impoffible to make a good tree from fuch as are grafted low, unlt the graft is raised upward.

The usual way with the nurfery gardeners is to bud their flocks in fummer, and fuch of them as mairry they graft the fucceeding fpring (the manner of thefe operations will be defcried under their proper heads.) Thofe trees where the buds have taken, muft be headed off in the beginning of March about fix inchi above the bud l and when the bud hath flax in it'um- mtr, if you fear its being blown out by the wind, you may fatten it Up with iumc bafs, ••• any other foft b'di to that pin of the folk wh>-li wji Jrfj abov<

the bud. The autumn following these trees will be fit to remove; but if your ground is not ready to receive them, they may remain two years before they are transplanted \ in doing which, you must observe not to head them, as is by many practised, for this very often is immediate death to them; but if they survive it, they seldom recover this amputation in five or six years.

If these trees are intended for a wall, I would advise the planting dwarfs between the standards; so that while the dwarfs are filling the bottom of the walls, the standards will cover the tops, and will produce a great deal of fruit \ but these, as the dwarfs arise to fill the walls, must be cut away to make room for them; and when the dwarf trees cover the walls, the standards should be entirely taken away. But I would advise, never to plant standard Cherries over other fruits, for there is no other sort of fruit that will prosper well under the drip of Cherries.

When these trees are taken up from the nursery, their roots must be shortened, and all the bruised parts cut off* and also all the small fibres, which would dry, grow mouldy, and be a great prejudice to the new fibres in their coming forth *, you must also cut off the dead part of the stock which was left above the bud, dole down to the back part of it, that the stock may be covered by the bud. If these trees are designed for a wall, observe to place the bud directly from the wall, that the back part of the stock that was cut may be hid from sight. The soil that Cherries thrive best in, is a freest hazel loam *, but if the soil is a dry gravel, they will not live many years, and will be perpetually blighted in the spring.

The sorts commonly planted against walls, are the Early May, and May Duke, which should have a fourth aspect wall. The Hearts and common Duke will thrive on a west wall *, and in order to continue this sort later in the season, they are frequently planted against north and north-west aspect walls, where they succeed very well *, and the Morello on a north wall, which last is chiefly planted for preserving. The Hearts are all of them ill bearers, for which reason they are seldom planted against walls: but I am apt to believe, if they were grafted upon the Bird Cherry, and managed properly, that defect might be remedied *, for this stock (as I am informed) will render Cherries very fruitful; and having the same effect on Cherries, as the Paradise stock hath on Apples, they may be kept in less compass, which is an experiment well worth the trial.

Your trees, if planted against a wall, should be placed at least twenty or twenty-four feet asunder, with a standard tree between each dwarf: this will be found a reasonable distance, when we consider, that Cherry-trees will extend themselves full as far as Apricots, and many other sorts of fruit.

In pruning these sorts of fruit, you should never shorten their shoots *, for the moil part of them produce their fruit buds at the extremities, which, when shortened, are cut off, and this often occasions the death of the shoot, at least a good part of its length: their branches should be therefore trained in at full length horizontally, observing in May, where there is a vacancy in the wall, to slip some strong adjoining branches, which will occasion their putting out two or more shoots *, by which means, at that season of the year, you may always get a supply of wood for covering the wall; and at the same time, should all upright shoots be displaced by the hand *, for if they are suffered to grow till winter, they will not only deprive the bearing branches of their proper supply of nourishment, but when they are cut out, it occasions the tree to gum in that part (for Cherries bear the knife the worst of any sort of fruit trees,) but be careful not to rub off the sides or piths, which are produced upon the two and three years old wood; for it is upon these that the greatest part of the fruit are produced, which sides will continue fruitful for several years. And it is for want of duly observing this caution, that Cherry-trees are often seen so unfruitful, especially the Morello, which the mo. e

it is cut the weaker it shoots *, and, at last* by frequent pruning, I have known a whole wall of them destroyed; which, if they had been suffered to grow without any pruning, might probably have lived many years, and produced large quantities of fruit.

Cherry-trees are also planted for orchards in many parts of England, particularly in Kent, where there are large plantations of these trees. The usual distance allowed for their standing is forty feet square* at which space, they are less subject to blight than when they are closer planted -, and the ground may be tilled between them almost as well as if it were entirely clear, especially while the trees are young; and often stirring the ground, provided you do not disturb their roots, will greatly help the trees; but when they are grown so big as to over-shadow the ground, the drip of their leaves will suffer very few things to thrive under them. These standard trees should be planted in a situation defended as much as possible from the strong westerly winds, which are very apt to break their tender branches *, this occasions their gumming, and is very prejudicial to them. The sorts best approved for an orchard, are the common Red, or Kentish Cherry, the Duke, and Lukeward; all which are plentiful bearers. But orchards of these trees are now scarcely worth planting, except where lands very cheap; for the uncertainty of their bearing, with the trouble in gathering the fruit, together with the small price it commonly yields, hath occasioned the destroying many orchards of this fruit in Kent within a few years past.

This fruit was brought out of Pontus, at the time of the Mithridatic victory, by Lucullus, in the year of the city 680, and were brought into Britain about 120 years afterward, which was An. Dom. 55; and were soon after spread through most parts of Europe, it being generally esteemed for its earliness, as being one of the first of the tree fruit that appears to us come in the approaching fruit season.

This sort of fruit hath been by many people grafted upon the Laurel, to which it is a congener; but the effect hath in the growth of the tree, as also in its fruit, will not recommend it to practice, the trees being of short duration, and seldom produce much fruit; though this practice is as old as Pliny, who says it gives the fruit a pleasant bitterness; but there is little to be depended upon in the writings of the ancients, with respect to the several sorts of trees being grafted upon each other \ very few of those which we find mentioned by them to have been frequently practised, will not succeed with us. Nor is it owing to the difference of climate, as some have supposed, who are inclinable to believe whatever they find related in those books, especially in the business of husbandry and gardening; whereas many of the rules for the practical part of husbandry, are not founded on experiments, but are mere theory; for from many repeated trials which have been made with the utmost care, by persons of the best skill, it appears, that no two sorts of trees, which are of different classes, will take upon each other. However, the Laurel and the Cherry being of the same genus, or so near of kin to be ranked together by most botanists, will take upon each other by grafting. But I have not yet seen any of the trees so grafted, which have lived to be of any considerable size; though I have seen many trees so grafted, which have lived a few years, but have made very poor progress; nor do I remember to have seen any fruit upon the Cherry-trees which were grafted on the Laurels, therefore cannot determine what effect this has on the flavour of the fruit.

There are some persons who graft the Duke, and other sorts of Cherries, upon the Morello Cherry, which is but a weak shooter, in order to check the luxuriant growth of their trees* which will succeed for three or four years: but they are not of long duration, nor have I ever seen one tree so grafted, which had made shoots above six or eight inches long, but they were chiefly covered with blossoms, so may produce

duce some fruit in a small compass; but these are experiments unfit to be carried into general use, and only proper to satisfy curiosity; for is it not much better to allow the trees a greater share of room against the walls, when one tree is planted and properly managed, will produce more fruit than twenty of these trees, or twice that number, when they are planted too close, though they are grafted upon the Black Cherry or any other free stock.

The Early or May Cherry is the first ripe, for one or two trees of this sort may be allowed a place in a garden, where there is room for variety. The next ripe is the May Duke, which is a larger fruit than the other, and is more valuable. After this comes the Archduke, which, if permitted to hang upon the tree till the fruit is quite ripe, is an excellent Cherry, but few persons have patience to let them hang their full time, for rarely have them in perfection, for these should not be gathered before July* and if they hang a fortnight longer they will be better. This is to be understood of the situation near London, where they ripen a fortnight earlier than in places forty miles distant, unless they have a very warm fluted situation. When this sort is planted against north walls, the fruit may be continued till the middle of August; but these must be protected from the birds, otherwise they will destroy them.

The Hertfordshire Cherry, which is a sort of Heart Cherry, but a firmer and better flavoured fruit, will not ripen earlier than the end of July, or the beginning of August, which makes it the more valuable for its coming when the other sorts of Cherries are gone. This is now pretty common in the nurseries; but as it is one of the best kind of Cherries, it is well worthy of being propagated in the nurseries.

The Morello Cherry, which is generally planted against walls to a north aspect, and the fruit commonly used for preserving; yet where they are planted to a better aspect, and suffered to hang upon the trees until they are thoroughly ripe, is a very good fruit for the table; therefore some of the trees of this sort should have place where there is plenty of walling, upon a south-west wall, where they will ripen perfectly by the middle or end of August, at which time they will be an acceptable fruit.

The Carnation Cherry is also valuable for coming late in the season; this has a very firm fleshy fruit, but is not the best bearer. This sort will some seasons ripen very well on espaliers, and by this means the fruit may be continued longer in the season.

The large Spanish Cherry is nearly allied to the Duke Cherry, from which it seems to be only a variety accidentally obtained; this ripens soon after the common Duke Cherry, and very often passes for it.

The yellow Spanish Cherry is of an oval shape and of an amber colour; this ripens late, and is a sweet Cherry, but not of a rich flavour; and being but a middling bearer, is not often admitted into curious gardens, unless where variety is chiefly considered.

The Corone, or Crown Cherry, is somewhat like the Black Heart, but a little rounder; this is a very good bearer and an excellent fruit, for should have a place in every good fruit-garden. This ripens the middle of July.

The Lukeward ripens soon after the Corone Cherry; this is a good bearer, and a very good fruit; it is of a dark colour, not so black as the Corone; this will do well in standards.

The Black Cherry is seldom grafted or budded, but is generally sown for flocks to graft the other kinds of Cherries upon; but where persons are curious to have the best flavoured of this sort of fruit, they should be propagated by grafting from such trees as produce the best fruit. This sort of Cherry is frequently planted in wildernesses, where it will grow to a large size, and, at the time of its flowering, will make a variety, and the fruit will be food for the birds.

The double-flowering Cherry is also propagated for the beauty of the flowers, which are extremely fine,

the flowers being as double and large as a Cinnamon Rose; and these being produced in large bunches on every part of the tree, render it one of the most beautiful trees of the spring. Some of the flowers which are less double, will often produce some fruit, which the very double flowers will not; but this defect is sufficiently recompensed in the beauty of its flowers. This is propagated by budding or grafting on the Black or Wild Cherry stock, and the trees are very proper to intermix with the second growth of flowering trees.

CERASUS RACEMOSA. See PADUS.

CERATONIA. Lin. Gen. Plant. 983. Siliqua. Tourn. Inf. R. H. 578. tab. 344. The Carob, or St. John's Bread, in French *Carouge*.

The CHARACTERS are,

It is male and female in distinct trees. The male flowers have large empalements, divided into five parts, they have no petals, but have five long filamina, terminated by large summits. The female flowers have empalements of one leaf, divided by five tubercles, they have no petals, but a fleshy germen situated within the receptacle, supporting a slender style, crowned by a stigma in form of a head. The germen afterward becomes a long, fleshy, compressed pod, divided by transverse partitions, each having one large, roundish, compressed seed.

This genus of plants is ranged in the third section of Linnæus's twenty-third class, entitled Polygamia Triœcia. The plants of this class have male, female, and hermaphrodite flowers on distinct plants.

We have but one SPECIES of this genus, viz.

CERATONIA (*Siliqua*.) H. L. The Carob-tree, or St. John's Bread. *Siliqua edulis* of Caspar Bauhin, and the Caroba of Dale.

This tree is very common in Spain, and in some parts of Italy, as also in the Levant, where it grows in the hedges, and produces a great quantity of long, flat, brown-coloured pods, which are thick, mealy, and of a sweetish taste. These pods are many times eaten by the poorer sort of inhabitants when they have a scarcity of other food, but they are apt to loosen the belly, and cause gripings of the bowels. The pods are directed by the College of Physicians to enter some medicinal preparations, for which purpose they are often brought from abroad.

In England the tree is preferred by such as delight in exotic plants, as a curiosity; the leaves always continue green, and being different in shape from most other plants, afford an agreeable variety when intermixed with Oranges, Myrtles, &c. in the greenhouse.

These plants are propagated from seeds, which, when brought over fresh in the pods, will grow very well, if they are sown in the spring upon a moderate hot-bed; and when the plants are come up they should be carefully transplanted each into a separate small pot filled with light rich earth, and plunged into another moderate hot-bed, observing to water and shade them until they have taken root; after which you must let them have air, in proportion to the heat of the weather. In June you must inure them to the open air by degrees; and in July they should be removed out of the hot-bed, and placed in a warm situation, where they may remain until the beginning of October, when they should be removed into the greenhouse, placing them where they may have free air in mild weather; for they are pretty hardy, and require only to be sheltered from hard frosts. When the plants have remained in the pots three or four years, and have gotten strength, some of them may be turned out of the pots in the spring, and planted into the full ground, in a warm situation, near a south wall, where they will endure the cold of our ordinary winters very well, but must have some shelter in very hard weather.

I have not as yet seen any of these trees produce flowers, though from some which have been planted some time against walls, it is probable there may be flowers and fruit in a few years; though it cannot be expected that the fruit will ever ripen in this country.

C E R

CERBERA. Lin. Gen. Plant. 260. Thevetia, Lin. Hort. Cliff. 76. Prod. Leyd. 413. Ahouai. Tourn. Inft. R. H. 657. tab. 434.

The CHARACTERS are,
The empalcment is composed of five Jharp-pointed leaves, which spread open and fall away, The flower is of one leaf, funnel-Jhaped, having a long tube spread open at the top, where it is divided into five large obtuse segments, standing oblique to the mouth of the tube; it hath five stamina situated in the middle of the tube, which are terminated by ere ft fummits \ these ft and clofe together. In the center is situated a roundish germen, supporting ajhort style, crowned by a stigma in form of a head. The germen afterward becomes a large, fleshy, roundish berry \ with a longitudinal furrow on the side, dividing it into two cells, each containing a Jingle, large, compressed nut. This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

- The SPECIES are,
1. CERBERA (Ahouai) foliis ovatis. Lin. Sp. Plant, 208. Cerbera with oval leaves. Ahouai. Thevet. Antartf. 66. Tourn. Inft. 658. The Ahouai.
 2. CERBERA (Thevetia) foliis linearibus, longissimis, confertis. Lin. Sp. Plant. 209. Cerbera with very long narrow leaves growing in clusters. Ahopai Nerii folio, flore luteo. Plum. Cat. 20. Ahouai with a Rose-bay leaf, and a yellow flower.
 3. CERBERA (Manghas) foliis lanceolatis, nervis tranfverfalibus. Flor. Zeyl. 106. Cerbera with spear-jhaped leaves and tranfverfe nerves. Manghas Iabteicen\$, foliis. Nerii crassis venosis, Jafmini flore, fructu Perfici funili venenato. Burm. Zeyl. 150. tab. 70.

The first fort grows naturally in the Brazils, and also in the Spanish, West Indies in plenty; and there are some of the trees growing in the British islands of America *, this rises with an irregular stem to the height of eight or ten feet, sending out many crooked diffused branches, which, toward their tops are garnished with thick succulent leaves about three inches long, and near two broad* of a lucid green, smooth, and very full of a milky juice, as is every part of the shrub. The flowers come out in loose bunches at the end of the branches, of a cream colour, having long narrow tubes at the top cut into five obtuse segments, which seem twisted, so as to stand oblique to the tube & these spread open, and have the appearance of the flowers of Oleander. It flowers in July and August, but never produces fruit in England. The wood of this tree stinks most abominably, and the kernels of the nuts are a most deadly poison; so that the Indians always caution their children against eating thereof, for they know of no antidote to expel this poison; nor will any of them use the wood of this tree for fuel, but they take the kernels out of the shells, into which they put small stones, then bore a hole through each shell, and firing them; these they tie about their legs, to dance with, as the morris-dancers use bells.

The second fort grows naturally in the Spanish West Indies, and also in some of the French islands in America, and hath lately been introduced into the British islands, from whence I received the seed* by the title of French Phytic Nut; but how it came by that appellation, I cannot imagine, because there is another plant which grows common there, and has passed under that title, many years.

This rises with a round stalk about the same height as the former dividing upward into many branches. These, when young, are covered with a green smooth bark, by and by grow older* the bark becomes rough, but changes to a gray or Asbi-colour. The leaves are four or five inches long and half an inch broad in the middle, ending in a sharp point of a lucid green, and come out in clusters without order, and are full of a milky juice, which flows out when they are broken. The flowers come out from the side of the branches upon long foot-stalks, each supporting two or three yellow flowers with long tubes, spreading open in the same manner as the former. It flowers

C E R

about the same time as the former, but never produces fruit in England.

The third fort grows naturally in India, and also in some parts of the Spanish West Indies, from whence I received the seed* this rises with a woody stem to the height of twenty feet, sending out many branches toward the top, garnished with long spear-shaped leaves, which are rounded at their ends; they are thick, succulent, and, on their upper side, of a lucid green, having several transverse nerves from the midrib to the side; on their under side they are of a paler green. The flowers are produced at the end of the branches, standing on long foot-stalks, each supporting two or three flowers shaped like those of the other species.

These plants may be propagated from their nuts, which must be procured from the countries where they grow naturally * these should be put into small pots filled with light earth, and plunged into a hot-bed of tanners bark in the spring, and treated in the same manner as other tender exotic seeds, giving them now and then a little water to promote their vegetation. When the plants are come up about two inches high, they should be transplanted each into a separate pot, filled with light sandy earth, and plunged again into a hot-bed of tanners bark, observing to shade the glasses in the heat of the day, until the plants have taken new root *, they must also be frequently refreshed with water, but it must not be given in too large quantities. As the summer advances, these plants should have air admitted to them in proportion to the warmth of the season; and when they have filled these small pots with their roots, they should be turned out and transplanted into other pots of a larger size, but they must not be too large; for the roots of these plants should be confined, nor should the earth in which they are planted be rich, but a light sandy soil is best for them; after they are new potted they should be plunged into the hot-bed again, observing to water them now and then, as also to admit air under the glasses every day in proportion to the warmth of the season. When the plants are grown about a foot high, they should have a larger share of air, in order to harden them before the winter, but they should not be wholly exposed to the open air. In the winter these plants should be placed in a warm stove, and during that season they should have very little water given to them, especially in cold weather, lest it should rot their roots. In the following spring these plants should be shifted again into other pots, at which time you should take away as much as you conveniently can of the old earth from their roots* and afterwards cut off the decayed fibres; then put them into pots filled with the same light sandy earth, and plunge them into the bark-bed again, for these plants will not thrive well unless they are constantly kept in tan: and as they abound with milky juice, they should be sparingly watered, for they are impatient of moisture, especially during the winter season.

When by any accident the tops of these plants are injured, they frequently put out shoots from their roots, which, if carefully taken up and potted, will make good plants, so that they may be this way propagated.

CERCIS. Lin. Gen. Plant. 458. Siliquastrum. Tourn. Inft. R. H. 646. tab. 414. The Judas-tree, in French Guainier.

The CHARACTERS are,
It hath a short broad Jhaped empalcment of one leaf, which is convex at the bottom, and full of honey liquor \ at the top it is indented in five parts. The flower hath five petals, which are inserted in the empalcment, and greatly resembles a papilionaceous flower. The two wings rise above the standard, and are reflexed \ the standard is of one roundish petal* and the keel is composed of two petals, in form of a heart, which inclose the parts of generation. It hath ten distinct stamina, which decline, four of which are longer than the rest, and are terminated by oblong, incurved stamens. It hath a long Jkndvr germen,

men fitting upon a slender stylob> crowned by an obtuse stigma; the germen afterward becomes an oblong pod with an oblique point, having one cell, indofing several roundish compressed feeds.

This genus of plants is ranged in the first section of Linnaeus's tenth class, intitled Decandria Monogynia, the flower having ten (lamina and one style. This genus is by all the writers placed with the papilionaceous flowers, before Linnaeus's System, which separates it from them; because the stamina in these flowers are all distinct; whereas the papilionaceous flowers have nine stamina joined together, and one separate.

The SPECIES are,

1. CERCIS (*Siliquastrum*) foliis cordato-orbiculatis glabris. Hort. Cliff. 156. *Cercis* with round, heart-shaped, smooth leaves. *Siliquastrum*. Caft. Duran. 415. and the Arbor Judae. Dod. Pemp. 786. "The common Judas-tree.
2. CERCIS (*Canadensis*) foliis cordatis pubescentibus. Hort. Cliff. 156. *Cercis*, with downy heart-shaped leaves. *Siliquastrum Canadense*. Tourn. Inf. R. H. 647. *Canada Arbor Juda*, or *Red Bud-tree*.

The first sort grows naturally in the south of France, Spain, and Italy* and is by the Spaniards and Portuguese, titled the Tree of Love: this rises with an upright trunk to the height of twenty feet, covered with a dark brown bark, dividing upward into many irregular branches, garnished with round, heart-shaped, smooth leaves, placed irregularly on the branches, having long foot-stalks; they are of a pale green on their upper, and of a grayish colour on their under side, and fall off in autumn. The flowers come out on every side the branches, and many times from the stem of the tree in large clusters, arising from the same point, having short foot-stalks; they are of a very bright purple colour, to make a fine appearance, especially when the branches are covered pretty thick with them: for they come out in the spring with the leaves, so are in full beauty before the leaves have obtained to half their size. The shape of the flower is the same as other papilionaceous (or butterfly) flowers; these have an agreeable poignancy, so are frequently eaten in fallads. When the flowers fall off, the germen becomes a long flat pod with one cell, containing one row of roundish feeds, a little compressed; but these do not often succeed the flowers in this country upon standard trees, for the birds pick off the flowers when fully open, but where they have been planted against good walled walls, I have seen great plenty of the pods, which, in warm seasons, have ripened very well.

These trees are usually planted with other flowering trees and shrubs for ornaments to pleasure-gardens, and for their singular beauty, deserve a place as well as most other sorts; for when they are arrived to a good size, they are productive of flowers, so as that the branches are often closely covered with them, and the singular shape of their leaves make a very pretty variety in the summer, and are seldom damaged by insects, so that, they are often entire, when many other trees have their leaves almost eaten up. This tree flowers in May, when planted in the full air, but against warm walls it is a fortnight or three weeks earlier.

The wood of this tree is very beautifully veined with black and green, and takes a fine polish, so may be converted to many uses.

There are two other varieties of this tree, one with a white, and the other hath a flesh-coloured flower, but these have not half the beauty of the first. Tournefort also mentions one with broader pods and pointed leaves, which I believe is only a variety of this. The second sort grows naturally in most parts of North America, where it is called Red Bud, I suppose from the red flower-buds appearing in the spring before the leaves come out * this grows to a middling stature in the places where it is a native, but in England rarely rises with a stem more than twelve feet high, but branches out near the root. The branches of this

is weaker than those of the first sort > the leaves are downy, and terminate in points; whereas those of the first are smooth, and round at the end where they are indented; The flowers of this are also smaller, 16 do not make so fine appearance as those of the first; but the trees are equally hardy, and will thrive in the open air very well.

The flowers of this sort are frequently put into fallads by the inhabitants of America; and the French in Canada pickle the flowers, but these have little flavour. The wood of this tree is of the same colour and texture as that of the first.

These plants may be propagated by sowing their feeds upon a bed of light earth, towards the latter end of March, or the beginning of April (and if you put a little hot dung under the bed, it will greatly facilitate the growth of the feeds -) when the feeds are sown, sift die earth over them about half an inch thick and, if the season prove wet, it will be proper to cover the bed with mats, to preserve it from great rains* which will sometimes burst the feeds, and cause them to rot, the feeds will often remain till the spring following before they come up, so the ground must not be disturbed till you are convinced that the plants are all come up; for some few may rise the first year, and a greater number the second.

When the plants are come up they should be carefully cleared from weeds, and in very dry weather must be now and then refreshed with water, which will greatly promote their growth: The winter following, if the weather is very cold, it will be proper to shelter the plants, by covering them either with mats or dry straw in hard frosts, but they should constantly be opened in mild weather, otherwise they will grow mouldy and decay.

About the beginning of April, you should prepare a spot of good fresh ground, to transplant these out (for the best season to remove them is just before they begin to shoot;) then you should carefully take up the plants, being careful not to break their roots, and plant them as soon as possible, because if their roots are dried by the air, it will greatly prejudice them.

The distance these should be planted, must be proportionable to the time they are to remain before they are again transplanted; but commonly they are planted two feet row from row, and a foot asunder in the rows, which is full room enough for them to grow two or three years, by which time they should be transplanted where they are designed to remain; for if they are too old when removed, they seldom succeed so well as younger plants.

The ground between the plants should be carefully kept clean from weeds in summer, and in the spring should be well dug to loosen the earth, that their roots may extend themselves every way; at that season prune off all strong side branches (especially if you intend to train them up for standard trees,) that their top branches may not be checked by their side shoots, which often attract the greatest part of the nourishment from the roots, and if their stems are crooked, you must place a strong stake down by the side of each plant, and fatten the stem to it in several places, so as to bring it straight, which direction it will soon take as it grows larger, and thereby the plants will be rendered beautiful.

When they have remained in this nursery two or three years, they should be transplanted in the spring where they are designed to remain, which may be in wilderness quarters among other flowering trees, observing to place them with trees of the same growth, so as they may not be overhung, which is a great prejudice to such plants.

CEREFOLIUM. See Cistaceae.

CEREUS. Par. Bat. 122. Boerh. Ind. alt. 1. 292. Just. Aft. R. Par. 171 & Cadus. Lin. Gen. Plant. 539. The Torch Thistle.

The CHARACTERS are,

It hath an oblong scaly empalement, which is covered with spines, and sits upon the germen. The flower is composed

of a peat number of narrow pointed petals* which spread open like the sun's rays. It hath a great number of declining flaming which are inserted to the base of the petals, and are terminated by oblong fummits. The germen, which is situated under the empalement, supports a long cylindrical styky crowned with a multifid stigma, in form of a head. The germen afterward becomes an oblong succulent fruit, with a prickly skin, full of small seeds inclosed in the pulp.

Dr. Linnaeus has joined the plants of this genus, and also those of Opuntia to the Cactus, making them only species of the same genus * but as the flowers of these plants differ greatly in their form from those of the Cactus, they should be separated and by preserving the title to this genus, by which it has been long known, it will prevent confusion, and by increasing the number of genera, the specific differences may be better ascertained, Linnaeus places the genus of Cactus in his twelfth class, entitled Cofandria, in which he includes those plants, whose flowers have from nineteen to thirty (lamina, which are fattened to the petals.

The SPECIES are,

1. CEREUS (*Hexagonus*) erectus, hexangularis, longus, angulis distantibus. Upright long Cereus with six angles, which are far distant. Cereus erectus altissimus Surinamensis Par. Bat. 116. Tallest upright Torch Thistle of Surinam.
2. CER^EUS (*Tetragonus*) erectus quadrangularis, angulis compressis. Upright Cereus with four compressed angles. Cereus erectus quadrangularis, costis alarum inflat affurgentibus. Boerh. Ind. alt. 293. Four-cornered upright Torch Thistle.
3. CEREUS (*Lanuginosus*) erectus octangularis, angulis obtusis, superne inermibus. Upright Cereus with eight obtuse angles, having no spines in the upper part. Cereus erectus, fructu rubro non spinoso. Par. Bat. 114. Upright Torch Thistle with a red fruit* having no spines.
4. CEREUS (*Peruvianus*) erectus octangularis, angulis obtusis, spinis robustioribus patulis. Upright Cereus with eight angles which are obtuse, and strong spreading spines. Cereus erectus maximus fructu spinoso rubro. Dadus. Par. Bat. 113. Greatest upright Torch Thistle with a red prickly fruit.
5. CSH-EUS (*Repandus*) erectus novemangularis, obfoletis angulis, spinis lanis brevioribus. Upright Cereus with nine angles, and spines shorter than the down. Cereus Curavicus, erectus, maximus, fructu rubro non spinoso, lanugine flavescente. Par. Bat. 115. Greatest upright Torch Thistle with a red fruit having no spines, and a yellowish down.
6. CEREUS (*Septagonus*) erectus octangularis, spinis lanis longioribus. Upright Cereus with seven of tight angles, and spines longer than the down. Cereus erectus craissimus maxime angulolius, spinis albis pluribus longissimis, lanugine flava. Boerh. Ind. alt. 293. Upright thick Torch Thistle having many angleSy&ueral very long white spines, and a yellow down.
7. CEREUS (*Rcyeni*) erectus novemangularis, spinis lana sequalibus. Upright Torch Thistle with nine angles* and spines of equal length with the down. Cereus erectus, gracilis, spinosissimus, spinis flavis, polygonus, lanugine alba pallecente. Boerh. Ind. alt. 293. Upright slender Torch Thistle, very full of yellowish spines, many angles, and a pale white down.
8. CEREUS (*Gracilis*) erectus gracilior novemangularis spinis brevibus, angulis obtusis. Slenderer upright Torch Thistle having nine obtuse angles and short spines. Cereus akiflimis, gracilior, fructu extus luteo intus niveo, feminibus nigris pleris. Tallest slender Torch Thistle with a fruit yellow without, white within, and full of black seeds.
9. CEREUS (*Triangularis*) regens triangularis, fructu maximo rotundo, rubro, esculento. Creeping triangular Torch Thistle, with very large, round, red, eatable fruit. Cereus (candens minor trigonus articulatis fructu suavisimo. Par. Bat. Prod. 118. Lesser, creeping, three-cornered jointed Torch Thistle, with a very sweet fruit, commonly called in the West Indies, the true prickly Pear, and by the Spaniards PUBaticya*
10. CEREUS (*Compressis*) repens triangularis, angulis compressis. Creeping triangular Torch Thistle, with compressed angles. Ficoides Americanum, f. Cereus erectus, cristatus, foliis triangularibus profundis canaliculatis. Pluk. Phyt. tab. 29. f. 3. Crested American Torch Thistle, with three angles deeply channelled.
11. CEREUS (*Grandiflorus*) repens subquinquangularibus. Creeping Torch Thistle with five* angles. Cereus scandens minor polygonus articulatis. Par. Bat. 120. Lesser jointed climbing Torch Thistle with many angles.
12. CEREUS (*Flagelliformis*) repens decemangularis. Creeping Cereus with ten angles. Cereus minor scandens, polygonus, spinosissimus, flore purpureo. Ed. Prior. Lesser climbing Torch Thistle, with ten spinous angles and a purple flower.

The first sort has been the most common in the English gardens. This grows naturally in Surinam, from whence it was brought to the gardens in Holland, where it produced flowers in the year 1681, and from the Dutch gardens, most parts of Europe have been supplied with this plant.

This rises with an upright stalk, having six large angles, which are far asunder, armed with sharp spines, which come out in clusters at certain distances, arising from a point, but spread open every way like a star, the outer substance of the plant is soft, herbaceous, and full of juice, but in the center there is a strong fibrous circle running the whole length, which secures the stem from being broke by winds. These will rise to the height of thirty or forty feet, provided their tops are not injured, if they have room to grow; but some of them have grown too tall to be kept in the stoves, so have either been cut off, or the plants laid down at length in winter, but whenever the stems are cut, or otherwise injured, they put out one, two, or sometimes three shoots, from the angles, immediately under the wounded part, and frequently one or two lower down. These (shoots, if they are not cut off, form so many distinct stems, and grow upright; but these seldom, are so large as the principal stem, especially if more than one is left on the same plant. The flowers come out from the angles on the side of the stem these have a thick, fleshy, scaly foot-stalk, round, channelled, and hairy, supporting a swelling germen, upon the top of which fits the scaly prickly empalement, closely surrounding the petals of the flowers, till a little time before they expand, which in most of the sorts is in the evening, and their duration is very short, for before the next morning they wither and decay. The flower of this sort is composed of many concave petals, which, when fully expanded, are as large as those of the Hollyhock; the inner petals are white, and crenated at their extremity. The empalement is green, with some purple stripes; the middle of the flower is occupied by a great number of stamens, which decline, and rise at their extremities, having roundish fummits. The flowers of this kind are never succeeded by fruit in this country, nor do the plants often produce their flowers here; but when they do, there are generally several on the same plant. I have some years had more than a dozen upon a single plant, which have all flowered within a few days of each other. The usual time of its flowering is in July.

This sort is not so tender as the others, so may be preserved in a warm green-house, without any artificial heat; but the plants should have no water given them in winter, when they are thus situated; for unless they are placed in a stove, where the moisture is soon evaporated, the wet will occasion them to rot. These plants naturally grow upon very dry rocky places, where their roots are confined, so they must not be planted in large pots, nor should they be planted in rich soil; the best composition for them is one third light earth from a common, a third of sea sand, and the other part fitted lime-rubble, if these are well mixed together, and often turned over before the plants are put into it, they will thrive the better. The directions for their management, will be hereafter exhibited.

The feond fort rifb with an upright ftem like the hrft, but it bach only four angles, which are com prffcd, and fmd far' afundcr. Thi; BTCry fubject to put out many moot* from the fides, whit [top ijiriglit growth, fo that tlic plants rardyrfc mo: than four or five feet high. This htth nor Btwnt in England, fo far as I have been able to learn. The third, fourth, fifth, fmh, feventh and eightl Ibra grow naturally in the Britiili iffemb of America, from whence I received them in the year 1728. Thefc have the fame form as the firft, but differ in the Cue of their ferns, the number of angles, and the length of their Jpincs, as is before exprffed in their titles; but, except the eighth fort, not any of them have flowered in Engine) as yet, though there are many of the plants which are more than twelve or fourteen feet high: the eighth fort hath die fmalldl fan of any of rhe upright forts which I have yet fan; this hath generally nine obiuic angles, which ait armed with litirt (bines, placed at farther diftances than thole of the other forts, nor are tlic channels between the metis near fo tkep. The flowers of this are produced from the angels, in the fame manner as the firft, but they are Imaller, and the emplicient is of a light green, without any mixture of colour. The fruit is about the fixe and ftwpc of a miAHim* Eerg^mot Pear, having many fift Ipima OB die ft in; the outlide is a pilc yellow, the inlide very white, full of pulp, having a greit number of fmall black (tedl lodged in it. This fort frequently (lowers in July, and in warm fcafans will pterel its fruit, whitth hath very little flavour in this country.

Thiefe forts are more impatient of cold than the firft, & require a ftovc to prefer** them in winter; nor fhoud they be expold abroad in fummer, but kept conftanty in the houfe, giving them a large fhare of air in warm weather.

The twelfth for: growl naturally in Peru, from whence it was fair to the royal garden at Paris; and .itc Year 173+, I was favoured with feme cuttings h by Dr. Bernard de JulHeu, demotiftrator of : lmts in thai garden. Thefc fucweded in the Chlfes garden, and have fince been communicated BO moft of the curious gardens in England. This b not 6 tender at the other forts, fo may be preferred in a good green-houfc, or placed under a hot-bed frame in winter, and in fummer fhould be <djX>fa) to die open air, which will prevent thie fhoots from drawing wcik, and thereby « greater number of floweru will be produced -, but during the time they remain in the open air, they fhould have little water; and S the tafon Ciould prove wet, the plants [hould be [crecenn] froii) it, otherwife ii irill caufc them t> lie bitwining winter. THu fart produces its flowers io May, Bid fomctimes earlier, when the I raiou is warm.

The ninth fort is, by the inhabitants of Barbados, trained up again; ib their (louies for the lake of its fruit, which is about the bignefs of a Bergatooi Pear, r.nd of a itintl delidouj flavour. This, and oil tenrit, clevtnth, and twelfth forts, are ten; require a warm Rave to preserve them. • tick fhould be placed ajainft the walls of the How.. • b they will infinate thleit rooU, and • extend themfelves to a greit length l and with a iict: help, in fattening them to the wall in a few place;. B ay be led up about the deling of the houfb, where they will appeal very hanJfome. And the eleventh lbrt, when arrived to a fufficent ilretigth, will pn • doce many eycccdjng hrpe., bwutiful, fweet-fecnte.; flowers, but they are like moft of the Bowtts of thefc kinds, of -cry fhort doratloh, fearely eontitiuing full blown iix' hours-, nor do the fatneBowen ever open jpain, when once clofed: they bq in to open in the evening be •ween feven and eight of the • ticks, are fully blown by die-, en, and by three or four the next morning f'ar, and hang <lov,n qu' : -e decorely, but, •uring their con ftituant, there is fcare any flower of greit beautt, or that makes a more mag-

nificent appearance \ for the caljr* of die (lower, whrn open, is near a foot diamctcti LIC infide of which being of a fplendid yeljaw colour, aprrin lib; tha rfyi of a bright Har, rhe outlide of a (jut brown , a-d the petals of ihc (lowers being of a pure white, adds to the luftre; and the vafll number of nturved Itamina, furrouading the ilyle in the center of the Bower, mike a fine appearance; and atid to this the fine fcent of the Rower, which perfumes the air to a con; • dorable diftance; there it force any plant which defeves » place in the hoi-houfc fo much as this, especially as it is to be trained i jEjinli the wall, where ic will not take up room. The uTuat fcafon of its flowering il iti July, and when the plants are large, they • produce a great number Of Howcn, fo that there will be a fucttion oi them fir feveral nights, and many of them will opo the fame night. I have frequH • tly had fix, eight, or ten flowers . Jpc at the fame time upon one pi • nt, which have miffed a moft magnificent ap] • arance by caufc -liglic, but nontof them have been fuctceded by any appearance of fruit.

The tenth fort produces a flower li • le inferior to the former, as I have been informal i • perfons who have fecn them, but I never had the good fortune to have any OI thefc planu which have been unJer my care fiowur; nor have I heard of more dun tv. • gardens where they have as yet flowered in England -, the firft of ihcm was many yrare finer in the roval gardens at Hampton Court, when there was a curi • uous toileffion of exotic pUnu kept in g<•/i order in thole gardens, which have fincc been gnraty neglected j the other was produced in the gardens of (he right hotnourabk the M.irquis of Rockingham, at Wentworth-Mall, in TorkfhiKr. Thdc arc the only garilens in this country where I hai'c heard of this fort having produced Howers; although th. • are many of thicfc pVinu in Jcvmi gardens, wlii'd aj • of « confiderabl agr, uul extt: • their branches as a very gnxt diftance.

The ninth fort has never producd any flower; as yet in England, nor hate we any good figure of the flower in any of the botanic bouki; but I have been informed by feme curious perioM who have r • d in America, that the flowers are not near fo bcrifical 3\$ thiufe of die tenth and eleventh, but the fruit u greatly eftemed by JII the inhabitaim.

The twelfth fort produces a greater number of flowerers rlimi either of the orlicr; thicfc arc of a fine Pink colour, both within and without; tlic JXTMIS jrr not fo nflmcrou5, and the mbe of the Bower is longer than thole of the other fpecics; and, tontrary to nil thie uthvr fiirt5, keep open thnx or four days, urovidcd the w • atber h not too hot, or the place where they ftand kept foa warm. During ttw continuance of thefe flowers, they make a fine appearance. Tilts fan has very ikmler trailing • fir •, wtdi require td be fupported; but tiitie do not extend fo far as thofe of the other fori, nor art their brandies jointed as thoiic arc, fo they cannot be trained (0 far agajift the w • lilt of the houfc; but as thie pro: • ce such beautiful flowers and in fo great plenty, it n-ny be placed among [lic • ft club of exotic plants. This plant has p; • du;cd fruit in the garden at Che •, but it hath nut as yet rip • ed.

Thicfc plants are • Il propagated by cuttine'i fw • if you intend to increafc thie numb • of them, you muft cur off the ftcms of thic upright; fums M whnr length you pleafe; thefc I • d be cut off - dry [Lcc to be l ihe part en, at least a fortnigl • /e'eki brfbre they arc planted; but if ilm • be a run: • li it 15 much thie bi-tter, and they will be in ! • danger of rotting, cipttUly thole lbrta which are the moft f • lent.

Tick-cuttings fhould be plantd in pots filled with thic mixture of wrth before due iW, laying • some fticks in thi boitom of the ; • to drain off the [jioiltuK; tlien place the poti • into a gen k hm-btd of • ujiers l>uk, to facilitate their rooting, giviog t! :cm once a week a g • ridc watering.

The best fun for this work is in June, or die beginning of July, that they may have unit to root towards the middle of Auguf you mult begin to give them air by degrees to liarJ.n [hem againft winter, bur they EhouJ not be wholly expofeatc the opci air or fun; at the end of September they'roult be removed into the fen, or grLi house, where they are to abide the winter, during WUL-JI tafoli you niuft be very careful not to let them liave much water i and always obfrve to place tlt; young plants, for the firft winter, in a little warmer lituatiuii than die older plants, as being fomewhar tenderer.

Theft plants flould always have a dry fituation in winter, for as (hey imbibe the grwieft part of their nourifhmen from the circumambient air, v if this be too irph tt with muttl particles, it will occafion their rotting; therefore they {hould not be expofed abroad, not even in the mklfl of J-immer, unkj they are bnder Jlicccr j for great mins, which often happen at that li-iftin, arc very injurious w [hem -, the tfrft rigfcl forts fhould b; Bwrcftrc placed fa as to enjoy a trte air in the lunimcr, but, at tlic fame time, forced from rains and grrac dews ; it will therefore be muth the better method u let them in an open glal> (love, wlcrc the windows may be fel open in good weather, and fbur in cold or wet. The other lour lorn niuil not be omofed too tnnch tu the open air, rveti in the hottcft fealbn, dj>eaaily it" you deSign to have them flower; and in winter they fhouM be ^ept very warin, anl bav* no viatii: given than.

When you hive once cut off the tops of iny of thefe plant], in order to increafe them, the lower parti will put forth freth ll-uots from tuicir angles, wnth D f'roivn ro be eight or nine indies long, may alii) be taken off to nuke fr/h plants^ and, by this means, the old plants will continually afford a iupply, lb thai you never need cut off above one plant of a fort, wlikh you (hould preferve for a brccoder. Thefc plants being fucculent, they will bear to be a long lime out of the ground; ther- for whoever hath a mind to get any of thrm from the Weft Indies, need give no other inflruaiojw to their friends, but to cut them off, and let thcm lit- two or ill; days to dry-, then put them up iit a box with (try hay, <r fraw, to keep them from wounding cadl utlier with their fjimrs, ind it' they ,irc iw or throe montlis on their paTage, they will keep very well, provided no wet get to them.

- 3. CEMNTHE (Gland) folia amplexicaudibus, integris, frigitibus gemiois, cord... Plant. 137. Hexefax: ... ibijialk., a fauU- rintlle minor. C. li. 1'. 2 Thefirir fort gr- naturally in Germany and Italy. This is m annual p] which rife with limooth branching falta a foft and half thick, granifhed with, oval, oblong, pri leaves, which are of a fca-green, fpottedwith white, anil embrace the flalks with tinir bale i He flowers are pi ched at -he end of the branches, Handing between the small leaves, which embrace the ft ill; their are long, the ailota, and blunt at the top, where the tube u' are en- large<3-, thrj .1: yellow, ulliavca. mdbus liquor in their cubes, with which the bees are mucli delighted i and an herbaeeuu, empalemt, cut into Hue parts, which ifft; and includes the feeds, these flowers have each four einbrj . • german, but only two 1 if them are fruifua. The top of the flalks are reH'xet! backward, fomewis. It flowers in June and July, and the feeds ripen in Auguft and September. If' tlic leads jrc not uki-n as loan as they change btack, rlioy drop out of the empielement in a ftiorf [ime] lu uilcft tlic' aie carefully gat i if red up, they -will vegcia^: with tlic firft moitl weather.

The ftTonil TOII is like the I J, but leaves are larger, stid fmooth, having no jiricki on them. The flowers of this are of a purplish red colour, and the plants grow larger. Thi grows in i only, md the louth of l'mnce v it is fdlb ?n - 1;J plant.

The third fort ; naturally on III; Alps, and other mountainous pi* the 1 iih. llenJcrv ihlks tlian either of the fornir, which rife twu feet high, and clofer garnifiaJ wirlt leaves than either of the others j these embrace the f alk with their bale, and are of a bluer grci-nolntir. The fiow. are small, their upper pan is deeply cut into ii.

bin the mourn of the 1 be is chiefly that up; .:hem- ptlement . . la ge, <: closely furrounds the flower. The flv. are . . . and appear at the last:it" : with the OIIIIT : . . . If the feeds of this are permitted to leatter, the y.ants will come up i iutuunn, and thefs . . . grow much taller, and lower in lirr than those which are sown in the spring; this hath been supposed a perennial plant by many, but from man) years observation, I could never find these plants to come after they haJ flowered and perfitted thcr feed!.

The species of tills plwit are propagated by seeds, wli • fi Uiotild hi: fown loon afte they are ripe; for, if they are kept till i; . . . the growing quality of them is often loft; or m least they be four months in the ground befo<- they grow; the plants are hardy, and ii' the ix-ds are !own in a warm situation, they will endure the winter's cold very well without shelter; these autumnal plants are also much sooner to produce ripe iieeds than those which are sown in the spring, whk! are generally lost in the field before they Bower-, ana erst: . . . frequently if the autumn should not prove very warm, thdr seeds would not be pcr- ti-ited.

ThiepSantsmakt- a pretty variety for large borders in gankai, where, if they are suffered to drop their seeds, the plants will iuili v.; . . . for that when a person is once furnished with the several varieties, he need be at no more trouble than fj allow each of them .1 . . . and with this culture, there is a greater certainty of preserving the best than in any othir manip- ment; . . . for when great quantities of the seeds havr [attered Upon the ground, some of them will bt buried fo deep, in v. . . grow the fell yi:ar; . . . upon being turned by

to the air the succeeding year, will come Up as well as new feeds.

CESTRUM. Lin. Gen. Plant. 231. Jafminoides. Dill. Nov. Gen. 170. Bastard Jafmine.

The CHARACTERS are,

// bath ajhort tubular empalement of one leaf, which is indented at the top into five parts, which are ere8. The flower is funnel-Jhaped, of one petal, having a long cylindrical tube, which Jpreads open at the top, where it is cut into five equal fegments; it hath five flender fiamina the length of the tube, to which they adhere, and are terminated by roundih four-cornered fummits. The oval cylindrical germen is fituated in the empalement, fupporting a flender fyle the length of theftamina, crowned by an obtufe thick stigma. JThe germen afterward becomes an oval oblong berry with one cell, inclojing feveral roundih feeds.

This genus of plants is ranged in the firft fe&ion of Linnaeus's fifth clafs, intituled Pentandria Monogynia, the flower having five ftamina and one fyle.

The SPECIES are,

1. CESTRUM (*Nofturnum*) floribus pedunculatis. Hort. Cliff. 490. *Ceftrum with flowers ftanding upon foot-ftalks. Jafminoides foliis Piihaminis, flore virefcente noftu odoratiflimo. Hort.Elth. 183. tab. 153. Bastard Jafmine with leaves of Pijhamin, and a green/b flower, fmelling very fweetly in the night.*
2. CESTRUM (*Diurnum*) floribus feffilibus. Hort. Cliff. 491. *Ceftrum with flowers growing to the branches. Jafmioides laureolae folio, flore candido interdiu odorato. Hort.Elth*. 186. tab. 154. Bastard Jafmine with a Spurge Laurel leaf, and a white flower, fnulling in the day.*
3. CESTRUM (*Nervofum*) foliis lanceolatis oppofitis nervis tranfverfalibus, pedunculis ramofis. *Ceftrum with fpear-Jhaped leaves growing oppofite, having tranfverfe veins, and branching foot-ftalks *to the flowers. Jafminoides Americanum, lauri folio, flore albo odorato. Houft. MSS. Bastard Jafmine of America with a Bay leaf, and a white, fweet, fmelling flower.*
4. CESTRUM (*Spicatum*) foliis ovato-lanceolatis, floribus fpicatis, alaribus & terminalibus. *Ceftrum with oval fpear-Jhaped leaves, and flowers growing in fpikes from the fides and tops of the branches.*
5. CESTRUM (*Confertum*) foliis oblongo-ovatis, obliquis, floribus alaribus confertis, tubo longiffimo & tenuiffimo. *Ceftrum with oblong oval leaves which are oblique, and flowers growing in clufters from the fides of the branches, with a very long flender tube.*
6. CESTRUM (*Venenatum*) foliis lanceolatis obliquis, floribus alaribus, pedunculis foliofis. *Ceftrum with oblique fpear-Jhaped leaves, flowers proceeding from the fide of the branches, and leafy foot-ftalks. Jafminum laurinis foliis, flore pallide luteo, fru&lu atroceruleo polypyreno venenato. Sloan. Hift. Jam. 2. p. 196. Jafmine with Bay leaves, a pale yellow flower, and a dark blue fruit with many feeds, which are poifonous.*

The firft fort was many years paft raifed in the curious gardens of the Duchefs of Beaufort, at Badmington, in Gloucefterfhire, and was from thence communicated to feveral gardens in England and Holland, where in the latter it paffes under the title of Badmington Jafmine to this time. This grows naturally in the ifland of Cuba, from whence I received the feeds by the title of *Dama de Noche*, i. e. *Lady of the Night*; which appellation I fuppofe was given it, from the flowers fending out a ftrong odour after the fun is fet.

It rifes with an upright ftalk about fix or feven feet high, covered with a grayifh bark, and divides upward into many flender branches, which generally incline to one fide; and are garnifhed with leaves placed alternate, which are near four inches long, and one and a half broad, fmooth on their upper fide, of a pale green, and on their under fide they have feveral tranfverfe veins, and are of a fea-green colour, having fhort foot-ftalks. The flowers are produced at the wings of the leaves, in fmall clufters, ftanding upon fhort foot-ftalks, each fupporting fodr or five

flowers, which have Very fhort empalements, wkli long flender tubes, which are enlarged at the top* where they are cut into five parts which are reflexed; tiefe arc of an herbaceous colour; they appear in Auguft, but are not fucceeded by berries in this country; but thofe which I received from America were fmall, and of a dark brown colour, inclojing feveral feeds.

The feeds of the fecond fort were fent the from the Havannah, by the title of *Dama de Dio*, or *Lady of the Day*; this rifes with an upright ftalk to the height of ten or twelve feet, covered with a fmooth light green bark, dividing upward into many fmall branches, garnifhed with fmooth leaves near three inches long, and one and a half broad, of a lively* green colour, and the confiftence of thofe of the Spurge Laurel; thefe are ranged alternately on thd branches. Toward the upper part of the fhoots come out the flowers from the wings of the leaves, ftanding in clufters clofe to the branches; they are very white, fliaped like thofe of the former fort, and fmell fweet in the day time, from whence it had the appellation of *Lady of the Day*. The bewies of this are fmallef than thofe of the firft fort. This flowers in September, O&ober and November.

The third fort was fent me from Carthfgena in New Spain, near which place it grows naturally; this rifes with a ffrubby ftalk five or fix feet high, covered with a brown bark, and divides upward into many fmall branches, garnifhed with fpear-fhaped leaves, about four inches long, and little more than one broad; they are fsmooth, of a light green, and have many horizontal veins running from the midrib to the fides, and are placed oppofite. From the wings of the leaves, toward the upper part of the branches, are produced the flowers, ftanding upon branching foot-ftalks, each fupporting four or five flowers, whofe tubes are fwelling at their bafe, juft above the empalement, but contraft upward to the mouth, where the petal is cut into five broad fegments which fpread flat; they are white, bur without fcent.

The fourth fort was fent me from Carthagenam the former. This rifes with a fhrubby ftalk ten or twelve feet high, covered with a light gray bark, and fends out many branches the whole length, garnifhed with oval fpear-fhaped leaves, ftanding without order; they are two inches and a half long, and one and a half broad, of a light green, with flender foot-ftalks. The flowers come out in loofe fpikes from the fide, and alfb the end of the branches, which are fhaped like thofe of the firft fort, and are of a whitifh green colour, without fcent. Thefe are fucceeded by roundifh purple berries, the fize of large Peafe, which have a foft juicy pulp, filled with flat feeds.

The fifth fort rifes with feveral fhrubby ftalks eight or ten feet high, covered with a white fsmooth bark, fending out many irregular branches, garnifhed with oblong oval leaves, which at their bafe are longer on one fide, fo that the foot-ftalk is oblique; they are placed on the branches without order, and are of a pale green. The flowers come out in clufters from the fide of the branches, many of them arifing from the fame point; thefe have very flender long tubes, which are cut at the top into five acute fegments which are ereft. They are of a pale yellow, and without fcent.

The fixth forf grows naturally in Jamaica, from whence it was fent me by the late Dr. Houftoun. This rifes with a woody ftem eight or nine feet high, covered with a fsmooth brown bark, and fends out many branches on the fide which grow ereft, garnifhed with oval fpear-fhaped leaves, whofe foot-ftalks are fhort; they are five inches long, and two broad, fsmooth, of the confiftence with Bay leaves, and are placed alternate on the branches. From the wings of the leaves the flowers are produced, moft part of the length of the branches; the foot-ftalks of the flowers arc garnifhed with fmall leaves, ftanding between each flower in a fingular manner, the flowers

riling one above the other *, and between, or opposite to each, is one, and sometimes two leaves, of the same form with those on the branches. The flowers are of a pale yellow, and emit a disagreeable odour. These are succeeded by oval berries of a Violet colour, full of juice, each containing several flat seeds; they are reckoned very poisonous, to have the appellation of Poison Berries in Jamaica.

This has been, by many of the writers on botany, supposed to be the same with the first; but any person who has seen both sorts growing, cannot doubt of their being distinct species; the shape and size of the leaves are very different, as are also their flowers and berries. Some have also supposed that the Parqui of Pere Feuillé, is the same with this, but that is a great mistake -, for the flowers of this plant are produced in loose bunches at the extremity of the branches, whereas those of this sort come out from the side, at the foot-joints of the leaves -, so that this plant is certainly different from either of these, but approaches nearest to the third.

The fifth sort I take to be the same as Pere Plumier's *Jasminum aliud arborecens, foliis folani, minus* *, for by an imperfect specimen of his plant which was shewn me, the leaves appear the same, but as the specimen was without flower or fruit, so I could not determine it.

The first and second sorts produce their flowers every year in England, but the others do but seldom flower here \ but as they retain their leaves all the year, so they make a pretty variety in the stove, during the winter season; and when they flower, the branches are commonly well garnished at their joints with bunches of flowers, so they make a fine appearance at that time.

All these plants grow naturally in very hot countries, so cannot be preferred in England without artificial heat *, therefore require to be placed in a warm stove, especially in the winter. The two first are hardier than the others *, these I have kept several years in a dry stove, with a moderate share of heat in winter, and in the middle of summer have set them in the open air, in a warm situation. With this management I have found them thrive, and produce flowers much better than when they have been placed in a greater heat *, but I have often endeavoured to keep these plants through the winter, in a green-house, or ■ ■ is safe, without fire, but could never succeed; for by the end of January, they commonly decayed.

The other sorts require a larger share of heat, especially when the plants are young; therefore they should be plunged in the tan-bed of the bark-stove, otherwise they will lose their leaves in winter, if they are not quite destroyed; but after three or four years growth, they will bear to be treated more, hardily, provided they are inured to it gradually.

These plants may be propagated from seeds, or by cuttings. Those which come from seeds are always the most vigorous, and straight plants; but as they do not produce seeds in England, so the other method is generally practised, because their seeds are rarely brought hither.

The best time to plant these cuttings is about the end of May, by which time the shoots will have had time to recover their strength, after their confinement during the winter season. The shoots which come out from the lower part of the (stalks, should always be chosen for this purpose. These should be cut about four inches long, and five or six of them may be planted in each halfpenny pot *, for the cuttings of most sorts of exotic plants, will succeed better when they are planted in these small pots, than they do in larger, as I have many years experienced. The earth in which these are planted, should be fresh and light, but not full of dung: when the cuttings are planted, the earth must be pressed pretty close to them, and then gently watered \ after which the pots must be plunged into a moderate hot-bed of tanners bark, and every day shaded from the sun. They must also have

fresh air admitted to them in warm weather, and two or three times a week refreshed with water. With this management the cuttings will put out roots in five or six weeks, when they should be gradually exposed to the sun *, and when they begin to put out shoots, they must have a greater share of fresh air admitted to them, to prevent their drawing up weak *, and their waterings should be oftener repeated, but given in small quantities, for their young tender fibres will not endure much wet. When they have made good roots, they should be carefully shaken out of the pots, and each put into a separate small pot, filled with the same sort of earth as before; then give them some water, to settle the earth to their roots, and plunge them again into the tan-bed; observing if any of their leaves hang down, to shade them from the sun in the middle of the day, until they have taken fresh root -, after which they should have a large share of air in warm weather, to strengthen them before winter. Their waterings in the summer should be frequent 5 and if they are sprinkled all over their leaves, it will wash and cleanse them from filth, which will greatly promote their growth; but their roots must not be kept too moist.

In the autumn the plants of the three last sorts must be removed into the bark-stove, and plunged into the tan-bed, where they must be treated in the same manner as other tender exotic plants; but the two first sorts may be treated otherwise, especially when they have obtained strength, yet the first winter they may be managed in the same way as the* others. There must be great care had in watering of these plants in winter, for they are all (except the second sort) very impatient of moisture, so that they are soon killed by being over-watered.

If the seeds of these are procured from the countries where they grow naturally, they should be sown in small pots filled with the earth before directed, and plunged into a moderate hot-bed of tanners bark, giving them now and then a little water. Sometimes the seeds will come up the same year, but they very often lie in the ground till the spring following; so that if the plants do not appear in six or seven weeks; after the seeds are sown, they will not come up that season; in which case the pots may be plunged in the tan-bed of the stove, between the other plants, where they will be shaded from the sun, and but little water given them; in this situation they may remain till the following spring, when they should be removed, and plunged into a fresh hot-bed, which will bring up the plants in a short time, provided the seeds were good.

When the young plants are fit to remove, they should be carefully shaken out of the pots, and each planted into a separate pot filled with the before-mentioned earth, and plunged into the hot-bed again, and afterward treated in the same way as hath been directed for the plants raised from cuttings.

C E T E R A C H. See ASPLENIUM.

C H ^ E R O P H Y L L U M. Lin. Gen. Plant. 320. Tourn. Inft. R. H. 314. tab. 166. [gai^fuM*, of *χαίρομαι*, to rejoice, and *πλευρον*, Gr. a leaf, because the leaves, steeped in wine, and drank, will exhilarate and cheer melancholy persons.] Chervil.

The CHARACTERS are,

It is an umbelliferous plant; the principal umbel is spreading and hath no involucre, composed of several small ones, called rays; the small ones have a five-leaved involucre, which is reflexed; the flowers have five heart shaped inflexed petals, and five stamina, which are terminated by roundish summits: the germen is situated below the flower, supporting two reflexed styles, crowned with obtuse stigmas. The germen afterward becomes an oblong pointed fruit, dividing in two parts, each having one seed, which is convex on one side and plain on the other.*

This genus of plants is ranged in the second section of Linneus's fifth class, entitled Pentandria Digynia, the flowers having five stamina and two styles.

The SPECIES are,

1. CH[^]EROPHYLLUM (*Sylvestre*) caule friato geniculis tumidiufculis. Flor. Suec. 2. N. 257. *Wild Chervil with friatedstalks, whose joints are /welling.* Myrrhis fylveftris feminibus laevibus. C. B. P. 160. *fVild Myrrh with fsmooth feeds.*
2. CH[^]EROPHYLLUM (*Bulbofum*) caule laevi, geniculis tumidis. Lin. Sp. Plant. 258. *Chervil with afmooth ftalk, and fwelling joints.* Myrrhis tuberofa & nodofa conyophillon. Mor. Umb. 67* *tuberous and knotted Myrrh with a Hemlock leaf.*
3. CH[^]EROPHYLLUM (*Temulum*) caule fcabro, geniculis tumidis. Lin. Sp. Plant. 258. *Chervil with a rough ftalk, and fwelling joints.* Chaerophyllum fylveftr. C. B. P. 152. *Wild Chervil*
4. CH[^]EROPHYLLUM (*Aureum*) caule squall, foliolis incifis acutis. Lin. Sp. Plant. 258. *Chervil with an equal ftalk, and leaves cut into acute fegments.* Myrrhis pennnis alba minor, foliis hifutis, femine aureo. Mor. Umb. 282.
5. CH[^]EROPHYLLUM (*Hirfutum*) caule aequali, foliolis incifis acutis, feminibus fubulatis. Lin. Sp. Plant. 371. *Wild Chervil with an equal ftalk, whose fsmall leaves are cut acutely, and awl-Jhaped feeds.* Myrrhis paluftris, latifolia rubra. C. B. P. 161.

The firft fort grows naturally on the fide of highways, and the borders of the fields in moft parts of England, fo is never cultivated in gardens. It is frequently called Cow Parfley, but for what reason I cannot fay, becaufe there are few animals who care to eat it, except the afs; for it is reckoned to have fomething of the quality of Hemlock, but in a lefs degree. It is a weed which fhould be rooted out from all paftures in the fpring, for it is one of the moft early plants in fhooting; fo that by the beginning of April the leaves are near two feet high. The feeds of this plant fspread greatly over the ground, and as the roots are perennial, they are often very troublefome weeds to deftroy.

The fecond fort grows naturally in Hungary and Iftria. This plant hath a thick tuberous root, from which come forth feveral leaves refembling thofe of Wild Chervil, which fspread horizontally near the ground. The ftalks rife fix or feven feet high, which are fotted with purple, and garnifhed with leaves of the fame form as thofe below. The knots at the joints of the ftalks fwell out on every fide, at which is placed one of thefe divided leaves; the ftalks are terminated by fmall umbels of white flowers, which are fucceeded by long narrow feeds. It flowers in June, and the feeds ripen in Auguft. If the feeds of this plant are permitted to fcatter, the plants will come up without any farther care, and only require to be kept clean from weeds.

The third fort grows naturally on the fides of foot-walks, and on the borders of woods in many parts of England, fo is not cultivated in gardens.

The fourth fort grows naturally in the paftures about Geneva, and in Switzerland; this hath a perennial root, from which come out in the fpring many leaves, lhaped like thofe of the firft, but narrower, hairy, and more divided. The ftalks are channelled, and rife three feet high, garnifhed with the like leaves; thefe are terminated by large umbels, formed of many fmall ones, which are compofed of flowers, having five heart-lhaped petals, which turn inward; thefe are fucceeded by long pointed feeds. The whole plant has an aromatic fmell and tafte.

The fifth fort grows naturally on the Alps, and the Helvetian mountains. It is a perennial plant, fomewhat refembling the firft fort, but their leaves are hairy, and their fegments are broader; the ftalk rife four feet high, terminated by large umbels of flowers, which in fome plants are red, and in others white; thefe are fucceeded by long pointed feeds, two being joined in the fame cover.

Thefe plants are preferred in botanic gardens for variety; but as their ufe either in medicine or the kitchen are not known, they are rarely admitted into other gardens.

CHAMⁱEROPS. Lin. Gen. Plant. 1084. Cham^{*}-riphes. Poit^{*} to^{*} Dod. Pempt. 820* Dwarf Palm, or Palmetto.

The CHARACTERS are,

It bath male and hermaphrodite flowers in diftinft plants; the hermaphrodite flowers are all included, in one common fpatha or hood, which is compreffed and bifid, and the fpadix or club is branching; each flower bath afmall bree-pointed empalement; they have one thick upright petal which is cut into three parts, and turns inward at the top, and five compreffed ftamina which join at their bafe[^] terminated by narrow twin fummits, joined to the interior part of the ftamina. They have three roundifh germen, each having a diftinft ftyle, which is permanent, terminated by pointed ftigma. The three germen afterward become fo many round berries, having 01ft cell, each containing a Jingle feed. The male flowers are tike the hermaphrodite, but the ftamina are not diftinft, nor have they any germen.*

This genus of plants is joined with the other kinds of Palms by Dr. Linnaeus, and placed in the appendix to his Genera Plantarum; but it fhould be ranged in his twenty-third clafs, or rather made a diftinft clafs by themfelves, becaufe their manner of fru&ification is very different from moft other plants.

The SPECIES are,

1. CHAM²EROPS (*Humilia*) frondibus palmatis, plicatis* ftipitibusfpinofis. Hort. Cliff. 482. *Dwarf Palm with folding palmated leaves, and prickly foot-ftalks.* Palma humilis, fc. Chamaeriphes. J. B. Hift. 1.368. *Dwarf Palm, or Palmetto.*
2. CHAMⁱBROPS (*Glabra*) foliis flabelliforcibus, maximis, ftipitibus glabris. J[^]warf Palm with very large fan-jhaped leaves, and fsmooth foot-ftalks. Palma non ipinofa humilima. *Dwarf Palm without fpines, commonly called fmall Palmetto Royal.*

The firft fort grows naturally in Spain, particularly in Andalusia, where, in the sandy land, the roots fspread and propagate fo faft, as to cover the ground in the fame manner as the Fern in England. The leaves of thefe plants are tied together to make boms for fweeping.

This never rife with an upright ftem, but the foot-ftalks of the leaves rife immediately from the head of the root, and are armed on each fide with ftrong fpines *, they are flat on their upper furface, and convex on their under fide. The center of the leaves are faftened to the foot-ftalk, which fspread open like a fan, having many foldings, and at the top are deeply divided like the fingers of a hand; when they firft come out, they are clofed together like a fan when fhut, and are faftened together by ftrong fibres which run along the borders of the leaves; and when the leaves fspread open, thefe fibres or frings hang from the fides and ends of the borders of the leaves[^] are finely fawed, and have white narrow edgings % they are from nine to eighteen inches long, and near a foot broad in their wideft part: as the lower leaves of the plants decay, their veftiges remain, and form a fhort ftump above ground, in the fame manner as our common male Fern does; from between the leaves comes out the fpadix or club, which fuftains the flowers; this is covered with a thin fpatha or hood, which falls off when the bunches open and di-

vide*

vide. As all the plants of this sort which I have seen flower were male, I cannot give any particular description of their fructification.

This plant is commonly propagated here by heads, which sometimes separate from the main root; if these are carefully taken off with fibres and planted, they will grow, but the plants so raised are not so good as those which are produced from seeds; so that if good seeds can be procured, that is by much the better way to propagate them. The seeds should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark, these must be refreshed now and then with water. If the seeds are fresh, the plants will come up in two months; these rise with a single long-pointed leaf. When they appear they must be now and then refreshed with water, but they must not have it in too great plenty. If the plants are not too close to each other in the pots, they will not require to be transplanted the first year; therefore they should remain in the tan-bed all the summer, but in warm weather they must have plenty of air admitted to them. In autumn the pots should be removed into the stove, and, if they are plunged into the bark-bed the first winter, it will greatly forward the growth of the plants. The following spring the plants should be carefully turned out of the pots, so as to preserve their roots entire; for all the sorts of Palms have tender roots, which, if they are cut off or broken, frequently kill the plants: then they should be each planted into a separate small pot filled with light, sandy, undunged earth, and plunged into a fresh hot-bed to encourage their taking root; the following summer they should be gradually hardened, by raising the glasses pretty high, so as to admit a large share of air to them, but they should not yet be wholly exposed to the open air. The autumn following the plants may be placed in a dry stove but as the plants advance and get strength, they may be treated more hardily, and in summer placed in the open air in a warm situation, and in winter may be preserved in a warm green-house without artificial heat.

As the plants advance in growth, they should be put into larger pots, but when this is done, there must be great care taken, that their roots are not cut or broken, nor should they have pots too large. In winter they must have but little water, and if they are exposed to the open air in summer, they will not require much, unless the season proves very warm and dry, in which case they may be sparingly watered two or three times a week.

The second sort grows naturally in the West Indies, where it never rises with a stem 5 the foot-stalks of the leaves are rounder than those of the former, and have no spines on their sides. When the plants are old their leaves are three or four feet long, and upward of two broad; these are folded in the same manner as those of the first, but the folds are broader, and the leaves are of a darker green, some of these plants have put out slender bunches of male flowers in England, which were too imperfect to form a description.

This sort rises freely from seeds, which may be easily procured from the islands in America, these must be sown in the same manner as the former, and the plants treated in the same way; but as they are natives of a warmer climate, they should be constantly kept in the bark-stove, where, if they are carefully managed, they will make good progress.

I have received seeds from Carolina of a Dwarf Palm, which is very like this, if not the same, but the plants do not make so good progress here, as those which came from Jamaica; the berries were so like, that I could not distinguish them; but as the plants advance, if they are different, it will appear.

CHAMBER UBUS. *SCCRUBUS*.

CHAMIESYCE. See *EUPHORBIA*.

CHEIRANTHUS. Lin. Gen. Plant. 730. *Leucogium*. Tourn. Inf. R. Ji. 220. tab. 107. Stock Gilliflower and Wall-flower to French *Giroffliou* *Viofor*.

The CHARACTERS are,

It hath a four-leaved compressed empalement, the tv) outer leaves are fuelling at their base. The flower hath four petals placed in form of a cross, these are longer than the empalement. It hath six parallel stamina, which are the length of the empalement, two of which are between the swelling leaves of the empalement, the other are a little shorter, and are terminated by erect bifid summits, which are reflexed at the top. It hath a four-cornered prismatic germen as long as the stamina, supporting a very short compressed style, crowned with an oblong divided stigma, which is reflexed and permanent. The germen afterward becomes a long compressed pod with two cells, opening with two valves, filled with compressed seeds.

This genus of plants is ranged in the second section of Linnaeus's fifteenth class, intitled *Tetrandynamia filiquosa*, the flowers having two long and four shorter stamina, and the seeds are lodged in long pods.

The SPECIES are,

- CHEIRANTHUS (*Eryfimoides*) foliis lineari-lanceolatis dentatis caule redo, filiquis tetragonis. *Cheiranthus* with narrow, indented, spear-shaped leaves, an upright stalk, and four-cornered pods. *Hesperis leucoides* folio ferrato, filiqua quadrangula. Tourn. Inf. R. H. 223. *Dames Violet* with a fawed Wall-flower leaf, and a quadrangular pod.
- CHEIRANTHUS (*Integerrimis*) foliis lanceolatis integerrimis, caule erecto, filiquis tetragonis. *Cheiranthus* with spear-shaped entire leaves, an upright stalk, and quadrangular pods. *Hesperis leucoides* folio non ferrato, filiqua quadrangula. Tourn. Inf. R. H. 223. *Dames Violet* with a Wall-flower leaf not fawed, and a quadrangular pod.
- CHEIRANTHUS (*Cbeiri*) foliis lanceolatis, acutis, glabris ramis angulatis? Hort. Cliff. 334. *Cheiranthus* with spear-shaped, pointed, smooth leaves. *Leucogium luteum vulgare*. C. B. P. *Common yellow Leucogium* or Wall-flower.
- CHEIRANTHUS (*Angustifolium*) foliis linearibus, unguibus petalorum calyce longioribus. *Cheiranthus* with narrow leaves, and the necks of the petals longer than the empalement. *Leucogium angustifolium* Alpium flore sulphureo. H. R. Par. *Narrow-leaved Wall-flower of the Alps*, with a sulphur-coloured flower.
- CHEIRANTHUS (*Annuus*) foliis lanceolatis, subdentatis, obtusis, incanis, filiquis cylindricis apice acutis, caule herbaceo. Lin. Sp. Plant. 662. *Cheiranthus* with spear-shaped leaves few with indented, obtuse, and hoary cylindrical pods, with acute points and an herbaceous stalk. *Leucogium incanum minus*. C. B. P. 200. *Lesser hoary Stock Gilliflower*, commonly called the *Ten Week Stock*.
- CHEIRANTHUS (*Incanus*) foliis lanceolatis, integerrimis, obtusis, incanis, filiquis apice truncatis, compressis, caule suffruticoso. Hort. Upfal. 187. *Cheiranthus* with very entire spear-shaped leaves, which are obtuse and hoary, compressed pods with truncated points, and a shrubby stalk. *Leucogium incanum majus*. C. B. P. 200. *Greater hoary Stock Gilliflower*, commonly called the *Queen's Stock Gilliflower*.
- CHEIRANTHUS (*Cocdnus*) foliis lanceolatis undatis, caule erecto indiviso. *Cheiranthus* with waved spear-shaped leaves, and an upright undivided stalk. *Leucogium incanum majus Coccineum*. Mor. Hist. 2. 240. *Greater hoary Stock Gilliflower* with a scarlet flower, commonly called the *Brompton Stock Gilliflower*.
- CHEIRANTHUS (*Albus*) foliis lanceolatis, integerrimis, obtusis, incanis, ramis floriferis axillaribus, caule suffruticoso. *Cheiranthus* with hoary, entire, spear-shaped, obtuse leaves, flower branches proceeding from the sides, and a shrubby stalk. *Leucogium album* five purpleum five violaceum. Ger. *The white, purple, or Violet Stock Gilliflower*.
- CHEIRANTHUS (*Glabrus*) foliis lanceolatis, acutis, petiolatis, viridibus, caule suffruticoso. *Cheiranthus* with spear-shaped acute leaves, which are great, having foot-stalks, and a shrubby stalk. *Leucogium album odoratissimum*, folio viridi. C. B. P. 2. 102. *Sweetest white Stock Gilliflower* with a green leaf, commonly called *white Wall-flower*.

 of the plants deccndent. The feeds
 fhould be fown in April, upon poor or unimproved foil,
 ir.d when the
 plants are fit to rumber, they fhould be
 tranfplanted into nurfery-beds, at about fix inches
 diftance each way, obferving to water and fize them
 until they have taken their roots after which they will
 require no farther care, but to keep them clear from
 weeds all the fummer; and at Michaelmas they may
 betr:
 1
 fplanted into the borders of the flower-garden
 wherf they are defigned to remain, that the plants
 may get good roots before the fruit comes on. This
 is the method which is commonly praftifed with thefe
 flowers; but if the feeds are fown upon poor land,
 O u o
 where

C H £

where they are defigted to remain, and hot tran-
planted, they will thrive, and endure the froft in win-
ter much better than thofe which are removed *, fo
that upon ruins or rubbilh the feeds of thefe plants
may be (own, where they will thrive and continue
much longer than in good land *, and in fuch places,
if they are properly dilpofed* they will be very orna-
mental, and their flowers having a ftrong odour, will
perfume the air to a confiderable diftance.

The Stock Gilliflowers are diftinguifhed from the
Wall-flowers, by their hoary leaves. Thefe agree with
each other in their botanical chara&ers* fo are gene-
rally included in the fame genus ; but the gardeners
remove them to a confiderable diftance, and treat
them very differently; yet there is fo great affinity
between them, as that they may be treated in the
fame manner, and both will grow equally upon old
walls or ruins 5 but as they have been feperated by
Aioft of the writers on gafdenerig, I have, in compli-
ance v/ith that cuftom, ranged them accordingly.

The fifth fort is now generally known by the appella-
tion of ten Weeks Stock, but it is what was former-
ly titled Annual Stock Gilliflower, which of late
has been applied to another fpecies, which is biennial.
This rifes with a round fmooth ftalk about two feet
high, dividing into feveral branches upward, garnifh-
ed with fpear-fhaped hoary leaves, which are rounded
at their ends, and placed without order, fometimes
being almoft oppofite, and others alternate, and fre-
quently three or four together of unequal fizes *, at
the ends of the branches the flowers are produced in
loofe fpikes, which are placed alternate \ the emplace-
ment of the flower is large, erect, and (lightly cut
into feveral acute parts at the top; the petals are
large and heart-fhaped, fpreading open in form of a
crofs *, the pods are long, cylindrical, and have a
longitudinal furrow on one fide, which opens in two
cells, which are filled with flat rundifli feeds, having
a thin border. It flowers in July and Auguft, and
the feeds ripen in October.

Of this fort there are the red, the purple, the white,
and ftriped, with fingle flowers, and the fame colours
with double flowers; thefe are very great ornaments
in the borders of the flower-garden in the autumn,
when there is a fcarcity of other flowers \ and if the
feeds are fown at two or three different times, the flow-
ers may be continued in fucceffion near three months.
The firft lowing fhould be about the middle of Fe-
bruary, upon a very tender hot-bed, juft to bring up
the plants, which muft be guarded againft froft; and
when they are fit to remove, they fhould be tran-
planted into the nurfery beds, at about three or four
inches diftance, obferving to water and (hade them
till they have taken root, and afterward to keep them
clean from weeds; in thefe beds they may remain
five or fix weeks to get ftrength, and may then be
planted into the borders of the flower-garden, where
they are to remain: if thefe are tranfplanted when
there is rain, they will foon take root, after which
they will require no farther care. From thefe early
plants good feeds may be expe&ed, therefore fome
of the fineft plants of each colour fhould be preferved,
and marked for feeds, which, when ripe, ihould
be carefully cut before the froft pinches it, and the
ftalks tied up in fmall bundles, and hung up in a drj
room till the pods are well dried, when the feeds may
be rubbed out and preferved for ufe.

The fixth fort is a biennial plant, though when the
feeds are fown early in the fpring, the plants often
flower the following autumn *, but thefe plants which
are fo forward, are often killed in winter % therefore
it is much better to fow them in May, that the plants
may not grow too rank the firft feafon; they will
live through the winter, and produce large (pikes
of flowers the fecond year.

This is commonly called the Queen's Stock Gilli-
flower by the gardeners, and differs greatly from the
ether forts, though many of the late botanifts have
fuppofed they were only feminal variations 5 but from
near forty years experience in the culture of thefe

C H E

plants, I can affirm, that the fpectes here enumerated,
do not alter from one to the other, though they
frequently vary in the colour of their flowers.

It rifes with a ftrong ftalk, which is almoft (hrubby,
a foot high or more, having oblong, fpear-fhaped,
hoary leaves, which are frequently waved on their
edges, and turn downward at the extremity; from
the ftalk is fent out many lateral branches, which are
garnifhed with the fame (haped leaves, but fmaller *
thefe fide branches are each terminated by a loofe
fpike of flowers, each having an oblong woolly em-
placement, and confift of four large roundilh petals,
which are indented at the end. Thefe ufually ap-
pear in May and June, but the fame plants frequently
continue flowering moft part of the fummer. The
feeds ripen in autumn, and the plants generally pe-
rih foon after; but when any of them grow in
dry rubbifh, they will laft two or three years and
become (hrubby 5 but thofe with fingle flowers, are not
worth preferving after they have perfected their feeds.
The flowers of this fort vary in their colour -, fome
are of a pale red, others are of a bright red, and fome
are curioufly variegated, but thofe of the bright red
are generally moft efteemed. There is always a
great number of double flowers produced, if the feeds
are well chofen, frequently three parts in four of the
plants will be double; and as the plants divide into
many branches, they make a fine appearance during
their continuance in flower.

The feventh fort is known by the title of Brompton
Stock Gilliflower, I fuppofe from its having been
there firft cultivated in England. This rifes with an
upright, ftrong, undivided ftalk, to the height of
two feet or more, garnifhed with long hoary leaves,
which are reflexed, and waved on their edges, and at
the top form a large head *, out of the center of thefe
arifes the flower-ftalk, which, when the plants are
ftrong, is frequently a foot and a half long, putting
out two or three fhort branches toward the bottom 5
the flowers of this kind have longer petals than any
of the other forts, and are formed into a pyramidal
fpike ; but thofe with fingle flowers are loofely di-
pofed, becaufe the flowers having but few petals, d<
not fill the fpike, as thofe do which are double; fo
thefe often have fo many petals, as to render each
flower as large and full as fmall Rofes; and whei..
they are of a bright red* make a pretty appearance
being excelled by none of the flowery tribe 5 but the
plants of this fort produce but one fpike, in which it
differs from all the other kinds, and being conftant in
this particular, I think is fufficient to eftablifh a dif-
tinct fpecies. This fort is generally biennial, though
many times the plants are preferved longer; but they
are always ftronger the firft year of their flower-
ing, than they will be after *, fo that the feeds are
fown every fpring, to continue afucceffion of flower-
ing plants.

The eighth fort" is the White Stock Gilliflower,
which is of longer duration than either of the other
forts. I have frequently had thefe plants live three or
four years, which have become (hrubby *, their ftalks
have been three feet high, and branched out on every
fide, fo as to appear like (firubs; thefe feldom fent
out flower-ftalks from the center of the plant, but it
is the fide branches which produce the flowers, and
thefe fide branches divide into feveral other, which is
not common to the other forts. There are always
many double flowers rife from feeds of this fort, when
they are well chofen -, fome years I have fcarce had
enough fingle flowers to preferve the kind. The va-
rieties of this are few, fometimes a few of the plants
will produce pale fiefh-coloured flowers, and now and
then fome have been purple 5 and as that fort of Stock
Gilliflower, which is titled the Twickenham Purple,
will fometimes come with flowers variegated with
white, I have been inclinable to think thefe two
may be varieties of each other; and the rather, be-
caufe the plants agree with each other in their exter-
nal habit 5 for neither of thefe put out their flower-
ftems from the center of the plants, but always on
their

their side, so that these are undoubtedly a distinct species from the former.

The ninth sort is known by the title of White Wall-flower, among the gardeners and florists. This rises with a greenish stalk a foot high, dividing into many branches, garnished with narrow, smooth, spear-shaped leaves, of a lucid green, and of thicker confidence than those of any of the other sorts; they come out without any order, are near three inches long, and about half an inch broad in the middle; the flowers are produced in loose spikes at the end of the branches, which are of a pure white, and have a great fragrant, especially in an evening or in cloudy weather-, the flowers are succeeded by oblong compressed pods like those of the other species. There is a variety of this with double flowers, which is propagated by cuttings or slips, in the same manner as the double Wall-flowers; but these plants require protection from great rains, and frost in Winter; so if they are planted in pots, and placed under a common frame in winter, where in mild weather they may enjoy the open free air, and be covered from hard rains and frost, they may be preferred several years. Sometimes many of the plants with double flowers will come up from seeds, but not so frequent as some of the other sorts. I have for several years raised more than one hundred plants in a season, without obtaining one double flower; and from the seeds of these, have the following year had more than half the plants with double flowers: but this is not to be expected often.

The seeds of the tenth sort were sent me by Dr. Linnaeus, from Upsal in Sweden. This plant rises about six inches high, with an herbaceous swelling stalk; the leaves are produced in clusters at the top, which are very hoary, waved on their edges, have obtuse points, and set very close to the stalk; the flowers are produced in slender spikes from the side of stalk; these are purple, but not so fragrant as many of the other sorts; the pods are woolly, and recurve backward at the end.

All these sorts flower in May and June, at which time they are the greatest ornament to the flower-garden, therefore deserve our care to cultivate them as much as any of the flowery tribe -, but in order to have many double flowers, there must be great care taken in the choice of plants for seeds, without which there can be little hopes of having these flowers in perfection. The only sure way of getting many double flowers, is to make choice of those single flowers which grow near many double ones; for I have always found those seeds which have been saved from plants growing in beds close to each other, where there happened to be many double flowers among them, have produced a much greater number of plants with double flowers, than those which have been saved from plants of the same kinds, which grew single in the borders of the flower-garden; so that there should be a small bed of each kind planted on purpose to save seeds in the flower-nursery; or if they are sown there, and the plants thinned properly when they are young, they need not be transplanted; for I have always observed the plants which have come up from scattered seeds, which have not been transplanted, endure the frost much better than those which have been removed; for as these plants send out horizontal roots from the bottom of their stems, which spread near the surface of the ground, so when they are transplanted, the roots are forced downward out of their natural direction; and if their stalks were grown tall before removal, they are generally planted low in the ground, whereby they are apt to rot, if the ground is moist, or the winter should prove wet; therefore where they can be left unremoved, there will be a better chance of their living through the winter -, and as these beds need not be of great extent, so when the winter proves very severe, it will not be much trouble or expence to arch the beds over with hoops, and cover them with mats in frosty weather, by which method they may be always preserved.

The ground where these seeds are sown, must have any dung, for in rich land the plants will grow very vigorous in summer, but when the frost comes on, or the heavy rains in autumn, either of which will soon destroy them; for these plants will thrive upon rocks or old walls, as was before observed; and in such situations they will live, when all those which are planted in gardens are destroyed. The best time to sow the seeds is about the beginning of May; and if the season should prove dry, it will be proper to shade the beds with mats every day, to prevent the earth from drying too fast; but the covering must be taken off every evening, to admit the dews of night, and they should be gently watered in the evening two or three times a week. When the plants first appear, with their two seed-leaves, they are often attacked by flies, especially in dry hot seasons; therefore to prevent their destroying of the plants, the covering should be continued over them during the heat of the day, and the plants frequently refreshed with water, which will keep them in a growing state, so the flies will not infect them; for I have always observed, they never attack any plants unless they have been stunted in their growth: when the plants have got strength, they will be secure from this danger, and the coverings may be removed; after this the plants will require no farther care but to keep them clean from weeds; and to be thinned to the distance of nine inches or a foot asunder, that they may have proper room to grow, and not draw each other up tall and weak. The plants which are drawn out of these beds to thin them, may be planted in the borders of the flower-garden, where they are designed to remain, and the sooner they are removed, when the plants have got six or eight leaves, the more likely they will be to live through the winter; because their roots will not have extended themselves so far, so cannot be planted deep in the ground, and may take their natural direction* therefore whenever these plants are removed, it is always the best way to do it when they are young.

The farther care of the plants which are left in the beds, will be to cover them in winter with mats; and when they come to flower, all those which are not of good colours, or whose flowers are small, should be drawn out as soon as they appear, that they may not impregnate those which are designed for seeds with their farina; but those with double flowers should by no means be removed; if should their flowers be cut off* but suffered to fade among the single ones, by which the seeds will be improved; it will also be a sure method of preferring each sort in perfection, to have them separate from each other, in distinct beds; though I think there is no danger of any of the species altering, by the mixture of their farina, but their colours are liable to be changed by it; so that in order to continue those pure, they should not stand too near each other.

The time for sowing the seeds before-mentioned, must be understood to be for the sorts which are biennial; for the annual, or ten Weeks Stock Gilliflower should be for the first season sown in February, as was before directed; and to succeed these, there should be another parcel sown in March; and those who are curious to continue these flowers late in the autumn, should sow a parcel of the seed the latter end of May; and if these last sown plants are upon a warm border, where they may be covered, by placing glasses before them in winter, or covering them with mats, they may be continued in flower till Christmas; and if some of the plants are potted, and put under a hot-bed frame in autumn, where they may enjoy the open air in mild weather, and be screened from hard rains and frost*, by which method I have known these plants kept flowering all the winter, when the winters have not been very severe.

There are some who propagate the double Stock Gilliflowers by slips and cuttings, which will take root when properly managed; but the plants so raised are never so strong as those which come from seeds, and

their

their spikes of flowery are always Very lhort, and livit hot half the beauty; therefore it is not worth while to pccrtife this method, unlefs for thofe forts which cannot be obtained with any certainty from feed.

The eleventh fort grows naturally in the fourth of France, Spain, and Italy, nerr the fea coaft. This rifes near a foot high, with a ligneous ftalk, dividing into many fmall branches, garnifhed with narrow hoary leaves, which are entire, and rounded at their extremity *, the flowers are produced in loofe fpikes at the end of the branches, which are fmaller than thofe of either fort before-mentioned, of a bright red at their firft appearing, but fade to a purple before they fall off. The ftalks, leaves, and the whole plant is very white, and by its woody ftalks hath the appearance of a perennial plant, but it generally perishes in autumn. The feeds of this fort fhould be fown in autumn, upon a warm border, where the plants are defigned to remain; when the plants come up, they will require no farther care but to keep them clean from weeds, and thin them where they come up too clofe. Thefe autumnal plants will flower early in June, fo will produce good feeds; but thofe which are fown in the fpring will flower in July and Auguft, fo that from thefe there cannot be any certainty of having ripe feeds: however, by fowing the feeds at two or three different feafons, there may be a fucceffion of flowers continued for three or four months.

The twelfth fort is commonly fown in gardens, fometimes as an edging for borders, but more generally in patches between taller growing flowers: it is titled fometimes Dwarf annual Stock Gilliflower, and by others it hath the appellation of Virginia Stock Gilliflower. This feldom rifes more than fix inches high, lending out many branches from the root, which intermix and grow irregular; thefe are garnifhed with fpear-ftaped leaves, rounded at their ends, and fit clofe to the branches; the flowers come out in loofe fpikes at the end of the branches, which are of a purple colour, compofed of four petals in form of a crofs, and are fucceeded by (fender pods like thofe of the other fort*. If the feeds of this fort are fown in patches, at two or three different times, the firft in autumn, the fecond the latter end of March, and the third the end of April, or the beginning of May, in the borders of the flower-garden, they will make a variety, when intermixed with other low growing annual flowers, for three months.

The thirteenth fort rifes near two feet high, fending out many upright branches from the bottom, which are thinly garnifhed with fpear-ftaped leaves, the lower ones being a little indented; the flowers come out fingle, at great diftances from each other, toward the upper part of the branches; thefe are fmall, of a purplifh red colour, and foon fall away, being fucceeded by long taper pods, with awl-ftaped points. This is an annual plant, which may be treated in the fame manner as the laft mentioned fort; but as it hath little beauty, it is not often cultivated in gardens. The fourteenth fort grows naturally on the fea coasts in Italy, Spain, and Portugal. This is alfo an annual plant, which branches out from the root into many declining ftalks; the lower leaves are about two inches long, and three quarters of an inch broad, very deeply finuated on their edges, and hoary; thofe upon the ftalks are of the fame form, but much fmaller *, the flowers are produced from the fides of the ftalks fingly, and at the top in loofe fpikes; the empalements of the flowers are covered with a white down, as are alfo the end of the branches; the flowers are purple, compofed of four leaves placed in form of a crofs; the pods are about three inches long, taper, woolly, and at their ends are divided into three parts, which fpread into a triangle. It flowers in July, and when the feafon is favourably the feeds will ripen in autumn; but if the feeds are fown in autumn on a warm border, the plants will live through the winter, and thefe will flower early in June, fo from thefe good feeds may be obtained from them.

The fifteenth fort grows naturally on the fea coasts in the fourth of France and Spain, where it continues three or four years; the ftalk is eredi, and the whole plant is covered with a white down; the lower leaves are broad, fpear-ftaped, obtufe, and alternately indented; the flowers are flefh-coloured, compofed of four petals like the other fpecies, and are fucceeded by long woolly pods.

This may be propagated by feeds in the fame manner as the other forts; and if the plants grow in rubbish, they will live through the winter better than in rich earth.

The fixteenth fort is of humble growth, feldom HGng above eight or nine inches high; the leaves are very narrow, and indented on their edges; the ftalk becomes fhubby, to which the flowers grow very clofe; thefe are of a worn out purple colour, fo make but little appearance. It grows naturally in Spain and Italy, and is not fo hardy as the other forts, therefore requires fome protection in winter.

The feventeent fort grows naturally in Portugal. This is a low annual plant with pointed leaves, whose borders are indented as if torn; the empalement of the flower is hoary; the flowers have four purple petals placed in form of a crofs, which are fucceeded by knobbed-pointed pods inclofing flat feeds.

If the feeds of this kind are fown in the fpring upon fheltered borders, where the plants are to remain, and they are thinned and kept clean from weeds, the plants will flower in July, and produce ripe feeds in autumn.

CHELIDONIUM. Tourn. Inft. R. H. 31. tab. 116. Lin. Gen. Plant. 572. *Chelidonium majus*. Raii Meth. Plant. 100. *Glaucium*. Tourn. Inft. R. H. tab. 130. *Celandine*, or *Greater Celandine*, in French *Cbetiodine* or *Eclair*.

The CHARACTERS are,

The flower hath a roundifh empalement, compofed of two concave obtufe leaves, which fall off; it hath four large roundifh petals, which fpread open and are narrow at their bafe; in the center is fituated a cylindrical germen, attended by a great number of ftamina, which are broad at the top and are terminated by oblong, compreffed, twin fummits. Upon the germen is fituated a bifid figma in form of a head. The germen afterward becomes a cylindrical pod, with one or two cells, opening with two valves and filled with many fmall feeds.*

This genus of plants is ranged in the firft fection of Linnaeus's thirteenth clafs, intituled Polyandria Monogynia, the flower having many ftamina and one fyle. To this genus he has joined the *Glaucium* of Tournefort, whose characters very well agree with thofe of *Celandine*, fo are very properly brought together.

The SPECIES are,

1. CHELIDONIUM (*Majus*) pedunculis umbellatis. Lin. Gen. Plant. 505. *Celandine with anumbellatedfoot-ftalk*. *Chelidonium majus vulgare*. C. B. P. 144. *Greater common Celandine*.
2. CHELIDONIUM (*Laciniatum*) foliis. quinque lobatis, lobis anguftis acute laciniatis. *Celandine whose leaves are compofed of five narrow lobes, which are cut into many acute figments*. *Chelidonium majus laciniato flore*. Cluf. Hift. 203. *Greater Celandine with a jagged flower*.
3. CHELIDONIUM (*Glaucium*) pedunculis unifloris, foliis amplexicaulis finuatis, caule glabro. Lin. Sp. Plant. 506. *Celandine with fingle flowers on the foot-ftalks, finuated leaves which embrace the ftalks, and a fmooth ftalk*. *Glaucium flore luteo*. Tourn. Inft. R. H. 351. *Glaucium with a yellow flower*; and the *Papaver corniculatum luteum*. C. B. P. 171. *Yellow horned Poppy*.
4. CHELIDONIUM (*Corniculatum*) pedunculis unifloris, foliis feffilibus pinnatifidis, caule hispido. Lin. Sp. Plant. 506. *Celandine with fingle flowers upon the foot-ftalks, leaves fet clofe to the ftalks which have winged points, and a rough ftalk*. *Glaucium hirsutum flore Phoenicio*. Tourn. Inft. R. H. 253. *Hairy Glaucium, or horned Peppy, with a fcarlet flower*.
5. CHELIDONIUM (*Glabrum*) pedunculis unifloris, foliis femiamplexicaulis, dentatis, glabris. *Celandine with*

foot-stalks having a Jink flower, and smooth indented leaves, which half embrace the stalks. Glaucium glabrum flore Phœnicio. Tourn. Inft. 254. *Smooth horned Poppy with a scarlet flower.*

6. CHELIDONIUM (*Hybridum*) pedunculis unifloris, foliis pinnatifidis, linearibus, caule levi filiquis trivalvibus. Lin. Sp. Plant. 724. *Celandine with single flowers upon the foot-stalk, many pointed narrow leaves, and a smooth flat Glaucium flore violaceo.* Tourn. Inft. 254. *Horned Poppy with a Violet-coloured flower.*

The first sort is the common Celandine which is used in medicine, and is esteemed aperitive and cleansing, opening obstructions of the spleen and liver, and is of great use in curing the jaundice and scurvy. This grows naturally on the side of banks, and in shady lanes in many parts of England, so is seldom cultivated in gardens; for if the seeds are permitted to scatter, the ground will be plentifully stored with plants to a considerable distance. It flowers in May, at which time the herb is in the greatest perfection for use.

The second sort is found growing in a few particular places, where the seeds have been formerly sown, or the plants cast out of gardens. This is by some supposed to be only a variety of the first but I have propagated this by seeds above forty years, and have constantly found the plants produced to be the same as those from which the seeds were sown, and never vary, nor have I ever observed the first alter to this. The leaves of this are divided into narrow long segments, which are deeply jagged on their edges, and the petals of the flower are cut into many parts, in which it differs from the first. If the seeds of this sort are permitted to scatter, they will fill the ground with plants. They both delight in shade. There is a variety of this with double flowers, which generally exceeds the same from seeds, which is not usual in many other plants; however, this variety may always be preferred by parting the roots.

The third sort is known by the title of Horned Poppy; it was so called from the resemblance which the flower bears to the Poppy, and the long feed-veffel, which is like a horn. It grows naturally upon the sandy and gravelly shores by the sea, in many parts of England, from whence the seeds have been brought into gardens, where it is sometimes allowed to have place for the sake of variety. This plant abounds with a yellow juice which flows out from every part, when broken. It sends out many thick gray leaves, which are deeply jagged; the stalks are strong, smooth, and jointed, which rise near two feet high, and divide into many branches. These are garnished with leaves at each joint; those on the lower part of the stalks are long, broad, and deeply jagged, but the upper leaves are entire and almost heart-shaped: they closely embrace the stalks with their base; from the bottom of the leaves come out the short foot-stalks of the flowers, each supporting one large yellow flower, composed of four broad petals, which spread open like the garden Poppy, in the center of which are a great number of yellow stamens, surrounding a long cylindrical germen, crowned by an arrow-pointed stigma, which is permanent, remaining upon the top of the horned feed-veffel, which grows nine or ten inches long, having a longitudinal furrow on one side, where it opens when ripe, and lets out the seeds. This is a biennial plant, which flowers the second year, and perishes soon after the seeds are ripe.

If the seeds of this plant are permitted to scatter, they will fill the ground near them with plants, so that it is not a proper plant for a flower-garden; but if a few of the seeds are scattered about in rock work, the plants will rise without trouble, and in such places will have a pretty effect. And if the seeds are permitted to scatter, there will always be a supply of young plants; so the only care they will require, is to pull them up when they multiply too fast. It flowers in June and July, and the seeds ripen in autumn.

The fourth sort grows naturally in Spain, Italy, and some parts of Germany, from whence the seeds have been brought to England. The leaves of it are deeply jagged and hairy, of a pale green, and grow close to the stalks: those at the bottom lie on the ground, and are broader than those above. The stalks are a foot and a half high, having a single jagged leaf placed at each joint; these have many divisions, from their origin to the point, which is extended longer than the lower leaves. The flowers come out from the bottom of the leaves; these are composed of five broad obtuse petals, which are of a dark scarlet colour, and soon fall off. In the center of each is situated an oblong germen, having no style, but supports a bifid stigma; this is attended by a great number of short stamens, terminated by obtuse summits. The germen afterward becomes a long taper pod, on the apex of which the bifid stigma remains, fitting on the middle partition, which divides the pod into two cells, which are filled with small seeds. The flower hath an empalement composed of two hollow leaves, which are closely set with short prickles; this falls away when the flower is expanded. It flowers in June and July, and the seeds ripen in autumn. As the flowers of this plant are but of short duration, they do not make any considerable figure; but the foliage of the plant is very elegant, and might be introduced by way of ornament to furniture with great advantage, being very picturesque: it may also be wrought into patterns for silks, and painted upon porcelain, where it would have a very good effect. If the seeds of this plant are sown in the autumn, they will more certainly grow than those which are sown in the spring; which frequently, in dry seasons, do not come up the same year, or at least not before autumn; whereas those sown in autumn, frequently come up soon after, or if not at that season, do not fail coming up in the spring; and these plants come early to flower, so that good seeds may always be obtained from them. They should be sown where the plants are to remain* and they will require no other care but to thin them where they are too close, and keep them clean from weeds.

The fifth sort differs from the fourth, in having broader leaves, which are not so deeply divided; the whole plant is smooth, and the flowers are larger, but are of the same colour: this is also an annual plant, and requires the same treatment as the last.

The sixth sort grows naturally among the Corn in some parts of England. This is also an annual plant, whose seeds should be sown in autumn, for those which are sown in the spring seldom succeed. The leaves of this sort are finely jagged, and divided into narrow segments, somewhat like those of Buckthorn Plantain; they are smooth, of a lucid green, and are commonly opposite. The stalks rise little more than a foot high, dividing into two or three branches upward, garnished with small leaves of the same form as those below. The flowers are sustained by slender foot-stalks, which come out from the wings of the leaves; these are composed of four obtuse petals, of a Violet colour, in the center of which is situated a cylindrical germen, attended by a great number of stamens; the germen afterward becomes a long cylindrical pod, like those of the other species. The flowers of this plant are very fugacious, seldom lasting above three or four hours before the petals drop off; especially in clear weather. It flowers in May, and the seeds ripen in July, and the plants soon after perish. If the seeds are permitted to scatter, the plants will come up without care as the others.

- CHELONE [*ix-xy*]. Or. a tortoise. Tourn. Aft. R. S. 1706. tab. 7. fol. 2. Lin. Gen* Plant. 666.

The CHARACTERS are,

*The empalement of the flower is of one leaf cut into five parts, and is permanent; the flower is of the ringent kind, having a short cylindrical tube, which is swollen at the chaps, where it is oblong, convex above, and plain below; the mouth is almost closed; the upper lip is obtuse and indented**

Jinted, • the kwer lip is lightly cut into three parts. It hath four ftawina, which are inclofed in the backfide of the petak the two fide ones being a little longer than the other', which are terminated by oval hairy fummits-. It hath an oval germen fupporting a Jlcnder fyle, crowned by an obtufefigma-, the germen afterward becomes an oval cupfuk having two cells', which are filled with flat roundifh feeds having a border.

"This genus of plants is ranged in the fecond fe&ion of Linnaeus's thirteenth dais, intitled Didynamia Angiofpernia, from the flower having two long and two fhort ftamina, and the feeds being included in a capfule.

The SPECIES are,

- i. CHELONE (*Glabra*) foliis lanceolatis* acuminatis, fedibus, obfolete ferratis, radice reptatrice. *Chelone with pointed fpear-Jhaped leaves, fet clofe to tht ftalks, with Jmall ferratures on their edges, and a creeping root. Chelone Acadienfis flore albo. Tourn. Aft. R. Par. 1706. Cbekne of Acadia, with a white flower.*

1. CKELONE (*Purpurea*) foliis lanceolatis, obliquis, petiolatis, oppofitis, marginibus acute ferratis. *Chelone with oblique fpear-Jhaped leaves, growing oppofite on foot ftalks, and their borders Jharply fawed. Chelone floribus fpeciofis pulcherrimis, colore rofae damafcenfe. Clayt. Flor. Virg. 71. Chelone with a very beautiful looking flower, the colour of the Damajk Rofe.*

3. CHELONE (*Hirfuid*) caule-fbliifque hirfutis. Lin. Sp< Plant. 611. *Chelone with hairy ftalks and leaves. Dig9 tatis Virginiaha, panacis coloni foliis, flore amplo, pallafcente. Pluk. Mant. 64. Virginia Foxglove with Clowns all-heal leaves, end a large pale flower.*

The firft fort grows naturally in moft parts of North America. This is called by Jofcelin, in his New England Rarities, the Humming Bird-tree. It hath a pretty thick jointed root, which creeps under ground to a considerable diftance, fending up fmooth channelled ftalks, which rife about twofeet high, garnifhed with two leaves at each joint, (landing oppofite without foot-ftalks; thefe are three inches and a half long, and about three quarters of an inch broad at their bafe, where they are broadeft, and diminifh gradually to a fharp point5 they have fmall ferratures on their edges, which (Scarcely appear. The flowers grow in a clofe fpike at the end of the ftalks; they are white, and have but one petal, which is tubular, and narrow at the bottom, but fwells upward, almoft like the Foxglove flower; the upper fide is bent over and convex, but the under is flat, and (tightly indented in three parts at the end. When the flowers fall off, the germen turns to an oval capfule fitting in the empalement, filled with roundifh compreffed feeds, which have a thin border. It flowers in Auguft, and when the autumn proves favourable, the feeds will fomeumes ripen in England* but as the plants propagate fo faft by their creeping roots, the feeds are feldom regarded. The beft time to tranfplant the roots is in autumn, that they may be well eftablifhed in the ground before the fpring, otherwife they will not flower fo ftrong, epecially if the feafon proves dry; but when they, are removed in the (pring, it (hould not be later than the middle of March, by which time their roots will begin to puff out new fibres. They will thrive in almoft any foil or fituation, but their roots are apt to creep too far, if they are not confined, and fometimes intermix with thofe of other plants; and then their ftalks ftand fo far diftant from each other, as to make but little appearance; therefore they fhould be planted in pots, which will confine their roots, fo that in each pot there will be eight or ten ftalks growing near each other, when they will make a tolerable good appearance. This plant is very hardy, fo is not injured by cold, but it muft have plenty of water in hot weather.

The fecond fort was difcovered in Virginia by Mr. Clayton, who fent it to England: the roots of this do not creep fo far as thofe of the firft, the ftalks are ftronger, and the leaves much broader, and are oblique; they are deeply fawed on their edges, and ftand upon fhort foot-ftalks: the flowers are of a

bright purple colour, fo make a finer appearance?*" This flowers at the fame time with the firft, and is propagated by parting of the roots in the fame manner.

The third fort I received from New England, thtere it grows naturally: this is near to the firft fort, but the ftalks and leaves are very hairy, and the flower is of a purer white. It flowers at the fame time with the former, and requires the fame treatment.

As thefe plants flower in the autumn, when there is a fcarcity of other flowers, it renders them the more valuable, epecially the fecond fort, whofe flowers make a very pretty appearance, when they are ftrong; and if fome of them have a (hady fituation in the fummer, they will flower later in the autumn.

CHENOPODIA - MORUS. See BLITUM.

CHENOPODIUM fowo'cW, Gr.] Tourn. Inft. R. H. 506. tab. 288. Lin. Gen. Plant- 272. Goofefoot, or Wild Orach.

The CHARACTERS are,

// hath a permanent empalement, compofed of five oval concave leaves: the flower hath no petal, but in the center it hath five Jiamina placed oppofite to the leaves of the empalement, and of the fame length, terminated by roundifh twin fummits \ it hath a round germen fupporting a Jhort double fyle, crowned by an obtufe figma. The germen afterward becomes a five-cornered fruit inclofed in the empalement, containing one roundifh depreffed feed. Linnaeus places this genus in the fecond fe&ion of his fifth clafs, intitled Pentandria Digynia, the flower having five ftamina and two fyles.

The SPECIES are,

1. CHENOPODIUM (*Bonus Henricus*) foliis triangulari-fagittatis, integerrimis fpicis compofitis aphyllis. Hort. Cliff. 84. *Goofefoot with arrow-Jhaped triangular leaves which are entire. Chenopodium folio triangulo. Tourn. Inft. 506. Goofefoot with a triangular leaf, called Englifh Mercury, All Good, cr Good Henry.*
2. CHENOPODIUM (*Vulvaria*) foliis integerrimis rhombo-ovatis, floribus conglomeratis axillaribus. Flor. Suec. 216. *Goofefoot with entire, oval, rhomboidat leaves, and flowers growing in dufiers on the fide of the ftalks. Chenopodium fetidum. Tourn. Inft. 506. Stinking Orach.**
3. CHENOPODIUM (*Scoparia*) foliis lineari-lanceolatis, planis, integerrimis. Hort. Cliff. 86. *Goofefoot with narrow fpear-Jhaped leaves, which are plain and entire. Chenopodium lini folio villofo. Tourn. Inft. R. H. Goofefoot with a hairy Flax leaf, commonly called Belvedere, or Summer Cyprefs.*
4. CHENOPODIUM (*Botrys*) foliis oblongis, finuatis, racemis nudis multifidis. Hort. Cliff. 84. *Goofefoot with oblong finuated leaves, and nakedmultifid Jpikes of flowers. Chenopodium ambrofioides folio finuato. Tourn. Inft. 506. Goofefoot, like Ambrqfia, with finuated leaves, commonly called Oak of Jerufalem.*
5. CHENOPODIUM (*Ambrofioides*) foliis lanceolatis, dentatis, racemis foliatis fimplicibus. Hort. Cliff. 84. *Goofefoot with fpear-Jhaped indented leaves, and Jingle leafy fpikes of flowe?s. Chenopodium ambrofioides Mexicanum. Tourn. Inft. 506. Mexican Goofefoot, like Ambrofia, commonly called Oak of Cappadocia.*
6. CHENOPODIUM (*Fruticofum*) foliis lanceolatis, dentatis, caule fruticofa. *Goofefoot with fpearjhaped indented leaves, and ajhrubby ftalk. Chenopodium ambrofioides Mexicanum fruticofum. Boerh. Ind. alt. 2. p. 90. Shrubby Mexican Orach.*
7. CHENOPODIUM (*Multifidum*) foliis multifidis, fegmentis linearibus, floribus axillaribus fefilibus. Lin. Sp. 320. *Goofefoot with multifid leaves, linear figments, and flowers fet clofe to the ftalk. Chenopodium lempervirens, foliis tenuiter laciniatis. Hort. Elth. 78.*

There are many other Ipecies of this genus, fome of which grow naturally on dunghills and the fide of ditches, in moft parts of England, where they often become very troublefome weeds *, for which reafon> I have not enumerated them here.

The firft fort is found growing naturally in fliady lanes in many parts of England, but it is very doubtful if the feeds have not been caft out of gardens originally,

CHE

originally, because this plant was formerly cultivated in kitchen-gardens for use; and in some of the northern counties, the people still preserve it in their gardens as an excellent herb; which in the spring season, they dress in the same manner as Spinach, for which it is a substitute. But, as the latter is a much better herb, it has obtained the preference very justly, in all the countries where the culture of the kitchen-garden is understood.

The second sort is very common upon dunghills, and in gardens, in most parts of England: it is seldom cultivated, except in some physic-gardens, for the markets in London are supplied with it by the herb-women, who gather it in the places where it grows wild.

The third sort is sometimes cultivated in gardens, it is a beautiful plant, which is naturally disposed to grow very close and thick, and in as regular a pyramid as if cut by art. The leaves are of a pleasant green; and were it not for that, it hath so much of the appearance of a Cyprus-tree, that at some distance it might be taken for the same, by good judges: the feeds should be sown in autumn; and in the spring, when the plants are come up, they may be planted into pots of good earth, and kept supplied with water in dry weather: these pots may be intermixed with other plants to adorn court-yards, &c. Where they will appear very handsome, until their feeds begin to swell and grow heavy, which weigh down and displace the branches; at which time the pots should be removed to some adjacent part of the garden, to perfect their feeds; which, if permitted to fall upon the ground, will come up the next spring; so that you need be at no more trouble in propagating these plants, but only to transplant them where you intend they should grow.

The fifth sort was formerly used in medicine; but although it still continues in the catalogue of simples annexed to the London Dispensatory, yet is very seldom used at present. This plant may be propagated by sowing the feeds in an open border of good earth in the spring, where it will perfect its feeds in autumn, which, if permitted to shed upon the ground, will arise as the former.

The fourth sort was brought from America, where the feeds are called Worm Seed, I suppose from some quality contained in it, which destroys worms in the body.

This is propagated by sowing the feeds in the spring, as the before-mentioned sort, and will perfect its feed in autumn; after which, the plant decays to the ground: but if the root be preserved in shelter under a common frame in winter, the stalks will rise again the following spring.

The leaves of this plant emit a very strong Odour when bruised, somewhat like those of the Ambrosia, for which the plants are preserved in gardens, for the flower hath no beauty. This plant grows naturally in most parts of North America, where it is generally called Worm Seed. It sends up several stalks from the root, which rise about two feet high, garnished with oblong leaves a little indented on their edges, of a light green, and placed alternately on the stalks; the flowers come out from the wings of the leaves on the upper part of the branches, in loose spikes: these appear in July, and the feeds ripen in September, which, if permitted to scatter, the plants will come up the following spring, when a few of them may be transplanted into pots filled with kitchen-garden earth, to be preserved through the winter, and the others may be planted in the common borders, where they will flower and perfect their feeds; but unless the winter is very favourable, the roots will be destroyed.

The feeds of all the species of this genus will succeed best, if they are sown in autumn, for when they are sown in the spring, they frequently lie a whole year before the plants come up: therefore where the feeds of any of them scatter, the plants will come up much better than those which are sown by hand.

CHI

The fifth sort is annual: this also grows naturally in North America, from whence I have frequently received the feeds. It is also a native of many of the warm countries in Europe. This hath many oblong leaves at the bottom, which are deeply furrowed on both sides, somewhat like those of the Oak-tree, from whence it received the title of Oak of Jerusalem. These are purple on their under side, and when bruised, emit a strong odour. The stalks rise about eight or nine inches high, dividing into several smaller branches. The lower part of these is garnished with leaves of the same shape with those below, but are smaller. The flowers grow in naked loose spikes, divided into many parts: they are small, herbaceous, and are succeeded by small round feeds. This sort flowers in June and July, and the feeds ripen in autumn.

The sixth sort hath leaves very like those of the fourth, and have the same scent: but this hath a shrubby stalk, which rises five or six feet high, and divides into many branches. It is a native of America, and must be housed in the winter, for it will not live through the winter in England in the open air. It is easily propagated by cuttings during any of the summer months, which, if planted in a shady border, and duly watered, will soon take root, and then may be planted in pots filled with light earth, and placed in the shade till they have taken new root, after which they may be placed with other hardy exotic plants in a sheltered situation during summer; and when the frost comes on, they must be removed into the green-house; but they only require protection from hard frosts, and should have plenty of air in mild weather. This grows naturally in the Brazils.

The seventh sort grows naturally at Buenos Ayres: this rises with a shrubby stalk three or four feet high, garnished with oblong leaves, which are cut into many linear segments; the flowers sit close to the stalks, which, like the other species of this genus, have no petals, but the empalement incloses five slender stamens: the germen supports two styles, crowned by obtuse stigma.

This is a perennial plant, which retains its leaves through the year, so will add to the variety in a green-house in winter, but has little other beauty to recommend it. This may be propagated by cuttings, which, if planted in a bed of light earth during any of the summer months, and duly shaded and watered, will put out roots; then they may be transplanted into pots, and may be placed with other hardy exotic plants in summer, but must be sheltered from frost in winter.

CHERRY-LAUREL. See PADUS.

CHERRY-TREE. See CERASUS.

CHEVIL. See SCANDIX.

CHESTNUT. See CASTANEA.

CHESNUT, the Horse. See Escaus.

CHIONANTHUS. Lin.Gen.Plant. 21. The Fringe, or Snowdrop-tree. This title was given to this plant by Dr. Van Royen, from the whiteness of its flowers: the inhabitants of America, where this tree is a native, call it Snowdrop-tree, for the same reason: and the Dutch call it Sneebaum, i. e. Snow-tree, on the same account.

The CHARACTERS are,

It hath a permanent empalement of one leaf, which is effective and cut into four acute parts \ the flower is of one petal, having a short spreading tube the length of the empalement, and the upper part is cut into four very long narrow segments, which are erect. It hath two short stamens inserted in the tube of the petal, which are terminated by upright heart-shaped summits. In the center is placed the oval germen, supporting a single style, crowned by an obtuse trifid stigma. The germen afterwards becomes a round berry with one cell, inclosing one hard feed.

This genus of plants is ranged in the first section of Linnaeus's second class, entitled Diandria Monogamia, the flower having two stamens and one style.

C H t

We have but one SPECIES of this plant in the English gardens, viz..

CHIONANTHUS pedunculifl. trifidis "trifloris. Lin. Sp. Plant. 8: *Snowdrop-tree, or Fringe-tree, with trifid foot-stalks supporting three flowers.* Amelanchier Virginiana laurocerasti folio. Pet. Hor. Sice, 241. Virginia Amelanchier with a Laurel leaf.

This shrub is common in South Carolina, where it grows by the side of rivulets, and seldom is more than ten feet high: the leaves are as large as those of the Laurel, but are of a much thinner substance, the flowers come out in May, hanging in long bunches, and are of a pure white, from whence the inhabitants call it Snowdrop-tree; and, from the flowers being cut into narrow segments, they give it the name of Fringe-tree. After the flowers have fallen away, the fruit appears, which becomes a black berry, about the size of Sloes, having one hard seed in each.

This tree is now more common in the curious gardens in England, than it was a few years since; there having been many young plants raised from the seeds, which have been brought from America lately: there have also been some plants propagated by layers, though there is great uncertainty of their taking root, which they seldom do in less than two years; nor will they ever take root, unless they are well supplied with water in dry weather.

The best way to obtain good plants, is from the seeds, which must be procured from America, for they never have produced any fruit in this country. The seeds should be sown in small pots filled with fresh loamy earth soon after they arrive, and should be placed under a hot-bed frame, where they may remain till the beginning of May, when they must be removed to a situation exposed to the morning sun, and screened from the sun in the middle of the day. In dry weather the pots must be watered, and kept clean from weeds, for as these seeds lie in the ground a whole year before the plants will come up, they should not be exposed to the sun the first summer, but the following autumn they should be removed, and placed under a frame, to protect the seeds from being injured by the frost, and if the pots are plunged into a moderate hot-bed the beginning of March, it will bring up the plants much sooner than they will otherwise rise; by which means they will get more strength the first summer, and be better able to resist the cold of the next winter. While these plants are very young, they will be in danger of suffering by severe frost; but when they have obtained strength, they will resist the greatest cold of our climate in the open air; therefore for the two or three first winters, it will be proper to keep them under shelter; so that the young plants may remain in the seed-pots all the first summer, and the following winter; and in the spring before they begin to shoot, they should be shaken out of the pots, and carefully separated so as not to break off their roots, and each planted in a small pot filled with light loamy soil, and plunged into a very moderate hot-bed, just to forward their taking fresh root; then they should be gradually inured to the open air, and during the following summer, the pots should be plunged into the ground, to prevent the earth from drying, in a situation where they may enjoy the morning sun, but screened from the great heat at noon. During the summer season, they will require to be frequently watered, and kept dean from weeds. The autumn following, they should be again placed under a hot-bed frame to screen them from frost; but they should enjoy the free air at all times, when the weather is mild. The April following, the plants may be shaken out of the pots, with the ball of earth to their roots, and planted where they are designed to remain.

This shrub delights in a moist, soft, loamy soil, and if it is planted in a sheltered situation, will endure the cold of our winters very well in the open air, but in dry land it is very subject to decay in warm seasons.

C H I

In the places where this shrub grows naturally* it produces great quantities of flowers, so that they seem covered with snow, which gave occasion to the inhabitants for titling it Snowdrop-tree, but in England the flowers are seldom so numerous, so do not make so good an appearance*

CHIRONIA. Lin. Gen. Plant. 227.

The CHARACTERS are,

The flower hath a permanent impaction of one leaf cut into five oblong segments: it hath one petal, with a roundish tube; the size of the empalement, divided into five equal parts above, which spread open: it hath five short broad stamina, which are fastened to the top of the tube, and are terminated by large oblong summits, which join together, and after the flowers drop are spirally twisted. It hath an oval germen, situated in the center supporting a slender declining style, crowned by a rising stigma in form of a bead. The germen afterward becomes an oval capsule with two cells, filled with small seeds.*

This genus of plants is ranged in the first federation of Linnaeus's fifth class, intitled Pentandria Monogynia* the flower having five stamina and one style.

The SPECIES are,

1. **CHIRONIA frutescens, capfulifera.** Lin. Sp. Plant. 190; *Shrubby Chironia bearing capsules.* Centaureum minus Africanum, arborefcens, latifolium, flor ruberrimo. Com. Rar. Pl. 8. tab. 8. *Leffer Tree-Hk* African Centaury, with a broad leaf, and a very red flower.*

2. **CHIRONIA frutescens baccifera.** Lin. Sp. Plant. 190. *Shrubby berry-bearing Chironia.* Centaureum minus arborefcens pulpiferum. Com. Rar. Pl. 9. tab. 9. *Leffer Tree-like Centaury with seeds surrounded with pulp.*

These plants grow naturally at the Cape of Good Hope, from whence their seeds were brought to Holland many years past, and the plants were raised in some of the curious gardens there, and have since been communicated to the curious in many parts of Europe. The seeds of the first sort were sent me from Paris, by Mr. Richard, gardener to the king at Versailles, from which I raised several plants, which have flowered in the Chelsea garden several years, but have not as yet perfected any seeds.

It hath a fibrous root, which spreads near the surface of the ground. The stalks are round, and inclining to be ligneous, but are of a very soft texture; these grow from two to three feet high, having several branches on every side, which grow erect, garnished with succulent leaves, which are an inch or more in length, and an eighth part of an inch broad, ending in an obtuse point. At the ends of each shoot the flowers are produced, which are tubulous, and spread open at the top like those of Periwinkle; these are of a bright red colour, and when there are a large number of the flowers open on the same plant, they make a very fine appearance. In the center of the flower is placed an oval germen, upon which there is fixed a recurved style, having a blunt stigma at the top, surrounded by five incurved stamina, each supporting a large summit. When the flowers fall away, the germen becomes an inflated capsule, which is filled with small seeds. The flowers are produced from June to autumn, and the seeds ripen in October. This plant should be placed in an airy glass-case in winter, where it may enjoy a dry air and much sun, but will not thrive in a warm stove nor can it be well preserved in a common green-house because a damp moist air will soon cause it to rot.

The seeds of this plant should be sown in small pots filled with light sandy earth, soon after they are ripe, and plunged into a moderate hot-bed, and must be frequently but gently watered; sometimes the seeds will lie a long time in the ground, so that if the plants do not appear the same season, the pots should not be disturbed, but preserved in flicker till the following spring, and then plunged into a fresh hot-bed, which will bring up the plants in a short time, if the seeds are good. When the plants are fit to remove, they should be transplanted into

small pots, four or five in each pot; then plunge the pots into a moderate hot-bed, and sprinkle them with water, and shade them every day from the sun till they have taken new root; after which they must lie a large share of air in warm weather, to prevent their drawing up weak: when the plants have obtained some strength, they must be gradually inured to bear the open air; but when they are exposed abroad, if there should happen much rain, the plants must be screened from it, otherwise it will cause them to rot: when the plants have filled the pots with their roots, they should be parted, and each put into a separate pot filled with light sandy earth, not rich with dung, placing them in the shade till they have taken fresh root; then they may be removed to a warm flickered situation, and mixed with such other plants as require but little water; in which situation they may remain till autumn, when they must be placed in a dry airy glass-case; and in the winter should have very little wet, but must enjoy the sun as much as possible; and in mild weather should have fresh air admitted to them, but must be protected from frost: with this management, the plants will thrive and produce flowers the second year from seed.

The second sort rises with a firmer stalk than the first, which is round, jointed, and divides upward into a greater number of branches, garnished with short narrow leaves, which are pretty thick and succulent. The flowers are produced at the end of the branches, in the same manner as those of the first, which are of a fine red colour, but not half so large as the flowers of the first, when these fall away, they are succeeded by oval pulpy berries, in which are included many small seeds. This sort continues flowering great part of summer and autumn, and in warm seasons the seeds will ripen in England.

It is propagated by seeds in the same manner as the former sort, and the plants require the same treatment.

CHIVES, as they are by some titled, are the stamina, which support the stamens in the center of flowers.

G-HIVETS, in French, are the small parts, or little offsets from the roots of bulbous plants, by which they are propagated.

CHONDRILLA. Lin. Gen. Plant. 815. Tourn. Inft. R. H. 475. tab. 268. [of X&Jfcta Gr. a cartilage.] Gum Succory.

The CHARACTERS are,

The common empalement is composed of many narrow cylindrical scales, which are equal. The flower is composed of many hermaphrodite florets, which are uniform, and imbricating like tiles on above; these have one petal, which is stretched out on one side like a tongue, and are indented at the top in four or five figments; they have each five short hairy stamina terminated by cylindrical stamens. The germen is situated under the floret, having a style the length of the stamina, crowned by two reflexed stigmas; the germen afterward becomes a single, oval, compressed seed, crowned with a fringe down, and inclined in the empalement.*

This genus of plants is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia aequalis. The flowers of this section are composed of only hermaphrodite florets, which are fruitful.

We have but one SPECIES of this genus, viz.

CHONDRILLA (*Juncea*.) Lin. Hort. Cliff. 383. Gum Succory. *Chondrilla juncea viscosa arvensis*. C. B. P. 30. *Viscous Field Gum Succory with rusty stalks.*

This plant grows naturally in Germany, Helvetia, and France, on the borders of the fields, and is seldom preferred in gardens, because the roots are very apt to spread, and become troublesome weeds, and the seeds having down on their tops, are carried by the wind to a great distance, so that the neighbouring ground is filled with the plants; the roots of this strike deep into the ground, and spread out with thick fibres on every side, each of which, when cut, or broken into many parts, will shoot up a plant so

that when this plant hath obtained possession of the ground, it is very difficult to root out. The roots send out a great number of slender stalks, which at their bottom are garnished with oblong finuated leaves, but those above are very narrow and entire. The flowers are produced from the side and top of the branches, which are like those of Lettuce, and are succeeded by seeds of the same form, crowned with down. It flowers in July, and the seeds ripen in September.

The other species of this genus which were enumerated in the former edition, are referred to the *Lactuca* and *Crepis*.

CHRISTMAS FLOWER, or Black Hellebore. See HELLEBORUS.

CHRISTOPHORIANA. See ACTEA.

CHRISANTHEMOIDES OSTEOSPERMON. See OSTEOSPERMUM.

CHRYSANTHEMUM. Tourn. Inft. R. H. 491. tab. 280. Lin. Gen. Plant. 866. *Leucanthemum*. Tourn. Inft. R. H. 492. [*xpvfr&is/Ao**, Gr. from χρυσός, gold, ἀνθή, a flower, that is to say, Golden Flower.] *Corn Marigold*.

The CHARACTERS are,

It hath a compound flower, the rays being composed of female florets, which are extended on one side like a tongue and are indented in three figments at the end; these have an oval germen, supporting a slender style, crowned by two obtuse stigmas. The hermaphrodite florets which compose the disk, are funnel-shaped the length of the empalement but are divided into five figments at the top, which are spread open; these have five short hairy stamens, terminated by tubular cylindrical stamens, and have an oval germen, with style and stigma like the female; the germen afterward becomes a single, oblong, naked seed.*

This genus of plants is ranged in the second section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia superflua. In this section all the central florets which compose the disk, are hermaphrodite and fruitful, and the rays are composed of female florets.

The SPECIES are,

1. *CHRYSANTHEMUM (Segetum) foliis amplexicaulibus; superne laciniatis, inferne dentato-ferratis*. Hort. Cliff. 416. *Corn Marigold with leaves embracing the stalks, the upper being jagged, and the lower indented like a saw.* *Chrysanthemum segetum*. Cluf. Hift. 1. p. 334. *Corn Marigold*.

2. *CHRYSANTHEMUM (Leucanthemum) foliis amplexicaulibus, oblongis, superne ferratis, inferne dentatis*. Hort. Cliff. 416. *Corn field-marigold with oblong leaves embracing the stalks, the upper ones being sawed, and the lower indented.* *Bellis sylvestris caule folioso major*. C. B. P. 261. *Greater wild Daisy with a leafy stalk.*

3. *CHRYSANTHEMUM (Serotinum) foliis lanceolatis, superne ferratis, utrinque acuminatis*. Hort. Cliff. 416. *Corn Marigold with spear-shaped leaves, those above being sawed, and pointed on all sides.* *Bellis major, radice repente, foliis latioribus, ferratis*. Mor. Hift. 3. p. 29. *Greater Daisy with a creeping root, and broad sawed leaves.*

4. *CHRYSANTHEMUM (Montanum) foliis imis spatulato-lanceolatis, ferratis, summis linearibus*. Sauv. Monfp. 87. *Corn Marigold with lower leaves pointed like a spear-shaped spatula, and sawed, and the upper ones linear.* *Leucanthemum montanum minus*. Tourn. Inft. 492. *Lesser Mountain Ox-eye.*

5. *CHRYSANTHEMUM (Graminifolium) foliis linearibus, fubintegerrimis*. Sauv. Monfp. 87. *Corn Marigold with narrow leaves, which are entire.* *Leucanthemum gramineo folio*. Tourn. Inft. 493. *Ox-eye with a Grass leaf.*

6. *CHRYSANTHEMUM (Alpinum) foliis pinnatifidis, laciniis parallelis, integris, caule unifloris*. Lin. Sp. Plant. 889. *Corn Marigold with many pointed leaves, whose figments are parallel and entire, and one flower on each foot-stalk.* *Leucanthemum alpinum, foliis coronopi*. Tourn. Inft. R. H. 493. *Alpine Ox-eye with a Hart/horn leaf*

7. CHRYSANTHEMUM (*Corymbiferum*) foliis pinnatis, incifo-ferratis, caule multifloro. Prod. Leyd. 174. *Corn Marigold with winged leaves, fawed fegments* and many flowers upon a stalk. Tanacetum montanum inodorum, minore flore. C. B. P. 132. Unfavoury Mountain Tanfy with a leffer flower.*
8. CHRYSANTHEMUM (*Coronarium*) foliis pinnatifidis, incifis, extrorfum latioribus. Hort. Cliff. 416. *Corn Marigold with wing-pointed cut leaves* whose exterior parts are broadest. Chryfanthemum Creticum. Cluf. Hift. i. p. 334. Corn Marigold of Crete.*
- §. CHRYSANTHEMUM (*Monfpelienfium*) foliis imis palmatis, foliolis linearibus, pinnatifidis. Sauv. Monfp. 304. *Corn Marigold* whose lower leaves are palmated* and the mailer linear, ending in many points. Leucanthemum montanum foliis Chryfanthemum. Tourn. Inf. 492. Mountain Ox-eye with Corn Marigold leaves.*
10. CHRYSANTHEMUM (*Frutefcens*) fruticofum, foliis linearibus dentato-trifidis. Hort. Cliff. 417. *Shrubby Corn Marigold with narrow leaves* having three indented-points. Leucanthemum Canariense, foliis Chryfanthemum, Pyrethri fapore. Tourn. Inf. 493. Canary Ox-eye with Corn Marigold leaves* and the tafte of Pelitry.*
11. CHRYSANTHEMUM (*Flofculofum*) flofculis omnibus uniformibus, hermaphroditis. Hort. Cliff. 417. *Corn Marigold* whose florets are all uniform and hermaphrodite. Bellis ipinofa, foliis Agerati. C. B. P. 262. Prickly Daify with Maudlin leaves.*
12. CHRYSANTHEMUM (*Pallidum*) foliis linearibus, infernè apice dentatis, fupernè integerrimis, pedunculis nudis unifloris. *Corn Marigold with narrow leaves* whose on the lower part being indented at their points* the upper entire* and naked foot-stalks with one flower. Chryfanthemum pallidum minimis, imifque, foliis incifis fuperioribus integris, capillaribus. Barrel. Icon. 421. Leafy Corn Marigold* with the under and leffer leaves divided* the upper entire.*

The firft fort is the common Corn Marigold, which grows naturally amongft the corn, and the borders of the corn-fields in divers parts of England, fo is rarely admitted into gardens *, but we have inferred this and the next to introduce the other fpecies.

The fecond fort is the greater Daify, which ftands in the lift of medicinal plants in the Colledge Difpenfatory: this grows naturally in moift paffures, almoft every where in this country. It rifes with (talks near two feet high, garnifhed with Oblong indented leaves, which embrace the ftalks with their bafe. The foot-ftalks are each terminated by one white flower, fhaped like thofe of the Daify, but four times as large. It flowers in June.

The third fort grows naturally in North America, but hath been long preferved in the Englifh gardens. The roots of this plant creep far under the furface, and fend up ftrong ftalks three or four feet high, garnifhed with long fawed leaves, ending in points; the ftalks divide upward into many fmaller, each being terminated by a large, white, radiated flower; thefe appear in September. It multiplies very faft by its creeping roots, and will thrive in any foil or fituation.

The fourth fort grows naturally upon the Alps, and other mountainous places. I received this from Verona, near which place it grows in plenty: this fends up a fingle ftalk a foot high, garnifhed with entire leaves above, but the under leaves are fawed on the edges. The ftalk is terminated by one large white flower, fhaped like thofe of the third fort. It flowers in June, and the feeds ripen in Auguft. This fort may be propagated by feeds, which, if fown in a fiady border, will come up in about fix weeks *, and the plants, when fit to remove, may be tranfplanted into a fiady border, where they are to remain, and will require no other care but to keep them clean from weeds.

The, fifth fort grows naturally about Montpellier, this hath a perennial root, from which fprings up many narrow Grafs-like leaves, and, between them, ftalks which rife a foot and a half high, garnifhed

with leaves of the fame form as thofe below. *f hē ftalks are each terminated by one large white flwver, with a yellow difk or middle. This dowers in June, but rarely perfe&s feeds in England, fo is propagated only by parting the roots: the beft time for this is in autumn, that the plants may get good root before winter.

The feventh fort grows naturally on the Alps, and other mountainous places in Germany: this fends out upright ftalks, garnifhed with leaves cut into many parallel fegments, fofnewhat like thofe of Buckihorn Plantain. The ftalks rife a foot and a half high, and are each terminated by a fingle flower of the fame form with thofe of the laft: it hath a perennial root, and may be propagated in the fame manner as the other.

The eighth fort has been many years cultivated in the gardens for the beauty of its flowers. Of this there are fingle and double with white, and the fame with yellow flowers *, and as thefe do not differ from each other in any thing except in the colour of their flowers, therefore they are generally efteemed but one fpecies *, but this difference is conftant, for I have never found the feeds faved from the white, produce plants with yellow flowers, nor thofe of the yellow produce white.

There is alfo a variety of thefe colours with fiftular florets, which has accidentally rifen from feeds of the other; thefe are generally titled Quill-leaved Chryfanthemum; but as the feeds faved from thefe degenerate to the common forts, fo they do not merit a particular denomination.

Thefe plants are always efteemed as annual, fo the feeds are ufually fown upon a flender hot-bed in the fpring, and the plants treated in the fame manner as the African Marigold, for the culture of which we fhall refer the reader to that article; but as the plants which rife from feeds, do many of them produce fingle flowers, although the feeds are faved from the beft double flowers, therefore many perfons now propagate thefe plants from cuttings, whereby they continue the double forts only -, thefe cuttings, taken from the plants the beginning of September, and plant'd in pots, will readily take root *, and if they are placed under a hot-bed frame to fcreen them from the froft in winter, letting them have free air in mild weather, they will live through the winter; and in the fpring thefe plants may be tranfplanted into the borders of the flower-garden, where they will flower in June, and continue in fuceffion till the froft puts a ftop to them *, by this method all the varieties may be continued without variation, but the plants which are propagated this way by cuttings will become barren foon, fo will not produce feeds.

The ninth fort is a perennial plant, fending out many ftalks from the root, which divide into branches, garnifhed with pretty thick leaves, deeply cut into many fegments, like thofe of the laft fort; thefe are of a pale green; the flowers are produced at the end of the branches, ftanding upon pretty long naked foot-ftalks *, they are very like thofe of the common Greater Daify, in fize and colour. It flowers in June, and continues till the end of September. This fort ripens feeds every year in England, by which the plant is eafily propagated; for if the feeds are fown in the fpring on a common border, the plants will come up in fix weeks; when thefe are fit to remove, they may be tranfplanted into a nurfery-bed at about a foot diftance every way, and kept clean from weeds till autumn, when they may be removed to the places where they are defigned to remain. As thefe plants extend their branches pretty far on every fide, they fhould be allowed at leaft two feet room; therefore they are not very proper furniture for finall gardens, where there is not room for thefe large growing plants *, but in large gardens, thefe may have a place for the fake of variety.

If thefe plants are planted in poor dry land, or upon lime-rubbifh, they will not grow fo vigorous as in good ground, fo they yrill endure the cold better,

and continue longer; for when their leaves and branches are replete with moisture, they are very apt to rot in the winter, so are seldom of long duration; but where the plants have grown from the joints of old walls, I have known them continue in vigour several years.

The tenth sort grows naturally in the Canary Islands, from whence it was first brought to England, where it has been long an inhabitant in some curious gardens. It has been frequently called by the gardeners Pellitory of Spain, from the very warm taste which it hath, much resembling the taste of that plant.

This rises with a shrubby stalk near two feet high, dividing into many branches, garnished with pretty thick succulent leaves, of a grayish colour, cut into many narrow segments, which are divided into three parts at their extremity. The flowers come out from the wings of the leaves, hanging upon naked footstalks singly, which greatly resemble those of the common Chamomile -, there is a succession of flowers upon the same plants great part of the year, for which it is chiefly esteemed. This plant will perfectly feed in England, when the seasons are favourable; but as the cuttings of it take root so easily, if planted during any of the summer months, the feeds are rarely sown.

As this plant is a native of warm countries, it will not live in the open air in England during the winter season; therefore when the cuttings have made good roots, they should be each planted into a separate pot, and placed in the shade till they have taken fresh root; then they may be removed to a sheltered situation, where they may remain till autumn, at which time they must be removed into the green-house to protect them from frost -, but in mild weather they should have plenty of free air, and, during the winter, they should be frequently refreshed with water, but it must not be given them in too great plenty. In summer they will require more moisture, and should be treated in the same manner as other hardier kinds of exotic plants.

The eleventh sort grows naturally at the Cape of Good Hope, from whence the feeds were brought many years past to Holland, where the plants were first raised, and from thence all the other parts of Europe have been supplied with this plant. It rises with a shrubby stalk about two feet high, which divides into many (tender branches upward, garnished with oblong leaves, much indented on their edges, each indenture terminating in a soft spine; these are of a pale green, set close to the branches. The flowers are produced on short footstalks from the wings of the leaves, toward the upper part of the branches *, these are globular, and formed of a great number of hermaphrodite florets, which are tubular and even, having no rays, so are naked, and of a deep yellow colour. The flowers appear in June, and continue in succession till the frost stops them. This may be propagated by cuttings in the same manner as the last, and the plants should be treated in the same way. The twelfth sort grows naturally about Madrid: this hath a low shrubby stalk, which seldom rises a foot high, putting out several slender ligneous branches, garnished with narrow, pale, green leaves -, those on the lower part of the branches are indented at their extremity in several parts, but the upper leaves are entire *, from the end of each branch is produced a naked footstalk six inches long, sustaining one radiated flower, * of a sulphur colour. The flowers come out in June and July, but there is seldom any feeds ripened in England *, this sort must be sheltered under a common frame in winter, for unless the winter proves very favourable, the plants will not live in the open air here. It may be propagated by cuttings in summer, as the two last sorts, but these cuttings do not so readily take root as those do.

CHRYSOBALANUS. Lin. Gen. Plant. 585. Icac. Plum. Nov. Gen. 44. Cocoa Plum.

The CHARACTERS are,
The § enpalement of the flower is of one leaf divided into

five parts, almost to the middle. The flower hath fog petals* which spread open, and ten stamina, five of which are longer than the petals; the other are shorter, and are terminated by heart-shaped summits. In the center is situated an oval germen, supporting a trifid short style, crowned by obtuse stigmas. The germen afterward becomes an oval fleshy berry, inclosing a nut with five longitudinal furrows.

This genus of plants is ranged in the first section of Linnaeus's thirteenth class, intitled Polyandria Monogynia; but it would be more properly placed in the third section of his tenth class, for the flowers have ten stamina and three styles.

The SPECIES are,

1. CHRYSOBALANUS (*Icac*) foliis ovatis, emarginatis, floribus racemosis, caule fruticoso. *Chrysobalanus* with oval indented leaves, flowers growing in bunches, and a shrubby stalk. Frutex Cotini ferè tblio crasso, in fumitate deliquium patiente, fructu ovali cseruleo officulum angulofum continente. Catefb. Car. *The Cocoa Plum*.
2. CHRYSOBALAKUS (*Purpurea*) foliis decompositis, foliis ovatis integerrimis. *Chrysobalanus* with decomposed leaves, whose lobes are oval and entire. Icac fructu purpureo. Plum. Nov. Gen. 44. *Icac* with purple fruit.

The first sort grows naturally in the Bahama Islands, and in many other parts of America, but commonly near the sea. It rises with a shrubby stalk about eight or ten feet high, sending out several side branches, covered with a dark brown bark, spotted with white; these are garnished with oval stiff leaves, which are indented at the end, in form of a heart, placed alternately on the branches. From the wings of the leaves, and also at the division of the branches, the flowers are produced, which grow in loose bunches; these are small and white, having many stamina in each, which are joined to the petals of the flowers, terminated by yellow summits. The flowers are succeeded by oval Plumbs about the size of Damsons; some of these are blue, some red, and others yellow; they have a sweet luscious taste. The Spaniards in the island of Cuba, make a conserve of these fruits. The (tone of the Plum is shaped like a Pear, and hath five longitudinal ridges on it. This grows naturally on moist land.

The feeds of the second sort were sent me from Jamaica, with Plunder's title-, the tones were exactly the same shape of those of the former, but the plants have leaves compounded of several winged lobes, which are branched out opposite, each having six or seven pair of pinnae (or lobes.) This sort hath not flowered in England, so I can give no farther account of it.

As these trees are natives of the warm parts of America, so they will not thrive in England, unless they are kept in a warm stove. They are propagated by feeds, which must be obtained from the countries where the plants naturally grow; these must be sown in the spring in small pots filled with light earth, and plunged into a hot bed of tanners bark, observing frequently to water the pots 5 but not let them have much at each time. In six weeks the plants will come up, and, if properly managed, will be fit to remove in a month's time after, when they should be carefully separated, and each planted into a separate small pot filled with light kitchen-garden earth, and then plunged into the hot-bed again, observing to shade them from the sun till they have taken fresh root j after which they must have air every day in proportion to the warmth of the season, and their waterings during the summer should be frequent, but sparing. In the autumn the plants must be removed into the bark-stove, and plunged into the tan-bed 5 and in winter the plants must not have too much water, lest it occasions their throwing off their leaves. In summer they must have a good share of air, and the plants in the stove should be constantly treated in the same manner as other tender plants from the same countries.

CHRYSOCOMA. Lin. Gen. Plant. 845. Dillen. Gen. 14. Coma aurea. Boerh. 1. p. 121. Goldylocks.

The CHARACTERS are,
The common empalement is imbricated* the feaks are narrow* the outer being convex and pointed; the flower is compofed of many hermaphrodite florets* which are tubular* equal* and funnel-shaped* cut into five fegments at the brim* which turnback* thefe have each five Jhort flender ftamina* terminated by cylindrical fummits* they have an oblong germen* Jupporting a flender Jtyle* crowned by two oblong depreffedftigmas. The germen afterward becomes a jingle* oblong* compreffed feed* crowned with hairy down*

This genus of plants is ranged in the firft: fection of Linnseus's nineteenth clafs, intitled Syngenefia Polygamia ^qualis 5 the plants of this fection have only hermaphrodite florets, which are fruitful.

The SPECIES are,

1. CHRYSOCOMA (*Unofyris*) herbacea, (pliis linearibus, glabris, calycibus laxis. Lin. Sp. Plant. 841. *Herbaceous Goldylocks with narrow fsmooth leaves* and loofe empakments.* Coma aurea Germanica linariae folio. Park. Theat. 688. *German Goldlocks.*
2. CHRYSOCOMA (*Biflora*) herbacea paniculata, foliis lanceolatis trinerviis, pun&atis, nudis. Lin. Sp. Plant. 841. *Herbaceous Goldylocks with flowers growing in panicles* and fpear-Jhaped leaves* having three nerves* and yellow flowers growing in umbels.*
3. CHRYSOCOMA (*Coma Aurea*) fruticofa foliis linearibus dorfo decurrentibus. Hort. Cliff. 397. *Shrubby Geldylocks with very narrow leaves* wbofe back parts run along theftalks.* Coma aurea Africana fruticans, foliis linearis auguftis, major. Com. Hort. Elth. 104. tab. 68. *Narrow-leaved* African* Jhrubby Fleabane* with a golden flower.*

The firft fort grows naturally in Germany, and alfo in France and Italy 5 this hath a perennial root; the ftalks rife two feet and a half high, are round, ftiff, and dofely garnifhed With long, narrow, fsmooth leaves, which come out without any order, of a pale green colour; the upper part of the ftalk divides into many flender foot-ftalks, each fuftaining a fingle head of flowers, which are compofed of many hermaphrodite florets, contained in one common empalement, having very narrow feales. The flowers are of a bright yellow, and ftand difpofed on the top of the ftalk, in form of an umbel. Thefe appear in July, and in favourable feafons' are fucceeded by feeds, which ripen in September, foon after which the ftalks decay to the root, and new ones arife the following fpring.

This plant is generally propagated by parting of the roots, that being the mod expeditious method -, for the feedling plants do not flower till the fecond or third year. The beft time to remove the plants and part their roots, is foon after the ftalks decay in autumn, that the plants may get frefh roots before winter. It delights in & dry loofe foil, in which it will live in the open air, and propagate by its roots very faft; bint in ftrdng wet land, the roots often rot in winter.

The fecond fort grows naturally in Siberia, from whence the feeds were fent to Peteriburgh, part of which I received from the late Dr. Amman, who was profeffor of botany in that imiverfity. This plant hath a perennial creeping root, which fpreads 01

every fide to a confiderable diftance, fending up many eredt ftalks, garnifhed with flat fpear-fhaped leaves, ending in points *, thefe are rough, and have three longitudinal veins; the upper part of the ftalks branch out, and form loofe panicles of yellow flowers, which are larger than thole of the former fort. This flowers in June and July, and the feeds ripen in autumn.

It propagates too faft by its creeping "roots to be admitted into the flower-garden, for the roots will often extend two or three feet every way in the compaft of one year, fo that they will interfere with the neighbouring flowers; but as the plants will grow in any foil or fituation, fo a few roots may be planted on the fide of extenfive rural walks round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

The third fort grows naturally at the Cape of Good Hope. This rifes with a ligneous ftalk about a foot high, dividing into many fmall branches, which are garnifhed with narrow leaves, of a deep green, coming out on every fide without order-, the back part of each leaf hath a fmall fhort' appendix, which runs along the ftalks. The flowers are produced at the end of the branches, on flender naked foot-ftalks *, thefe are of a pale yellow, and fhaped like thole of the former forts, but are larger. This plant flowers great part of the year, for which it is chiefly eftemed; the feeds ripen very well in autumn, which if fown on a common border of light earth in the fpring, the plants will come up, and may be tranfplanted into pots, to be removed into fhelter in winter, for thefe plants will not live through the winter in the open air in England.

The moft expeditious method of propagating this plant is by cuttings, which, if planted in a common border in any of the fummer months, and covered with hand-glaffes, will eafily take root, provided they are fhaded from the fun and duly watered: when thefe have gotten good roots they fhould be carefully taken up, and each planted in at feperate pot, filled with light earth, placing them in the fhade till they have taken new root; then they may be expofed with other hardy exotic plants till autumn, when they muft be removed into the green-houfe during the winter feafon; they fhould enjoy a large fhare of free air in mild weather, for they only require protection from froft, fo muft not be too tenderly treated.

The fourth fort is a native of the Cape of Good Hope, from whence I received the feeds *, this is a lefs plant than the former, it hath a fhubby ftalk, branching out in the fame manner -, the leaves are fhorter, and a little hairy; the flowers are not half fo large, of a pale fulphur colour, and nod on one fide before they are blown. This alfo flowers great part of the year, and ripens feeds very well *, but this is generally propagated in the fame manner as the former, and the plants require the fame treatment.

The fifth fort is alfo a native of the fame country as the two former -, this hath a low fhubby ftalk, which branches out on every fide, very narrow, (hort, rough, and reflexed 5 the flowers ftand fingle on the top of haked foot-ftalks, which arife from the upper part of the branches; thefe flpwers are larger than thole of the laft, and ftand eredt. This plant requires the fame treatment as the two former, and is propagated by cuttings in the fame manner.

CHRYSOPHYLLUM. Lin. Gen. Plant. 233. Cainito. Plum. Nov. Gen. 9. tab. 9. The Star Apple.

The CHARACTERS are,

The empalement is permanent* and conffts of five finally roundijh* concave petals* the flower is compofed of five petals* which fpread open* and are cut in the middle into two parts*, it hath five ftamina placed alternate to the fegments of the petals, terminated by heart-fhapei fummiu : the oval germen is fituated in t ht center* fupporting;

ing ahortfyk, crowned by an obtufe jigm. The germen afterward becomes a large, oval, flefity fruit, inclofing three or four fiat feeds, having hardjhells.

This genus of plants is ranged in the firft fe&ion of Linnaeus's fifth clafs, intituled Pentandria Monogynia, the flower having five (lamina and one ftyle.

The SPECIES are,

1. CHRYSOPHYLLUM (*Cainito*) foliis ovatis, parallelis fubtus, tomentofis nitidis. Jacq. Amer. 15. *Chryfophyllum with oval leaves, with parallel veins and neat woolly leaves on their under fide.* Cainito folio fubtus aureo, fructu olivae formi. Plum, Nov. Gen. 10. *The Damfon-tree.*

2. CHRYSOPHYLLUM (*Glabrum*) foliis utrinque glaberrimis. Jacq. Amer. 15. *Chryfophyllum with very fmooth leaves.* Cainito folio fubtus aureo, fructu maliformi. Plum. Nov. Gen. 10. *The Star Apple.*

Thefe trees grow naturally in the Weft-Indies, where the firft fort rifes from twenty to thirty feet high, dividing into many branches, garnifhed with oval leaves, fmooth above, and of a gold colour on their Under fide 5 the flowers come, out from the fide of the branches, at the fetting on of the leaves, in round clufters, which are fucceeded by oval, fmooth, pulpy fruit, inclofing three or four hard fiat feeds.

The fecond fort rifes with an upright trunk to the height of thirty or forty feet, dividing into many (ender branches, garnifhed with fpear-lhaped leaves, coming out without order; from the wings of the leaves, and alfo at the extremity of the branches, the flowers are produced in bunches, which are fucceeded by round pulpy fruit the fize of a Golden Pippin, containing many flat hard feeds.

The fruit of both thefe trees is very rough and aftringent at firft, but by lying fome time after they are gathered, they become mellow, like the Medlar. The timber of both thefe trees is ufed in buildings, and for fhingles to cover houfes.

Thefe plants are preferred in feveral curious gardens for the beauty of their leaves, efppecially the firft fort, whofe under fides fhine like fattin, the upper fides are of a deep green. The leaves continue all the year, fo make a very pretty appearance in the ftove at all feafons.

Thefe trees, being natives of the warmeft parts of the world, cannot be preferred in this country, without being kept in the warmeft ftoves; and fhould always remain in a hot-bed of tanners bark, otherwife they will make but little progrefs. They are propagated by feeds, which muft be procured from the places of their growth, for they do not produce fruit in Europe. Thefe feeds muft be freffi, otherwife they will not grow; and if they are fent over in fand, it will preferve them from drying too much j when the feeds arrive, they muft be fown as foon as poffible in fmall pots filled with light frelh earth, and plunged into a good hot-bed of tanners bark. If the feeds are good, and the bed in a proper temperature of warmth, the plants will appear in five or fix weeks; and in about two months after, will be ftrong enough to tranfplant; in doing of which, the plants, with all the earth, fhould be fhaken out of the pots very carefully, and feparated with their roots entire, and each planted into a fingle fmall pot filled with freffi rich earth, and plunged again into a hot-bed of tanners bark, watering and (hading them until they have taken freffi root. If the hot-bed in which thefe plants are plunged, is from time to time ftirred, and a little freffi tan added to it, to renew the heat when it declines, the plants will make good progrefs, and in three or four months will be near a foot high, and may then be fhifted into pots a fmall fize larger than thofe they before were in. If thefe plants are conftantly kept in a warm bed in the ftove, and lhifted twice a year, to renew the earth to their roots, they will thrive very faft, and put out their fide branches, fo as to make a handfome appearance in the ftove, with other curious plants of the fame country j for though they do not produce

feitheh flowed of fruit, yet as they keep their leaved through the year, which are fo very beautiful, they delerve a place in the ftove, better than nroth other plants. The chief care they require, is to keep them conftantly in a proper degree of heat, and never to put them into too large pots; arid in winter they fhould not have too much Water, about twice a week will be often enough to water them-, and in the depth of winter, they fhould not have much at each time.

Thefe trees are frequently propagated in the Weft-Indies, by planting of their branches (as I have been informed by perfons of credit;) but I have not heard of their being propagated in England by that method.

CHRYSOSPLENium. Lin. Gcn. Plant. 493. [*Χρυσοσπένιον*, of *Χρυς*, Gold, and *σπένιον*, the spleen 5 q. d. a plant, the flowers of which are of a golden colour, and good againft difeafes of the spleen.] Golden Saxifrage.

The CHARACTERS are,

The empalement is divided into four or five parts which fpread open, are coloured, and permanent. The flower bath no petals, but eight or tenftamina, which arefhoru ereff, and ft and oppofite to the angles of the empalement terminated by fingle fummits: the germen is immerfed-in the empalement, fupporting two Jhort ftyles, crowned by obtufe ftigma. The germen afterward becomes a capfule with two beaks, opening with two valves, and filled with fmall feeds.*

This genus of plants is ranged in the fecond feftion of Linnseus's tenth clafs, intituled Decandria Digynia, the flowers having ten ftamina aftd two ftyles.

The SPECIES ate,

1. CHRYSOSPENIUM: (*Alternifolium*) foliis alternis. Flon Suc. 317. *Golden Saxifrage with alternate leaves.* Saxifraga aurea foliis pediculis oblongis infidentibus. Rail Syn. Hift. 206. *Golden Saxifrage with leaves growing upon long foot-ftalks.*
2. CHRYSOSPENIUM (*Oppofitifolium*) foliis oppofitis. Sauv. Monlp. 128. *Golden Saxifrage with oppofite leaves.* Chryfolpenium foliis amplioribus auriculatis. Tourn. Inf. 146. *Golden Saxifrage with larger eared leaves.*

Thefe two plants are found growing wild in many parts of England, upon marfhy foils and bogs, as alfo in moift fhady woods, and are feldom propagated in gardens *, where, if any perfon has curiofity to cultivate them, they muft be planted in very moift fhady places, otherwife they will not thrive- They flower in March and April.

CIBOULS, or CHIBOULS. See CEPA.

CICER. Lin. Gen. Plant. 783. Tourn. Inf. R. H. tab. 210. [This plant is called Cicer, of *Κίκαρος*, ftrength', becaufe it is faid to ftrengthen: it is alfo called Arietaria, becaufe the feeds of it refemble the head of a ram.] Cicer, or Chich Peafe-

The CHARACTERS are,

The empalement of the clover is cut into five fegments, four of which lie upon the ftandard-, the two middle, which are the longeft, are joined, the other is under the keel. The flower is of the butterfly kind-, the ftandard is large roundifh, and plain \ the wings are muchfhorter and obtufe, the keel is fhorter than the wings, and is Jharp-printed. It bath tenftamina, rine of them are joined, and the tenth is feparate, terminated by fingle fummits. It bath an oval germen fupporting a fingle ftyle, crowned by an obtufe ftigma. The germen afterward becomes a turgid fuelling pod of a rhomboidal figure, inclofing two roundifh feds, with a protuberance on theirfid.*

This genus of plants is ranged in the third fe&ion of Linnseus's feventeenths clafs, intituled Diadelphia Decandria, from the flower having ten ftamiiSa joined in two bodies.

There is but one SPECIES of this genus, viz.

- CICER (*Arietinum*) foliolis ferfatis. Hort. Cliff. 370. *Chich Peafe with fawed leaves.* Cicer fativum. C. B. P. 347. *Garden Chich Peafe.*

There is a variety of this with a red feed, which differs from it in nothing but the colour.

It is much cultivated in Spain, being one of the ingredients in their oils, and is there called Garavance; it is also cultivated in France, but in England it is rarely sown.

This plant is annual, (shoots out several hairy stalks from the root, which are about two feet long*, garnished with long winged leaves of a grayish colour, composed of seven or nine pair of small roundish leaves (or lobes) terminated by an odd one, which are sown on their edges. From the side of the branches come out the flowers, sometimes one, at other times two together. They are shaped like those of Pease, but are much smaller and white, standing on long foot-stalks; these are succeeded by short hairy pods, including two seeds in each, which are the size of common Pease, but have a little knob or protuberance on one side.

The seeds of this plant may be sown in the spring, in the same manner as Pease, making drills with a hoe, about an inch and a half deep, in which the seeds should be sown at about two inches asunder, then with a rake draw the earth into the drill to cover the seeds. The drills should be made at three feet distance from each other, that there may be room for their branches to spread, when the plants are fully grown, as also to hoe the ground between them, to keep it clean from weeds, which is all the culture these plants require.

This plant flowers in June, and the seeds ripen in August; but unless the season proves warm and dry, the plants decay in this country before the seeds are ripe.

CICHORIUM. Lin. Gen. Plant. 825. Tourn. Inf. R. H. tab. 272. [σιπτεριον, or κισσοριον, of *xiyifa** to find, because found every where in walking.] Succory.

The CHARACTERS are,

The flower hath a common scaly empalement which at first is cylindrical^ but is afterward expanded* the scales are narrow* spear-shaped* and equal. The flower is composed of many hermaphrodite florets* which are plain* uniform* and flat and circularly* each having one petal* which is tongue-shaped* and cut into five segments. They have five short hairy stamina* terminated by five-cornered cylindrical summits. The germen is situated under the petal* supporting a fimmier style* crowned by two turning stigmas: the germen afterward becomes a Jingle seed* inclosed with a down* and shut up in the empalement.*

This genus of plants is ranged in the first section of Linnaeus's nineteenth class, intitled Syngenesia Polygamia aequalis. The plants of this section have only hermaphrodite fruitful florets.

The SPECIES are,

1. **CICHORIUM** (*Intybus*) floribus geminis sessilibus, foliis runcinatis. Flor. Suec. 650. *Succory with two flowers fitting close to the stalk.* Cichorium sylvestre five officinarum. C. B. P. 126. *Wild Succory.**
2. **CICHORIUM** (*Spinofum*) caule dichotomo spinoso floribus axillaribus sessilibus. Hort. Cliff. 388. *Succory with a prickly forked stalk.* Cichorium spinosum. C. B. P. 126. *Prickly Succory.*
3. **CICHORIUM** (*Endivia*) floribus foliariis pedunculatis, foliis integris, crenatis. Hort. Cliff. 389. *Succory with single flowers on foot-stalks* and entire crenated leaves.* Cichorium latifolium, five endivia vulgaris. C. B. P. 125. *Broad-leaved Succory* or common Endive.*
4. **CICHORIUM** (*Crippum*) floribus foliariis pedunculatis, foliis fimbriatis, crispis. *Succory with Jingle flowers on foot-stalks* and fringed curled leaves.* Endivia crispata. C. B. P. 125. *Curled Endive.*

The first sort grows naturally by the sides of roads and in shady lanes, in many parts of England: this has been supposed to be no other way differing from the garden Succory, but by the latter being cultivated in gardens; indeed, most of the writers on botany, have confounded the two sorts together, for the Garden Succory which is described in most of the old books, I take to be the broad-leaved Endive, which is the third sort here enumerated, for I have many years cultivated both sorts in the garden, without finding either of them alter. There is an essential

difference between these, for the wild Succory hath a perennial creeping root, whereas the other is at most but a biennial plant; and if the seeds of the latter are sown in the spring, the plants will flower and produce seeds the same year, and perish in autumn, so that it may rather be called annual. The wild Succory sends out from the roots long leaves, which are jagged to the midrib, each segment ending in a point* from between these arise the stalks, which grow from three to four feet high, garnished with leaves, shaped like those at the bottom, but are smaller, and embrace the stalks at their base. These branch out above into several smaller stalks, which have the same leaves, but smaller and less jagged; the flowers are produced from the side of the stalks, which are of a fine blue colour; these are succeeded by oblong seeds, inclosed in a down. It flowers in June and July, and the seeds ripen in September.

The second sort grows naturally on the sea-coasts in Sicily and the islands of the Archipelago. This sends out from the root many long leaves, which are indented on their edges, spreading flat on the ground; from between these arise the stalks, which have very few leaves, and those small and entire: the stalks are divided in forks upward, from between these come out the flowers, which are of a pale blue, and are succeeded by seeds (shaped like those of the common* sort; the ends of the smaller branches are terminated by star-like spines, which are very sharp. The plant is biennial with us in England, and in cold winters is frequently killed. It flowers and is ready about the same time with the former sort, and may be treated in the same way as the *JEndive*.

The broad leaved Succory or Endive, differs from the wild sorts in its duration, the root always perishing after it has produced seeds: the leaves are broader, rounder at the top, and not lacinated on the sides as the leaves of the wild; the branches are more horizontal, and the stalks never rise so high.

This sort is not much cultivated in the English gardens at present, for the curled Endive being tenderer, and not so bitter, is generally preferred to it. The broad-leaved and curled Endive has been supposed to be only varieties from each other, which hath accidentally been produced by culture; but from having cultivated both near forty years, I could never find that they ever altered, otherwise than by the curled sort coming more or less curled, the leaves of this sort have only a few slight indentures on their edges, and the stalks grow more erect, having but few leaves upon them. This, when blanched, has a bitter taste, which has occasioned its being generally neglected in England, but in Italy it is still cultivated in their gardens.

All the sorts of Succory are esteemed aperitive and diuretic, opening obstructions of the liver, and good for the jaundice; it provokes urine, and cleanses the urinary passages of slimy humours, which may stop their passage.

The curled Endive is now much cultivated in the English gardens, being one of the principal ingredients in the salads of autumn and winter, for which purpose it is continued as long as the seasons will permit. I shall therefore give directions for the managing of this plant, so as to have it in perfection during the autumn and winter months.

The first season for sowing of these seeds is in May, for those which are sown earlier in the year, generally run up to seed, before they have arrived to a proper size for blanching; and it frequently happens, that the seeds sown in May in the rich ground near London, will run to seeds the same autumn; but in situations which are colder, they are not so apt to run up, therefore there should be some seeds sown about the middle or latter end of that month. The second sowing should be about the middle of June, and the last time in the middle of July. From these three different crops, there will be a supply for the table during the whole season; for there will be plants of each sowing, very different in their growth, so that

there will be three different crops from the same beds.

When the plants come up they must be kept clean from weeds, and in dry weather duly watered, to keep them growing till they are fit to transplant, when there should be an open spot of rich ground prepared to receive the plants, in size proportionable to the quantity intended. When the ground is well dug and levelled, if it should be very dry, it must be well watered to prepare it to receive the plants; then the plants should be drawn up from the feed-bed carefully, so as not to break their roots, drawing out all the largest plants, leaving the small ones to get more strength; which, when they have room to grow, by taking away the large ones, they will soon do. As the plants are drawn up, they should be placed with their roots even, all the same way, and every handful as they are drawn, should have the tops of their leaves shortened, to make them of equal length: this will render the planting of them much easier, than when the plants are promiscuously mixed, heads and tails: then the ground should be marked out in TOWS at one foot alunder, and the plants set ten inches distant in the rows, cloving the earth well to their roots, and let them be well watered; and repeat this every other evening, till the plants have taken good root, after which they must be kept dean from weeds.

When the plants of the feed-bed have been thus thinned, they should be well cleaned from weeds and watered, which will encourage the growth of the remaining plants, so that in ten days or a fortnight after, there may be another thinning made of the plants, which should be transplanted in the same manner. And at about the same distance of time, the third and last drawing of plants may be transplanted.

Those plants which were the first transplanted, will be fit to blanch by the latter end of July at farthest, and if they are properly managed, in three weeks or a month, they will be sufficiently blanched for use, which will be as soon as these fallads are commonly required; for during the continuance of good Coss Lettuce, few persons care for Endive in their fallads; nor, indeed, is it so proper for warm weather. If any of the plants should put out flower-stems, they should be immediately pulled up and carried away, being good for nothing, so should not be left to incommode the neighbouring plants. As the quantity of roots necessary for the supply of a middling family is not very great, so there should not be too many plants tied up to blanch at the same time, therefore the largest should be first tied, and in a week after, those of the next size; so that there may be three different times of blanching the plants, on the same spot of ground. But as in some large families there is a great consumption of this herb for soups, so the quantities of plants should be proportionably greater, at each time of planting and blanching. The manner of blanching is the next thing to be treated of, therefore in order to this you should provide a parcel of small Osier twigs (or bafs mat) to tie up some of the largest heads to blanch, which should be done in a dry afternoon, when there is neither dew nor rain to moisten the leaves in the middle of the plants, which would occasion their rotting soon after their being tied up. The manner of doing it is as follows, viz. You must first gather up all the inner leaves of the plant in a regular order, into one hand, and then take up those on the outside that are found, pulling off and throwing away, all the rotten and decayed leaves which lie next the ground; observing to place the outside leaves all round the middle ones, as near as possible to the natural order of their growth, so as not to cross each other: then having got the whole plant close up in your hand, tie it up with the twig, bafs, &c. at about two inches below the top, very close; and about a week after go over the plants again, and give them another tie about the middle of the plant, to prevent the heart leaves from

bursting but on one side; which they are subject to do, as the plants grow, if not prevented this way.

In doing of this you heed only tie up the largest plants first, and go over the piece once a week, as the plants increase in their growth; by which means you will continue the crop longer, than if they were all tied up at one time: for when they are quite blanched, which will be in three weeks or a month after tying, they will not hold found and good above ten days or a fortnight, especially if the season proves wet: therefore it is that I would advise to sow at three or four different seasons, that you may have a supply as long as the weather will permit. But in order to this, you must transplant all the plants of the last sowing under warm walls, pales, or hedges, to screen the plants from frost; and if the winter should prove very sharp, you should cover them with some Pease haulm, or such other light covering, which should be constantly taken off in mild weather: these borders should also be as dry as possible, for these plants are very subject to rot, if planted in a moist soil in winter.

Although I before directed the tying up of the plants to blanch them, yet this is only to be understood for the two first sowings; for after October, when the nights begin to be frosty, those plants which are so far above ground will be liable to be much prejudiced thereby, especially if they are not covered in frosty weather; therefore the best method is, to take up your plants of the latter sowings in a very dry day, and with a large flat-pointed dibble, plant them into the sides of trenches of earth, which should be laid very upright, planting them sideways, on the fourth side of the trenches, towards the sun, with the tops of the plants only out of the ground, so that the heavy rains may run off, and the plants be kept dry, and secured from frosts.

The plants thus planted, will be blanched fit for use in about a month or five weeks time, after which it will not keep good more than three weeks, before it will decay; you should therefore continue planting in successive ones into trenches every fortnight or three weeks, that you may have a supply for the table; and those which were last transplanted out of the feed beds, should be preserved till February, before they are planted to blanch; so that from this you may be supplied until the beginning of April, or later: for at this last planting into the trenches, it will keep longer than in winter, the days growing longer; and the sun, advancing with more strength, dries up the moisture much sooner than in winter, which will prevent the rotting of these plants; but if the weather should prove frosty, these latter plantations of Endive should be covered with mats and straw to preserve it, otherwise the frost will destroy it, but the coverings must always be taken off when the weather is favourable.

When your Endive is blanched enough for use, you must dig it up with a spade; and after having cleared it from all the outside green and decayed leaves, you should wash it well in two or three different waters to clear it the better from lugs, and other vermin, which commonly shelter themselves amongst the leaves thereof, and then you may serve it up to the table with other fallading.

But in order to have a supply of good feeds for the next season, you must look over those borders where the last crop was transplanted, before you put them into the trenches to blanch; and make choice of some of the largest, foundest, and most curled plants, in number according to the quantity of feeds required for a small family, a dozen of good plants will produce feeds enough; and for a large, two dozen or thirty plants.

These should be taken up and transplanted under a hedge or pale, at about eighteen inches distance, in one row about ten inches from the hedge, &c. This work should be done in the beginning of March, if the season is mild, otherwise it may be deferred a fortnight

C I C

fortnight longer. When the flower-stems begin to advance, they should be supported with a packthread, which should be fattened to nails driven into the pale, or to the flakes of the hedge, and run along before the stems, to draw them upright close to the hedge or pale, otherwise they will be liable to break with the strong winds. Observe alib to keep them clear from weeds, and about the beginning of July your feeds will begin to ripen -, therefore, as soon as you find the feeds are quite ripe, you must cut off the stalks, and expose them to the sun upon a coarse cloth to dry -, and then beat out the feeds, which must be dried, and put up in bags of paper, and preserved for use in some dry place. But I would here caution you, not to wait for all the feeds ripening upon the same plant; for if so, all the first ripe and best of the feeds will scatter and be lost before the other are near ripe -, but great a difference is there in the feeds of the same plant being ripe.

The wild Succory (of which there are some varieties in the colour of the flowers) is seldom propagated in gardens -, it growing wild in unfrequented lanes and dunghills in divers parts of England, where the herb women gather it, and supply the markets for medicinal use.

C I C U T A properly signifies an hollow intercepted between two knots, of the stalks or reeds of which the shepherds used to make their pipes, as Virgil sings ;

*Eft tuihi difparibus feptem compafta Cicutis
Fijiula—*

C I C U T A. Lin. Gen. Plant. 316. Sium. Raii Syn. 212. Water Hemlock.

The CHARACTERS are,

It is a plant with an umbelated flower > the principal umbel is composed of several/mailer (called rays -) these are equal, roundish, and bristly: the great umbel hath no involucre, but the smaller have, which are composed of many short leaves. The flowers have each five oval petals nearly equal, which turn inward \ they have five hairy stamina, which are longer than the petals, terminated by single summits. The germen is situated below the flower, supporting two slender styles, which are permanent and longer than the petals, crowned by stigmas in form of a head. The germen afterward becomes a roundish channelled fruit dividing into two parts, containing two oval feeds, plain on one side and convex on the other.

This genus of plants is ranged in the second section of Linnaeus's fifth class of plants, intitled Pentandria Digynia, the flower having five stamina and two styles. The title of this genus has been generally applied to the common Hemlock, which grows naturally on the banks by highways, in moist parts of England. But to that plant Dr. Linnaeus has applied the old title of Conium, and added this title to the poisonous Water Hemlock described by Webber.

The SPECIES are,

1. C I C U T A (*Virofa*) *umbellifera* oppositifolia, petioli marginatis. Lin. Sp. Plant. 255. *Hemlock with umbels opposite to the leaves, and obtuse margined foot-stalks.* Sium eruce folio. C. B. P. 154. *Sium with a Rocket leaf* Cicuta aquatica Gefneri. J. B. in. 2. p. 175. *Water Hemlock of Gefner.*
2. C I C U T A (*Maculata*) foliorum ferraturis mucronatis, petioli membranaceis, apice bilobis. Lin. Sp. Plant. 256. *Hemlock with pointed ferratures to the leaves, and membranaceous foot-stalks ending in two lobes.* Angelica Virginiana foliis acutioribus, femine striato minore, cumini sapore & odore. Mor. Hist. 3. p. 281. *Virginia Angelica with pointed leaves, and a small channelled feed, having the taste and smell of Cumin.*
3. C I C U T A (*Bulbifera*) ramis bulbiferis. Lin. Sp. 367. *Hemlock, whose branches bear bulbs.- Ammi foliorum lacinulis capillaribus, caule angulato.* Flor. Virg. 31. The first sort grows naturally in standing waters in many parts of England, so is never propagated in gardens * for unless there is a considerable depth of

C I N

standing water for the plants to root in, they will not grow. I have several times transplanted these plants into ponds, where they have grown one summer, but have not continued through the winter.

It grows near four feet high, with a branching hollow stalk, garnished with winged leaves. The stalks are terminated by umbels of yellowish flowers, which are succeeded by small channelled feeds like those of Parsley. It flowers in June and July, and the feeds ripen in autumn.

The second sort grows naturally in North America, from whence the feeds have been brought to England, where the plants are preserved in botanic gardens for the sake of variety. This is propagated by feeds, which should be sown in autumn in a shady border, where the plants will come up in the spring, and require no other care but to keep them clean.

The third sort is a native of North America. This is sometimes preserved in botanic gardens for variety, but being a plant of no great beauty or use, is seldom allowed a place in other gardens. It is propagated by feeds, which should be sown in autumn, and the plants afterward treated as those of the second sort.

C I C U T A R I A. See LIGUSTICUM.

C I N A R A. See CYNARA.

C I N E R A R I A, Sea Ragwort.

The CHARACTERS are,

It has a simple empalement, composed of many small equal leaves. The flower is radiated. The disk is composed of many hermaphrodite florets, which are funnel-shaped, cut into five segments at the top -, these have five slender stamina, crowned by cylindrical summits, and an oblong germen, supporting a very slender style, crowned by two erect stigmas. The germen afterward becomes a narrow four-cornered feed, covered with downy hairs. The female florets which compose the rays are tongue-shaped, indented at their points \ these have an oblong germen with two styles, and have feeds like the hermaphrodite florets, which are included in the empalement.

This genus of plants is ranged in the second order of Linnaeus's nineteenth class, intitled Syngenesia Polygamia superflua, the flowers being composed of hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. C I N E R A R I A (*Geifolia*) pedunculis ramosis, foliis reniformibus fuborbiculatis fublobatis dentatis petiolatis. Lin. Sp. 1242. *Ragwort with branching foot-stalks, kidney-shaped, orbicular, indented leaves upon foot-stalks.* Jacobaea Africana, hederæ terrestris folio, repens. Hort. Amft. 2. p. 145.
2. C I N E R A R I A (*Maritima*) floribus paniculatis, foliis pinnatifidis tomentosis, laciniis finuatis, caule frutescente. Lin. Sp. 1244. *Sea Ragwort with a Jhrubby stalk, woolly wing-pointed leaves, and flowers growing in panicles.* Jacobaea maritima. C. B. P. 131. *Sea Ragwort.*
3. C I N E R A R I A (*Jmelloides*) pedunculis unifloris, foliis ovatis oppositifolia, caule suffruticoso. Lin. Sp. 1245. *Ragwort with an underflimb stalk, oval leaves placed opposite, and foot-stalks with one flower.* After caule ramoso scabro perenne, foliis ovatis fessilibus, pedunculis nudis unifloris. Fig. pi.
4. C I N E R A R I A (*Othonnites*) pedunculis unifloris, foliis oblongis indivisis fubdentatis petiolatis alternis nudis. Lin. Sp. 1244. *Ragwort with oblong undivided leaves slightly indented, and foot-stalks with one flower.* Jacobaea Africana frutescens, crassis & fucculentis foliis. Hort. Amft. 2. p. 147.
5. C I N E R A R I A (*Tomentosa*) foliis pinnato-finuatis dentatis fubtus tomentosis, floribus paniculatis, caule frutescente. *Ragwort with finuated, wing-shaped, indented leaves, downy on their under side, flowers in panicles, and a Jhrubby stalk.* Jacobaea maritima latifolia. C. B. P. 69.

There are several other species of this genus than are here enumerated, but being plants of little use or beauty are omitted, as they are rarely cultivated in gardens.

The first fort grows naturally at the Cape of Good Hope. The root of this is composed of many small fibres; the (talks are weak, so trail on the ground, if they are not supported; but if they are will rise four feet high, dividing into many branches, garnished with roundish kidney-shaped leaves, circled on their edges; the flowers are produced at the extremity of the branches in small clusters, they are yellow, and in shape like those of the common Ragwort, which are succeeded by feeds, crowned with down.

This sort is easily propagated by cuttings, which, if planted in a shady border during the summer months, and duly watered, will put out roots in a month or five weeks; (boil after which it will be proper to transplant them into pots, because their roots are very apt to spread in the full ground; so when the plants are taken up, many of their roots are torn off, whereby the plants are endangered. This is also often the case of the plants in pots. When they are not often removed, their roots will shoot through the holes in the bottom of the pots into the ground, and the plants will grow luxuriantly; but when the pots are removed, and those roots torn off the plants are often killed thereby. As this plant grows naturally at the Cape of Good Hope, it is too tender to live through the winters in England in the open air; yet if it is nursed tenderly, it is very apt to draw up weak, and thereby is destroyed; therefore the illicit method to preserve it, is to make young plants annually from cuttings, and to place them in a common hot-bed frame in winter, where they may enjoy the full air in mild weather, but be screened from the frost, and in summer place them abroad with other of the hardier sorts of exotic plants.

The second sort grows naturally on the sea-coasts in some parts of England and Wales, in particular the arm spots, but in the South of France and Italy, it is very common. This hath many ligneous (talks, which rise two or three feet high, dividing into many branches, which have a white downy bark, and are garnished with very woolly leaves six or eight inches long, deeply sinuated, and jagged on their borders into many winged points; they are downy on both sides. The (talks which support the flowers are a foot or more in length, having two or three small leaves on each, shaped like those below, and are terminated by many yellow flowers growing in panicles. It is a common Raswort; these appear in June, July, and August, and are succeeded by feeds, which ripen the beginning of October.

This sort is also easily propagated by planting cuttings or slips of it on a shady border during the summer months, observing to water them duly. When these are well rooted, they should be planted in a dry rubbishy soil, where they will resist the cold of our ordinary winters very well, and continue many years, but in rich moist ground, the plants are often very luxuriant in summer, as to be killed in winter when there is much frost.

The third sort grows naturally at the Cape of Good Hope. This hath branching (talks, which are (hrubby, and rise from two to three feet high, garnished with oval leaves placed opposite: the footstalks of the flower long, naked, and support one blue flower at the top, whose rays are reflexed; these appear great part of the year, and those which grow in summer are succeeded by compressed feeds crowned with down.

This may be propagated by sowing the feeds on a bed of light earth the beginning of April, and when the plants are fit to remove, they should be part of them planted in pots, that they may be sheltered in winter under a hot-bed frame; the remainder may be planted in a shady border. In poor ground, where, if the winter proves favourable, they will live; but if they fail, those in the frame will be secured. It may also be propagated by cuttings, in the same manner as the first mentioned.

The fourth sort hath (hrubby branching (talks which

rise three or four feet high, garnished with oblong thick, undivided leaves, of a glaucous colour. The flowers are produced on branching footstalks, arising toward the end of the branches; they are yellow, shaped like those of the other sorts, but are rarely succeeded by feeds in England. This is easily propagated by cuttings any time in summer: the plants, when rooted, must be planted in pots, that they may be removed into flicker in winter, for they will not live abroad in England. It grows naturally at the Cape of Good Hope.

The fifth sort grows naturally on the sea coasts of Italy and Sicily. This has great resemblance to the second sort, but the (talks are more woody, rise higher, and do not branch so much. The leaves are broader, not so much sinuated, and are of a black green colour on their upper side. The flowers are produced in small bunches on the top of the footstalks, and are like those of the second sort, but are rarely succeeded by feeds; in England, nor are the plants so hardy, therefore, they should be flickered in winter. It is easily propagated by cuttings during the summer months, in the same way as the second sort.

CIRCEA. Lin. Gen. Plant. 24, Tourn. Inf. R. H.

[It is said to be so called from Circe, the vain nihil enchantress, said to have enchanted Lily lies and his companions, Boerhaave supposes it to be so called, because the fruit of this plant takes hold of peoples cloaths, and by this means draws them to it, as the enchantress Circe was wont to do by her enchantments.] Enchanter's Nightshade.

The CHARACTERS are,

The root is of the fibre of two oval concave leaves. - the flower hath two heart-shaped petals, which are equal and spread open; it hath two trefoil hairy fruit. - the fruit is of a yellowish green colour. - the germen is situated under the flower, supporting a slender joint, cream coloured, obtuse bordered stigma. The empagement afterward becomes a rough oval capsule with two cells opening lengthways each containing a single seed.

This genus of plants is ranged in the first section of Linnaeus's second class, in titled Diandria Monogynia, the flower having two stamens and one style.

The SPECIES are,

1. CIRCEA (*Lytetiana*) caule erecto, racemis pluribus. Lin. Sp. Plant. p. 155. Enchanter's Nightshade, with an upright stalk and many spikes of flowers. Circea lytetiana. Lob. Icon. 266. Common Enchanter's Nightshade.

2. CIRCEA (*A'pitia*) caule adscendente, racemo unico. Lin. Sp. Plant. p. 155. Enchanter's Nightshade, with an ascending stalk and single spike. Circea minima. Col. p. 2. 80. Enchanter's Nightshade.

The first sort grows naturally in shady woods, and under hedges, in many parts of England. This plant hath a creeping root, by which it multiplies greatly. The (talks are upright, and rise a foot and a half high, garnished with heart-shaped leaves, placed opposite, upon very long footstalks: these are of a dark green on their upper side, but are pale on their under side. The (talks are terminated by loose spikes of flowers, which are branched out into three or four small (pikes. The flowers are small and white, having but two petals, opposite to which are situated the two stamens. After the flowers fall away, the impalement of the flower becomes a rough capsule, inclosing two oblong feeds.

The second sort grows at the foot of mountains in many parts of Germany. It also grows naturally in a wood near the Hague, from whence I brought it to England. This sort seldom rises more than six or eight inches high, with a slender (talk, garnished with leaves shaped like those of the former sort, but smaller, and are indented with oil their edges. The flowers are produced on single loose spikes at the top of the stalks, which are smaller than those of the former sort, but of the same form and colour. These plants flower in June, and their feeds ripen in August; but they both multiply exceedingly by their creeping

roots, it is seldom kept in gardens, unless for the sake of variety.

If the roots are planted in any shady moist part of a garden, they will increase fast enough without any care.

CIRCULATION of the sap. See SAP.

CIRRI are those fine firings or fibres put out from the stalks of plants, by which some plants fasten themselves to walls, pales, or trees, in order to their support, as Ivy, &c.

CIRSIUM. See CARDUUS.

CISSAMPELOS. Lin. Gen. Plant. 993. Caapeba. Plum. Nov. Gen. 33. tab. 29.

The CHARACTERS are,

It is male and female in different plants; the male flowers have no empalement they have four oval plain petals and a wheel-shaped nectarium in the disk* with four small filamina joined together* crowned by plain summits. The female flowers have neither empalement or corolla* instead of petals* there is a large nectarium* whose membranes stand round the hairy oval germen* which afterward becomes a succulent berry* inclosing a single seed.*

This genus of plants is ranged in the twelfth section of Linnæus's twenty-second class, intitled Dioecia Monodelphia, the male and female flowers being on different plants, and the male flowers have four stamens, which are joined in one body.

The SPECIES are,

1. CISSAMPELOS (*Pariera*) foliis peltatis cordatis emarginatis. Lin. Sp. 1473. *Cissampelos with target heart-shaped leaves which are indented at their top.* Caapeba folio orbiculari, & umbilicato Uevi. Plum. Nov. 33. *Caapeba with a round* smooth* umbilicated leaf.*

2. CISSAMPELOS (*Caapeba*) foliis basi petiolatis integris. Lin. Sp. 1473. *Cissampelos with leaves having footstalks* and entire at their base.* Caapeba folio orbiculari non umbilicato. Plum. Nov. Gen. 33. *Caapeba with a round leaf not umbilicated* called Velvet Leaf in America.*

These plants grow naturally in the warmest parts of America, where they twist themselves about the neighbouring shrubs, and rise to the height of five or six feet. The first sort hath round heart-shaped leaves, whose footstalks are set within the base of the leaf, resembling an ancient target; these are hairy on their under side, and have pretty long (tender footstalks. Toward the upper part of the stalks the flowers come out from the wings of the leaves; those of the male plants grow in short spikes or clusters, and are of a pale herbaceous colour*, but the female flowers are produced in long loose racemi from the side of the stalks, and are succeeded by a single pulpy berry inclosing a single seed.

The second sort hath round heart-shaped leaves, which are extremely woolly and soft to the touch; these have their footstalks placed at the base between the two ears; the flowers of this come out in bunches from the side of the stalks, in the same manner as the first. The stalks and every part of the plant is covered with a soft woolly down.

The seeds of both these plants were sent me from Jamaica, by the late Dr. Houftoun, which succeeded in the Chelsea garden, where the plants produced their flowers for several years; and the fruit of the first sort were produced, but these would not grow, though they seemed to be perfectly ripened; but the plants grew at some distance from the male, so were probably not impregnated.

These plants are propagated by seeds, which should be sown upon a hot-bed in the spring, and the plants must afterward be treated in the same way as other tender exotics, keeping them constantly in the bark-stove, otherwise they will not live in this country.

The first sort is supposed to be the *Pariera*, whose root has been so much esteemed as a diuretic. But by a specimen which I received from the late Dr. Houftoun, under the title of *Pariera*, it should rather be ranged under the genus of *Smilax*.

CISSUS, WildGrape.

The CHARACTERS are,

It hath a small many-leaved empalement and four concave petals to the flower* with a large nectarium at the border of the germen* and four stamens the length of the corolla inserted in the nectarium* crowned by roundish summits. The germen is four-cornered* supporting a slender style the length of the stamens* crowned by an acute stigma. The cover of the flower afterward becomes a berry inclosing one roundish seed.*

This genus of plants is ranged in the first section of Linnæus's fourth class, intitled Tetrandria Monogynia, the flowers having four stamens and one style.

The SPECIES are,

1. *Cissus (Cordifolia) foliis cordatis integerrimis.* Lin. Sp. 170. *WildGrape with entire heart-shaped leaves.* Vitis folio subrotundo, uva corymbosa caeruleo. Plum. Gen. 18.

2. *Cissus (Sicyoides) foliis ovatis nudis fetacco ferratis.* Lin. Sp. 170. *Wild Grape with oval leaves which are jawed.* Bryonia alba geniculato, violas foliis, baccis e viridi-purpurascensibus. Sloan. Hift. Jam. 1. p. 106.

3/ *Cissus (Adda) foliis ternatis oblongis carnosis incisis.* Lin. Sp. 170. *Wild Grape with trifoliate leaves* which are oblong* fleshy* and cut on their edges.* Vitis trifolia minor corymbosa, acinis nigrioribus turbatis. Plum. Sp. 18.

4. *Cissus (Trifoliata) foliis ternatis subrotundis subdentatis.* Lin. Sp. 170. *WildGrape with roundish trifoliate leaves* which are slightly indented.* Bryonia alba triphylla maxima. Sloan. Hift. Jam. i. p. 106.

These plants all of them grow naturally in the island of Jamaica, and in some of the other islands in the warm parts of America, where they tend out (tender branches, having tendrils at their joints, by which they fasten to the neighbouring trees, bushes, and any other support, mounting to a considerable height.) The first sort produces bunches of fruit, which are frequently eaten by the negroes, but are chiefly food for birds and wild fowl, as indeed are most of the fruit of the other sorts, as they all grow in the uncultivated parts.

The plants are preserved in some of the European gardens, more for the sake of variety, than for use or beauty, as they rarely produce either fruit or flowers in moderate climates. They are propagated either by laying their flexible branches down in pots of earth, where they will put out roots in four or five months, or by planting cuttings in pots filled with light earth, which should be plunged into a moderate hot-bed of tanners bark, covering the pots closely with hand-glasses to exclude the outer air: the cuttings must be frequently refreshed with water, but not too much given at each time. When these or the layers are well rooted, they should be carefully taken up, and each planted in a small pot filled with light earth, and plunged into the hot-bed of tan, where they should constantly remain, being too tender to thrive in England, but with this care. Therefore they should be shifted into larger pots when it is necessary, and their branches must be supported with stakes, to prevent them from trailing over the neighbouring plants, and in warm weather the plants should have free air admitted to them daily. With this treatment they will thrive very well.

CISSUS. Lin. Gen. Plant. 598. Tourn. Inft. R. H. 259. tab. 136. [It is so called from *It/We*, or *TLurvU** Gr. Ivy, because its small femoral vessel is inclosed in a cysta, or little chest.] Rock-rose.

The CHARACTERS are,

The flower hath a five-leaved empalement which is permanent two of the middle alternate leaves being smaller than the other. The flower hath five large roundish petals which spread open* it hath a great number of hairy stamens, which are shorter than the petals* and are terminated by small roundish summits. In the center is situated a roundish germen* supporting a single style the length of the stamens* crowned by a plain orbicular stigma. The germen afterward becomes an oval clove capsule* homing in some five* and others ten cells* filled with small roundish seeds.*

This genus of plnnts is ranged in the first section of Linnau's thirteenth class. It is distinguished from the other genera of the class by having many flowers and but one style.

L iii us folki kdimi longiuri-

These plants all grow naturally in the fyvid of Prance in Spain, and Portugal, from whence their seed have been brought to England, where mod of the sorts are OK cultivated in the nurseries for f3k. The first has a strong woody stem, covered with rough scurf, wkh rises three or four feet high, riding into many brandies, (o a) to form a large bushy head. The leaves are oval hairy leaves, placed opposite, and the flowers are small, and the fruit smaller leaves of the same shape, and the flowers are produced at the end or in the middle of the stems, four or five (landing together, abioft tann of in uinbd, but nrely mare than one is at the lime time; these are surrounded by five large romidilli petals of A purple colour, which is the Role, having a grc3f number of stamens, surrounding the ovj gernicn in die center, terminated by small, ratmdith, yellow funimie; these flowers are bvic or (hort duration, generally falling off the day they expand; hut dicre is a succession of fresh flowers every day for a considerable time. After the flowers are part, the germen l wells to 1 oval lucil-vcllr!, fitting in the cm pa I emeu t, which is hairy, ihcfe capful" liave ten cell), which arc full of froal rauntliih feeds. This fiili flowers in Mai and June, and the l'cdi riptn in Hl' and i there h Kencrally mott fiowrs produc^ in September* and October, in the autumn proves favours • I, imd where the plant is not protected from frost, they frequently pwdu flowers all the winter li ifon.

The second sort differs from the first in the l'hytc of tile lea vis, which are longer and whiter; thoe on the lower pun of the brinthes are oval, and join at thir biff, furrounding the itaiks, biL the upper leaves arc (pear-lhaptil and tutliiu, the flowers are larger, and of a darker purple colour. This flowers and seeds ripen at the same time with the first. The third sort differs from both the former, in having fluyter and greener leaves which arc joined at then base, and are hairy. The fourth sort differs from the former in having longer leaves, and the flowers are smaller, but of a deeper purple. This flowers and seeds at the same time with the first. The fifth sort differs from the former, in having rounder leaves, either of the former, which, are hairy, and smooth on their upper side, but rough, imd full of veins iin their under side, the branches are white, hairy, and the (lowers air very large, and of a light purple colour. This sort grows at the (tax time with the fanner.

The fifth sort doth not rife fo high as either of the former, hut fends out branches near the root, which are hairy and ttt&f g>miOied with fpear-shaped leaves, of it dirk green colour, whitn join at the base.

The ninth fut grows umnUly in the ilkntls of the
Archipelago j this is the pi¹ which produ¹ the
labi¹ hereafter mctuionccl; itrifea three
or four feet high, with a woody flalk, fending out
many lateral branches, covered with a brown feark,
gain. The leaves are broad, fpear-shaped, hairy
above, and have long foot-ftalks; they are of a deep purple colour, and
the furfuji- i lower*
i liurt hairy
abi) the fir of a fngle flalk; thals a ipMriaJone
and July.

The tenth fort riles with a flubby flalk about four
feet high, the branches are very hairy, glutinous,
and are garnifhed with long, narrow,
hair, leaves, ending in points, of a deep green on
both fides, having a deep longitudinal furrow on their
upper fide, made by the midrib, which is pro-
minent; the flowers ftand upon long foot-ftalks at the
end of the branches, which are of a pale fulphur colour,
having a bordered empalement, which is cut into
five acute parts at the top. This flowers in June,
July, and Auguft, and the feeds ripen in autumn.

The eleventh fort riles with a ftrong woody flalk to
the height of five or fix feet, fending out many erect
branches, garnifhed with fpear-shaped leaves
in points; thefe are thick, white on their under fide,
and of a dark green above, and very glutinous in
warm weather. The flowers are produced at the end of
the branches, upon long naked foot-ftalks, which
branch on their fides into feveral foot-ftalks, each
bearing one large white flower, having a hairy
empalement. This fort flowers in June and July.

The twelfth fort riles with a flubby flalk
four or five feet high, fending out many flender
lignous branches, covered with a flmooth brown bark,
garnifhed with oblong fpear-shaped leaves, which are
broad, and have long foot-ftalks. The flowers are
produced at the end of the branches, ftanding upon
pretty long foot-ftalks; they are white, and appear
in June, July, and Auguft, but rarely produce any
feeds in England.

The thirteenth fort riles with a flender flubby flalk,
from three to four feet high, fending out many

C I S

bnwclies from the borrm itjward, which arc hairy,
garnifhed with l'lx;ir-)ilipcd leaves, of a very dark-
green colour, having three bnj radial veins in each,
mU ii' warm weather. Are covered with a CIUL
fweet-fented fublante, which exfudes from i
ports. Th* flom is •; at the end
O) Lhc branches, arc long, raked, (ant) iuftain many
white Howers, riling above each oilier-, their em-
jialeinents are bordered, and end in [harp points.
This flowers at the fame time witli the iit men-
uorred.

Tiie fourteenth fort rifa wkh a wotriy ilem to the
height of Bve or Gx fett, fending otic many flce
branches from the borrm, the flalk is le length; thefe
are fuprvnh, covered witii a reddilh brown bark, ^r-
mjlu'ii *ith narrow fjicar-diaped leaves, whitilh on
their undtr fulc, of a dork (green above, having ih
long radial veins. The ilowers arc produced at the
end of the brandits, on Ihnrt f • flalks, and arc
compoiid of Hvc very larpi", rouutiitih, white ; petals,
each having a large purple fpot at their baf. The
whole plan) exfui is a fweet glutinous Jubilance in
warm weather, which hath a very drong bilfami-
icrnt, fo as 10 perfume ihe circumambimt air to a
great ditlanctr. This flower in June, July, and
Auguft.

There is a variety of thi with white flowers, ;iving
no purple fpts, which is in all otlwr refpects the fame
with this.

The fifteenth iort hath a fliff, (lender, woody fUtk,
which fends out many branches of •• whole length, and
rife to the height of fix or feven feet; the leaves are nit-
tear-shaped, and of a light green colour;

the flowers are produced at (he end of the branches
upon naked foot-ftalks; they are white, and foon drop
on. Their flower-vin Junt and July, and is at j
pretty rare in the tngldh pirdens.

The iittecmb fort hath weak, flender, woody branche?,
which fjiead horiionally, to fiddum rife more
than two ot tine. The flalk is four feet high, garnifhed with fpefr-
QMPed hairy leaves, which are iniknted on their
upper fides, and have thin longitudinal veins mnting
through the middle of the flalk; the flowers are white, coming
out upon naked foot-ftalks from the wings of the leaves,
and are fucceeded by round white berries, which are
leaving irvcnl cell., and with fliff foot-ftalks. This
flowers in June ami July, and the feeds nXN in An-
gull and September.

The fiventeenth fort hath 3» upright flirubby flalk,
which riles four or five feet high, fending out many
branches from the erect upward, to a K» form *
large hum. The branches are dmncHcil and hoiry.
The flalks are oval, (landing upright i thofe on the
lower part of the branches have tooi-ftstks, but u¹
ward they become a ilieir bafe, and ihround the
ftalk; the lire very white. The I of flalks i" the
(lowers which rife at the end of the branch*. are a
flalk in length, naked, hairy, ?M put out two or
four ftioner foot-ftalks in the lide, each fupporting
three or four fluwms. The (lowers are larg, of a
bright yellow colour, but of Jhortd
pahincjils art- liair,¹ and Iharp-pointed. This flowers
in Juiw and July, and at prefer* hbot in few EngVifh
gardens.

The eighteenth [bit hath been long preferred in rlw
English gardens; this riles with a Iknder woody
flalk three or four feet high, fending out many
flender branches, garnifhed with narrow, fpear-shaped,
hairy, wad leaves; from the wings of the leaves
come out Iknder branches, which I have two or three
pair of flalk leaves, fupported by loolc bum. The
flowers are of a dirty fulphur colour, and appear in
June and July, but arc never fucccedrd by feeds in
this country.

This fort will not live abroad in the winter, fo is
always placed in a green n-lnjiilv, wlietr, by its hmr>
leaves, wbkh continue all the year, it makes > vi-
tary.

All the various kinds of *Cistus* are very great ornaments to a garden; their flowers are produced in great plenty, which though but of a short duration, yet are succeeded by fresh ones almost every day for above two months successively; these flowers & many of them about the bignoni of a middling Roll, but single, and of different colour; in the plants continue their leaves all the year.

Their plants are all of them, except the soft, hard enough to live in the open air in England, unless in very severe winters, which often destroys many of them; so that a plant or two of each sort may be kept in pots, and sheltered in winter, to preserve the kinds; the rest may be intermixed with other shrubs, where they will make a pretty appearance; and in such places where they are flickered by other plants, they will endure the cold much better than where they are scattered singly in the borders. Many of the plants will grow to the height of five or six feet, and will have large spreading heads, provided they are permitted to grow uncut; but if they are ever trimmed, it should be only for as much as to prevent their heads from growing too large for their stems; for whenever this happens, they are apt to fall on the ground, and appear unprofitably.

These shrubs are propagated by seeds, and also from cuttings; but the latter method is seldom practised, unless for those sorts which do not produce seeds in England; these are the twelfth, seventeenth, and eighteenth sorts; all the others generally produce plenty of seeds, especially the whole plant which came from seeds; for those which are propagated by cuttings are very subject to become barren, which is common to many other plants.

The seeds of these plants may be sown in the spring upon a common border of light earth, where the plants will come up in six or seven weeks, and, if they are kept clear from weeds, and thinned out, they are too close, they will grow eight or ten inches high the first year; but as these plants, when young, are liable to injury from hard froil, then they should be transplanted when they are about an inch high, into small pots filled with light earth, that they may be removed into shelter in winter, and the others into a warm border, at about ten inches distance each way; those which are potted, must be put in a shady situation till they have taken new root; and those planted in the border must be shaded every day with mats till they are rooted, after which the litter will require no other care, but to keep them clear from weeds till autumn, when they should have a mat placed over them, that they may be covered in frost; in the spring, if they are in the pots, they may be removed into an open situation, if they have taken new root, where they may remain till the end of October, but during the summer they must be shifted into larger pots, and be frequently watered; in the end of October they should be placed in a hot-bed of straw to screen them from the cold in winter, but, at all times, when the weather is mild, they should be fully exposed to the open air, and only covered in froils; with this management, the plants will thrive much better than when they are more tenderly treated.

The above method is what the gardeners generally practise; but those who are desirous to have their plants come forward, should sow the seeds in a moderate hot-bed in the spring, which will bring up the plants very soon; but these must have plenty of air when they appear, otherwise they will draw up very weak; when the plants are to be removed, they should be each planted into separate small pots, and plunged into a very moderate hot-bed, observing to have plenty of air admitted to them every day in good weather, to prevent their drawing up weak; and by degrees they may be hardened, so as to be removed into the open air the beginning of June, and then they may be treated in the same manner as is directed for the other feeding plants. By the bringing

of the plants forward in the spring, in the first year they will grow to the height of two feet, or more, the first summer, and will bear many lateral branches, so will be strong enough to stand in the open ground in the spring, and will flower the first summer where they are sown; the flowers which are sown in the open ground, rarely flower till the year after.

The plants which are sown in the open ground, in the first year, are to be removed into the open ground in the spring following, and to be planted in the open ground, with all the earth preserved, and planted in the places where they are to remain (for they are bad plants to K: old.) observing to give them now and then a little water, until they have taken fresh root; after which time, they will require no farther care than to train them upright in the manner you would have them grow; but those plants which are sown in the open ground, should be covered over, and covered with mats in cold weather, during the first winter, but may be transplanted the following spring. In moving these plants, you should be careful to preserve as much earth about the roots as you can; and if the plants are to be sown in a hot and dry soil, you may water them until they have taken fresh root; which will be in about two months time, when you may transplant them into pots filled with good soil.

The plants which are sown in the open ground, should be covered over, and covered with mats in cold weather, during the first winter, but may be transplanted the following spring. In moving these plants, you should be careful to preserve as much earth about the roots as you can; and if the plants are to be sown in a hot and dry soil, you may water them until they have taken fresh root; which will be in about two months time, when you may transplant them into pots filled with good soil.

The fourth sort of *Cistus* is the most beautiful of all the flowers, which are as big as a large Rose, and of a fine white, with a deep purple spot on the bottom of each leaf. These plants are full of a sweet glutinous liquor, which exudes through the pores of the leaves in a plentiful manner in hot weather, that the surfaces of the leaves are covered therewith; this plant is thought to be gathered in great quantities in the mountains of Spain, where he law vast quantities of this shrub growing.

The fifth sort of *Cistus* is the most beautiful of all the flowers, which are as big as a large Rose, and of a fine white, with a deep purple spot on the bottom of each leaf. These plants are full of a sweet glutinous liquor, which exudes through the pores of the leaves in a plentiful manner in hot weather, that the surfaces of the leaves are covered therewith; this plant is thought to be gathered in great quantities in the mountains of Spain, where he law vast quantities of this shrub growing.

Mon. Tournefort also relates the same in his travels, where he says, that the shrub, which produces the ladanum, grows in the mountains of the Archipelago, and that he observed several of the country fellows in their itineraries and drawers, that were filled with the ladanum, which they had drawn out of the leaves of the shrub; he also relates, that he had seen several of the country fellows, who had taken the ladanum, and had kicked upon the leaves, which he supposed to be part of the shrub, which is the plant, which exudes through the pores of the leaves, where it remains till it is taken up, in which it is clear as turpentine.

When the shells are sufficiently laden with this ^reafe, they take a knife, and scrape the e clean off the ifraps and make it up into a mass of cakes of oilers; :-flzes; this is what comes to us under the name of ladamim, or labdanum. A nv.i that is diligent, will y, or more, whkh this work is r.ithi-r. Hi, btraufc it must be done in the hotted time o in the greatitcalm; and yet tht piirett Udanum is nut free from filth, becaofe illt? winds of the preceding dim have blown upon thrfc Ihrilbs. which, by the glewy fubfiance u;vm the furfuts of the k: .l and mixed therewith. But to add weight to this d it up with a very fine blackifh l. which is found in thofc parts, as if nature hcr- Do teath them how to adulterate this commodity. It is noeafy thins; to difcover thkeheat, when I the Und has been well blended with the ladanumi in order to which you must chew ir fur time, to find whether it crackles between the teeth* and if it doth, you mull firft difflbvc it, and then (train it, in order to purify away what has been added l.

Dr. Linnmcu'j hav joinwl the Aurantium ind Li men 10 thii genus, making them only different Ipct: of the faint genus; but ali the Tirictkl of Citron which

I have examined, have but ten ftamfru in their flow-
ers, whereas thofe of the Orange have more, fo that
they may be feparated on that difference; but Tour-
nefort adds, as a diftinguifhing chara&er to this ge-
nus, the appendix which grows to the foot-ftalk of
the leaf. However, I fhall not fo clofely follow Lin-
naeus, in joining thofe things together, which have
by all the writers on botany and gardening been
kept feparate, left I fhould render this work unin-
telligible to thofe who have not made botany their
ftudy.

The SPECIES are,

- i. CITRUS (*Medico*) fruftu oblongo, majori, mucrona-
to, cortice craffo rugofa. Citron with a larger, oblong,
pointed fruit, having a thick rough rind. Malum
Citreum dulci medulla. Fer. Help. 72. *The Sweet
Citron.*

- 2< CITRUS (*Tuberofa*) fru&u oblongo, cortice tuberofa
rugofa. Citron with an oblong fruit, having a rough
knobbed rind. Malum Citreum vulgare. Fer. Help.
57. *The common Citron.*

There are feveral varieties of this fruit, with which
the Englifh gardens have been fupplied from Genoa,
where is the great nurfery for the feveral parts of Eu-
rope for this fort, as alfo Orange and Lemon-trees ;
and the gardeners who cultivate them there, are as
fond of introducing a new variety to their colle&ion,
as the nurfery-men in England are of a new Pear, Ap-
ple, Peach, &c. fo that the varieties being annually
increafed, as are many of our fruits from feeds, there
is like to be no end of the variety of thofe, nor of
the Orange and Lemon-trees.

The fruit of the Citron is feldom eaten raw, as thofe
of the Orange, but they are generally preferred, and
made into fweetmeats, which are by fome perfons
greatly eftemed; and as thefe are kept till winter
id fpring, when there is a fcarcity of fruit for fur-
tiffing out the defert, they are the more valuable;
>ut unlefs the feafons are warm, and the trees are
veil managed, the fruit rarely ripens in England.
Some of the faireft fruit which I have feen growing
in England, were in the gardens of his late grace the
Duke of Argyle, at Whitton, where the trees were
trained againft a fourth wall, through which there
are flues contrived for warming the air in winter,
and glafs-covers to put over them when the weather
begins to be cold. In this place the fruit were as
large, and perfectly ripe, as they are in Italy or Spain.
The feveral forts of Citrons are cultivated much in
the fame manner as the Orange-tree, to which I fhall
refer the reader, to avoid repetition; but fhall only
remark, that thefe are fomewhat tenderer than the
Orange, and (hould therefore have a warmer fite in
winter, -otherwife they are very fubje&t to call their
fruit. They fhould alfo continue a little longer in the
houfe in the fpring, and be carried in again iboner in
the autumn; as alfo have a warmer and better de-
-ended fite in the fummer, though not too much
expofed to the fun in the heat of the day.

And as their leaves are larger, and their fhoots
ftronger, than thofe of the Orange, they require a lit-
tle more water in the fummer; but in winter they
fhould have but little water at each time, which
muft be the oftener repeated. The foil ought to be
much the fame as for the Orange-tree, but not quite
fo ftrong.

The common Citron is much the beft flock to bud
any of the Orange or Lemon kinds upon, it being
the fraiteft and freed growing tree. The rind is
fmoother, and the wood lefs knotty, than either the
Orange or Lemon; and will take -either fort full as
well as its own kind, which is what none of the other
forts will do: and thefe flocks, if rightly managed,
will be very ftrong the fecond year after lowing, capa-
ble to receive any buds, and will have ftrength to
force them out vigorously, whereas it often happens,
when thefe buds are inoculated into weak flocks, they
frequently die, or remain till the fecond year before
they put out; and thofe that fhoot the next fpring af-
ter budding, are oftentimes fo weak as hardly to be

fit to remain, being incapable to make a frait hand-
-fome fte;n, which is the great beauty of thefe trees.

C I T R U L SeePEPO.

CLARY. SeeScLAREA.

CLAYTONIA. Gron. Flor. Virg. Lin. Gen. Plant.
253.

The CHARACTERS are,

*The flower hath a two-leaved oval empalement, with a
tranfverfe baje: it hath five oblong oval petals, which
are indented at the top, and five awl-jhaped recurved fla-
mina, which are fhorter than the petals, terminated by
oblong fummits. In the center is fituated an oval germen,
fupporting a Jingle ftyle, crowned by a trifid figma. The
germen afterward becomes a roundifh capfule, having three
cells, opening with three ebjtic valves, and filled with
round feeds.*

This genus of plants is ranged in the firft fe&iqn of
Linnaeus's fifth clafs, intituled Pentandria Monogynia,
the flower having five ftamina and but one ftyle.

The SPECIES are,

1. CLAYTONIA (*Virginica*) foliis linearibus. Lin. Sp.
Plant. 294. *Claytonia with very narrow leaves. Orni-
thogalo affinis Virginiana, flore purpureo pentapeta-
loide. Pluk. Aim. 272.*

2. CLAYTONIA (*Siberica*) foliis ovatis. Lin. Sp. Plant.
294. *Claytonia with oval leaves. Limnia. A&. Stockh.
1746.*

The firft fort grows naturally in Virginia, from
whence it was fent by Mr. Clayton to England, and
received its title froiji him.

It hath a fmall tuberous root, which fends out low
(tender ftalks in the fpring, about three inches high,
which have each two or three fucculent narrow leaves
about two inches long, of a deep green colour. At
the top of the ftalk are four or five flowers produced,
ftanding in a loofe bunch, thefe are compofed of
five white petals which fpread open, and are spotted
with red on their infide; after thefe fall away, the
germen becomes a roundifh capfule divided into three
cells, which are filled with roundifh feeds. The flow-
ers appear in April, and the feeds ripen in June, fbon
after which the plant decays to the root.

The fecond fort grows naturally in Siberia. This la
a low plant, feldom riling more than two or three
inches high; the root is tuberous, fending out three
or four oval leaves * the foot-ftalk of the flower arifes
immediately from the root, fuftaining two or three
fmall white flowers of the fame fliape with thofe of
the firft fort, fo make but little figure in a garden.

The plants are both propagated by feeds, and alfo
from offsets fent out from the roots: the feeds fhould
be fown upon a fhady border of light earth, or in
pots filled with the like mould, foon after they are
ripe; for if they are kept out of the ground till
fpring, the plants will not come up till the next year;
whereas thofe which are fown early in the autumn,
will grow the following fpring, fo that a whole year
is gained. When the plants come up, they will re-
quire no other care but to keep them clean from
weeds, and in the autumn, if fome old tanners bark
is fspread over the furface of the ground, it will fe-
cure the roots from being injured by froft, which, if
i: fhould prove very fevere, might injure the young
plants, but in mild winters they will not require pro-
tection.

The beft time to tranfplant the roots is about Micha-
elmas, when they are inactive -, but as they are fmall,
if great care is not taken in opening the ground,
the roots may be buried and loft; for they are of a
dark colour, fo are not eafily diftinguifhed from the
ground.

CLAVICLE [Clavicus, *lat.*] a clafper or tendril.

CLEMATIS. Lin. Gen. Plant. 616. Clematitis.

C. B. P. 300. [K*ip<r2r, of K>^*, a twig or clafper,
&c. becaufe it climbs up trees with clafpers, like
thofe of Vines. Hence it is called Virgultum duc-
tile, Ranunculus obfequiofus; and alfo Antrogeno-
mene, and Flammula, as though producing a car-
buncle; for the leaves being bruifed, and applied to
the fkin, burn it into carbuncles, as it is in thepefti-
k-nee;

lence; and Flammula, because if brise leaf be cropped in a hot day in the summer season, and bruised, and presently put to the nostrils, it will cause a smell and pain like a flame.] Virgin's Bower.

The CHARACTERS are,

The flowers have no empalement^ they have each four loofe oblong petals, with a great number of stamina, which are shorter than the petals, and the stamens adhere to their side. They have many germen, which are roundish and compressed; the awl-shaped style, which is longer than the stamina, is crowned by a single stigma. The germen afterward become so many roundish compressed feeds* with the styck fitting on their top, and are collected into a head, the styles of the several species being of various forms.

This genus of plants is ranged in the seventh section of Linnaeus's thirteenth class, intitled Polyandria Polygynia, the flowers of this section having many stamens and several styles.

The SPECIES are,

- i. CLEMATIS (*Refta*) foliis pinnatis, foliolis ovato-lanceolatis, integerrimis, caule erecto. Hort. Cliff. 225. *Clematis with winged leaves, whose lobes are oval, spear-shaped, entire, and an upright stalk. Clematis five flammula fure&a alba.* J. B. 2. 127. *Upright white Climber.*
- %. CLEMATIS (*Integrifolia*) foliis simplicibus, ovato-lanceolatis. Hort. Cliff. 225. *Clematis with single leaves, which are oval and spear-shaped. Clematis caerulea, crefta.* C. B. P. 300. *Upright blue Climber.*
3. CLEMATIS (*Hifpanica*) foliis pinnatis, foliolis lanceolatis, acutis, integerrimis, caule erecto. *Clematis with winged leaves, whose lobes are spear-shaped, pointed, and entire, and an upright stalk. Clematis Hispanica fure&a altera & humilior flore albicante.* H. R. Par.
4. CLEMATIS (*Vitalba*) foliis pinnatis, foliolis cordatis, scandentibus. Hort. Cliff. 225. *Clematis with winged leaves, whose lobes are heart-shaped and climbing. Clematis latifolia integra.* J. B. 2. p. 125. *Climber with broad entire leaves* commonly called Viorna, or Traveller Jay.*
5. CLEMATIS (*Canadensis*) foliis ternatis, foliolis cordatis, acutis, dentatis, scandentibus. *Clematis with trifoliate, heart-shaped, pointed leaves, which are indented, and climbing. Clematis Canadensis latifolia & triphylla.* Sar. *Broad-leaved Canada Climber.*
6. CLEMATIS (*Flammula*) foliis inferioribus, pinnatis, laciniatis, fummis simplicibus, integerrimis, lanceolatis. Hort. Cliff. 225. *Clematis whose lower leaves are winged and jagged, and the upper ones single, spear-shaped, and entire. Clematis five flammula repens.* C. B. P. 300. *Creeping Climber.*
7. CLEMATIS (*Cirrhofofa*) cirrhofo scandens foliis simplicibus. Hort. Cliff. 226. *Clematis with climbing tendrils, and simple leaves. Clematis peregrina, foliis pyri incifis.* C. B. P. 300. *Foreign Climber with cut Pear-shaped leaves.*
8. CLEMATIS (*Viticella*) foliis compofitis decompositifque, foliolis ovatis, integerrimis. Hort. Cliff. 225. *Clematis with compound and decomposed leaves, whose small leaves are oval and entire. Clematis caerulea vel purpurea repens.* C. B. P. 300. *Single blue Virgin's Bower.*
9. CLEMATIS (*Alpina*) foliis compofitis ternatis ternatifque, foliolis acutis ferratis. *Clematis with compound leaves, whose lobes are sharply fawed. Clematis Alpina geranii folio.* C. B. P. 300. *Alpine Climber with a Cranes-bill leaf*
10. CLEMATIS (*Viorna*) foliis compofitis decompositifque, foliolis quibusdam trifidis. Flor. Virg. 62. *Clematis with compound and decomposed leaves, some of whose lobes are trifid. Clematis purpurea repens, petalis florum coriaceis.* Raii Hist. 1928. *Creeping purple Climber, with coriaceous petals to the flower.*
11. CLEMATIS (*Orientalis*) foliis compofitis, foliolis incifis angulatis lobatis cuneiformibus, petalis interne villofis. Lin. Sp. 765. *Clematis with compound leaves, whose small leaves are cut into angular wedge-shaped lobes, and the inside of the petals are hairy. 14. CLEMATIS (*Americana*) foliis ternatis, foliolis cordato-acuminatis, integerrimis, floribus corymbosis. *Three-leaved Climber with heart-shaped pointed lobes, which are entire, and flowers collected in round bunches. Clematis Americana triphylla, foliis non dentatis.* Houft. MSS.
15. CLEMATIS (*Crippa*) foliis simplicibus, ternatifque, foliolis integris trilobifve. Lin. Sp. Plant. 543. *Climber with single and trifoliate leaves, whose small leaves are either entire, or have three lobes. Clematis flore crifpo.* Hort. Elth. 86. *Climber with a curled flower.*

The first sort grows naturally in the south of France, Italy, Austria, and several parts of Germany, but hath been long cultivated in the English gardens for ornament. This hath a perennial root. The stalks are upright, about three or four feet high, garnished with winged leaves standing opposite, which are composed of three or four pair of lobes, terminated by an odd one, they are oval, spear-shaped, and entire: the flowers are produced in large loose panicles at the top of the stalks, these are composed of four white petals, which spread open; and the middle is occupied by a great number of stamens, furrrounding five or six germen, which afterward become so many compressed feeds, each having a long tail or beard fitting on the top. It flowers in June, and the feeds ripen in September.

The second sort grows naturally in Hungary and Tartary, but hath been long an inhabitant in the English gardens. The root of this is perennial, sending many slender upright stalks, from three to four feet high, garnished with opposite single leaves at each joint, having short foot-stalks; the leaves are near four inches long, and an inch and an half broad in the middle, of a bright green, smooth, and entire, ending in a point: the flowers come out from the upper part of the stalks, standing upon very long naked foot-stalks, each supporting a single blue flower, composed of four narrow thick petals which spread open, and many hairy stamens furrrounding the germen in the center. After the flowers are pail, the germen become so many compressed feeds, each having a tail or beard. It flowers and feeds at the same time with the former sort.

The third sort is very like the first, from which it differs in having pair but two or three pair of lobes in each leaf, which are narrower and stand farther asunder: the stalks are shorter, and the flowers larger.

The fourth sort grows naturally in the hedges, in most parts of England. This hath a tough climbing stalk, sending out claspers, by which it fattens to the neighbouring bushes and trees, and sometimes rises more than twenty feet high, sending out many side branches, so as often to cover all the trees and bushes of the hedge. This puts out many bunches of white flowers in June, which are succeeded by several flat feeds joined in a head, each having a long twisted tail fitting on the top, which is covered with long white hairs; and in autumn, when the feeds are near ripe, they appear like beards, from whence the country people call it Old Man's Beard. The branches of this being very tough and flexible, are used for tying up faggots; from whence, in some countries, it is called Bindwith.

There are two varieties of this, one with indented leaves, which is the most common, and the other hath entire leaves, but as these are supposed to arise accidentally from feeds, they are not distinguished by later botanists.

tlir fifth fon grows naturally in molt parts of fvorl America, from whence the fecht have twen brought r> Kuropr. Tins ii in its iirit appenmice very like tic hit tort, bur th* leaves arc brosrJer, and grow b) threes on the lame foor-ftalk, whereas chute of the former have five or Seven lobes in each leaf. The flowers appear at the fame rime with rite former, but the feeds do not ripen it) England, unV the feafon is very warm. There ts little beauty in chit fon.

The Mi forthaihahdimbirig flak like the fourth ; rhc lower leaves of this arc winged, and deepl on their ctUtta, but the upper leaves are [ingle, fpcar-shaped, and enure. The flowers of this fort arc U'hirc, and niiprar in June or July. This grow* naturally in the Jourh of France, and in Itjdy.

The ibvenrli for mirilly in Spain and Portugal. Thiis hath adimbm; li ilk, which will rift to the height of eight or ten feet, finding out branches from every joint, whereby it becomes a very thick bulhy plant; the lcm are fometimes double, at other times double, and frequently trifoliate, bcinz indented on their edges. Jiirle k^rp their verdure all the year: oppofiteto the leaves come out fppers, tvhii hatten themselves to i he neighbouring Dirthti, by which the branches are fupport&l, ottiCrwif: they would fall fo theground. The flowers ^reproduced from the fide of the branches j thec arc large, of an herbaceous colour, and appear ihs;)'s alout ilie wid of Dccomber, or beffinningaf January, which being a faubn wjen few perlbn s vifit gardens for information, thdb Bowers have ricped their notice, fo that many have Itippofnl thk Tort dotl not produce flowers in England; and the flowers being nearly the fame colour of the leaves, tliofc who have been more confant vilitors of gardens, hart' paffed by this plane, without noticing the flowers; but for many years rogettier, it hath produced plenty of flowers in the gar-3cn at Chcfica, and always at the rainrcnfon.

The feventh fort is cultivated in the nrrfery; fpeaks for f.,c, and ti known by the title (if Virgin's Bower. There are four varieties of ir which arc preferred in ihe gardens of the curious, and have been by fome trrected as fo many difinft ipecics j but ai their only difiotneet confifi either in thecojooi ofihdr Howera, or the multiplicity of their petals, they arc now only efteemed asfemii: al variations; but m th(-y ire iliftioguilhed by tlic nurlery-gardenurs, I (hall juft mentiou client.

- 1. Single hluc Virgin's Bower.
- 2. Single j:trj>lc Virgin's Bower,
- 3. Single red Virgin's Bower.
- 4. Double purple Virgin's Bower.

Thec have no difference in their Italics or kavtet, fo I hat tilt fame defcription will (it them all, excepting tlic colour or multiplicity of petals in their flowers. Tin-IbJks of ihcfe plants are very (ender and weak, bivin many jnils, from whence come out fidt lcafo, which arc again divided into fmal. If thcfe arc lupponct, they will rife to the height of r-^ht or ten ttcc, and arc garnifhed with comj winged leaves, placed oppofite at the joints. Thec beav ti out into many divilions, ca-h of which hath • fleidcr fiut-llalk, with three final! leaves, which are oval and tniire: from thrCtmejoint, generally four fbot-ftidks arifr, two on each fide i the two lower hive three of rhec <liv i i i i, re each com-PCted offline imalltcavrsorloheSi but the two uj^)cr haveonly two oppofite leavei on each, and b' woen thec wife three flendef foot-ftalks, each foppting one flower. The Howm have each four; rcale, which are nttfov at their bafe, but arc broad it the top and rounded: in one they afeof a dark woi n-out purple, in another blue, and lilt third of 3 bright purple or red colour. The double fort, which w common in the : English gardens, is of the worm-on ii purple colour: but the foreign crails ounmention double fiowm of both the other colours, which may probably be found in fome of their gardens s but as I have not icen ihcm mjfdf, I haw not noticed

them. T he double Bower, have no Jhin: germen, but in lieta of them, thew is a multiplicity of peilil, IF] :-i: sr- narrow, and turn inward' at the rop.

The plants grow naturally in the woods in Spain and Portugal, but have been long cultivated in the English gardens for ornament. They flower June iiiiid July, bu: i ripen feeds m EngEtmI, and,the double fort continues with end cf Auuiihl. The ninth fon grown in the Jie Alps, u: other mountains in Italy, I received it from mount Bald us.

where It growi in plenty. This hath a flender climbing talk, which rics three or four feet high, fupporting itfclf by latching to the neighbouring plants or (hrubi. The icam of this arc compofed of nine lobtt orfv.rili leaves, Van: <: (UnJing upon c^hfoot-ftalk, fo that it is what the forriKi write, - flie a nine-leaves i pbur. The flowers come out w the j>-: of the Ihlk, in rhr fame manner as the common Travellers Joy, wbkh arc white, fo mike no great appearance. This fort (towers in May.

The tenth fort groiv'i naturally in Virginia and Carolina, from both"; these countries I have reced "d die feeds. Thii hath many flender flalks, garnifhed with comiMund luingtd l«M at each joint, and are generally compofed of m(r leave), (landing by threes, it be tholi; ot tie tight It fort, but the fmal feaves or lubti of thii are nearly of s he*rt-fhape. The flowers of this fhnc! upon nSort foot-italkt, which come out from the wings oi the leaves, one on each fide thetalk. The flowers arc compofed of four thick p<ak, which are purple on llicir outside, aiid blue within. They appear in July, and if the autumn proves warn, the feeds .siU ripen in September.

The fcvenni fort was difcovered by Dr. Tournefort in the Levant, from whence he fent ihe feech to tlic myal gmdtn it Paris, whete they fuccceded and perfctterl letd fo that trol of the gatilens in Europe hjvc been tumillHrJ with the feah fram thence: this hwh weak climbing ilalk*, which fatten themiHves by their claffer, to ^ny pbnu or flirubs which ftand near tliem, and thereby rife to the height of fevenor eight feet, ^riiifltd with compound winged leaves, confiding of nine fmal leaves (or lobes) which aru angular and fhai; pointed. Thr lower^ come out from the winjp ul the leaves, which areof a yt-Ji-with grcen, and the ptwis aic reflexec! backwiud; they come out in April and May, and in warm ieafoni the fcils will ripen very well, il'he pi inn have a good fit it:.

The twelfth fort grows natural; in Sitjert.i, from whence the [cediwere fine rathe imperial garden at Penrfburgh, where they fuccceded and produced feeds, part of which were fent me in the year 1733. Thec grfw, and the JIJHW have flowered feveral year in tile ChellM ganlcn. I* liatl weak elimbbg flalks, which require Kippon, that rife from four to fix or eight feet high t the joints are fr nunder; at each <• thcfe come out two compound winged leaves, whoibfmal! caves of lobes are placed by threesithec are deeply fawed • at their edges, and terminate in fharp points. The flowers come om from tin; wings of the leaves fmgk ftanding upon long naked foot-ftalks, and aiv compofeirffiwr broad obtiie pi shs, which rced open in form of a crofi, of a whitish yellow colour. In the center is place! feveral germen, furrounded by a peat numbe of flamina, with flat comj L-fled tirttrmits, of the fane i colour with the petals of the Dower (after theft arc julV, the grnncn txcron? to many comprcted feeds, each having a bearded tail. It flitwec in February Mjrch am April, and the leedirpccil in Jul or Augul.

The thirteenth fort was first met from Jamaica by the Ute Dt. Houliout. This hath flender climbing flalks, which fiden themselves to the trees and tvTrutii which ftand near them, and thereby rife to the height of eight or twelve feet, garnifhed with trifoliate leaves, coming mil on each fide the flalk, the lobes are large, 01 sh, and entire, having three longitudinal veins. The foot-ftalks of the flowers are it tlie

same joint, close to those of the leaves, one on each side the stalk: these are long, naked, and jointed horizontally, extending beyond the leaves before they divide and branch; then there comes out three or four pairs of narrow petals, which are notched back, but the lamina all hand-reft,

Thji hath been by liirac perfons Cupped to be the fame with the com/no.. Travellers Joy, but some who have seen the PO plants cannot doubt of their being distinct species.

The fourteenth sort was sent me from Cimpeath by late Dr. J. Tournefort. This is a strong climbing plant, which falls themfeive by their clasping to the neighbouring trees. there by they are supported, and rise to the height of twenty feet or more, garnished at each joint by trifoliate leaves, which are heart-shaped, pointed, and entire. The growing stem is naked, bearing a pair of spreading foot-stalks, which rise from the wings of the leaves (they are white, and collected in bunches); these are succeeded by licks Jhaped like thole of the comon fart, but have a DS curling Uiriir. to card, which art finely fringed.

The fifteenth sort grows naturally in Carotin*) from whence I received the seeds in the year 1726. This hath weak stalks which rise near the ground, and their leaves fall themselves to the neighbouring trees, whereby they are supported. The leaves come out opposite at the joints, these are sometimes single, sometimes double, and some of the leaves are divided into three lobes. The flowers are small, and arise singly from the sides of the branches upon short stalks, which have one or two pair of leaves below the flowers which are oblong and bluish.

The flowers have four or five peals, like those of the common fart, their colour is purple, and their smell is sweet. The SOWCH in July, and the seeds ripen in Septenibur.

The three last sorts have perennial roots, which multiply yearly, but their stalks die away every year, and new ones arise in the spring, in which particular they differ from all the other species, therefore require different management, and are propagated in a different manner; the first give directions for their culture.

The second sort is propagated by cutting the roots into pieces of an inch or two long, and planting them in a bed of earth, which should be kept moist, and the plants will rise in the spring. The best season for parting the roots is in October or November, either just before they decay, or before they rise again in the spring.

They will grow almost in any soil or situation, but if the soil is very dry, they should always be watered in the autumn, otherwise their flowers will not be so large, but if the soil be wet, it is better to defer it until the spring. The roots should be cut through with a sharp knife, observing to leave an inch or two of the crown, and the pieces should be planted in a bed of earth, which should be kept moist, and the plants will rise in the spring. The best season for parting the roots is in October or November, either just before they decay, or before they rise again in the spring.

These plants are extremely hardy, enduring the coldest winters in the open air, and are very proper ornaments for large gardens, either to be planted in large borders, or intermixed with other hardy flowers in quarters of flowering shrubs, where, by being placed promiscuously in little open places,

they will up to the beginning of autumn, and are supported by the beginning of autumn, and often continue to produce fresh flowers until August, which renders them valuable, especially if they require very little care in their culture; for they may be suffered to remain several years without being cut down, where there is no want to part them, which will not in the least prejudice them.

The fourth sort is issued wild in several parts of England, growing upon the sides of banks under hedges, and extends its trailing branches over the trees, and shrubs that are near it. This plant in the autumn is generally covered with seeds, which are collected into little heads, each of which having, as it were, a tough plume adhered to it, hath procured the country people the name of OH Man's-hear. It is taken by Label and German, Vitorrt; and by Do-doivci. Vitis alba: it is native of the country people in the name of OH Man's-hear. It is taken by Label and German, Vitorrt; and by Do-doivci. Vitis alba: it is native of the country people in the name of OH Man's-hear. It is taken by Label and German, Vitorrt; and by Do-doivci.

The fifth and sixth sorts have no more beauty than the first, but they are both very useful for the Dike of viridity. They are both very useful for the Dike of viridity. They are both very useful for the Dike of viridity.

The seventh sort retain its larva all the year, which warden it is a great advantage. This was formerly preferred in green-houses in the winter, supposing it too tender to live in the open air in England; but now it is generally planted in the full sun, and the plants thrive much better in pots, and produce plenty of flowers, which they never did when they were more tenderly treated, nor have I found that the plants have suffered from severe frosts; for those which have been growing in the open air at Chelsea, more than thirty years, have withstood the greatest cold without coming to any damage.

This sort does not produce seeds in England, but is propagated by layers, and also from cuttings. If they are propagated by layers, it will be done in the beginning of the month of October, when the lame year only (should be chosen for the purpose) for the older branches do not put out roots in less than two years, whereas the new ones will put out roots in a good many months. The plants should be cut down into the ground, in the first year, and in the second year they will have two or three inches of root, which being cut off, may be injured by severe frosts; therefore these layers will not be taken from the following autumn, when they may be taken from the plant, and planted in a bed of earth, which should be kept moist, and the plants will rise in the spring.

When the plants are cut down by cutting, they should be planted in a bed of earth, which should be kept moist, and the plants will rise in the spring. The best season for parting the roots is in October or November, either just before they decay, or before they rise again in the spring.

These plants are extremely hardy, enduring the coldest winters in the open air, and are very proper ornaments for large gardens, either to be planted in large borders, or intermixed with other hardy flowers in quarters of flowering shrubs, where, by being placed promiscuously in little open places,

... the most beautiful, so that it is preferred to those with double flowers, as they only should be planted for variety. They are all equally hardy, so are seldom injured by frost, excepting in very severe winters; when sometimes the very tender flowers are killed; but if thric are cut off in the spring, the stems *IJ put out new (hoou. The tenth, tieventli, ;od fifteenth sorts ^re also very hardy plants, and have climbing branches, so may be disposed in the same manner as the other: they are also propagated by layers, which will succeed, if performed at the same time, and in the same manner as is directed for them. The other sorts are natives of the vrarorf. ;arts of America, so will not thrive in this country, unless they are preserved in hives; but as these are great rarities and plants of no great beauty, they are seldom preserved in Europe, but in botanic gardens for the sake of variety. These may be propagated by layers, in the same manner as the other sorts; or may be raised from seeds, obtained from the countries where they naturally grow; but these must be treated in the same manner as other exotic plants from the same country.

CLEOME L. 1. Gc^, Plant. 740. Sinapiftrum. Tourn. Inst. R. 1. i. ;jt. tab. 116. H. 1. :>fx »r nmrt I

The first sort grows naturally in Asia, Africa, and America; I have received the seeds of it from Aleppo, and the coast of Guinea, and in the earth which came from the West-Indies with other plants; this bush comes up as a weed. It rises with an herbaceous stalk about a foot high, furnished with smooth leaves, composed of five small leaves or lobes, joining at their base to one center, and spread out like the fingers of a hand. The leaves on the lower part of the stalk stand upon long foot-stalks, which are gradually shortened to the top of the stalk, where they almost join it: the flowers are produced in loose spikes at the end of the stalks and branches; these have four petals of a flesh colour, which stand erect, spreading from each other, and below these are placed the filament and style, which consist at the bottom, and are stretched out beyond the petals, where they spread open, after the flower is past, the germen which fits upon the style, becomes a taper pod, about two inches long, filled with round seeds. This is an annual plant, which dies soon after the seeds are ripe.

The second sort grows naturally in the Levant, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, and from thence most of the botanic gardens in Europe have been furnished with it: this

... in the Levant, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, and from thence most of the botanic gardens in Europe have been furnished with it: this

... which are incurved, having rising funnits fast to their stalk: it hath a single flou, supporting an oblong germen, which is of the same length as the funnits, and crowned by a short stigma. The germen afterward becomes a long cylindrical pod, fitting open at the top, having one cell, opening with two valves, and filled with round seeds.

This genus of plants is ranuwl in the JI-toitit] feSaaa of Linnæus's strength (this, named Tetrastemma Sidaquata, the plants of this section have in the flowers but long and two short funnits, and their seeds are included in long pods.

The Species are,

1. Cleome (Polemonia) floribus pyramidalibus, foliis quinatis caule terribi. Linn. Sp. 923. Grows with flowers having such and such parts, five lobes, and simple ll. ilb. Sii;^; arum Indicum, pentaphyllum, flore rubro, minus, non spinosum. H. L.

2. Cleome (Gratiopisoides) floribus hexandris, foliis ternatis, lobulis ovato-lanceolatis. Linn. Sp. Plant. 940. Grows with leaves having five funnits, ovate lobes, and four-angled stalk. Sinapiftrum Orientale, triphyllum, ornithogalli siliqua. Tourn. Cor. 17.

3. Cleome (Lappacea) floribus hexandris, foliis ternatis, lobulis linearibus, siliquis bisulcatis. Grows with flowers having five funnits, trifoliate leaves, narrow four-angled stalk, and pods having two valves. Sinapiftrum Linnæicum, triphyllum, flore rubro. Tourn. Inst. R. H. 151.

4. Cleome (Vicia) floribus hexandris, foliis quinatis ternatis. Linn. Sp. 141. Clam; with flowers having seven funnits, trifoliate and quadrifoliate leaves. Sinapiftrum Zeylanicum, triphyllum & pentaphyllum videlicet, flavo fere. Mart. Dec. 2.

5. Cleome (Triphala) floribus hexandris, foliis ternatis, lobulis intermedio majore. Grows with flowers having five funnits, and trifoliate leaves, which middle lobe is the largest. Sinapiftrum Indicum, triphyllum, flore viridato non spinosum. H. L.

6. Cleome (Eragrostis) floribus hexandris, foliis septematis, caule spinoso, siliquis pendulis. Grows with flowers having five funnits, leaves with three lobes, a prickly stalk, and hanging pods. Sinapiftrum Egyptianum, hi'pr. iplijllurn, in ramco, iiiijs spinosum. H. L.

7. Cleome (Spiraea) floribus quinatis ternatis, caule spinoso. Grows with flowers having five funnits, leaves composed of five oval lobes, and a prickly stalk. Sinapiftrum Indicum spinosum, flore caeruleo, hinc triudo vel quinquedo. H. 1. MSS.

8. Cleome (Mimosa) floribus hexandris, foliis simplicibus, petalis ovato-lanceolatis. Flor. Zeyl. 243. Grows with five funnits in the flowers, and five lobes, which are equal four-angled. Sinapiftrum Zeylanicum viciniam, folio linnario, flore flavo, siliquis terribi. H. 1. Tab. 117.

The first sort grows naturally in Asia, Africa, and America; I have received the seeds of it from Aleppo, and the coast of Guinea, and in the earth which came from the West-Indies with other plants; this bush comes up as a weed. It rises with an herbaceous stalk about a foot high, furnished with smooth leaves, composed of five small leaves or lobes, joining at their base to one center, and spread out like the fingers of a hand. The leaves on the lower part of the stalk stand upon long foot-stalks, which are gradually shortened to the top of the stalk, where they almost join it: the flowers are produced in loose spikes at the end of the stalks and branches; these have four petals of a flesh colour, which stand erect, spreading from each other, and below these are placed the filament and style, which consist at the bottom, and are stretched out beyond the petals, where they spread open, after the flower is past, the germen which fits upon the style, becomes a taper pod, about two inches long, filled with round seeds. This is an annual plant, which dies soon after the seeds are ripe.

The second sort grows naturally in the Levant, from whence Dr. Tournefort sent the seeds to the royal garden at Paris, and from thence most of the botanic gardens in Europe have been furnished with it: this

with an upright (talk about the fame lwU>ht as the firli, garnished with leaves coEnpofed of three (pear-lhaped lobe*, Handing upon lthon foot-ftalks; the flowers come out (ing!; frwh the Bk • of the (talks, and have (bur red petals, wlich stand In the lame form as thofe of the former fort: th-Jc art fucceded by (lenderpod? tv-o inches long, which fweli in every divifion, where each feed is lodged. : appear like joints, *s thoi;- do of" the Bira's-ibot Trts foil; when the feed* are ripe, the whole plant decays. feLETHR A. Groni. Fl. Virg. 43. Lin. Gen. Plant. 489.

The CHARACTERS are*

The flower hath a permanent empalement of one leaf which is cut into five parts; // bath five oblong petals, which are longer than the empalement; it hath ten ftamina which are as long as the petals, and are terminated by oblong ereft fummits; in the center is fituated a roundifh germen fupporting a permanent erell ftyle, crowned by a trifid ftigma. The germen afterward becomes a roundifh capfule inclofed by the empalement having three cells, which are full of angular feeds.

This genus of plants is ranged in the firft fe&ion of Linneus's tenth clafs, intitled Decandria Monogynia, the flowers having ten ftamina, and one ftyle.

We know but one SPECIES of this genus at prefent, viz.

CLETHRA (*Alnifolia*) Gron. Virg. 47. *There is no Englifh title to this plants it is the Alnifolia Americana ferata, floribus pentapetalis albis in ipicam diipofitis. Pluk. Aim. 18. American Shrub with an Alder fawed leaf and white five-leaved flowers, difpofed in afpike.*

This fhrub is a native of Virginia and Carolina, where it grows in moid places, and near the fides of rivulets, rifing to the height of eight or ten feet, but in this country it rarely rifes to half that height: the leaves are in fhape like thofe of the Alder-tree, but are longer; thefe are placed alternately upon the branches: the flowers are produced at the extremity of the branches, in clofe fpikes: they are compofed of five leaves, are white, and have ten ftamina in each, which are nearly of the fame length with the petals, this plant flowers in July, and when the autumn proves favourable, there are often fome fpikes of flowers again in Oftober.

This is hardy enough to bear the open air in England, and is one of the mod beautiful fhubs at the feafon of its flowering; which is very little later than in its native country, being commonly in flower here by the beginning of July; and if the feafon is not very hot, there will be part of the fpikes in beauty till the beginning of Auguft; and as moft of the branches are terminated with thefe fpikes of flowers, fo when the fhubs are ftrong, they make a fine appearance at that feafon.

This will thrive much better in moift land than in dry ground, and requires a flickered fituation, where it may be defended from ilrong winds, which frequently break off the branches, where they are too much expoied to its violence. It is propagated by layers, but they are generally two years before they get root, fo that at prefent it is rare in England. The fineft fhubs of this kind, which I have yet feen, are in the curious garden of his grace the late duke of Argyle, at Whifton near Hounflow, where they thrive as well as in their native country. They may alfo be propagated by fuckers, which are fent out from their mots -, if thefe are carefully taken off with fibres in the autumn, and plained into a nurfery-bed, they will be ftrong enough in two years to tranfplant where they are to remain.

It may alfo be propagated by feeds, which muft be procured from the countries where it grows naturally, for the feeds are not perfected in England. But as thefe feldom arrive here till fpring, fo when they are ibwn at that feafon, the plants will not come up till the following fpring. Therefore the feeds fhould be ibwn in pots, and placed in a fhady fituation till autumn, then placed under a frame in winter -, the plants will come up the next fpring, and in autumn may be tranfplanted into a nurfery-bed, to get ftrength before they are placed to remain for good.

CLIFFORTIA. Lin. Gen. Plant. 1004.

The name was given to this genus of plants by Dr. Linnaeus, in honour of Mr. George Clifford of Amfterdam; a great collector of plants, and a patron of botanifts, who has printed a folio book of the plants in his garden, with feveral copper-plates, exhibiting the figures of many of the moft curious plants. We have no Englifh name for it*

The CHARACTERS are,

// hath male and female flowers in different plants: ihi. male flowers have a fpreading empalement, compofed of three fmaU, oval, concave leaves. It hath no petals* but agiat number of hairy upright ftamina, which are the length of the empalement, terminated by compreffed, oblong; twin fummits. The female flowers have a permanent empalement, compofed of three leaves which are equal, fitting upon the germen; thefe have no petals, but the oblong germen which is fouated below the empalement, fupports two long, fiender, feathered ftyles, terminated by a Jingle ftigma 5 the germen afterward becomes an oblong taper capfule, with two cells crowned by the empalement, including one narrow taper feed.

This genus of plants is ranged in the tenth fe&ion of Linneus's twenty-fecond clafs, intitled Dicecia Polyandria -, the plants of this fe&ion and clafs have male and female flowers on different plants, and the male flowers have a great number of ftamina.

The SPECIES are,

1. CLIFFORTIA (*Ilicifolia*) foliis fubcordatis, dentatis. Lin. Sp. Plant. 1308. *Cliffortia with hearUfhaped indented leaves. Arbutula Afr. folio acuto ilicis caulem amplexo rigido. Boerh. Ind. alt. 2.*
2. CLIFFORTIA (*Trifoliata*) foliis ternatis, intermedio tridentato. Prod. Leyd. 253. *Three-leaved Cliffortia, whose middle leaf is cut in three parts. Myrica foliis ternatis, intermediis cuneiformibus tridentatis. Hort: Cliff. 456.*
3. CLIFFORTIA (*Ruscifolia*) foliis lanceolatis, integerrimis. Hort. Cliff. 463. *Cliffortia with fpear-Jhaped leaves which are entire. Frutex /Ethiopicus conifer, fructu parvo, fparfim intra folia rufci, feminibus cylindracei?.*

The firft fort grows naturally at the Cape of Good Hope, but hath been long cultivated in many of the Englifh gardens; however it was not reduced to any genus, till Dr. Linnaeus eftablifhed this, and gave it the title. By fome former writers it was called Camphorata, to which genus it had no relation.

It riles with a weak fhubby ftalk four or five feet high, fending out many diffuled branches, which fpread out on eveiy fide, requiring fome fupport: thefe are garnifhed with leaves, which are heart-fhaped at their bafe, but broad at their ends, where they are fharply indented. They are very ftiff, of a grayifh colour, and clofely embrace the ftalks with their bafe, and are placed alternate on the branches; from the bofom of thefe arife a fingle flower, fitting clofe to the branch, having no foot-ftalk. Before the empalement is fspread open, it forms a bud, in lhape and fize of thofe of the Caper 5 this empalement is compofed of three green leaves, which afterwards fpread open, and then the numerous ftamina appear ftanding ereft; thefe, as alfo the inner furface of the empalement, are of ayellowifh green colour. The flowers appear in June, July, and Auguft, but the leaves continue in verdure through the year.

AH the plants which I have feen of this fort, either in the Englifh or Dutch gardens, were male, nor have I heard of any female plants being in any of the European gardens.

This plant is eafily propagated by cuttings, which may be planted in any of the fummer months 5 if thefe are planted in fmall pots filled with light earth, and plunged into a very moderate hot-bed they will foon take root, provided they are fcreened from the fun and duly watered; when they have taken root, they muft be gradually inured to bear the open air, to which they fhould be expofed, to prevent their drawing up weak: therefore they fhould be placed abroad till they have obtained fome ftrength, then they may be each tranfplanted into a feparate fmall pot, and placed in the lhade until they have taken frefh root; after which they may be placed with other of the hardy kinds of exotic plants in a fheltered fituation till October, when they fhould be removed into the green-houfe, or placed under a common hot-bed frame, where they may be fcreened from the hard froft, but

*noy the free air at all times when the weather is mild.

When the plants advance in height, their stems and branches must be supported, otherwise they will trail upon the ground. In summer they must be placed in the open air, with Myrtles and other hardy green-house plants, and in winter the plants may be treated in the lime matter as those, but must have little water in winter. This plant has endured the cold of our ordinary winters* when planted near a south-west wall without covering, but in severe winters they are always destroyed.

The second sort is a native of the same country as the first -, this hath very slender ligneous stalks, which must be supported, otherwise they will fall to the ground. These send out slender branches on every side, which are closely garnished with trifoliate leaves standing close to the branches -, the middle lobes of these are much larger than the two sides, and are indented in three parts. The flowers of this come out from the bottom of the leaves, having very short foot-stalks, and are shaped like those of the first, but are smaller *, these appear in July and August. Of this sort we have only male plants in the English gardens, which can only be propagated by layers; and as these are two years before they take root, the plants are at present very rare in England. This sort requires the same management as the first, and is equally hardy, but must not be over watered in winter. The leaves of this sort continue green all the year, and being singularly shaped, they make a variety in the green-house during the winter season.

The third sort rises with a weak shrubby stalk about four feet high, sending out lateral branches, which are covered with a whitish bark, and are garnished with leaves, placed in clusters without order; these are stiff, of the confidence and colour of the Butchers Broom, but are narrower, and run out to a longer point. Between these clusters of leaves the flowers come out in loose bunches, these have a great number of yellowish stamens, included in a three-leaved empalement. We have only the male plant of this sort, which is very difficult to propagate, so is very rare in Europe at present.

This plant is tenderer than either of the former sorts, so should be placed in a warm green-house in winter, and during that season, they must have but little water. In the summer they may be exposed to the open air in a sheltered situation, but they should not remain abroad too late in the autumn *, for if there should be much rain at that season, it would endanger these plants if they are exposed to it.

CLIMATE [of Kxi]*, Gr. an inclination,] is a part of the surface of the earth bounded by two circles parallel to the equator; so that the longest day in that parallel, nearest to the pole, exceeds the longest day in that parallel nearest to the equator by some certain space of time, viz. half an hour, till you come to places situated nearly under the arctic circle and a whole hour, or even several days when you go beyond it.

The ancient Greek geographers reckoned only seven climates from the equator towards the north pole, and denominated them from some noted place, through which the middle parallel of the climate passed but the moderns reckon up twenty-four.

The beginning of the climate is the parallel circle, wherein the day is the shortest.

The end of the climate is that wherein the day is the longest.

The climates therefore are reckoned from the equator to the pole; and are so many bands or zones, terminated by lines parallel to the equator though in different parts there are several climates in the breadth of one zone.

Each climate only differs from its contiguous ones, in that the longest day in summer is longer or shorter by half an hour in one place than the other.

As the climates commence from the equator, the first climate at its beginning has its longest day pre-

cisely twelve hours long; at its end twelve hours* and a half: the second, which begins where the first ends, viz. at twelve hours and a half, ends at thirteen hours: and so of the rest, as far as the polar circles.

Here what geographers call hour-climates terminate, and month-climates commence.

As an hour-climate is a space comprised between two parallels of the equator, in the first of which the longest day exceeds that in the latter by half an hour; so the month-climate is a space between two circles parallel to the polar circles, whose longest day is longer or shorter than that of its contiguous one by a month, or thirty days.

The ancients, who confined the climates to what they imagined the habitable part of the earth, only allowed of seven, as had been said: the first they made to pass through Merbe, the second through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the sixth through Pontus, and the seventh through the mouth of the Borysthenes.

The moderns, who have failed farther towards the poles, make thirty climates on each side -, and because the obliquity of the sphere makes a little difference in the length of the longest day, some of them make the difference of the climate but a quarter of an hour instead of half an hour.

The term climate is vulgarly bestowed on any country or region differing from another, either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants, without any regard to the length of the longest day.

CLINOPODIUM. Lin. Gen. Plant. 644. Tounu Inf. R. H. 194. tab. 92. Field Basil.

The CHARACTERS are,

// bath an involucre cut into many parts, is the length of the empalement, Upon which the whorls sit. The empalement is of one leaf with a cylindrical tube, which is divided into two lips -, the upper lip is broad, trifid, acute, and used; the under lip is cut into two narrow segments, which turn inward. The flower is of the lip kind, with a short tube enlarging to the mouth the upper lip is ereff, concave, and indented at the top, which is obtuse the under lip is trifid and obtuse, the middle segment being broad and indented. It hath four stamens under the upper lip, two of which are shorter than the other, terminated by roundish summits in the center is situated the quadrupartite germen, supporting a slender style the length of the stamens, crowned by a single compressed stigma. The germen afterward become four oval seeds shut up in the empakment.

This genus of plants is ranged in the first section of Linnaeus's fourteenth class, intitled Didynamia Gymnospermia. The flowers of this class and section, have two long, and two short stamens, which are succeeded by four naked seeds.

The SPECIES are,

1. CLINOPODIUM (*Vulgare*) capitulis subtundhr, hispida, bracteis fetaceis. Lin. Sp. Plant. 587. Field Basil with roundish prickly heads, and bristly bractea* CK-nopodium Origano simile* elatius, majore flore. C. B. P. 225. Common English Field Basil.
2. CLINOPODIUM (*Incanum*) foliis subtus tomentosis, verticillis explanatis, bracteis lanceolatis. Lin. Sp. Plant. 588. Field Basil with leaves which are woolly on the under side, broad plain whorls, and spear-shaped bractea. Clinopodium menthae folio incanum, & odoratum. Hort. Elth. 87.
3. CLINOPODIUM (*Rugosum*) foliis rugosis, capitulis axillaribus, pedunculatis, explanatis, radiatis. Lin. Sp. Plant. 588. Field Basil with rough leaves, plain beads growing on the sides of the stalks, which have foot-stalks, and are radiated. Clinopodium rugosum, capitulis scabiosis. Hort. Elth. 88.
4. CLINOPODIUM (*Humile*) humiliter ramifolium, foliis rugosioribus, capitulis explanatis. Low branching Field Basil with rougher leaves, and plain heads. Clinopodium Americanum humile, foliis rugosioribus. Dale.

§. CLINOPODIUM (*CaroHniahūn*) caule erecto, non rambfo, foliis fubtus villofis, verticillis paucioribus, bracteis calyce longioribus. *Field Bafil with an upright unbranching ftalk ^ leaves hairy on their under fide ^ fewer whorls ^ and fraSea longer than the empalement.* Clinopodium Amtricanum, eredtum, non rimofum foliis longioribus, internodiis longiffimis. Dale.

6. CLINOPODIUM (*JEgyptiacum*) foliis ovatis ttigofis, verticillis omnibus diitantibus, i. e. *Field Bafil with ayal rough leaves, and the whorls of flowers ftanding at to great diftance.* Clinopodium -fEgyptiacum, vulgari fimile. Dill. *Jgyptian Field Bafil like the common.*

The firft fort grows naturally by the fide of hedges and in thickets, in many parts of England; this hath a perennial fibrous root, which fends up feveral ftiff fquare Italics afoot and a half high, from which come out a few lateral branches toward the top, garnifhed with oval hairy leaves, placed oppofite; at the top of the italics the flowers come out in round whorls, or heads; one of thefe terminate the (talk, and there is generally another which furrounds the ftalk at the joint immediately below it. The flowers are fometimes purple, at others white, for they vary from one colour to the other, when they are propagated by feeds, fo that both colours are found naturally in the fields. The whorls (or heads) grow very clofe, and each foot-ftalk fuffains feveral flowers; each flower hath a tubular empalement, ending in five fharp points, which ftand eredt; at the bafe of the empalement ftand two brittle fpines, which Linnaeus terms the bradtea; thefe ftand almoft horizontal under the empalement. The flower is of the labiated, or lip kind, according to Tournefort, Ray, &c. which is now ftyled ringent, or grinning, from the appearance which the upper part has to the mouth, or chaps of animals. The upper lip is broad and trifid, but the under is cut into two narrow fegments; each flower is fucceeded by four naked feeds, fitting at the bottom of the empalement. This flowers in June.

The fecond fort grows naturally in Penfylvania and Carolina, from both of thefe countries I have frequently received the feeds, this hath a perennial root, which fends up many fquare ftalks about two feet high, which put out a few fhort fide branches toward the upper part, garnifhed with oblong oval leaves, about the fize of thofe of Water Mint, ftanding oppofite, clofe to the ftalk; they are hoary, and foft to the touch, and have a ftrong odour, between that of Marjoram and Bafil. The upper furface of the leaves is of a pale green, but their under fide is hoary and woolly, they are lightly indented on their edges. The flowers grow in flat fmooth whorls round the ftalks, each ftalk hath generally three of thefe whorls, the upper which terminates the ftalk being fmaller, the other two increafing, fo that the lower is the greateft. The flowers are of a pale purple colour, and fhaped like thofe of the firft fort, but the ftamina of this ftands out beyond the petal, and the bradtea at the bafe of the empalement are large, fpear-fhaped, and indented on their fides. This plant is called Snake-weed in fome parts of America, fuppofing it a remedy for the bite of rattle fnakes. This flowers in July in England.
